Editorial Preface

From the Desk of Managing Editor…

It may be difficult to imagine that almost half a century ago we used computers far less sophisticated than current home desktop computers to put a man on the moon. In that 50 year span, the field of computer science has exploded.

Computer science has opened new avenues for thought and experimentation. What began as a way to simplify the calculation process has given birth to technology once only imagined by the human mind. The ability to communicate and share ideas even though collaborators are half a world away and exploration of not just the stars above but the internal workings of the human genome are some of the ways that this field has moved at an exponential pace.

At the International Journal of Advanced Computer Science and Applications it is our mission to provide an outlet for quality research. We want to promote universal access and opportunities for the international scientific community to share and disseminate scientific and technical information.

We believe in spreading knowledge of computer science and its applications to all classes of audiences. That is why we deliver up-to-date, authoritative coverage and offer open access of all our articles. Our archives have served as a place to provoke philosophical, theoretical, and empirical ideas from some of the finest minds in the field.

We utilize the talents and experience of editor and reviewers working at Universities and Institutions from around the world. We would like to express our gratitude to all authors, whose research results have been published in our journal, as well as our referees for their in-depth evaluations. Our high standards are maintained through a double blind review process.

We hope that this edition of IJACSA inspires and entices you to submit your own contributions in upcoming issues. Thank you for sharing wisdom.

Thank you for Sharing Wisdom!

Integrating Observability with DevOps Practices in Financial Services Technologies: A Study on Enhancing Software Development and Operational Resilience

Ankur Mahida
Barclays, Whippany, USA

Abstract—**The finance market closely depends on translation and high-quality software solutions when performing crucial transactions and processing important information and customer services. Thus, systems' reliability and good performance become crucial when these systems become complicated. This paper aims to focus on the implementation of the observability concept with the DevOps approach in financial services technologies, where its strengths, weaknesses, opportunities, and threats are also discussed with regard to the future. The concept of observability is intertwined with DevOps since, with its help, it is possible to gain deep insights into the system's inner state and further enhance status monitoring, detect problems in less time, and optimize performance constantly. When organized and analyzed properly, observability data can, therefore, play a critical role in increasing software quality in financial institutions, aligning with regulatory standards, and decreasing development and operations teams' silos. However, the implementation of observability within an organization using DevOps best practices in the financial services industry has some challenges, which include The issue of security, especially when it comes to data, the Challenge of data overload, the challenging task of encouraging the right organizational culture for continuous and consistent observability. The article presents a guide that discusses how to incorporate observability with DevOps: the step-by-step process of defining observability needs, choosing the most suitable tools, integrating with other tools in the existing DevOps frameworks, laboratory of alarms, and constant enhancement. Furthermore, it considers examples of how some financial organizations have applied observability to reduce risks, improve efficacy, and enrich customers' interactions. In addition, the article also deliberates on the future perspectives of observability, for instance, artificial intelligence and machine learning are quickly emerging as means through which different tasks of observability can be automated, and there are increasing concerns with security when it comes to the implementation of observability in the financial services industry. By adopting observability and aligning it with DevOps, financial institutions can develop and sustain sound, reliable and high-quality infrastructure and maintain the industry's leadership.**

Keywords—Observability; monitoring; integrated analysis; DevOPs; integration; operational resilience

I. INTRODUCTION

Most of the financial service functions are dependent on software to enable transaction processing, data management or the delivery of services to consumers. While these systems continue to become intricate, it becomes crucial to establish their sound development and system functionality. Due to such consequences, disruptions or failures of financial software systems can significantly affect organizations and their stakeholders economically and reputably, and attract regulatory repercussions. In the last few years, the application of DevOps has become quite popular in the financial services industry. DevOps' concept helps in amalgamation of the development and operations of a company so that they can quickly and effectively deliver software products and services [1]. Based on DevOps best practices, it is essential for an organization to attain flexibility, and quality, and to ensure the delivery of goods and services faster through the integration of the development and operation entity, automation of processes, and coming up with the development and delivery pipeline [15]. New valuable features have been brought with the help of DevOps techniques; however, applying such approaches offers evidence that a better understanding of the behavior and functioning of the software systems are needed. This is where observability comes in to strengthen the situation. The term observe is a technique that is used with the aim of getting to observe how a certain system works, and its inner structure with the ultimate aim of being able to monitor, analyze, and improve the structure [3]. The inclusion of observability into the DevOps tradition in financial services technologies yields key benefits, including increased velocity of issue identification and remediation, better code quality, compliance, and end-to-end teamwork. But all these present organizational integration challenges, like security issues, information overload, and having to change a firm's culture.

II. LITERATURE REVIEW

A. Overview

The financial services sector has been going through a period of radical change throughout the past few years, primarily due to the integration of digital and software technologies as well as the need to enhance the flexibility and reliability of software solutions. DevOps is derived from the two words 'development' and operations; it has now become an important practice that provides the needed heuristic to organisations so that they can increase the speed at which they release their software products and services to the market [4]. However, the observers must understand that as the development of their numerous applications of financial services becomes more intricate and dispersed, there will be difficulty in observing the internal state as well as the conduct of the particular systems if they are not carefully managed. To introduce the concept, it is essential to define how the practices of observability align with the principles of DevOps and what opportunities and difficulties can exist when applying observability in the context of financial services technologies; what practices would be effective for integrating observability into the technologies; and reflect on further improvement of the process of creating and operating software. Besides, the degree to which the internal states of a software system may be deduced from its external outputs is measured by its observability [3]. It gives organizations a comprehensive picture of the system itself, including its performance and health, by utilizing the data and insights that tracking generates [3]. Therefore, a portion of the system's observability is determined by how well the monitoring metrics are able to decipher the performance indicators of that system. This brings, an important topic when it comes to observability; monitoring. Monitoring and observability depend on each other, though they are distinct (as presented in Table I).

TABLE I. COMPARISON BETWEEN OBSERVABILITY, MONITORING AND DEVOPS

Aspect	Monitoring	Observability	DevOps
Definition	The practice of collecting and analyzing data about the performance and availability of systems and applications.	The ability to understand the internal state of a system based on its external outputs.	A set of practices and tools that combines software development (Dev) and IT operations (Ops) to shorten the systems development life cycle.
Focus	Monitoring focuses on gathering and presenting data about specific metrics and thresholds.	Observability focuses on understanding the full context and behavior of a system.	DevOps focuses on the collaboration and communication between development and operations teams.
Data Sources	Monitoring primarily relies on logs, metrics, and alerts from various system components.	Observability utilizes a wide range of data sources, including logs, metrics, traces, events, and user feedback.	DevOps leverages tools and processes for continuous integration, continuous delivery, infrastructure as code, and automated testing.
Purpose	To detect and alert on system issues or performance degradation.	To gain insights into system behavior and root causes of issues.	To accelerate software delivery, improve quality, and enable collaboration between teams.
Tools	Monitoring tools like Nagios, Prometheus, and New Relic.	Observability tools like Jaeger, Zipkin, and Honeycomb.	DevOps tools like Jenkins, Ansible, Terraform, and Docker.
Scope	Monitoring typically focuses on individual components or services.	Observability provides a holistic view of the entire system and its dependencies.	DevOps encompasses the entire software development and delivery lifecycle.
Approach	Monitoring is reactive, alerting when issues occur.	Observability is proactive, enabling teams to understand system behavior before issues arise.	DevOps is a collaborative and iterative approach to software delivery.

Monitoring is specifically the process of keeping track of a system's performance throughout its lifespan. Monitoring tools gather, examine, and synthesize system data to produce insights that can be put to use [5, 6]. An organization can find out if a system is functioning properly or poorly or if there is an issue with application performance by using monitoring technologies like application performance monitoring (APM). Making more general conclusions about the system can also be aided by tracking data aggregation and correlation [5]. For instance, developers can learn more about the user experience of a website or app by observing load times. In between observability and monitoring are DevOPs. DevOps is a culture, a way of thinking, as well as a stated and practiced method used to resolve the dissolution between developers and operators. It encourages collaboration, integrates automation and promotes the practice of CI/CD processes and pipelines [7, 32]. In DevOps, changes in application delivery should frequent and rapid while focusing on operations effectiveness and robustness.

B. *DevOps, Monitoring, and Observability Correlation*

Complementary principles like DevOps, monitoring, and observability are essential to today's development and operations procedures. Understanding this relationship as a whole is essential for building strong and effective software systems, especially in the financial industry where legal compliance, security, and dependability are critical. Monitoring is one of the most significant practices that needs to be carried out when working within the DevOps paradigm [8]. However, what might be the single most important aspect of DevOps is its iteration and feedback, both of which are specifically driven by the analysis of data that is collected through monitoring [9]. By integrating the monitoring into CI/CD pipeline, it is possible for the teams to collect and analyze system attributes, logs, and other metrics that are defined across the different phases of the software development life cycle. This makes it possible to find the causes of the problems at their inception, is effective in rectifying the problem, and can enable an organization to improve on the implementation of solutions that are already available. Observability makes the inferences in the field of DevOps less rigorous concerning the monitoring operations

[10, 11]. Whereas this is about tracking the occurrence of certain issues that need management intervention, observability is a method used to examine and understand the issues as well as the patterns that lead to these specific issues. In other words, applying the concept of observability within DevOps enhances the ability of teams to understand the system's performance status, challenges and, if there are any pacemakers, identify the problems and optimize the system.

As presented in Fig. 1, collaboration between development and operations teams is only one aspect of DevOps. It goes beyond just methods and equipment. DevOps is a way of thinking and a cultural change where teams take on new methods of operation. By extension, observability is all-encompassing and signifies considerably more than simple monitoring. Of note, the overlying concept of observability is sometimes mistaken for the actual data and metrics collected from monitoring processes; nonetheless, there exist other approaches to articulate, correlate, and analyze the gathered data. Observability is an extension of the monitoring information combined with distributed traces, profiling and similar current practices to provide first overall visibility of the external and internal behaviour of the system.

C. A Model for Integrating Observability with DevOps

When implemented side by side with DevOps, the use and adoption of specific observability practices become essential for companies in the financial services sector to deploy solid, efficient, and fully compliant systems [12]. Therefore, this integration has to be carried out systematically in a way that accounts for the demands and issues of this industry.

1) Define observability requirements: When integrating observability with DevOps in the financial sector to ensure software development and operational resilience, the first step is to define the scope of the observability that is going to be utilized in measuring and revealing the state of the financial services applications and systems [13]. This should be done in line with the organization's regulatory compliance requirements, critical performance issues, leverage target and overall workflow objectives as encapsulated by the organization's critical activities. For instance, in a trading platform used by a large investment bank, observability requirements might include:

a) Measures concerning the time taken to execute trades, size of order books, latency of the market data feed, and degrees of usage of system resources. They are so useful when it comes to achieving the best in trading and to also pinpoint if there is an issue with capacity within a trading business.

b) Logs capturing user transactional data, trade data, risk management data, and system data audits. These logs are helpful for compliance with the different rules and regulations belonging to different authorities, like Securities and Exchange Commission (SEC) and the Financial Industry Regulatory Authority (FINRA), which have standard rules for record keeping and audit trails [15].

c) Open telemetry for reconstruction of intricate trade execution dependencies in multiple microservices like order routing, risk management and settlement services [14]. These traces furnish full-fledged information regarding trade lifecycles, indicating potential problems or failures in the distributed system quickly.

d) Therefore, by clearly specifying observability needs related to the nature of financial services applications, organizations can learn how to make the right calls when it comes to the points of observation and the data to be collected in order to remain operationally resilient.

Selecting the Right Observability Tools

Since applications and infrastructure in the financial services segment are intricate, and lots of data are produced in the observability framework, a tool alone is inadequate. Rather, organizations should use a set of observability tools [2], wherein the tools that different organizations will use are dependent on the type of need they have.

These tools may include:

a) Log management solutions: Tools like Logstash or Elasticsearch or cloud solutions like AWS Cloud Watch logs or Splunk can help in pulling petabytes of log data from different sources [16].

b) Distributed tracing tools: Jaeger, Zipkin or similar or AWS X-Ray, can aid in distributed tracing, which provides insight on how the requests go through the MS and where the slow or failed requests are likely to come from.

c) Application Performance Monitoring (APM) solutions: APM tools, such as 'AppDynamics', 'Dynatrace', or 'New Relic' that work at the application work level and the code level can monitor metrics, behavior and traces of an application to help in the identification of performance issues easily [17].

d) Infrastructure monitoring tools: Some of them are Prometheus, Datadog, or Azure Monitor, where metrics and logs of subtier components of the technology stack, mostly servers, databases, and networks, are collected for top-down system level observability.

The choice of observability tools can also be narrowed by certain potentially valuable characteristics, such as the products' ability to integrate with other systems and their compliance with standard protocols of industries the business is active in, as well as the question of whether the products are scalable, such as the incorporation of the Financial Information eXchange (FIX) protocol, data visualization tools, analytics, security, and data privacy compliance.

2) Integrate with DevOps toolchain: Like with any other tool that generates data, to get the most value from observability data, it needs to fit seamlessly into the current DevOps toolchain. This makes it possible that observability data follow the program from the time it is coded, tested and deployed to when it is run in a production environment. For example, observability tools can be integrated with:

a) Continuous Integration/Continuous Deployment (CI/CD) Platforms: It is further ideal for developers to incorporate observability along with CI CD tools like Jenkins, GitLab, and Azure Pipelines to collect and visualize observability data for build-test-deploy phase to be able to determine where the problems lie closely and fix them with speed [18].

b) Issue tracking systems: Links with other tools like Jira, Azure DevOps Boards, or GitHub Issues make it possible and easy to build or monitor issues directly according to the observability data insights and ensure that the operations and development teams are in sync [2019].

c) Collaboration tools: Real-time notifications and alerts are enabled by the integration of observability data with collaboration platforms like Slack, Microsoft Teams, or PagerDuty. This expedites the process of responding to and resolving incidents.

It is crucial to note that financial services organizations should adopt observability as a DevOps practice to address the issues of the separated development and operations teams. This will inform all team members about the system's behavior so that they can collectively work on bringing about changes and improvements.

3) Establish alerting and notification strategies: Observability data is of most use when it identifies and triggers the resolution of potential problems before they manifest themselves in their negative effects on customers or the business at large. Thus, depending on the observability data, financial services organizations should set the alerting thresholds and notification processes firmly. An alerting strategy for a trading platform, for example, might involve:

a) Applying time thresholds for the execution of trades with the help of historical data and the requirements of the company. When the execution time of the trades is beyond these thresholds, the alarms can be raised with the relevant groups to perform analysis and deal with relevant issues, if any.

b) Setting up alerts regarding the latency of the market data feed because possible delays in this type of data may put traders in a compromising position when it comes to making decisions on the stock to buy and sell, or in case they need to avoid certain securities, thus leading to incurring a loss.

c) Setting up alarms for security activities, for instance, extraneous access attempts or suspicious user activity using logs [20]. These alerts can be forwarded to the security group for further examination and action to be taken.

d) Designation of the notification channels and procedures depends on the categorization of the problem and its possible consequences. Some critical alerts can notify the on-call engineers, while others might go to the monitoring dashboards or ticketing systems. Alerting/notification can effectively solve the problem before it arises, reducing losses, business downtime, and damage to reputation.

4) Promote continuous improvement: As with most organizational practices, the use of observability within DevOps is a continuous process, thus requires constant fine-tuning based on feedback coming from development, operations, and clients. While implementing financial services systems, new regulatory requirements or business needs may arise, and as a result of these changes, observability must catch up to the changes so that the collected data is useful.

To promote continuous improvement, financial services organizations should:

a) Ensure the interactions so critical for development, operations, and business teams are effectively communicated and executed. Forums or assemblies, whether global or per-functionality, can be crucial to receiving opinions about the data obtained through observability, as well as precisely observing where refinement might be needed or where observability adheres to business change [21].

b) Regularly update the decision-makers on changes in the observability need, data feeds, and alert generation techniques. New services or features that are rolled out should prompt changes to the observability practices to incorporate the data that is needed as well as proper alert generation.

c) Support exchange of information and knowledge about the observability tools and practices, as well as training on the tools. There is no one-size-fits-all fix for healthy culture, and it could require constant reinforcement, but providing regular training and documentation could be beneficial to continuously remind teams to be good at using the observability data and tools.

d) Taking that into consideration, the analysis provide insights on how to make use of the observability data and apply them to enhance processes and make optimizations. For instance, defining frequent performance issues or failure trends increases the chances of rectifying, redesigning or optimizing the application. Focusing on the improvement of the observability data as the feedback loop enables financial services organizations to sustain operational resilience and optimize system performance while aligning with ever-changing regulations and business requirements.

Fig. 2. Integrating observability into financial services DevOps.

Fig. 2 represents the process of integrating observability into financial services DevOps. From the image, the steps are as follows;

1) Defining what needs monitoring (e.g., trade execution time) based on regulations and business goals.

2) Choosing the right tools (e.g., log management) to collect that data.

3) Integrating those tools with your existing DevOps tools (e.g., CI/CD pipeline).

4) Setting up alerts to notify personnel of issues based on the data.

5) Continuously improving by sharing information, updating decision-makers, and analyzing data to optimize systems.

III. Results

There are certain observability needs that are unique to the financial services business, having to do with regulatory compliance, data business critical performance, and overall business workflow. For example, in a trading platform, the observability requirements may be defined as the trade execution time, the order book size, the market data feed latency, computing resource consumption, users' transactional logs, trading logs, risk management logs, audit logs, and the open telemetry for reconstruction of the trade execution dependencies between microservices. With these parameters specified, organizations guard themselves against data inflation, while focusing on the right observability needs and, consequently, the right signals to observe and gather for workloads to be resilient. The financial services industry is made up of a number of applications and complex structures, hence requiring a combination of observability tools. All the organizations must have an assemblage of solutions with versatility that falls under the category of observability solutions and they include log management solutions, for example, popular logging tools (including Jaeger, Zipkin, and AWS X-Ray), Application Performance Monitoring (APM) solutions (e.g., AppDynamics, Dynatrace, and New Relic), and infrastructure monitoring tools [22]. Well-known APMs that can be used for similar purposes include, Prometheus, Datadog, and Azure Monitor. According to the characteristics, the choice of tools should be based on the integration of the instruments, and conformity to the norms of a certain industry. E.g. FIX (Financial Information eXchange Protocol), big data, business intelligence tools, visualization, security and information security compliance [23, 24]. In addition to that, the observability data has to blend with the readily-available DevOps toolset. This is an extension of the observation process involving the integration of observability tools in CI/CD platforms (e.g., Jenkins, GitLab, and Azure Pipelines); bug tracking systems include integrated project management tools (Jira, Azure DevOps Boards, GitHub Issues), and collaboration tools such as Slack and Microsoft Teams, PagerDuty, Unito, and Airtable. By ensuring observability throughout the application development process, from coding through testing and deployment and into production, organizations can quickly remediate problems, which enhances the relationship between development and operations [21].

Also, operational data is most useful when the captured data points indicate and prompt action for likely issues before they are realized to affect the customers or the business. Based on the observability data from the financial services organization, alerting thresholds and notifications should be set up. For instance, on a trading platform, it is possible to set alerts relating to trade execution times that do not exceed a certain time limit, real time data feed and security events such as attempts at unauthorized access or any abnormal activity of a particular user. The notification channels and procedures should be decided based on the problem type and severity and the consequences of the problem, and to make sure important notifications get to the on-call engineer, while less important ones go to a monitor dashboard or to a ticketing system. Integrateing observability with DevOps is an endless process, that depends on the feedback of development, operations and clients [25]. The financial services organizations should encourage transparency between the various working teams, implement periodic reporting of the evolution of the observability needs, the data feeds, and the alert generation approaches and encourage knowledge sharing and training on observability tools and practices among the teams. Also, by enhancing the observability practice and using observability data to improve the lasting operative stability and system efficiency conforming to the new regulations as well as client's demands, organizations can maintain the operative resilience.

With these results, organizations and their financial services can adopt and include observability while improving the company's DevOps that can be utilized in software development and having a strong operational system as well. Such an approach allows for avoiding non-compliance with the regulation, improving the solution's performance, and strengthening collaboration between developers and ops, which results in more robust financial services technology solutions.

IV. Discussion

A. Benefits of Integrating Observability with DevOps

1) Faster incident detection and resolution: Typically, metrics and trends are not only provided to specific thresholds but also to preconfigured alarm systems, which may appear insufficient when it comes to large- scale distributed systems. While compared to observability, metrics provide a direct window into the system and are easier to understand, observability unifies metrics, log data and distributed tracing [26]. This broad plan and action help to focus on problem search and diagnosis and, therefore, accelerate the resolution of such problems. For instance, think of the case of an organization that is in the financial sector, and has a trading floor where its personnel trade securities. The problem with traditional monitoring is that it does not allow the identification of the source of the problem, which can be in any component or dependency. On the other hand, by using observability data, including distributed tracing, the developers and operation teams will easily point to the particular service or component that is most likely to be the cause of the bottleneck so that adequate measures can be employed to rectify the situation. The benefit of faster incident resolution is that it could lead to fewer impacts on business and, thereby, a lesser amount of revenue lost. Time is a key factor in the financial services industry, so the capability to address issues sustainably can serve as a major advantage in retaining customers' trust and be less of a disadvantage in terms of revenues lost.

2) Improved software quality: Observability helps to continuously monitor the system after, during, and before the code is deployed in various steps such as development, testing, and production. The observability data can be gathered and analyzed during the development and testing of the software so that issues such as bugs, potential performance problems and bottlenecks may be ironed out prior to the software being rolled out to production. Such measures can be applied to ensure that financial software offered to the public [19] will provide the best quality, security and firmness since financial data is sensitive. Thus, the financial institutions can reduce the potential for costly shocks, decrease the time that the systems are out of order, and satisfy the customer by releasing higher quality software.

3) Enhanced regulatory compliance: This segment involves various rules and regulations covering the field, like companies, the Securities and Exchange Commission (SEC), the Financial Industry Regulatory Authority (FINRA), and the Basel Committee on Banking Supervision [27]. Aiding to these regulations attracts severe penal consequences in terms of fines, legal procedures, and reputation. Observability data becomes extremely valuable in meeting auditing and reporting criteria. For instance, the regulation from the US Securities and Exchange Commission known as Regulation Systems Compliance and Integrity (Reg SCI) demands that financial institutions have strict measures for the operational continuity of their systems. Observability data could allow an organization to meet the elements of Reg SCI regarding risk management, incident reporting, and systemic testing of the systems.

4) Streamlined collaboration: Observability is beneficial to DevOps teams as it helps them to discuss and work with a mutual understanding of application behavior. When decision makers from different parts of the organization are presented with the same observability data, they are in a position to solve observed problems more efficiently, find the causative factors to problems more efficiently, and come up with solutions to the observed issues more efficiently. This integrated approach also minimizes mysteries and fosters DevOps, the practice that aims at everyone's responsibility in creating quality software and high-performing systems. Development and operations are two sides of one coin and, when combined in the most efficient manner, are capable of increasing the rate of solving incidents, making changes more smoothly, and providing a higher value to customers.

B. Challenges and Considerations

1) Security concerns: Financial services include the operation of customers' information, such as their identity details and financial status. Therefore, handling observability data has to be done with a lot of caution in regards to their storage, collection, and access [28]. Observability's implementations within financial services must ensure that data in transit and at rest is encrypted, that effective and proper access control grant mechanisms are in place, and that data is anonymized. In the same respect, there should be security audits at least once a year, along with security assessments for potential risks.

2) Data overload: There are three things that an observability system produces, and they are events or logs, performance metrics, and distributed traces [29]. However, failing to screen and rank such huge information streams appropriately can become a problem since useful and relevant information may be lost in the flow of large amounts of information, and potential inefficiencies and even issues can be left unnoticed. In order to meet this challenge, it is necessary for financial institutions to consider applying approaches to the selection and organization of key observability data. It is possible to use approaches like the logs' correlation, anomalies, and metrics' grouping to pay only attention to significant data.

3) Cultural shift: It is common that the implementation of observability is aligned with DevOps methodology, and this change usually takes some time at the organizational level. The current approach of reacting to issues as they arise has to be replaced by continuous monitoring, which is supported by observability. Really encouraging the reactivity of the observability into teams, DevOps means raising awareness among every member of the team of the added values of the observability, the professional development of the tools of the observability, and the constant evolution of the mindset of the observability [30]. All in all, this became a generational shift, which can be seen as both a weakness and a strength when seeking to utilize all the potential of observability in financial services technologies.

V. Future Trends in Observability

1) Artificial Intelligence (AI) and Machine Learning (ML): Observability and AI and machine learning—what may have been the case even a year ago has since changed drastically. AI/ML tools can be applied to different processes dealing with observability, from the root cause analysis of problems to the prediction of equipment failures and incident solving. For instance, supervised machine learning can be used on recorded observability to predict likely problems that may occur in the future in order to prevent worst-case scenarios. These models can also suggest the possible measures that should be taken to correct the problem and thus facilitate the solving of the incident. Besides, using the observability data, AI/ML can be used to predict hardware or software failures and prevent them from occurring, thus reducing system downtime.

2) Security considerations for observability in financial services: As observability practice deployment comes into light in the financial services industry, organizations must guarantee the security measures of acquired observability data [29]. The openness of financial data, coupled with the nature of observability, which offers a great deal of information in comparison to traditional approaches, requires a global approach to security. Security features are also important, with attention paid to the encryption of data both in transit and at rest in order for observability to be implemented. Financial institutions should also ensure the observability of data privacy through encryption via standard security protocols. Another key component is access control systems, which must restrict the availability of observability data to employees who need it for their work. Implementing RBAC and multi-factor authentication can avoid or minimize the chances of an incident such as firewall intrusion or leakage of employees' databases.

3) Data minimization is another factor whereby it is required that financial institutions only acquire and retain the observability data that is relevant for the use cases of that institution. This eradicates the chance of data leakage and helps in adherence to the set information technology data privacy provisions. This operational reality suggests that there should be frequent systematic security reviews and reporting to determine and fix any existing gaps in the use and deployment of observability in organizations. It is important that such audits encompass all the data collection processes, storage procedures, ways of accessing and analyses of the observability infrastructure.

VI. Conclusion

Applying observability in synergy with DevOps methodologies for financial services technologies leads to multiple advantages, including swift identification of issues and their resolution, improved applications' quality, compliance with regulations, and improved cooperation between the development and operational departments. Thus, understanding the specifics of their software systems' behavior enables financial institutions to prevent certain problems, reduce service interruptions, or provide a high-quality customer experience. Observability transforms monitoring into a proactive process that continues throughout the organization's operations, allowing organizations to be prepared for various problems and maintain operational readiness. However, the process of attesting observability with DevOps practices in the financial service domain also comes with challenges such as; security compliance issues and data overload problems that arise from a paradigm shift in the organisational culture. To manage these challenges, there is a need to adopt a multifaceted approach that embraces proper security measures, an efficient manner of handling data, and a culture of consistent learning and development. With the advancements in AI and ML in place, observability automation has the potential to be used for functions as simple as root cause analysis, predictive upkeep/repair, and incident diagnosis, among others. These technologies can complement the benefit that observability data brings to financial institutions in the sense that it can provide deeper and more proactive optimization of their operations. Comprehending the requirements for constructing and managing sound, resilient and secure financial services technologies in the era of rapid innovation, observability is an indispensable player. Hence, when financial institutions adopt observability and bring it together with DevOps, they will be able to contest and meet the regulatory requirements while at the same time offering commendable customer service and thus be a forerunner in the market.

Enhancing Administrative Source Registers for the Development of a Robust Large Language Model: A Novel Methodological Approach

Adham Kahlawi, Cristina Martelli
Department of Statistics, Computer Science, Applications, University of Florence, Florence, Italy

***Abstract*—Accurate statistical information is critical for understanding, describing, and managing socio-economic systems. While data availability has increased, often it does not meet the quality requirements for effective governance. Administrative registers are crucial for statistical information production, but their potential is hampered by quality issues stemming from administrative inconsistencies. This paper explores the integration of semantic technologies, including ontologies and knowledge graphs, with administrative databases to improve data quality. We discuss the development of large language models (LLMs) that enable a robust, queryable framework, facilitating the integration of disparate data sources. This approach ensures high-quality administrative data, essential for statistical reuse and the development of comprehensive, dynamic knowledge graphs and LLMs tailored for administrative applications.**

Keywords—Statistical information systems; administrative data reuse; ontology; database; semantic web; knowledge graph; LLM

I. Introduction

In the face of the increasing complexity of modern societies, innovative governance and decision-making approaches are essential to navigate the evolving socio-economic and political landscapes [1]. Recent shifts towards the autonomy of local actors, the creation of new institutional arenas, global economic repositioning, decentralization, and a transition to network societies have underscored the importance of network structures over hierarchical ones, creating a demand for knowledge bases capable of understanding and managing these complexities [2]. Administrative data, defined comprehensively by Eurostat as data collected for non-statistical programs by both governmental and private organizations, have emerged as a focal point. The strategic use of this data can generate administrative and statistical information, which serves as both a tool for harmonizing administrative processes and decision-making, and a means of communication within and outside organizations [3].

The essence of governing complex socio-economic environments lies in the profound understanding of their actors, relationships, and processes, necessitating systems that are deeply rooted in reality and supported by active observation [4]. The Organization for Economic Cooperation and Development highlights the role of administrative data as a reliable source for statistical information, emphasizing the importance of their collection, processing, and storage. Technological advancements have enhanced data production processes, presenting new opportunities and challenges in data utilization, transparency, and integration [5].

Typically, the details about the administrative sources are dispersed across various isolated databases created by different departments and divisions. This fragmentation prevents Public Administrations from offering a thorough understanding of their key entities and their interactions. Lately, knowledge graphs have emerged as a solution to organize vast data sets effectively, but they primarily depict a fixed snapshot of the world. They often overlook the dynamic aspects and the evolution over time [6].

This paper suggests an approach grounded in semantic web technology to develop administrative systems, designed to be statistically reusable and ready to be represented as a graph structure. This aims to create administrative sources suitable for querying Linked Data Models (LLMs), capable of bridging the gap between administrative and statistical information and ready to be integrated with various sources. This effort addresses the challenges of generating big data and reusing statistical data.

This approach recognizes the inherent limitations of current big data management practices, such as issues of data quality, coverage, and cost, and seeks to overcome these by leveraging administrative data as a mean to describe the granularity, complexity and interconnectivity of reality. By focusing on the early stages of the data production process and employing new technologies for data integration and modeling [7, 8], this study aims to ensure that administrative data are not only valuable in their own right but also fit for statistical reuse and capable of representing the socio-economic complexity of our world.

Finally, we can summarize the core of this paper in four points:

- Problem Statement and Questions:

Administrative data, collected by both governmental and private organizations, have emerged as crucial but are often marred by inconsistencies and low quality, impeding their full utilization for governance and decision-making. How can we improve the quality and integration of administrative data to better support complex governance needs?

- Objectives:

This study aims to explore the potential of semantic technologies in enhancing the quality and utility of administrative data. By integrating these technologies with administrative databases, we seek to develop a robust method for producing high-quality administrative data that is statistically reusable and supports complex decision-making processes.

- Significance:

The strategic use of improved administrative data could revolutionize decision-making processes, providing a more coherent and dynamic understanding of socio-economic environments. This could lead to more informed policies and efficient governance systems.

- Presentation of the Study:

In this paper, we propose a novel methodological approach using semantic web technologies to address the challenges associated with administrative data. Our approach not only enhances data quality but also facilitates the integration of diverse data sources, laying a foundational structure for creating LLM capable of bridging the gap between administrative records and statistical information needs.

The structure of this paper is as follows: Section II presents a review of the literature relevant to our study; Section III outlines the methodology we adopted; Section IV discusses the application of this methodology and the results obtained; and Section V concludes the paper with a summary of our findings and suggestions for future research.

II. Related Works

In the realm of enhancing data quality and interlinking public datasets with knowledge graphs (KGs), notable contributions have emerged, offering innovative approaches and methodologies. Among these, the work presented in study [9] by Haklae Kim stands out by addressing the challenges of utilizing government codes within public datasets. The paper highlights how government codes, crucial for standardizing administrative procedures, often become obscured when included in public data, thereby limiting their utility and impeding dataset interlinking. Kim proposes employing the administrative codes generated by the Korean government as a standard in public data environments, leveraging an ontology model to encapsulate the data structure and meaning of administrative codes. This approach, through the construction of a comprehensive knowledge graph, seeks to enhance the quality and connectivity of coded information in public datasets, thus facilitating standardized access to administrative codes beyond government systems.

Similarly, [10] by Dimitris Zeginis and Konstantinos Tarabanis introduces an event-centric knowledge graph (ECKG) model to improve data governance and analysis within public administrations (PAs). Recognizing the vast amounts of data generated by PAs and their often fragmented nature across different databases, Zeginis and Tarabanis pinpoint a gap in existing KG models that tend to represent static data, neglecting the dynamic nature of data interactions. By prioritizing events as primary entities for knowledge representation, their model aims to capture the dynamic aspects of public service interactions, offering a more comprehensive overview of interactions between core entities like citizens, businesses, and PAs themselves. This method not only facilitates citizen-friendly public administration but also enables advanced data analytics and AI applications by integrating data both in representation and in context. Expanding on this concept, [6] by the same authors applies the ECKG model to the Greek PA, demonstrating its potential to provide a comprehensive view of public administrations (PA) interactions, support data analytics, and aid in real-time decision-making. This model uses Core Public Service Vocabulary Application Profile (CPSV-AP) to describe public services, distinguishing between event-aware and event-agnostic concepts, thereby efficiently managing public service versions and variants. A case study on the " birth registration " life event in Greece showcases how the ECKG model can capture PA interactions' complexity, enhancing data integration, analytics, and providing a 360-degree view of end-users.

In the healthcare domain, [11] by Arif Khan, Shahadat Uddin, and Uma Srinivasan utilizes administrative health data to predict the risk of Type 2 Diabetes (T2D). Applying data mining and network analysis techniques on a dataset comprising 1.4 million records from 0.75 million patients, the study develops a prediction framework that enhances prediction accuracy through innovative graph theory and social network-based measures. This approach offers a cost-effective method for healthcare providers and insurers to identify high-risk cohorts for preventive strategies, aiming to mitigate the burden of chronic diseases on healthcare resources.

In the data integration domain, [12] by Enayat Rajabi, Rishi Midha, and Jairo Francisco de Souza address the challenge of integrating disparate datasets within open government data portals. Through the use of Semantic Web technologies and the transformation of datasets into the Resource Description Framework (RDF) format, the authors illustrate the benefits of applying Semantic Web standards to government datasets, enabling sophisticated querying capabilities. Also, in study [13] by Luis M. Vilches-Blázquez and Jhonny Saavedra introduce a pioneering approach for the integration and management of heterogeneous land administration data through graph-based knowledge representation. The study acknowledges the considerable challenges arising from the variety of data formats, models, and standards spread across different Colombian land administration agencies. To address these challenges, the authors propose an ontology-based framework that aligns with both national and international standards for land administration. This innovative framework is designed to promote the harmonization, interoperability, sharing, and integration of data across decentralized and multi-jurisdictional agencies without necessitating modifications to their existing processes, models, or vocabularies. Employing a methodology that constructs knowledge graphs based on ontology, the framework connects various datasets through a unified identifier for land administration features and enriches these graphs with spatial connections and data sourced from the Linked Open Data cloud. Through a case study focusing on the integration of data from the Colombian National Geographic Institute (IGAC) and the Bogota cadastre, the paper effectively demonstrates how knowledge graphs can address semantic heterogeneity and enhance the management and utilization of data in land administration.

Some studies have explored the relationship between Knowledge Graph and Large Language Models such as: [14] by Qing Huang et al. explores enhancing API recommendation systems by integrating Large Language Models (LLMs) guided by a Knowledge Graph (KG). This study tackles the challenges of utilizing government codes within public datasets by proposing the use of administrative codes as a standard in public data environments. By employing an ontology model to represent the data structure and meaning of these codes, the research assesses the accuracy and connectivity of administrative codes in public data, showing potential for enhancing the quality and connectivity of coded information in public datasets. Also, [15] by Shuang Yu, Tao Huang, Mingyi Liu, and Zhongjie Wang introduces BEAR, a service domain KG constructed to address the lack of large-scale, high-quality KGs in the service computing community. Utilizing LLMs for zero-shot knowledge extraction and guided by a well-designed service domain ontology, BEAR demonstrates significant advancements in domain-specific KG construction methodologies, containing over 130,000 entities, 160,000 relations, and approximately 424,000 factual knowledge attributes. This construction process leverages the semantic understanding and reasoning capabilities of LLMs to overcome challenges related to data scarcity and complexity, highlighting the potential to drive application and algorithm innovation within the service computing field. Additionally, [16] by Linyao Yang et al. explores the enhancement of large language models (LLMs) with knowledge graphs (KGs) to improve factual accuracy in text generation. Categorizing methods into before-training, during-training, and post-training enhancements, the paper advocates for the combination of KGs and LLMs to address factual reasoning limitations, suggesting new research avenues. Furthermore, [17] by Shirui Pan et al. offers a comprehensive framework for the integration of large language models (LLMs) like GPT-4 with knowledge graphs (KGs), aiming to augment the capabilities of both technologies and mitigate their individual limitations. The roadmap presented in the paper is organized around three core frameworks: KG-enhanced LLMs, LLM-augmented KGs, and a synergized integration of LLMs and KGs. The first framework, KG-enhanced LLMs, is focused on embedding KGs into the training and inference phases of LLMs to supply external knowledge, thereby improving inference and enhancing interpretability. The second framework, LLM-augmented KGs, leverages the computational power of LLMs to address challenges in KG tasks, including embedding, completion, construction, and question answering, which are often hindered by incompleteness and the difficulty of incorporating new knowledge. Lastly, the synergized framework proposes a bidirectional enhancement strategy, whereby LLMs and KGs mutually benefit from each other, thus fostering advanced knowledge representation and reasoning capabilities. This roadmap meticulously categorizes research efforts within these frameworks, explores emerging advancements, and outlines the challenges and future directions, underscoring the significant potential of merging LLMs' proficiency in language processing with the structured knowledge representation of KGs for a variety of applications. Lastly, [18] by Amir Hassan Shariatmadari et al., and "Unifying Large Language Models and Knowledge Graphs: A Roadmap" by Shirui Pan et al. both emphasize the synergy between LLMs and KGs. The former investigates the use of Cross-Modal Attention mechanisms to improve LLM explainability in the biomedical domain, while the latter presents a roadmap for integrating LLMs and KGs to enhance their collective capabilities, identifying challenges and future directions in knowledge representation and reasoning across various applications. These studies collectively highlight the evolving landscape of knowledge representation, emphasizing the significant potential of integrating diverse methodologies to address complex challenges in data analysis, management, and utilization.

III. Methodology

Fig. 1 depicts the methodology, structured into four steps (represented by the horizontal segments with arrows and identified by their respective numbers). Each step unfolds through one or more activities.

A. Domain Analysis

The figure depicts a scenario where administrative data is stored in multiple administrative databases. The first activity (identified by segment -1-) will therefore involve extracting the structure of the databases by analyzing the tables, their relationships, along with the names of all the columns within the tables.

In the second activity (segment -2-) we examine all the columns in the databases and sort them into three groups. The first group consists of columns that can be assigned or derived from a classification. The second group contains columns in which the information can be standardized into fixed options. Lastly, the third group comprises all columns that do not fall into either of the previous two groups.

B. Create the Domain Ontology

The creation of the ontology for the domain served by the considered administrative sources begins by representing in terms of ontologies the concepts represented in the columns of the analyzed databases.

In the third activity (segment -3-), we begin by creating an ontology for each classification that represents one of the columns within the standard classification group. Next, we create an ontology for each standard concept which is identified through the columns in the standard concept group.

After having translated the columns of the databases into ontological terms, the next step involves constructing the overall ontology of the domain.

Moving on to the fourth activity (segment -4-) we start by building an ontology of the administrative resource from the database schema. This is done by following four rules:

1) Create a class for each table in the database, unless the table contains only foreign keys.

2) Create an object property to connect two classes that are related through their tables.

3) Create an object property for each column belonging to the first and second group, to connect its table's class with the ontology created from it.

4) Create a data property for each table's column that belongs to the third group.

Fig. 1. Methodology of proposed model.

C. Generate the New Database

In the fifth activity (segment -5-), we will generate a new database by utilizing the ontology created in the fourth activity. In this process, each class in the ontology will be transformed into a table in the database. Similarly, each data property will be turned into a column in the table, and each object property will establish a relationship between the tables.

However, it's important to keep in mind that the conversion process from an ontology to a database requires several controls to ensure its accuracy and efficacy. The following rules apply while converting an ontology into a table:

1) The classes that have an available number of individuals will be converted to a table; in contrast, if these classes were part of a hierarchical classification, their individuals would be fused together and placed in a table that takes the higher class's name in this classification;

2) All the classes with a limited number of individuals will be converted to a column in the table that was the domain class for the object property that was the range class for it;

3) All the data properties will be converted to a column in the table that was the domain class for it; and

4) The object properties can be converted in three ways depending on the restriction type used in the ontology. In the first type, restrictions are placed between the two classes on a one-to-one basis. In the second type, restrictions are placed on a one-to-many basis. In the third way, the two classes are related on a many-to-many basis; in this case, a new table will be created with two columns, one with the primary key of the domain class table and the second with the primary key of the range class table. The relationship between these three methods can be described as domain-to-now table, one-to-many table same as for now able-to-range table.

The new database and ontology will be fully compatible with each other to operate together, and this compatibility will be ensured once the new system is in use.

The sixth activity of the system allows the data received from the users to be inserted into the database and the triple store simultaneously, without needing any input from the user.

This is an important step to document, through the semantic web, any innovative administrative archives best practice, while also dynamically updating the domain ontology in response to field developments.

The first way involves inserting the data into the database, which will be used to manage the administrative source and meet its needs. The second way involves inserting the data into a triple store, which is the physical location where the data is stored. The data stored in the triple store is machine-readable and machine-understandable, as it is written in the Resource Description Framework language. This language represents any resource with a unique Uniform Resource Identifier (URI), even if that resource is found in different domains. The triple store has a simple structure, like a text file, which means that adding new data to it does not require any pre-processing and can be combined with previous data by the computer without human intervention, using URIs. This triple store will be used in the next activity to integrate data from various administrative sources.

D. Generate the National Ontology and the National Triple Store

In the process of creating a national database from different administrative sources, the seventh activity involves merging the ontologies of these sources. This step is made possible by the presence of shared classes that represent standard classifications and concepts developed in the second step. The merging process is automated. The eighth activity involves building a national triple store by collecting data from different administrative sources. This data will be used for statistical studies to support decision-makers at local and national levels.

IV. Methodology Application and Result

During the construction of the Italian high-speed trains, a methodology was developed to integrate different and diverse data sources, derived from partial and not harmonized administrative views of the problematic area. The purpose of this study was twofold. Firstly, it aimed to set up a methodology to integrate different administrative information systems that were already on the site, yet were heterogeneous and not integrable. Secondly, it aimed to build an asset for automatically generating an administrative database that is statistically reusable by design.

The first objective is derived from the experience of constructing the knowledge base for the Italian high-speed trains construction sites. The administrative information systems were already on site, but they were not integrable. Therefore, the methodology to integrate these data sources had to be developed. The second objective is to propose a similar information system to different construction sites, so that management processes can be carried out effectively and the produced data can be immediately reusable without the efforts paid in the first experience.

Both of these objectives rely on a construction site ontology, which is the starting point for generating the administrative database. In the first case, the construction site ontology is derived from the already existing and not integrable databases. In the second case, the ontology is used to generate the administrative database.

In this study, we will clarify the process of applying the methodology to one of the database tables, and in the appendix 1 we will explain the results of the conversion process for the entire database.

We analyzed Table I and found columns for standard classifications and concepts.

Consequently, as we mention in the second step of the methodology, we will create sub-ontologies for all standard classification and concept categories. Fig. 2 illustrates the ontology of the Nomenclature of Economic Activities NACE.

TABLE I. The Analysis of the Firm's Table

Fig. 2. Ontology of economic activities NACE.

In the third step of creating the case study, we develop an ontology based on the database structure and the ontologies created in the previous step. Fig. 3 illustrates how the firm's table was transformed into four primary classes. Each of these classes contains subsets. For instance, the Italian Address class comprises four subclasses representing the structure of any address, including street name and building number. During this transformation, we considered data property, and economic activities contain hierarchical subclasses defined by 109 subclasses.

The individuals of the four classes will have different object properties governing their relationships. However, the relationship between the "firm" and "Italian Address" will be governed by the individuals of the subclass "postal code". This is because the relationship between the individuals of the "Italian Address" subclasses is fixed and was defined at the time of the creation of the ontology.

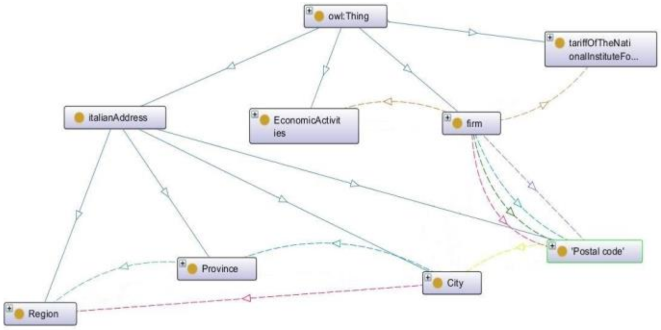

Fig. 3. Ontological representation of firms' table.

The Appendix 2 displays the ontological structure that depicts the ontology of the case study.

This ontology defines and specifies every concept used in the original database, supports creation of a harmonised language among different construction sites, and can be translated into a coherent relational database.

We will proceed to create a new database from the ontology constructed in the second step, taking into account all the rules established in the methodology. The Appendix 3 presents the structure of the database obtained directly from the ontology. Comparing it with the original database, we can see that it has a similar structure, but it is more efficient since it has undergone a rigorous process of creating classes and properties. As a result, proactive service is provided to the institution whose data is reused in an information system to support decision-making. Instead of burdening them with coding, we provide them with the structure to be used directly.

When the new database is used to manage the domain, it will effectively organize and manage its data, as well as generate a triple store. After that, the integrated ontology and the integrated triple store will be created automatically, taking advantage of what was built in the previous steps. The integrated ontology is an ontology that is created by integrating a group of ontologies that represent different domains. The connection between these ontologies is made through the sub-ontologies established in the first step. The integrated triple store is the triple store that is created by integrating a group of triple stores, which are developed by applying the previous steps to different domains.

All in all, the prior related works provided only partial solutions and did not address issues at a holistic level, unlike the methodology implemented in this research, which aims to offer a comprehensive solution. Additionally, this work focuses on improving the existing data collection system to enhance the management of administrative resources. It also involves developing a parallel system that ensures the integration of data from various administrative sources in a cohesive manner and guarantees the effective reusability of the data.

V. Conclusion

The emergence of new semantic technologies presents a challenge, an opportunity, and a risk to official statistics. On one hand, these technologies offer unprecedented processing power to manage quantitative information; on the other hand, there is a risk of generating information systems that fall short of the quality standards necessary for statistical analysis.

In this study, we explore the statistical reuse of administrative sources in light of the potential for conscious integration with semantic technology. By rethinking the reuse of administrative data, we can contain the key waste of public memory that arises from the difficulty of integrating sources. We need information systems that are suitable for managing problems and services, but also support the reuse of their data.

While big data methodologies exist and are increasingly popular, they may not provide the necessary level of detail, quality, and precision required for specific and delicate domains, such as the ones served by PA. Therefore, we focus on using semantic web technologies to support the entire process of generating archives, starting from the moment of their conceptualization.

Our study shows that semantic web technologies can be used to accurately analyze and describe a domain, which can help build a high-quality database. They can also aid in integrating data from different sources without the need for manual intervention, allowing for the reuse of data for statistical and non-statistical purposes simultaneously. The national RDF triple store represents the national administrative knowledge graph that we can use to create or fine-tune the administrative LLM.

Our study also highlights the unprecedented areas of presence for statistical agencies, such as the supervision of language and conceptualizations. Adopting these methods on a broader scale would lead to a different quality of administrative sources. This integration not only supports the broader dissemination of official codifications but also recognizes the methods of experts from different domains, allowing for their integration and official dissemination.

The possibility of connoting each concept with an official identifier stored on the internet, the choice of having these methods adopted by social and economic actors, and the constitution of large texts that can be interpreted automatically shifts the usual horizons of those who deal with statistical information systems. This creates new challenges for the statistical community, such as processes for linkage or testing the conditions of respect for privacy.

In future work, we will seek to create an administrative resource LLM and establish the mechanism for its use and the controls that will govern this use.

Abstract*—Diabetes mellitus stands as a major public health issue that affects millions globally. Among the various complications associated with diabetes, diabetic retinopathy presents a significant concern, affecting approximately one-third of diabetic patients. Early detection of diabetic retinopathy is paramount, as timely treatment can significantly reduce the risk of severe visual impairment. The study employs advanced machine learning techniques to predict diabetes and assess risk levels for retinopathy, aiming to enhance predictive accuracy and risk stratification in clinical settings. This approach contributes to better management and treatment outcomes. A diverse array of machine learning models including Logistic Regression, Random Forest, XGBoost, voting classifiers was used. These models were applied to a meticulously selected dataset, specifically designed to include comprehensive diabetic indicators along with retinopathy outcomes, enabling a detailed comparative analysis. Among the evaluated models, XGBoost demonstrated superior performance in terms of accuracy, sensitivity, and computational efficiency. This model excelled in identifying risk levels among diabetic patients, providing a reliable tool for early detection of potential retinopathy. The findings suggest that the integration of machine learning models, particularly XGBoost, into the healthcare system could significantly enhance early screening and personalized treatment plans for diabetic retinopathy. This advancement holds the potential to improve patient outcomes through timely and accurate risk assessment, paving the way for targeted interventions.

Keywords*—*Machine learning; diabetes prediction; artificial intelligence in healthcare; XGBoost; Random Forest

I. Introduction

A. Diabetes Mellitus

Diabetes mellitus (DM) is a complex metabolic disorder categorized by raised blood glucose levels, resulting from defects in insulin secretion, insulin action, or both. This condition represents a key health concern worldwide, affecting millions of individuals and imposing an extensive economic problem on healthcare systems [1]. The occurrence of diabetes has been progressively rising, fueled by sedentary lifestyles, poor dietary habits, obesity, ethnicity, advancing age and genetic predisposition. Type 1 diabetes mellitus (T1DM) is characterized by autoimmune destruction of pancreatic beta cells, leading to absolute insulin deficiency [2]. T1DM often develops early in life, although it can occur at any age. Individuals with T1DM require lifelong insulin therapy to survive. Type 2 diabetes mellitus (T2DM), the most prevalent form accounting for most cases worldwide, typically arises from a combination of insulin resistance and inadequate insulin secretion [3]. It typically develops in adulthood, although there has been a concerning rise in its occurrence among children and adolescents due to the increasing prevalence of obesity and sedentary lifestyles [4]. In T2DM, the body becomes resistant to the action of insulin, and the pancreas may fail to produce enough insulin to compensate for this resistance. This results in elevated blood glucose levels. While genetic factors play a role in predisposing individuals to T2DM, lifestyle factors such as poor diet, lack of physical activity, and obesity are significant contributors to its development [5]. Gestational diabetes (GDM) occurs during pregnancy and is associated with increased risk of both maternal and fetal complications. GDM poses risks to both the mother and the fetus, including an increased likelihood of complications such as macrosomia (large birth weight), birth trauma, hypoglycemia in the newborn, and an elevated risk of developing type 2 diabetes for both the mother and child later in life [6]. While GDM typically resolves after childbirth, affected women are at an increased risk of developing T2DM in the future.

The economic impact of diabetes spans healthcare costs, productivity losses, and societal implications. Direct healthcare expenditures include medication, hospitalizations, and complications management. Additionally, indirect costs arise from productivity declines due to disability, absenteeism, and premature mortality [7]. The socioeconomic consequences extend to reduced quality of life, disparities in healthcare access, and strained healthcare systems. Addressing this global health challenge requires a multifaceted approach encompassing prevention strategies, early detection, lifestyle modifications, access to healthcare services, and effective management and treatment options.

B. Diabetes and Retinopathy

In addition to its metabolic manifestations, diabetes predisposes individuals to numerous complications, including cardiovascular disease, neuropathy, nephropathy, and retinopathy. Among these, diabetic retinopathy (DR) stands out as a significant cause of preventable blindness, highlighting the importance of understanding its pathogenesis and management. This condition affects the eyes, specifically the retina, the light-sensitive tissue at the back of the eye. It is a microvascular complication of diabetes that affects the retinal vasculature, leading to progressive damage and vision loss [8]. DR, whose incidence is high in the working-age population, prevails all over the world and is estimated to reach 191 million cases by 2030 [9, 10]. The pathogenesis of DR is multifactorial, involving chronic hyperglycemia, oxidative stress, inflammation, and vascular dysfunction [11]. Hyperglycemia-induced metabolic abnormalities contribute to the development of microaneurysms, capillary nonperfusion, and increased vascular permeability, culminating in retinal ischemia and neovascularization. Chronic inflammation further exacerbates vascular damage and promotes the release of angiogenic factors, perpetuating a vicious cycle of retinal injury. It progresses through several stages, starting with non-proliferative diabetic retinopathy (NPDR), where small blood vessels in the retina weaken and leak fluid into the surrounding tissue, causing swelling and leading to blurry vision. As the disease advances, it can enter the proliferative stage, characterized by the growth of abnormal blood vessels on the surface of the retina. These vessels are fragile and prone to bleeding, leading to further vision impairment and, in severe cases, retinal detachment [11]. Additionally, diabetic macular edema (DME) can occur, where fluid accumulates in the macula, the central part of the retina responsible for sharp, central vision, leading to significant vision loss. These changes can impair vision and, if left untreated, result in blindness. Symptoms may not be noticeable in the early stages, but as the condition progresses, individuals may experience blurred vision, floaters, and even complete vision loss. The risk factors for diabetic retinopathy include the duration of diabetes, poorly controlled blood sugar levels, high blood pressure, and high cholesterol [11]. Early detection and timely intervention are crucial for preventing vision loss in DR. Several diagnostic modalities are available for the assessment of DR, including dilated fundus examination, fundus photography, optical coherence tomography (OCT), and fluorescein angiography.

The management of diabetic retinopathy is multifaceted and involves lifestyle modifications, optimizing glycemic control, blood pressure management, and lipid-lowering therapy to reduce systemic risk factors. Patient education and regular ophthalmic screenings are essential components of comprehensive diabetes care to minimize the impact of retinopathy on visual function. Collaborative care between endocrinologists, ophthalmologists, and other healthcare providers is essential to provide comprehensive management and minimize the impact of this potentially sight-threatening complication of diabetes.

C. *Machine Learning Significance*

Machine learning (ML) incorporates a suite of computational techniques that enable systems to learn from and make predictions or decisions based on data. In predictive modeling, ML algorithms use historical data as input to predict new output values [12]. These models iteratively learn from the data, improving their accuracy over time without being explicitly programmed to perform specific tasks. This capability makes ML an invaluable tool across various domains, including finance, marketing, and notably, healthcare.

D. *Predictive Modeling Importance*

In the realm of healthcare, predictive analytics plays a pivotal role, especially in the early detection of diseases and the stratification of patient risk levels. For chronic conditions like diabetes mellitus [13], early prediction and diagnosis can significantly improve patient outcomes and reduce healthcare costs. According to the International Diabetes Federation, approximately 537 million adults (20-79 years) were living with diabetes in 2021, and this number is expected to rise to 643 million by 2030 and 783 million by 2045 [14]. Specifically, in the context of diabetic retinopathy [15], Diabetic retinopathy is a leading cause of blindness in working-age adults, and early detection and management are crucial to prevent vision loss [16]. However, current methods for predicting diabetes and evaluating the risk of retinopathy often rely on traditional statistical models, which may not capture the complex relationships among various risk factors. Machine learning has emerged as a powerful tool in healthcare, offering advanced methods for predicting and diagnosing diseases by analyzing large datasets and identifying patterns that may not be apparent with traditional methods [17]. Machine learning models can analyze complex datasets to predict disease onset and progression, enabling healthcare providers to prioritize patients with a high risk of vision loss for early treatment, thereby optimizing resource allocation and improving patient outcomes [17]. Recent studies highlight the importance and advancements in healthcare predictive models, such as Darmadi *et al.* (2023) [18] who enhanced global health system resilience post-COVID-19 through grounded theory approaches, Lampezhev *et al.* (2022) [19] who developed methods for analyzing the uniqueness of personal medical data, and Muthaiyah *et al.* (2023) [20] who presented a binary survivability prediction classification model for osteosarcoma prognosis. These studies underline the critical role of advanced machine learning techniques in modern healthcare. Additionally, Duong-Trung et al. (2019) [21] proposed a workflow for medical diagnosis through the lens of the machine learning perspective, emphasizing the integration of machine learning to boost automatic medical decision-making and reduce data overload.

By leveraging machine learning algorithms, this study aims to enhance the accuracy and reliability of diabetes mellitus prediction and retinopathy risk evaluation, ultimately improving patient outcomes and reducing healthcare costs.

This study introduces a novel machine learning-based approach for predicting diabetes and evaluating the risk of diabetic retinopathy. This research integrates multiple advanced machine learning algorithms, including XGBoost, to enhance predictive accuracy.

II. Aim of the Study

This study aims to harness the power of machine learning to enhance the prediction and risk assessment capabilities for diabetes and its consequential complication, diabetic retinopathy. The primary objectives of this research are:

1) To develop and implement multiple advanced machine learning models such as Logistic Regression, Random Forest, XGBoost, Voting classifiers.

2) To compare these models based on their accuracy, precision, recall, F1-score, ROC-AUC, and computational efficiency in predicting diabetic outcomes and classifying diabetic retinopathy risk.

3) To identify the most effective machine learning models for use in clinical settings, providing a foundation for targeted screening and personalized management strategies for patients at elevated risk of diabetic retinopathy.

Through these objectives, the study will contribute to the broader goal of reducing the incidence and impact of diabetic retinopathy by integrating sophisticated analytical techniques into the clinical decision-making process.

III. Materials and Methods

A. Data Description

The primary application of the Diabetes Prediction Dataset is in the development of predictive models using machine learning techniques. The dataset, sourced from Kaggle [22], is comprised of 100,000 electronic health records (EHRs) with nine features collected from multiple healthcare providers, used by researchers for research and analysis. It integrates medical and demographic data from patients diagnosed with or at risk of developing diabetes, emphasizing its utility for constructing machine learning models aimed at predicting diabetes likelihood. The dataset features include age, gender, body mass index (BMI), hypertension, heart disease, smoking history, hemoglobin A1c (HbA1c) levels, and blood glucose levels, each critical for assessing the patient's health status. Each entry is labeled with the diabetes status of the patient, categorized as positive or negative, allowing for the creation of machine learning models that can predict diabetes onset based on existing health data.

The dataset’s demographic range includes precise age values, particularly for children under two years, represented in decimals (e.g., 0.08 equivalent to 1 month, 1.32 equivalent to 1 year and 4 months). This precision enables a nuanced understanding of diabetes risk factors across early age groups. For patients visiting Emergency Rooms, Hospitals, or Clinics, blood glucose levels were captured randomly, without specific fasting requirements, providing a broad but non-standardized snapshot of glucose regulation in potentially acute scenarios.

The dataset does not distinguish between type 1 and type 2 diabetes, making it crucial for predictive models to consider both types. Additionally, the smoking history variable categorizes individuals into six groups: never, not current, former, current, ever, and no info, reflecting varying degrees of exposure to smoking—a known risk factor for diabetes.

B. Data Collection Methodology

The data for this dataset was collected through various means including direct surveys, review of medical records, and laboratory tests from patients diagnosed with or at risk of developing diabetes. This approach ensures a comprehensive gathering of relevant health indicators which are critical in diabetes prediction. Post-collection, the data underwent rigorous processing to refine and standardize the information, ensuring its readiness for analytical applications [22].

The dataset includes 100,000 entries with demographic and medical attributes (0 for negative, 1 for positive).

The Diabetes Prediction dataset includes the following columns: gender: Gender of the patient. Three categories (Female, Male, Other), age: Age of the patient, hypertension: Whether the patient has hypertension (1) or not (0), heart disease: Whether the patient has heart disease (1) or not (0), smoking history: Smoking history of the patient. Six categories (No Info, current, ever, former, never, not current), BMI: Body Mass Index of the patient, HbA1c_level: Hemoglobin A1c level, a measure of average blood glucose over the past three months, blood glucose level: Current blood glucose level, and diabetes: Diabetes status (1 for positive, 0 for negative).

C. Exploratory Data Analysis

1) Observations: Age: Patients range from 0.08 to 80 years old, indicating inclusion of all age groups with an average age of approximately 41.89 years. Hypertension: 7.485% of patients have hypertension. Heart Disease: 3.942% of patients have heart disease. BMI: Ranges from 10.01 to 95.69 with a mean value of approximately 27.32, which indicates overweight on average according to the BMI scale. HbA1c level: Ranges from 3.5 to 9.0 with an average of 5.53, which is in the normal to slightly elevated range. Blood Glucose Level: Ranges from 80 to 300 mg/dL with a mean of approximately 138.06 mg/dL. Diabetes Status: 8.5% of the dataset is labeled as having diabetes mellitus.

2) Depth observation and analysis: In this section, an in-depth Exploratory Data Analysis (EDA) is conducted to understand the nuances of diabetes through several key objectives. Initially, the focus is on the distribution of crucial variables such as age, BMI, blood glucose levels, and HbA1c levels to establish baseline data behaviour (Fig. 1). The relationships these variables have with diabetes status are then explored, using advanced visualization techniques like pair plots. These plots specifically allow for the examination of interactions among the variables, categorized by diabetes mellitus status to discern patterns and anomalies effectively.

Further analysis leverages a robust Random Forest Machine Learning classifier to pinpoint the most significant predictors of diabetes. This model not only processes a vast amount of data but also provides insights into critical factors such as weight, sugar levels, age, and smoking history. Understanding these predictors aids healthcare professionals in early identification and intervention for those at high risk of developing diabetes mellitus.

The distribution plots in Fig. 1 effectively illustrate the key variables' distributions, highlighting the dataset's diversity and relevance for diabetes-related predictive analytics.

Age Distribution**:** The age distribution shows a relatively uniform spread across different age groups, with noticeable peaks in the younger and older populations. There is a significant increase in frequency around ages 70-80, indicating a higher number of elderly individuals in the dataset. The distribution suggests a broad age range, making the dataset suitable for age-related predictive analysis.

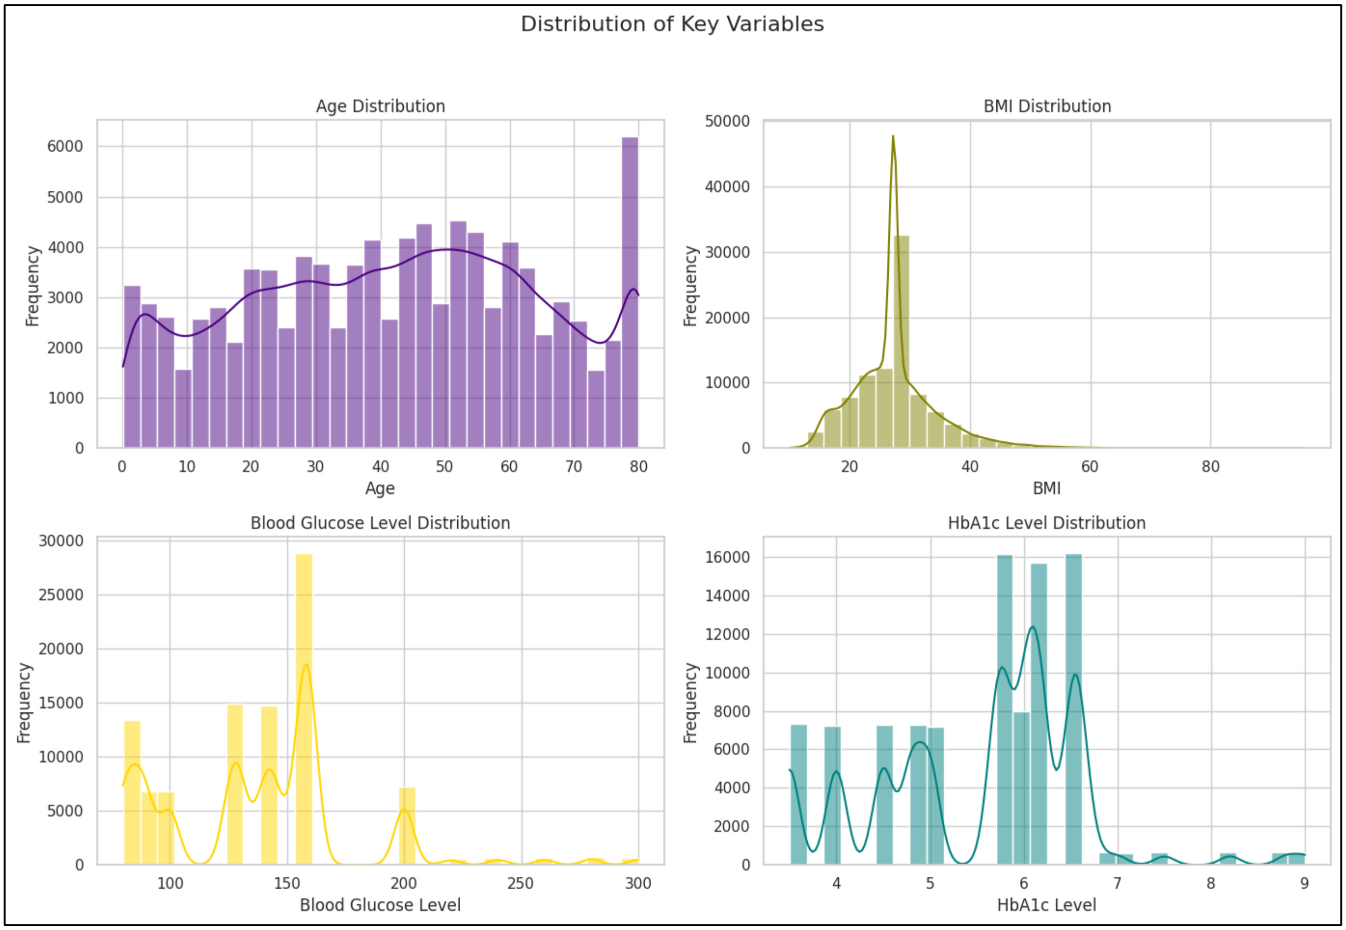

Fig. 1. Visual analysis of key variables.

BMI Distribution**:** The BMI distribution is skewed to the right, with most individuals having a BMI between 20 and 30. There is a noticeable peak around BMI 25, indicating that a significant portion of the population falls within the overweight category according to BMI classifications (BMI 25-29.9). This skewed distribution indicates a higher prevalence of overweight and moderately obese (BMI 30-34.9) individuals, which is relevant for diabetes and retinopathy risk assessment.

Blood Glucose Level Distribution**:** The distribution of blood glucose levels shows several peaks, with a significant one around 150 mg/dL. There are multiple smaller peaks indicating varying levels of blood glucose among the population. The distribution highlights a wide range of blood glucose levels, which is essential for predicting diabetes risk.

HbA1c Level Distribution**:** The HbA1c level distribution shows distinct peaks around values of 5, 6, and 7%. This indicates that there are clear clusters of individuals with specific HbA1c levels, which correspond to normal, pre-diabetic, and diabetic ranges. The presence of these clusters suggests that the dataset contains individuals across the spectrum of diabetes risk, from normal to high risk.

The relationships between these variables and diabetes mellitus status are then explored in Fig. 2 as follows:

- Diabetes Prevalence by Gender: In the female category, the count of non-diabetic individuals is significantly higher than that of diabetic individuals, with a noticeable but smaller group of diabetic females. For males, a similar pattern is observed: non-diabetic males have a higher count compared to diabetic males, though the number of non-diabetic males is less than non-diabetic females. The "Other" category has a very low count for both diabetic and non-diabetic individuals, indicating this category has fewer samples in the dataset.

- Diabetes Prevalence by Smoking History: Among those who have never smoked, most individuals are non-diabetic, but there is a small proportion of diabetics. The "No Info" category, similar to the "never" category, mostly consists of non-diabetic individuals, with a small number of diabetics. For current smokers, the count shows a higher number of non-diabetic individuals, but there is also a noticeable group of diabetics. In the former smokers category, there is a higher number of non-diabetic individuals, with a small number of diabetics. The "Ever" category, similar to "current" smokers, has more non-diabetic individuals with a small diabetic group. Finally, the "Not Current" category, which includes individuals who have smoked in the past but not currently, predominantly consists of non-diabetic individuals, with a smaller diabetic group.

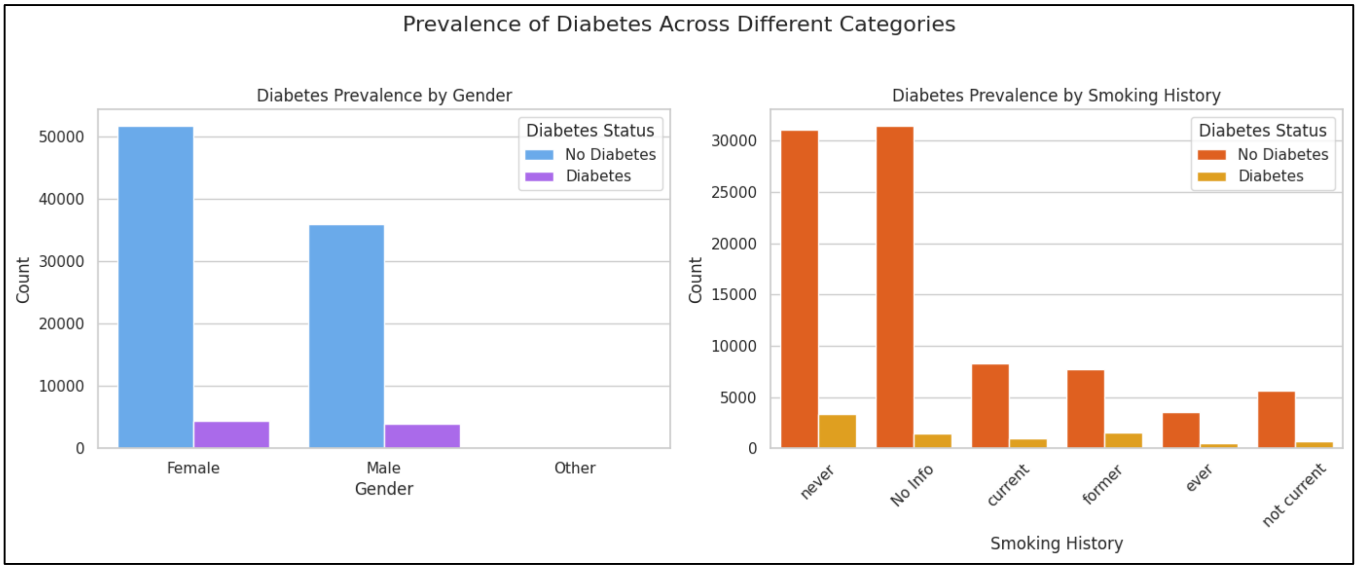

Fig. 2. Analysis of diabetes prevalence by gender and smoking history.

Factor Analysis was done where advanced visualizations were employed to explore the relationships between key variables related to diabetes mellitus (Fig. 3). Specifically, pair plots are utilized to analyze the interactions among age, BMI, blood glucose levels, and HbA1c levels. These plots segment data by diabetes status (0 for non-diabetic and 1 for diabetic), enabling to identify patterns and outliers clearly. This visualization helps highlight how these variables correlate with each other and their collective impact on diabetes prevalence.

Fig. 3 provides a detailed interpretation of the visual data gathered:

- In the Age and Diabetes: There is a noticeable density peak in the age distribution among diabetics at around 55-70 years, indicating a higher prevalence of diabetes in this age group compared to younger individuals.
- BMI: The distribution of BMI values is similar across both diabetics and non-diabetics. However, there is a slightly higher density of diabetic individuals with a BMI above 30, suggesting a potential link between higher BMI and increased diabetes prevalence.
- Blood Glucose Level: Generally, diabetic individuals display elevated blood glucose levels, as evidenced by the clustering of green dots (diabetics) above typical threshold values.
- HbA1c Level: There is a clear distinction in HbA1c levels, with diabetic individuals typically showing higher levels, often exceeding 6.5%, a commonly used diagnostic threshold for diabetes.
- Inter-variable Relationships: The data reveals notable patterns, such as the positive relationship between BMI and blood glucose level, as well as between BMI and HbA1c level, which are more pronounced in diabetic individuals.

Coding Reference: For detailed technical insights, please refer to Appendix A, which contains the GitHub repository link.

Overall, the visualization indicates distinct distributions for diabetic individuals in terms of blood glucose and HbA1c levels and suggests a correlation between age, BMI, and the likelihood of having diabetes. The relationships presented can inform healthcare professionals in identifying high-risk profiles and tailoring interventions accordingly.

3) Key factors for predicting diabetes: The study employs a robust Random Forest machine learning classifier to identify the factors that most significantly affect the likelihood of developing diabetes. A comprehensive dataset is analyzed using the Random Forest algorithm, which serves as a powerful tool to determine key predictors of diabetes. This analysis highlights important indicators such as weight, sugar levels, age, and smoking habits. This helps doctors figure out who might get diabetes and how to help them early (Fig. 4).

The bar plot in Fig. 4 visualizes the feature importance determined by a Random Forest classifier for predicting diabetes. HbA1c level and blood glucose level are the top factors, indicating their strong predictive power for diabetes. BMI and age are also significant, whereas smoking history, hypertension, heart disease, and gender have less influence on the model's predictions.

The Random-Forest classifier has provided the following feature importance, which indicates how much each feature contributes to the model's ability to predict diabetes (Fig. 4):

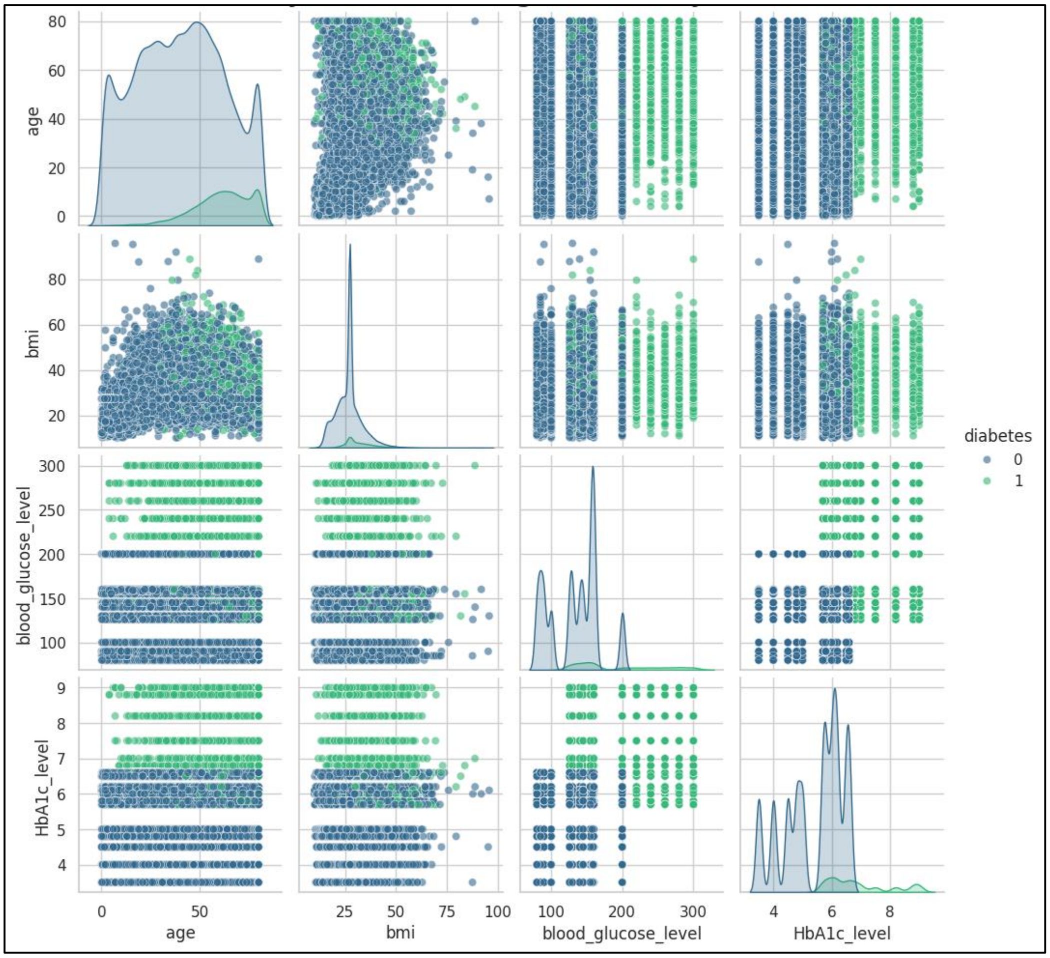

Fig. 3. Pair plot of key variables segmented by diabetes status.

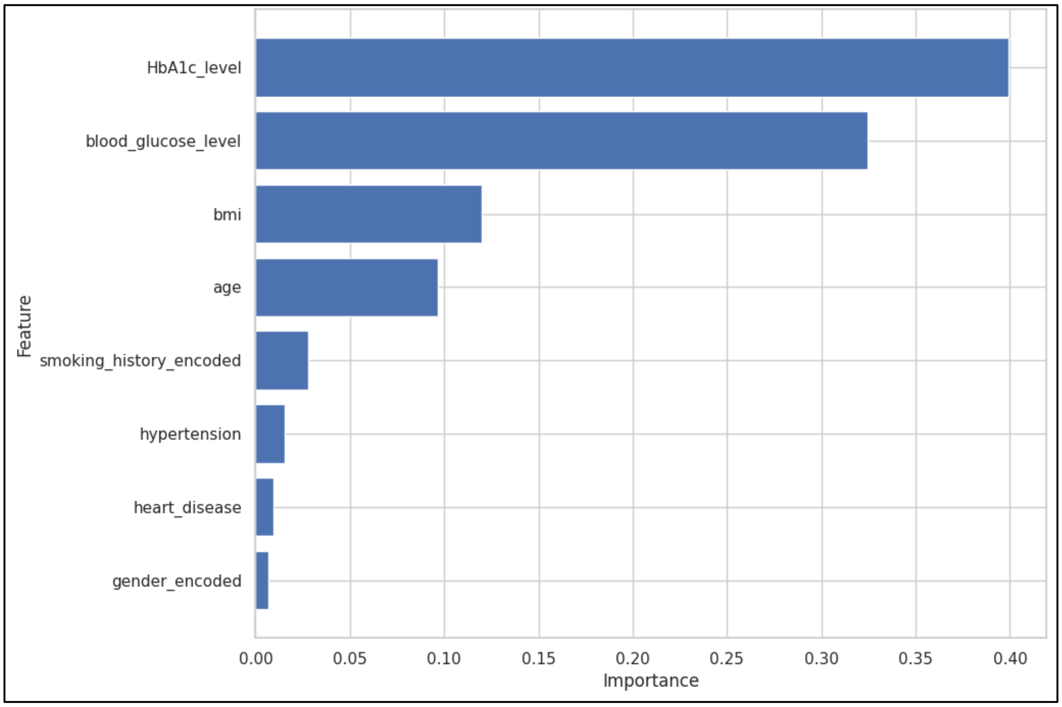

Fig. 4. Feature importance for diabetes prediction.

HbA1c_level (39.31%): The most important feature. HbA1c levels reflect average blood glucose levels over the past few months, making it a critical indicator of diabetes. Blood Glucose Level (32.67%): The second most significant predictor, which is directly related to diabetes, as it measures the current sugar levels in the blood. BMI (12.06%): Body Mass Index also plays a significant role, reflecting the obesity level which is a known risk factor for diabetes. Age (9.88%): Age is another important factor, as the risk of developing diabetes increases with age. Smoking History Encoded (2.73%): Smoking history has a moderate impact, potentially due to its influence on general health and cardiovascular risk, which is related to diabetes. Hypertension (1.59%): Hypertension is moderately important, likely due to its association with cardiovascular health. Heart Disease (1.03%): Similarly, heart disease shows a small impact, which correlates with overall metabolic health. Gender Encoded (0.72%): Gender has the least importance according to this model, suggesting it has a minimal direct impact on diabetes risk in this dataset.

These results help identify which features are most predictive of diabetes in the dataset and can guide further data analysis, feature engineering, and the development of intervention strategies.

D. *Data Pre-processing*

Data preprocessing is a critical step that involves preparing the raw data for machine learning models. This step typically involves several sub-steps:

1) Cleaning: Includes handling missing values and removing duplicates. This is crucial because missing values can introduce bias or inaccuracies into the model, and duplicates can lead to overfitting and the result skew the model training.

X_{cleaned}=f(dropna,drop_duplicates(X)), Where X represents the initial dataset.

Equation: Cleaned Data=Raw Data − (Missing Values + Duplicates)

In this context, the equation represents the removal of undesirable data elements, ensuring that only valid, unique data points are used for further analysis.

Data Cleaning Summary

- Missing Values: There are no missing values in any of the columns.
- Duplicate Rows: There are 3,854 duplicate entries in the dataset.
- Data Consistency: There are no negative values in columns such as 'age', 'bmi', 'HbA1c_level', or 'blood glucose level'.

2) Encoding categorical variables: The dataset includes a mix of categorical and numerical variables:

- Categorical: gender, hypertension, heart disease, smoking history, diabetes (target variable to be used for prediction).
- Numerical: age, bmi, HbA1c_level, blood glucose level

Since many machine learning models require a format suitable for machine learning models which is numerical input. Therefore, categorical variables need to be converted into a numerical format. One-hot encoding is a common technique used where each categorical value is converted into a new categorical column and assigned a 1 or 0.

$$X_{\text{encoded}}=\text{OneHotEncoder}(X_{\text{categorical}})$$

3) Correlation analysis: The relationships among these variables were explored using a correlation matrix. This will help identify which factors are most strongly associated with diabetes. As shown in Fig. 5, the correlation matrix highlights relationships between features: Age shows a mild positive correlation with diabetes, indicating that risk increases with age. Hypertension and heart disease also show positive correlations with diabetes status, suggesting that these conditions are associated with higher diabetes risk. BMI has a slight positive correlation with diabetes, supporting the known link between obesity and increased diabetes risk. The blood glucose level and HbA1c level have stronger positive correlations with diabetes, as expected, since they directly measure aspects of blood sugar management.

E. *Model Design*

Fig. 6 illustrates a comprehensive workflow for predicting diabetes and categorizing the risk of retinopathy. It is divided into two main phases: Phase I involves the development and evaluation of machine learning models for diabetes prediction, while Phase II focuses on assessing the risk of retinopathy for patients identified as diabetic. This systematic approach ensures accurate prediction and effective risk stratification, facilitating timely and appropriate medical interventions.

In the same context, Fig. 7 depicts a visual representation of the entire workflow for the diabetes prediction system. It outlines each step from the initial data acquisition to the final model evaluation. The process begins with the collection and cleaning of the diabetes dataset, followed by various preprocessing techniques to prepare the data for machine learning algorithms [30]. It includes steps such as data scaling, encoding, and addressing class imbalances. The diagram also illustrates the model selection, hyperparameter tuning, and cross-validation processes, culminating in the deployment of the most effective model for diabetes prediction. This systematic approach ensures the development of a robust and reliable prediction system (Fig. 6 and Fig. 7).

Fig. 6. Flowchart: steps of conducting the study.

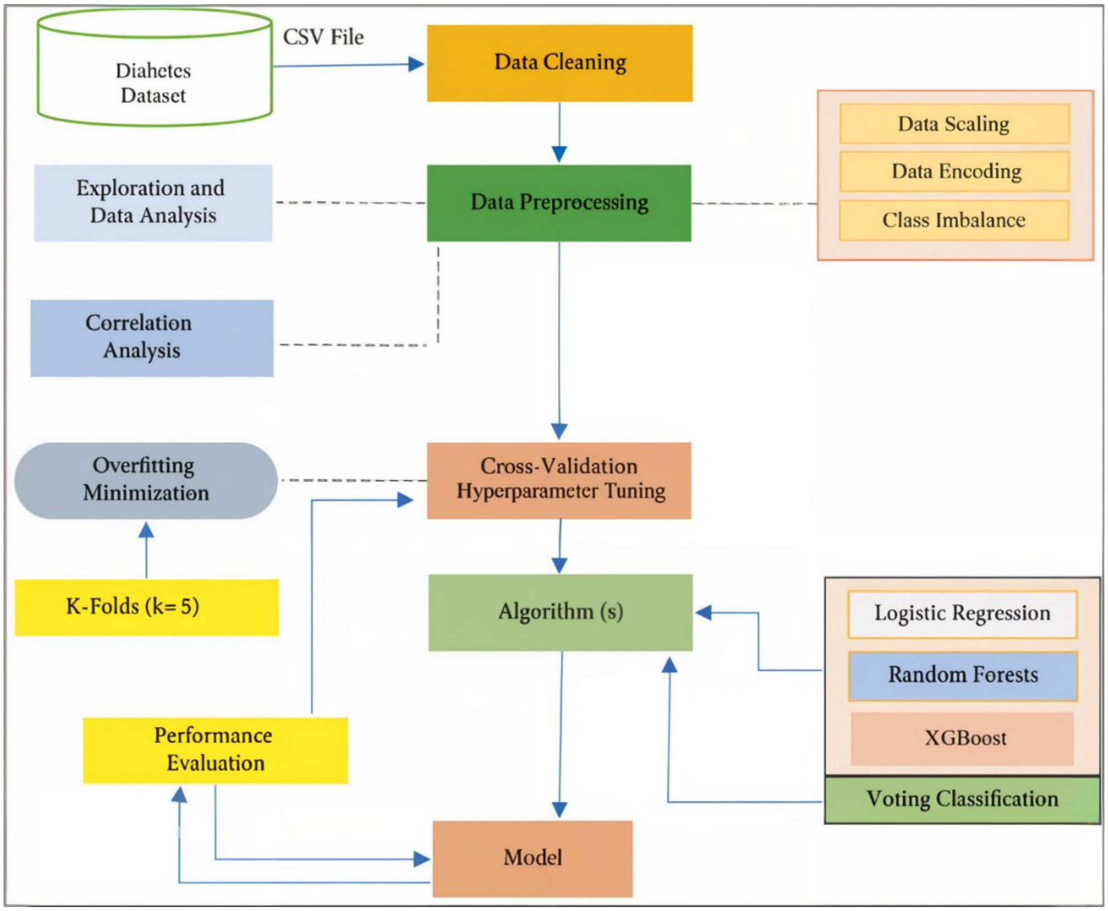

Fig. 7. Block diagram and operational mechanism flow for machine learning in diabetes prediction.

1) Phase 1 - machine learning for diabetes predictions: In the first phase of the study, the objective was to develop and fine-tune machine learning models capable of predicting diabetes. This involved the following steps:

a) Model selection: In selecting models for diabetes predictions, algorithms were chosen for their ability to effectively handle the complexity and variability of medical data, ensuring both high predictive accuracy and robustness against overfitting. This strategic selection helps tailor the approach to accurately capture the nuanced relationships within diabetes-related variables. In predicting diabetes, the selection of machine learning models is critical due to the need for high accuracy and the ability to generalize well from medical datasets. Here's a deeper look into the significance and roles of each chosen model:

- Logistic Regression: This model serves as a fundamental baseline in medical prediction tasks due to its simplicity and interpretability. It uses a logistic function to estimate probabilities, making it particularly useful for binary outcomes like diagnosing diabetes. Its coefficients provide insights into the influence of each feature, aiding clinicians in understanding risk factors.

Objective function: $\hat{y} = \sigma(x\beta + b),\ \sigma(z) = \frac{1}{1-e^{-z}}$ where σ is the logistic function, β is the coefficient vector, b is the bias, and $\hat{y}$ is the predicted probability [23].

- Random Forest: As an ensemble of decision trees, Random Forest mitigates the risk of overfitting associated with individual decision trees by averaging multiple predictions, thereby enhancing the model's stability and accuracy. Its ability to handle large datasets with many features makes it invaluable for capturing complex, nonlinear relationships that are typical in medical data.

Objective Function: $\hat{y} = \frac{1}{N}\sum_{i=1}^{N} T_i \cdot (x)$, Where T_i represents an individual tree's prediction and N is the number of trees [24].

- XGBoost: Known for its efficiency and performance, XGBoost is a sophisticated version of gradient boosting that has proven to be extremely effective in various Kaggle competitions involving medical predictions. It optimizes both speed and prediction accuracy by building trees sequentially, each one correcting errors made by the previous, which is crucial for a nuanced disease like diabetes where early detection can significantly alter patient outcomes.

Objective Function: $\hat{y}_i = \sum_{k=1}^{k} f_k \cdot (x_i)$, where f_k € F. F is the space of trees and f_k represents an individual tree [24].

- Voting classifier: This ensemble technique combines predictions from the Logistic Regression, Random

Forest, and XGBoost [25] models. By using a soft voting mechanism, it computes the final output based on the probability estimates from each model, rather than simple majority rules. This approach helps in reducing variance and bias, leveraging the strengths while balancing the weaknesses of the constituent models, resulting in more reliable and robust prediction capabilities [26].

These models are selected not only for their individual merits but also for their collective ability to provide a comprehensive understanding of the predictive landscape. This ensemble strategy enhances predictive performance, ensuring that the diagnostic tool is both accurate and reliable in a clinical setting.

b) Preprocessing Techniques [27][28][29]: Preprocessing techniques in ML involve cleaning and transforming raw data to improve model performance. Common methods include handling missing values, normalizing data, encoding categorical variables, and addressing class imbalances. Fig. 8 illustrates the operational mechanism of ML models designed for predicting diabetes.

The effectiveness of machine learning models significantly depends on the quality of the data they are trained on. Therefore, rigorous data preprocessing is imperative. Hence, the data was further processed using the following techniques to enhance predictions:

- Data Scaling [31]**:** All numeric features were scaled using the Standard Scaler method to normalize the distribution, aiding in faster convergence during the training phase. Data is standardized to have zero mean and unit variance. Xscaled =$\frac{x-\mu}{\sigma}$, where μ and σ are the mean and standard deviation of the features, respectively. Standardization is crucial for models that are sensitive to the scale of input data.

- Handling Class Imbalance [31]**:** The SMOTE (Synthetic Minority Over-sampling Technique) algorithm was employed to address class imbalance in the dataset, ensuring that the minority class is adequately represented during model training. To address class imbalance in the dataset, SMOTE is applied: $X_{resampled}$, $y_{resampled}$ = SMOTE(X_{train}, y_{train}). SMOTE generates synthetic samples from the minority class, making the class distribution equal and thus preventing model bias towards the majority class.

- Cross-Validation [32]: Stratified K-Fold cross-validation with five folds was employed, which is particularly useful for imbalanced datasets. This method ensures that each fold of the dataset has the same proportion of examples in each class as the complete set. This approach provides a robust estimate of the model's performance, as it iteratively trains the model on k−1 folds and validates it on the remaining fold, cycling through all k folds as the validation set. It provides confidence that the models are stable and perform well across different subsets of the dataset, reducing the likelihood of model overfitting and ensuring that the predictions are reliable.

- Hyperparameter Tuning [33]: GridSearchCV was implemented to automate the process of tuning parameters to find the best combination for each model. This exhaustive search over specified parameter values for an estimator is crucial for optimizing the learning algorithm. Each model was assessed using the ROC-AUC score as the scoring metric, which measures the ability of the model to distinguish between the classes across all possible thresholds. This tuning of parameters optimizes model performance on the dataset, ensuring that the predictions are as accurate as possible, which is critical for medical applications where the cost of false predictions can be high.

- Optimal Parameters and Model Evaluation: After tuning, the optimal parameters for each model were established and used to train the models on the processed training set. The evaluation of these models on a hold-out test set involved the following metrics:

- 'Logistic Regression': LogisticRegression(C=0.01)
- 'Random Forest': RandomForestClassifier(max_depth=20, n_estimators=200)
- 'XGBoost': XGBClassifier(learning_rate=0.1, max_depth=6, n_estimators=150)
- 'Voting Classifier': VotingClassifier(estimators=[('lr', LogisticRegression(C=0.01)), ('rf', RandomForestClassifier(max_depth=20, n_estimators=200)), ('xgb', XGBClassifier(learning_rate=0.1, max_depth=6, n_estimators=150))], voting='soft'

These parameters were then used to train each model on the entire training set processed through SMOTE and scaled appropriately. The trained models were evaluated on a hold-out test set to gauge their effectiveness, using metrics such as accuracy, precision, recall, F1-score, and the ROC-AUC.

- Model Training**:** After preprocessing the data (as detailed in previous discussions), four key models were trained using the best hyperparameters identified through GridSearchCV. These models included Logistic Regression, Random Forest, XGBoost, and Voting.

- Model Evaluation**:** Each model was rigorously evaluated on a split test set to assess their performance in accurately predicting diabetes. Metrics such as accuracy, precision, recall, F1-score, and AUC-ROC were employed to compare each model's effectiveness.

c) Performance Evaluation [34][35]: To evaluate the effectiveness of different models, several metrics are used:

- Accuracy**:** The proportion of true results among the total number of cases examined.

- Precision**:** The proportion of positive identifications that were actually correct.

- Recall**:** The proportion of actual positives that were correctly identified.

- F1-Score**:** The harmonic mean of precision and recall.

- ROC-AUC: The area under the receiver operating characteristic curve, which plots the true positive rate against the false positive rate at various threshold settings.

Equations**:**

$$\text{Accuracy} = \frac{\text{TP+TN}}{\text{TP+TN+FP+FN}} \quad (1)$$

$$\text{Precision} = \frac{\text{TP}}{\text{TP+FP}} \quad (2)$$

$$\text{Recall} = \frac{\text{TP}}{\text{TP+FN}} \quad (3)$$

$$\text{F1} = 2\times \frac{\text{Precision . Recall}}{\text{Precision+Recall}} \quad (4)$$

Where TP represents instances where the model correctly predicts a positive outcome. FP refers to cases where the model predicts a positive outcome, but the actual result is negative. TN indicates instances where the model correctly predicts a negative outcome, while FN refers to cases where the model predicts a negative outcome, but the actual result is positive.

- Running Time: Running time indicates the computational efficiency of each model.
- Confusion Matrix: The confusion matrix provides a detailed breakdown of true positive, false positive, true negative, and false negative predictions. It compares the actual target values with those predicted by the machine learning model, providing a holistic view of the model's performance and highlighting the types of errors it makes (Fig. 8).

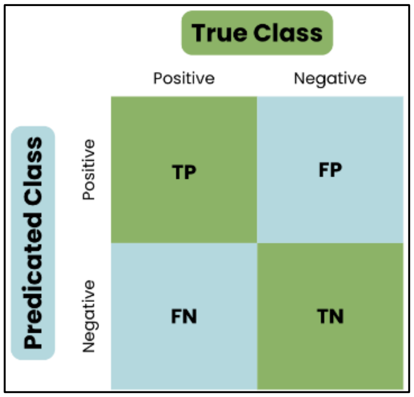

Fig. 8. The basic structure of a confusion matrix.

d) Selection of optimal models: Based on the evaluation, models that exhibited the highest efficacy in terms of AUC-ROC and F1-score are favored. This ensured that the chosen models were not only accurate but also balanced in terms of precision and recall.

e) Significance of accurate diabetes predictions: Accurate diabetes predictions enable timely interventions that can prevent or delay the onset of complications like retinopathy. By identifying individuals at risk of developing diabetes or managing those already diagnosed more effectively, healthcare providers can implement preventative measures such as lifestyle modifications, regular monitoring, and early pharmacological intervention.

2) Phase 2 - Application on new dataset and risk assessment for retinopathy: Upon successfully training and selecting the best models, the next phase involved applying these models to a new dataset (Appendix B). This dataset comprised unseen data, simulating a real-world scenario where the models predict diabetes status in new patients. Following the prediction, a detailed risk assessment for diabetic retinopathy was conducted:

- Prediction on New Data**:** The trained models were applied to the new dataset to predict diabetes (Appendix B). This step tested the models' generalizability and their ability to function accurately outside the training data environment.
- Risk Assessment for Retinopathy**:** Risk Scoring Function**:** A custom function was developed to assign scores to various features based on their significance and impact on retinopathy risk. This included typical and atypical values and ranges for features such as HbA1c levels, hypertension, BMI, age, and smoking history. Each feature's contribution to the risk score was weighted according to established medical research indicating its influence on retinopathy.

Table I summarizes the scoring rules and conditions that represent how different factors contribute to a risk score when predicting diabetes. It provides a comprehensive scoring system to predict diabetes risk by evaluating various health and lifestyle factors. Each condition is assigned a score based on specific ranges or values, contributing to an overall risk score. The factors include HbA1c level, hypertension, heart disease, BMI, age, smoking history, gender, and blood glucose level. By aggregating the scores from these conditions, healthcare providers can better classify patients' risk levels and prioritize interventions.

- Retinopathy Risk Categorization (only for diabetic predicted patients)**:** Based on the cumulative risk score derived from the scoring function, each patient was categorized into No, Low, Medium, or High Risk for developing diabetic retinopathy.
    - No Risk (score range 0-5): Diabetic patients with no risk of retinopathy do not require additional retinal screenings**.**
    - Low Risk (score range 5-7): Patients predicted with low probability of diabetes might require less frequent retinal screenings.
    - Moderate Risk (score range 7-9): Patients showing borderline or moderate probabilities may need more regular follow-ups to monitor any progression in retinal changes.
    - High Risk (score range >9): Patients predicted to be highly likely to have or develop diabetes should undergo comprehensive and possibly more frequent retinal examinations to detect early signs of retinopathy.

TABLE I. RETINOPATHY SCORING CONDITIONS TABLE

Condition	Range/Value	Score
Predicted Model Output	0 – Non-Diabetic	0
	1 – Diabetic	Continue scoring
HbA1c Level	≤ 7	0
	> 7 and ≤ 8	1
	> 8 and ≤ 9	2
	> 9	3
Hypertension	0	0
	1	1
Heart Disease	0	0
	1	1
BMI	< 25	0
	≥ 25 and < 30	1
	≥ 30	2
Age	< 40	0
	≥ 40 and < 50	1
	≥ 50 and < 60	2
	≥ 60	3
Smoking History	'never', 'No Info'	0
	'ever', 'not current'	1
	'former'	2
	'current'	3
Gender	'Other'	0
	'Male'	0
	'Female'	0
Blood Glucose Level	< 100	0
	≥ 100 and < 126	1
	≥ 126 and < 200	2
	≥ 200	3

This categorization helps in prioritizing medical attention and preventive measures.

IV. RESULTS

Predictions were conducted on testing data, comprising 20% of the original dataset in the first phase, and on a completely new dataset (Appendix B) in the second phase. Predictions are structured such that a result of 0 indicates the patient does not have diabetes, thereby assigning a risk score of zero for retinopathy. Conversely, if the prediction indicates diabetes, the patient's clinical results must undergo a risk assessment scoring system. This system categorizes patients as low, medium, or high risk, based on the severity of their scores. In the second phase, machine learning models are trained on the entire original dataset to leverage known diabetes outcomes and apply predictions to a new, separate dataset. This approach enables the prediction of diabetic status and subsequent assessment and categorization of retinopathy risk.

A. Phase 1: Classifiers' Result

In Phase 1 of the study, the performance of various classifiers on the task of predicting diabetes was evaluated. The classifiers tested include Logistic Regression, Random Forest, XGBoost, and a Voting Classifier. Each model was assessed based on several performance metrics: Accuracy, Precision, Recall, F1-Score, AUC-ROC, Running Time, and Confusion Matrix. The results, summarized in Table II, provide a comprehensive comparison of the models' effectiveness and efficiency in diabetes prediction.

TABLE II. PERFORMANCE METRICS OF CLASSIFIERS IN DIABETES PREDICTION

Classifier	Accuracy	Precision	Recall	F1-Score	AUC-ROC	Running Time (s)	Confusion Matrix
Logistic Regression	0.87	0.41	0.86	0.55	0.95	4.9359	[[15461, 2073], [237, 1459]]
Random Forest	0.94	0.66	0.78	0.72	0.96	882.9681	[[16871, 663], [364, 1332]]
XGBoost	0.96	0.84	0.73	0.78	0.97	45.2544	[[17300, 234], [451, 1245]]
Voting Classifier	0.95	0.73	0.77	0.75	0.96	15.0121	[[17071, 463], [385, 1311]]

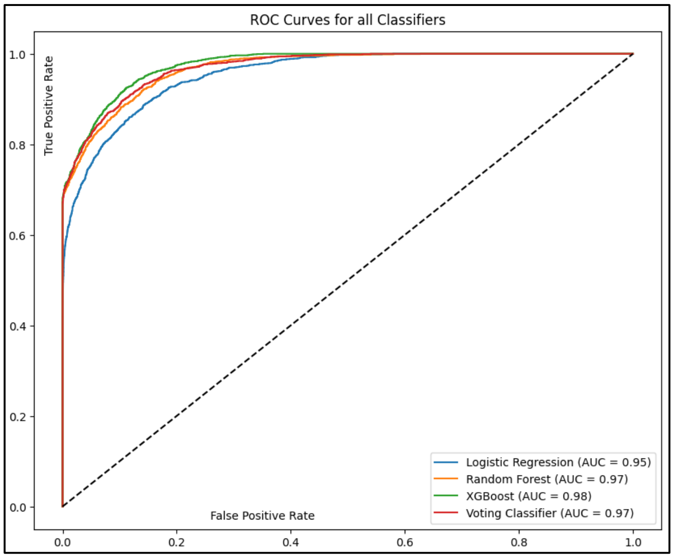

Fig. 9. ROC curves for all classifiers.

Additionally, the ROC Curves for all classifiers, depicted in Fig. 9, illustrate the true positive rate versus the false positive rate, providing insight into the models' ability to distinguish between classes. This visual representation, combined with the detailed performance metrics, helps to identify the strengths and weaknesses of each classifier, guiding the selection of the most suitable model for further development.

1) Comparative analysis of classifiers for diabetes prediction: In the realm of diabetes prediction, the performance of classifiers can significantly influence the effectiveness of diagnosis and subsequent patient management. The evaluation of four classifiers—Logistic Regression, Random Forest, XGBoost, and a Voting Classifier—provides insights into their efficacy across various metrics that are crucial for medical decision-making.

Logistic Regression is notable for its high recall of 86.03%, indicating its ability to identify a high number of true positive cases, which is critical in medical diagnostics to ensure that few cases of diabetes go undetected. However, its precision is relatively low at 41.31%, suggesting a higher rate of false positives that could lead to unnecessary anxiety or treatment. Despite these trade-offs, its rapid processing time of under 5 seconds and an AUC-ROC score of 95.48% demonstrate its utility in scenarios where speed and general accuracy are prioritized over precision.

Random Forest shows a marked improvement in overall accuracy (94.66%) and precision (66.77%) compared to Logistic Regression, suggesting better balance in identifying true positives while reducing false positives. Its recall of 78.54% remains robust, albeit lower than Logistic Regression, reflecting a more conservative but precise approach. The main limitation of Random Forest in this context is its computational demand, with a significantly longer running time, which might be a constraint in real-time prediction environments.

XGBoost emerges as the strongest performer in terms of accuracy (96.44%) and AUC-ROC (97.54%), underscoring its capability to effectively separate the diabetic and non-diabetic classes. With the highest precision (84.18%) among the classifiers, XGBoost offers a reliable prediction model that minimizes false positives—a desirable feature in clinical settings. Nevertheless, the trade-off here involves its recall (73.41%), which is lower than Logistic Regression's, pointing towards a potential underdiagnosis risk.

The Voting Classifier combines the strengths of the above models and achieves an accuracy of 95.59%, with well-balanced precision (73.90%) and recall (77.30%). This classifier harnesses the collective insights of Logistic Regression, Random Forest, and XGBoost, potentially leading to more consistent predictions across diverse patient profiles. The Voting Classifier's middle-range running time (15.01 seconds) and high AUC-ROC (96.95%) make it a viable option for both accuracy and efficiency in clinical applications.

2) Further experiments: This section explores machine learning techniques for improving diabetes prediction accuracy by addressing class imbalance and optimizing prediction thresholds. Detailed quantitative results are provided in Appendices C and D.

a) Handling Class Imbalance (Appendix C): First, SMOTE (Synthetic Minority Over-sampling Technique) was used to address class imbalance, which significantly improved recall and minimized false negatives in diabetes prediction (Table A1). ADASYN (Adaptive Synthetic Sampling) was also tested, focusing on generating samples near decision boundaries, but it did not surpass SMOTE's performance (Table A2). Additionally, experiments with BorderlineSMOTE (Table A3), which selectively generates samples around the decision boundary, yielded mixed results, confirming SMOTE as the primary method.

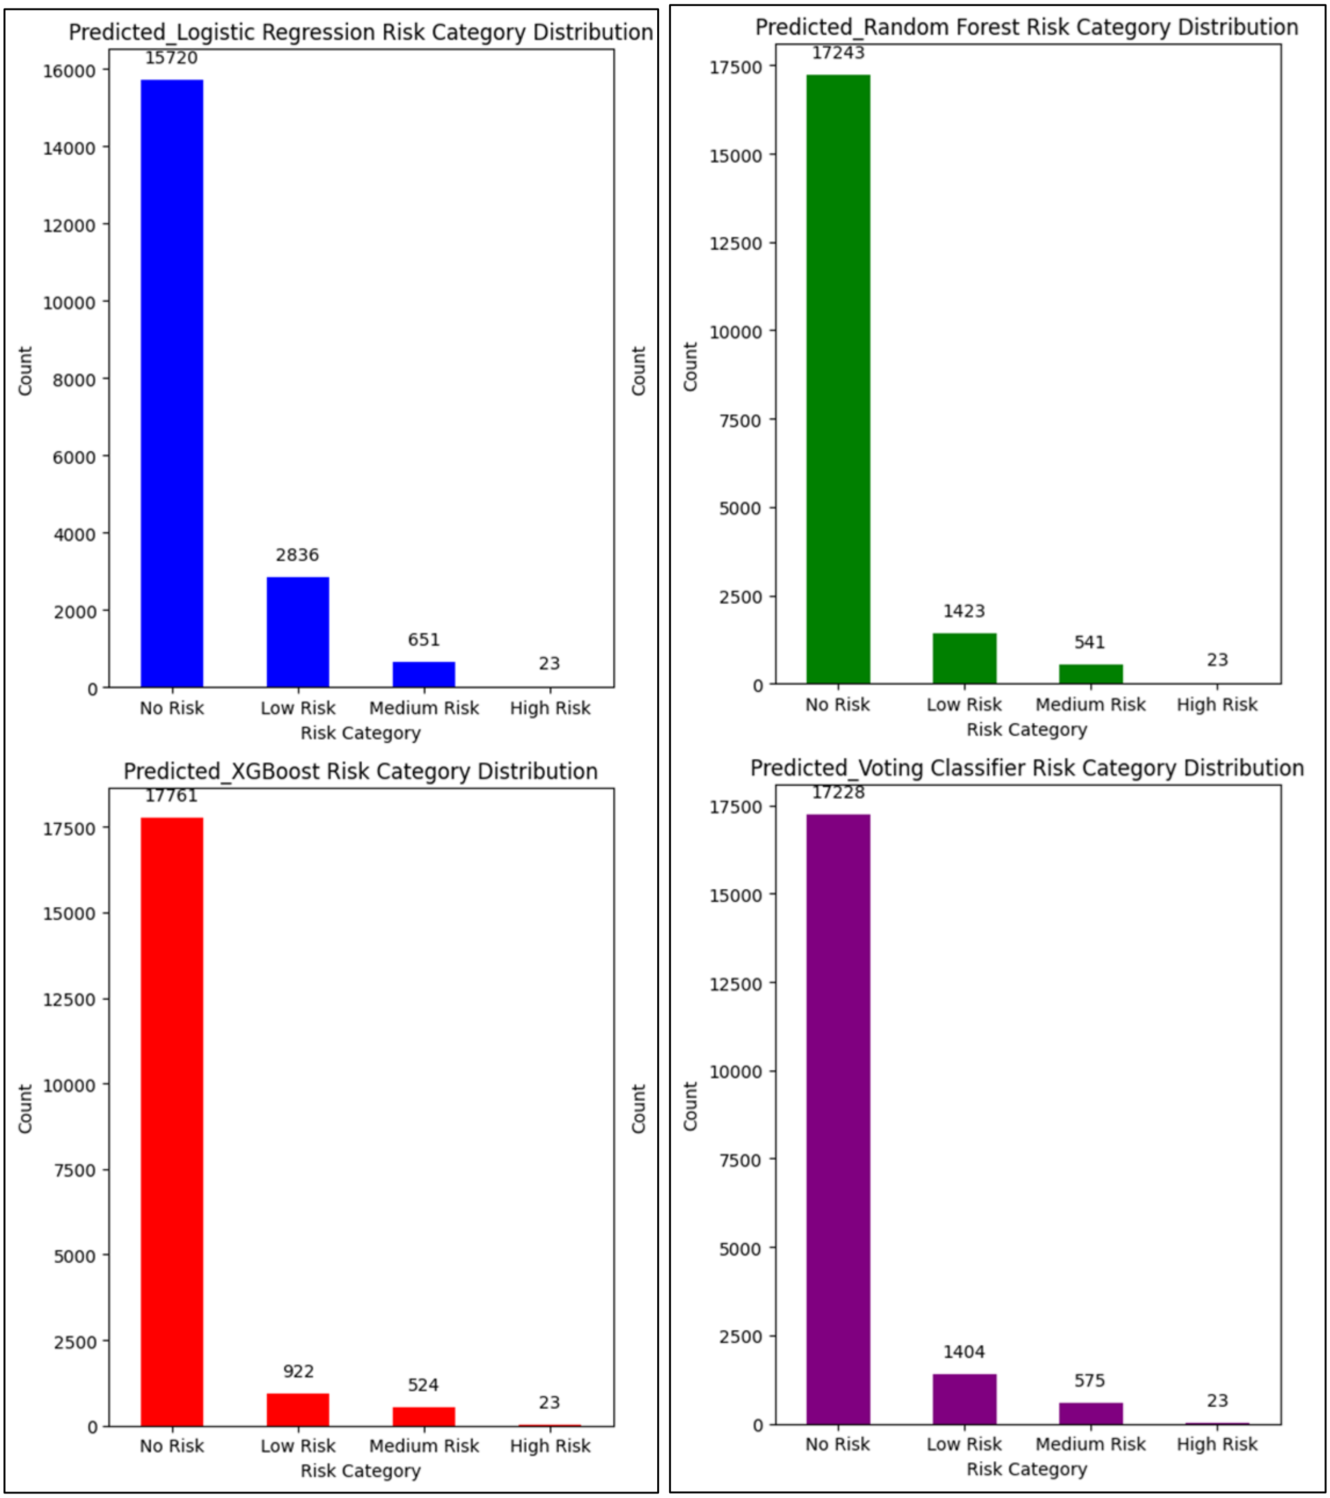
b) Optimizing Prediction Thresholds (Appendix D): To enhance clinical utility, prediction thresholds were adjusted to improve recall, aiming to reduce false negatives. Thresholds of 0.5, 0.6, 0.25, and 0.4 were tested, observing their impacts on precision, recall, and F1-score. A lower threshold (0.25 or 0.4) maximized recall, suitable for screening to identify as many positive cases as possible. A higher threshold (0.6) improved precision, suitable for diagnostic settings where false positives are costly. Detailed metrics for these adjustments are in Tables B1 to B3 (Appendix D).

These experiments highlight the importance of tailored approaches in machine learning for healthcare. Adjusting class imbalance handling and prediction thresholds can significantly enhance model performance and suitability for specific healthcare applications, particularly in early and accurate diabetes detection.

B. Phase 2: Retinopathy Risk Assessments’ Result

In Phase 2 of the study, the risk of retinopathy was assessed using various classifiers. The classifiers tested include Logistic Regression, Random Forest, XGBoost, and a Voting Classifier. The goal is to categorize individuals into different risk levels: No Risk, Low Risk, Medium Risk, and High Risk.

The distribution of predicted risk categories for each classifier is illustrated in Fig. 10A and Fig. 10B. All models heavily favor "No Risk" predictions, indicating an imbalanced dataset with more non-risk instances. Very few predictions in the "High Risk" category across all models. Logistic Regression and Random Forest are more balanced compared to the conservative XGBoost, which shows the highest "No Risk" predictions. The Voting Classifier balances predictions, indicating the benefit of ensemble methods for nuanced risk detection. These insights can guide model selection with balanced parameters and dataset management for more accurate and trustworthy AI predictions.



(a) (b)

Fig. 10. (a) A Classifiers risk category distribution_XGBoost, (b) Classifiers risk category distribution_Voting Classifier

V. Discussion and Conclusion

The comparative analysis reveals that while XGBoost offers the highest precision and overall accuracy, making it suitable for settings where the cost of a false positive is high, the Voting Classifier provides a balanced solution that might be preferred in clinical environments where both types of errors (false positives and false negatives) carry significant consequences. Logistic Regression, with its high recall, could be particularly useful in initial screening tests were missing a positive diagnosis could be detrimental. Random Forest, with its strong performance across metrics but slower execution, might be more applicable in situations where computational time is less of a constraint. The results demonstrate significant improvements in predictive accuracy compared to traditional models. For instance, the XGBoost model achieved an accuracy of 96.43%, which is approximately 9.60% higher than the commonly used logistic regression model, 1.88% higher than the random forest model, and 0.88% higher than the voting classifier. Additionally, the study identified novel patterns and risk factors that were previously unreported in the literature. These findings address critical gaps in existing research, particularly in the early detection and risk assessment of diabetic retinopathy.

The present study's use of XGBoost and Random Forest models for diabetes prediction demonstrated accuracies of 96.43% and 94.65%, respectively. These results, although slightly lower than the 97.82% accuracy reported for Random Forest by Alam et al. (2024) [36], reflect the comprehensive preprocessing steps undertaken, which were not fully implemented in the referenced studies, thereby enhancing the reliability and robustness of the findings. Furthermore, the Logistic Regression model in this study achieved an accuracy of 87.98%, compared to 96.06% reported by Gaur et al. (2024) [36]. Additionally, Voting Classifier achieved an accuracy of 95.59%, and KNN achieved 95.28%, aligning closely with the findings of Gaur et al. (2024) who reported 96.02% for KNN and 96.45% for SVM. Alshenawy and Almetwally (2023) [37] reported the highest accuracy for KNN at 99.99%, which underscores the potential of advanced models. Notably, our study also evaluated running time, revealing that XGBoost (45.25 seconds) and Voting Classifier (15.01 seconds) were more efficient than Random Forest (882.97 seconds), an aspect not considered in previous studies. This highlights the practicality of the models in real-life scenarios, where computational efficiency is crucial.

The choice of classifier in diabetes predictions should align with specific clinical priorities—whether it is reducing the risk of undiagnosed cases or minimizing the burden of false positives on the healthcare system. Each classifier has its strengths and scenarios where it might perform optimally, emphasizing the importance of context in model selection for medical applications.

When it comes to assessing the risk of diabetic retinopathy, the choice of classifier for diabetes and its complication predictions involves balancing various factors including accuracy, speed, and the specific medical consequences of false positives and false negatives. High-performing classifiers that effectively balance precision and recall, such as XGBoost and the Voting Classifier, are particularly valuable in these settings. Their use helps in creating stratified medical responses that optimize care for each patient based on their individualized risk profile, potentially leading to better clinical outcomes and more efficient use of healthcare resources.

Classifiers can categorize patients based on the likelihood of disease progression. The performance of each classifier can impact the assessment. Models with higher precision, such as XGBoost in this analysis, are crucial in this context. High precision reduces false positives, which means fewer patients are incorrectly categorized as at high risk of retinopathy. This is vital to avoid unnecessary treatments, which can be invasive and costly.

High recall rates are equally important because they ensure that most patients who are at risk of retinopathy are correctly identified for further testing and early treatment. Logistic Regression showed the highest recall, suggesting it could be useful in initial screening phases to ensure comprehensive identification of at-risk individuals. High overall accuracy and AUC-ROC, as seen with XGBoost and the Voting Classifier, indicate strong overall performance in distinguishing between patients at different levels of risk. This is essential for categorizing patients accurately into risk groups, which can guide the intensity and frequency of monitoring and intervention. In environments where real-time analysis is critical—such as in clinical settings during patient visits—models with shorter running times like Logistic Regression may be preferable despite other limitations.

The analysis underscores the crucial role of sophisticated machine learning classifiers in enhancing diabetes management and preventing its complications, notably diabetic retinopathy. Accurate diabetes prediction models can lead to early identification of individuals at risk, facilitating timely interventions that can significantly mitigate the progression of the disease and its associated complications.

The comparative analysis of different classifiers such as Logistic Regression, Random Forest, XGBoost, and Voting Classifier reveals that no single model fits all scenarios. Each classifier brings its strengths in terms of precision, recall, accuracy, and operational efficiency. For instance, XGBoost stands out for its high precision and accuracy, making it particularly useful in settings where reducing false positives is crucial. Meanwhile, Logistic Regression, with its high recall, is invaluable for initial screenings to ensure comprehensive identification of potentially at-risk individuals.

The choice of a classifier can significantly impact clinical outcomes. Precision in predictions minimizes the risk of unnecessary treatments, which is particularly important in managing diabetic retinopathy, where interventions can be as severe as laser surgery or injections. High recall is essential to avoid missing any cases of potential diabetes and its complications, ensuring that all at-risk individuals are monitored and treated appropriately.

The integration of these classifiers into healthcare systems implies a move towards more personalized medicine. It enables healthcare providers to categorize patients not just based on static factors but also through dynamic, data-driven insights, allowing for tailored monitoring schedules and treatments. This approach not only improves patient outcomes but also optimizes resource allocation within healthcare systems.

Unlike previous studies [36] [37] [38] that primarily focused on predicting diabetes alone, this research extends to evaluating the risk of diabetic retinopathy based on available data. If more features and detailed data were available, it could potentially extend to other diabetes-related complications. This study's approach of integrating multiple machine learning techniques, comparing them in terms of various metrics including computational efficiency, and analyzing a comprehensive dataset provides a more robust and accurate prediction framework. Novel risk factors were identified that were not highlighted in previous studies, addressing critical gaps in existing research. The study also ensures that all necessary preprocessing steps are implemented, enhancing the reliability and robustness of the findings by making the data well-prepared for machine learning applications without introducing bias. Additionally, the study uniquely evaluates the running time of each model, highlighting practical efficiency and applicability in real-life scenarios. This aspect was not fully addressed in previous studies. By categorizing patients into preliminary risk levels for retinopathy, the work helps reduce the cost of unnecessary eye scans and other related examinations. The improved predictive accuracy enables earlier detection and intervention for at-risk patients, potentially reducing the incidence of severe complications and associated healthcare costs. This research provides a scalable and effective tool for diabetes and retinopathy risk evaluation, contributing significantly to the field by offering broader practical implications for healthcare providers.

Thus, this study proposes an automatic diabetes prediction system that can be deployed on a website and an Android smartphone application using the XGBoost machine learning framework. Users can input relevant data such as gender, age, hypertension, heart disease, smoking history, BMI, HbA1c level, and blood glucose level. The system will provide instantaneous diabetes prediction along with the risk of retinopathy through the designed web application using real data.

There is a clear need for ongoing research and development in this area to refine these models, reduce their computational demands, and enhance their adaptability to real-world clinical settings. Additionally, the adoption of these technologies must be accompanied by training for healthcare professionals to maximize the benefits of such advanced tools.

Ultimately, leveraging advanced classifiers for diabetes prediction and retinopathy risk assessment represents a significant step forward in the fight against diabetes and its debilitating complications. As technology advances, the potential for these tools to become integral components of personalized healthcare grows, promising not only better patient outcomes but also more efficient healthcare systems globally.

Appendix C – Section IV, 2, a:

This appendix provides supplementary data and experimental results aimed at identifying optimal techniques, values, and parameters for the diabetes prediction program. The details outlined below encompass a variety of approaches and the corresponding performance metrics.

Experiment 1: Application of SMOTE for Class Imbalance

- Methodology: Synthetic Minority Over-sampling Technique (SMOTE) was utilized to address class imbalance.
- Results: Performance metrics for various classifiers are presented in the table below:

TABLE A1

	Classifier	**Accuracy**	**Precision**	**Recall**	**F1-Score**	**AUC-ROC**	**Running Time (s)**	**Confusion Matrix**
0	Logistic Regression	0.879875	0.413080	0.860259	0.558148	0.954829	4.935908	[[15461, 2073], [237, 1459]]
1	Random Forest	0.946594	0.667669	0.785377	0.721756	0.968865	882.968163	[[16871, 663], [364, 1332]]
2	XGBoost	0.964379	0.841785	0.734080	0.784252	0.975445	45.254451	[[17300, 234], [451, 1245]]
3	Voting Classifier	0.955902	0.739008	0.772995	0.755620	0.969480	15.012164	[[17071, 463], [385, 1311]]

Experiment 2: Application of ADASYN (Adaptive Synthetic Sampling)

- Methodology: ADASYN was applied to generate synthetic samples adjacent to hard-to-classify minority class samples.
- Results: The performance metrics are as follows:

TABLE A2

	Classifier	**Accuracy**	**Precision**	**Recall**	**F1-Score**	**AUC-ROC**	**Running Time (s)**
0	Random Forest	0.964025	0.863055	0.703250	0.775000	0.966764	330.501986
1	XGBoost	0.966186	0.895981	0.697118	0.784138	0.971217	5.990814
2	Neural Network	0.945930	0.673841	0.748620	0.709265	0.962576	3595.085286
3	Logistic Regression	0.835629	0.340054	0.920294	0.496609	0.957930	2.282274

Experiment 3: Application of BorderlineSMOTE

- Methodology: BorderlineSMOTE was used to focus on generating synthetic samples near the borderlines of class distributions.
- Results: The results are shown below:

TABLE A3

Classifier	Accuracy	Precision	Recall	F1-Score	AUC-ROC	Running Time (s)	Confusion Matrix	
0	Logistic Regression	0.860062	0.375656	0.886203	0.527646	0.953037	2.844599	[[15036, 2498], [193, 1503]]
1	Random Forest	0.936453	0.605804	0.800118	0.689533	0.968058	950.399149	[[16651, 883], [339, 1357]]
2	XGBoost	0.952522	0.714286	0.769458	0.740846	0.975019	43.765607	[[17012, 522], [391, 1305]]
3	Voting Classifier	0.946854	0.664390	0.803066	0.727176	0.968929	17.103075	[[16846, 688], [334, 1362]]

Staying on SMOTE emerged as the best option since it outperforms all other techniques.

Appendix D – Section IV, 2, b

A second approach was explored by changing the prediction threshold for ML models to achieve higher Recall values, which is a crucial metric in the context of diabetes predictions.

The results for normal predictions are as follows:

TABLE B0

Classifier	**Accuracy**	**Precision**	**Recall**	**F1-Score**	**AUC-ROC**	**Running Time (s)**	**Confusion Matrix**	
0	Logistic Regression	0.879875	0.413080	0.860259	0.558148	0.954829	4.935908	[[15461, 2073], [237, 1459]]
1	Random Forest	0.946594	0.667669	0.785377	0.721756	0.968865	882.968163	[[16871, 663], [364, 1332]]
2	XGBoost	0.964379	0.841785	0.734080	0.784252	0.975445	45.254451	[[17300, 234], [451, 1245]]
3	Voting Classifier	0.955902	0.739008	0.772995	0.755620	0.969480	15.012164	[[17071, 463], [385, 1311]]

Experiment 4: Adjusting the Prediction Threshold to 0.6

- Methodology: The prediction threshold was raised to 0.6 to evaluate the impact on precision and recall, prioritizing the reduction of false positives which is crucial for clinical diagnostics where confirming the presence of diabetes is critical.

- Results: The performance metrics with this higher threshold are detailed in the appendix. This adjustment typically resulted in higher precision but slightly lower recall, indicating fewer false positives at the expense of missing some true positives.

TABLE B1

Classifier	Accuracy	Precision	Recall	F1-Score	AUC-ROC	Running Time (s)	Confusion Matrix	
0	Logistic Regression	0.906344	0.481714	0.815448	0.605649	0.954829	0.264111	[[16046, 1488], [313, 1383]]
1	Random Forest	0.958658	0.779640	0.740566	0.759601	0.968689	26.816174	[[17179, 355], [440, 1256]]
2	XGBoost	0.970203	0.936965	0.709906	0.807783	0.975445	1.323363	[[17453, 81], [492, 1204]]
3	Voting Classifier	0.962611	0.822868	0.734080	0.775943	0.970382	26.425162	[[17266, 268], [451, 1245]]

Experiment 5: Adjusting the Prediction Threshold to 0.25

- Methodology: The threshold was lowered to 0.25 to maximize recall. This approach is aimed at reducing false negatives, essential for early screening where capturing as many potential cases as possible is more critical than the precision of each prediction.

- Results: This lower threshold significantly improved recall but at the cost of precision, as detailed in the appendix. The increase in recall makes this threshold suitable for preliminary screenings.

TABLE B2

Classifier	Accuracy	Precision	Recall	F1-Score	AUC-ROC	Running Time (s)	Confusion Matrix	
0	Logistic Regression	0.781539	0.280225	0.941627	0.431913	0.954829	0.329488	[[13432, 4102], [99, 1597]]
1	Random Forest	0.886271	0.430077	0.890330	0.579988	0.968202	26.290070	[[15533, 2001], [186, 1510]]
2	XGBoost	0.917681	0.519584	0.883844	0.654442	0.975445	2.742484	[[16148, 1386], [197, 1499]]
3	Voting Classifier	0.857046	0.375385	0.935142	0.535720	0.970287	25.459364	[[14895, 2639], [110, 1586]]

Experiment 6: Adjusting the Prediction Threshold to 0.4

- Methodology: A moderate threshold adjustment to 0.4 was tested to find a balance between recall and precision. This setting aims to maintain a reasonable rate of true identifications while controlling the number of false positives.

- Results: The results, as detailed in the appendix, show that this threshold offers a balanced trade-off, making it a potentially viable option for contexts where both identifying cases and maintaining precision are important.

TABLE B3

Classifier	Accuracy	Precision	Recall	F1-Score	AUC-ROC	Running Time (s)	Confusion Matrix	
0	Logistic Regression	0.849922	0.359338	0.896226	0.512994	0.954829	0.263994	[[14824, 2710], [176, 1520]]
1	Random Forest	0.927665	0.560878	0.828420	0.668888	0.968033	25.806485	[[16434, 1100], [291, 1405]]

***Abstract*—Sound classification is a multifaceted task that necessitates the gathering and processing of vast quantities of data, as well as the construction of machine learning models that can accurately distinguish between various sounds. In our project, we implemented a novel methodology for classifying both musical instruments and environmental sounds, utilizing convolutional and recurrent neural networks. We used the Mel Frequency Cepstral Coefficient (MFCC) method to extract features from audio, which emulates the human auditory system and produces highly distinct features. Knowing how important data processing is, we implemented distinctive approaches, including a range of data augmentation and cleaning techniques, to achieve an optimized solution. The outcomes were noteworthy, as both the convolutional and recurrent neural network models achieved a commendable level of accuracy. As machine learning and deep learning continue to revolutionize image classification, it is high time to explore the development of adaptable models for audio classification. Despite the challenges associated with a small dataset, we successfully crafted our models using convolutional and recurrent neural networks. Overall, our strategy for sound classification bears significant implications for diverse domains, encompassing speech recognition, music production, and healthcare. We hold the belief that with further research and progress, our work can pave the way for breakthroughs in audio data classification and analysis.**

Keywords*—Deep learning (artificial intelligence); data augmentation; audio segmentation; signal processing; frame blocking; fast fourier transform; discrete cosine transform; feature extraction; MFCC; CNN; RNN

I. INTRODUCTION

Deep learning techniques have enabled the classification of audio, which has numerous practical applications. This technology can be used to recommend music, categorize various musical instruments, recognize music genres, organize music collections, develop streaming services, differentiate between male and female speech, distinguish between different languages or accents, build speech recognition systems, and analyze audio recordings from surveillance equipment to detect sounds indicating a threat or emergency. Consequently, deep learning-based audio classification has become an essential tool that can be employed in diverse contexts to analyze and classify audio data.

Lately, there has been a notable surge in the utilization of Digital Signal Processing (DSP) for musical instrument processing and speech analysis. In addition, there is an increasing demand for online access to music data on the internet, and this has led to a rise in computational tools for development such as summarization, analysis, classification, and indexing. Music Information Retrieval (MIR) provides solutions for music-related tasks, including the subtask of sound classification of musical instruments, which involves identifying different musical instruments [1]. MIR is also used for a variety of applications, including beat tracking, beat recognition and separation, automatic music transcription, and polyphonic audio processing [2].

Instrumental music frequently contains insightful information regarding current events. Although automatic sound processing is thought to be the state of the art, robots are still far behind humans in their ability to perceive and distinguish between wide varieties of sound events. More research is needed today to create a dependable system that can accurately identify a wide spectrum of audio, including different musical instruments [3].

Generally speaking, there are three sub-categories of audio classification tasks: music classification, acoustic scene classification, and speech recognition (acoustic model). Each of these activities includes various signal qualities, which causes changes in the audio data input aspects. Recent significant deep learning breakthroughs have made it possible to build a single audio or musical instrument model that is adaptable enough to handle diverse cross-domain tasks. The potential of a CRNN (Convolutional Recurrent Neural Network) model was harnessed by Adavanne et al. [4] for the detection of sound events, the classification of auditory birds [5], and the recognition of musical emotion [6]. The selection of parameters for representing time-frequency as input has a substantial impact on the efficacy of audio classification models for various tasks, according to recent breakthroughs in the field. Unfortunately, a large number of existing models use non-optimal filter bank size and type, time-frequency magnitude compression, and resolution. Particularly concerning the choice of 2D or 1D convolutional layers and the shape of the filter, these decisions have a significant impact on the model's architecture [7]. Waveform-based models, which directly handle unaltered input signals, offer an inventive way to get around these problems. Regarding the aforementioned problems, this strategy has promise. Notably, Schrauwen and Dieleman [8] recently showed the effectiveness of CNN models using raw waveforms as input for automatically tagging music, opening up new potential for enhancing audio categorization performance. This approach helps overcome the limitations of traditional audio classification methods by allowing the model to learn directly from the raw audio signals. Consequently, waveform-based models have the potential to significantly improve the accuracy and efficiency of audio classification in a wide range of applications.

Most of the previous research in music information retrieval (MIR) has focused on monophonic music [9], while this approach predominantly utilizes monophonic data for instrument classification. For speech identification, Sainath et al. [10] employed a convolutional long short-term memory deep neural network (CLDNN), whereas Dai et al. [11] used a deep convolutional neural network (DCNN) with residual connections to identify environmental sounds. The majority of the investigations employed frame-level filters with carefully designed first convolutional layers made up of extensive samples.

The method for extracting musical instrument features and categorizing instrumental audio in our study is based on these attributes. Fig. 1 shows the block diagram describing the procedure in detail for this operation.

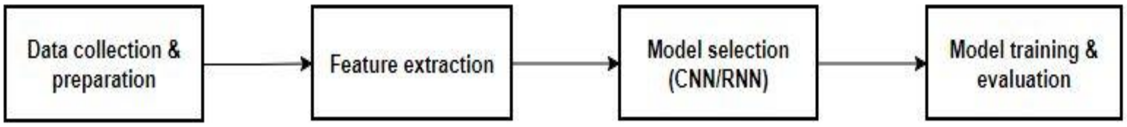

Fig. 1. Basics of audio tagging and feature extraction.

We arranged this paper as follows, in Section I, the introduction is given, in Section II, the related work is explained, in Section III, the feature extraction techniques are described, in Section IV, the dataset is explored, in Section V, the pre-processing steps are discussed, in Section VI, the model is built and explained, in Section VII, a comprehensive analyses of the results are conducted, and in Section VIII, conclusion is drawn.

II. Related Work

The classification of musical instruments is a topic that is actively being researched, and many approaches have been suggested by scholars and it is clear from the literature study that more research is still needed in this area to get the best results with greater precision, especially when working with tiny datasets.

Meinard Müller, Daniel P. W. Ellis, Anssi Klapuri, and Gal Richard examined numerous signal processing techniques to categorize musical instruments in a notable work [12]. With a focus on musical signal processing, this article provides a thorough overview of numerous research fields. Among the methods investigated, the use of MFCCs (Mel Frequency Cepstral Coefficients) in the classification of musical instruments attracts a lot of interest and debate.

In a noteworthy study, Jadhav, P. S. [13] proposed a unique method for identifying musical instruments by fusing MFCCs with Timbral Associated Descriptors of Audio. They used a binary tree, SVM (Support Vector Machine), and k-nearest neighbor as part of their feature extraction technique. The research demonstrated an insightful investigation into improving musical instrument recognition by further examining and evaluating the identification accuracy attained through various combinations of classification algorithms and feature extraction methods.

D. G. Bhalke, C. B. Rama Rao, and D. S. Bormane [1] pioneered the use of FFT (Fractional Fourier Transform) in conjunction with MFCCs for categorizing musical instruments in a different work that has been discussed in the introduction section. They also used temporal traits like assault time, zero-crossing rates, decay time, and energy to their advantage to support their classification strategy. The method for calculating the zero-crossing rate, Eq. (1), was introduced in the study, offering important insights into the development of musical instrument categorization algorithms.

$$ZCR = \frac{1}{T}\sum_{0}^{T-1} \mid \mathrm{sgn}[\mathrm{x(y)}] - \mathrm{sgn}[\mathrm{x(y-1)}] \mid \qquad (1)$$

Here, T denotes the sample in each frame, while x(y) and x(y-1) denote the signals of the yth and (y-1) samples, respectively.

The Eq. (2) was utilized to compute the energy of the sound sample.

$$Energy = \sum_{n=0}^{T-1} (|\mathrm{m(n)}|)^{2} \qquad (2)$$

The signal of the nth sample is represented by m(n), while T signifies the number of samples present in one frame.

Essid, S., Richard, G., & David, B. suggested that the sound samples feature be used for MFCCs [14]. They provided more information on how using the derivative of MFCCs over time can be used to exploit the Delta MFCC capabilities. The SVM technique was used to classify data. Spectral characteristics such as spectral centroid and spectral breadth were used. One mapping vs one SVM was used to train the data. M. Erdal Ozbek, Nalan Ozkurt, and F. Acar Savaci [15] classified musical instruments using wavelet decomposition up to the first three stages and wavelet ridges (Fig. 2). By using this method, three precise coefficients and one estimated coefficient are extracted, allowing for accurate classification.

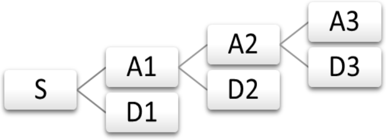

Fig. 2. Three Stages of wavelet decomposition.

Herein, the signal frame denoted as S, is calculated as the sum of the approximate coefficient (A) and the detailed coefficients (D) at levels 1 to 3, where D1, D2, and D3 correspond to the detailed coefficients at each respective level.

Farbod and Karthikeyan suggested using wavelet-dependent time scale information to categorize musical instruments [16]. In order to obtain the required qualities, they continuously took the wavelet transform signal frame and extracted features relating to bandwidth and temporal fluctuation.

A support vector machine (SVM) employing Mel-Frequency Cepstral Coefficients (MFCC) as feature vectors was suggested in a prior study for the classification of musical genres. While melody is crucial for understanding music data, it is not a suitable feature for classification. Music genres are strongly correlated with the timbre of music, which corresponds to the frequency characteristics of sound signals. Therefore, previous studies commonly use MFCC as feature vectors for music genre classification [17]. Another study combines audio and lyrics features to detect music emotions, using a synchronized dataset of chorus audio and lyrics. The audio features extracted include dynamics, rhythm, timbre, pitch, and tonality, while lyric features include psycholinguistic, stylistic, and statistical features. Weighting the audio and lyric features using a Naive Bayes probability value shows that the audio feature is dominant with an 80% weighting ratio [18].

The application of these diverse feature extraction techniques is evident in numerous research papers. An article discusses how cardiovascular diseases are a major cause of deaths worldwide and identifies the importance of detecting heart disease at an early stage. The article presents an approach for classifying heart audio samples using deep learning techniques and compares the results of various machine learning algorithms. The approach involves implementing existing segmentation techniques and feature engineering in the audio domain. The precision values indicate that the Hybrid CNN model performed best with a precision of 1 for artifact, 0.906 for normal, and 0.859 for murmur categories [19].

Another study shows that Vehicle classification is a crucial task in managing traffic and road infrastructure, with new challenges continuously emerging. Through classifier fusion techniques, the complementary nature of information has previously been used to enhance classifier performance. This hasn't been looked at in the context of a multi-modal categorization system that uses only neural networks. To increase performance, this study suggests a complementarity-based multi-modal vehicle categorization system. The system uses sets of Mel Frequency Cepstral Coefficients (MFCC) as the feature vectors for the audio modality to perform vehicle classification with two distinct modalities using Convolutional Neural Network (CNN) classifiers. At the decision level, the predictions from the base classifiers are combined to provide a final prediction, increasing accuracy. The study finds that in a fully neural network-based multi-modal system, decision-level fusion is an efficient method for enhancing vehicle classification accuracy [20].

III. MFCC Feature Extraction

Generally, Automated Speech Recognition (ASR) systems require feature extraction from speech signals that are non-stationary in nature [21]. Feature extraction becomes difficult due to speech variability constraints such as differences between speakers, intonation, and changes in speech production. A good feature extraction technique should identify specific linguistic properties and discard irrelevant information such as background noise and emotion. Commonly used feature extraction techniques include Mel Frequency Cepstral Coefficients (MFCC), Linear Predictive Coefficients (LPC), Perceptual Linear Predictive (PLP) Coefficients, Discrete Wavelet Transform (DWT), and Principal Component Analysis (PCA).

Our study aims to demonstrate the process of sound feature extraction using the MFC technique, which is currently popular. The vocal tract's shape, including the shape of the tongue and teeth, filters spoken sounds and defines the sound made. Accurately determining the shape provides an accurate phoneme representation, which is reflected in the short-time power spectrum's envelope. MFCCs precisely represent this envelope. To classify instrumental music, identifying various audio signal components and eliminating background noise or dead space is the initial step.

The use of Mel Frequency Cepstral Coefficients (MFCCs) for audio feature extraction in various recognition applications has become commonplace in the present day. Because of their effective classification accuracy in a clean environment, MFCCs have been around since Davis and Mermelstein first introduced them in the 1980s [22]. Fig. 3 shows the steps involved in the MFCC feature extraction approach, which has recently gained in popularity [23].

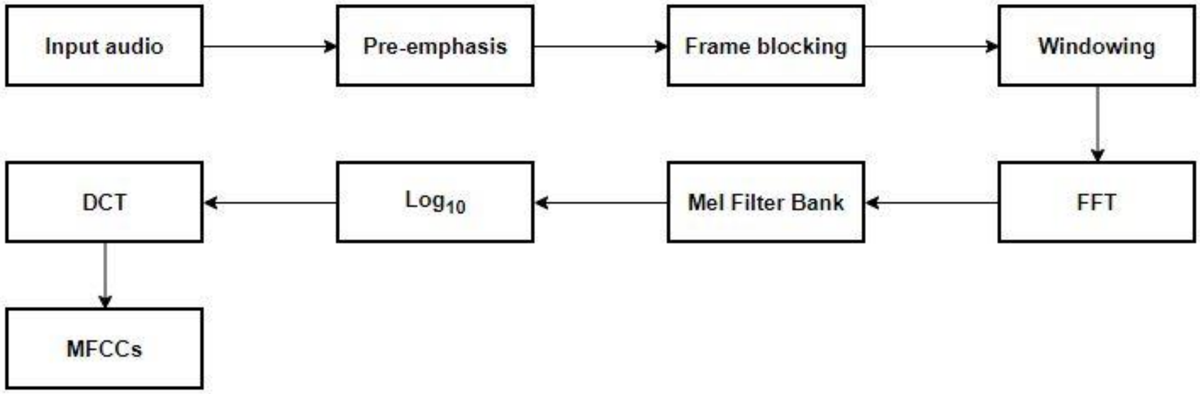

Fig. 3. MFCCs block diagram.

So, to extract features from a signal, it is common to partition it into short frames, estimate the power spectrum for each frame using periodogram analysis, apply a mel filterbank to the power spectra and calculate the energy within each filter, compute the logarithm of the filterbank energies, apply the discrete cosine transform (DCT) to the logarithmic energies, and then keep only the DCT coefficients while discarding the rest.

Further processing steps may include appending the frame energy and delta and delta-delta features to the feature vectors, as well as filtering the final features. Fig. 3 illustrates these proposed steps.

When implementing feature extraction, MFCCs are often preferred over other techniques due to their relative simplicity and robustness across various conditions [24]. MFCCs are designed to mimic the human auditory system. Steps of MFCCs (Fig. 3) are described below:

1) Pre-emphasis: To optimize an audio signal for subsequent processing, it is standard practice to apply a pre-emphasis filter. The purpose of this filter is to boost the energy levels of the higher frequencies, thereby emphasizing them in the overall signal.

Through the use of a first-order infinite impulse response (FIR) filter, pre-emphasis filtering can be carried out by conducting spectral flattening [25], [26]. The FIR filter used in this stage of the process is specifically represented by Eq. (3).

$$H(z) = 1 - az^{-1}, \quad 0.9 \leq a \leq 1.0 \qquad (3)$$

By applying this filter, the audio signal's energy distribution is altered, with the higher frequency components becoming more prominent. This can help improve the signal-to-noise ratio and enhance overall signal quality, making it easier to extract useful information from the audio data.

2) Frame blocking: When analyzing time-varying signals like audio, it is vital to balance the need for signal accuracy with the practicalities of signal processing. This is particularly true when it comes to frame blocking, the process of dividing a signal into smaller segments, or frames, to facilitate analysis. If the signal is too long, its properties may be altered, while too-short frames can compromise the resolution of narrow-band components. To achieve an optimal balance between these considerations, audio signals are typically divided into frames of 20-30 milliseconds, with adjacent frames separated by M samples (where M<N). M is frequently set to 100, and N to 256.

For the analysis of time-varying signals whose characteristics are fixed over short time intervals, framing is needed. By segmenting the signal into smaller frames, spectral analysis can be conducted on individual segments, enabling a more precise analysis of the signal's characteristics.

3) Windowing: After dividing the audio signal into frames, the next step is to apply a window function to each frame. The Hamming window, which is provided by the equation, is a frequent option for this:

$$w(n) = 0.54 - 0.46 \cos\left(\frac{2\pi n}{N-1}\right) \qquad (4)$$

In this case, 'n' varies from 0 to N-1, with 'N' being the window length, pertaining to audio signals sampled at 16 kHz, a standard frame length of 25 ms is used, which translates to a frame length of 400 samples. The frame step is typically set to 10 ms (or 160 samples), which allows for overlapping between adjacent frames. The first frame starts at sample 0, followed by the next frame starting at sample 160, and so on until the end of the signal. In cases where the audio file cannot be evenly divided into frames, zero padding is used to make up the difference.

Fredric J. Harris [27] compares the various sorts of windows that are accessible in detail. Fig. 4 displays the Hamming window function's resulting plot (with 200 samples).

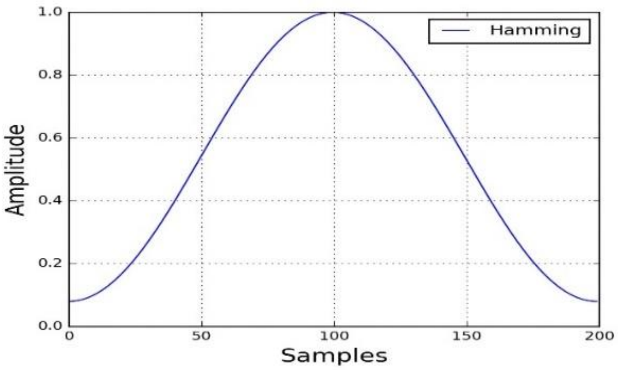

Fig. 4. Hamming window.

4) FFT (Fast Fourier Transform): The Fourier transform changes a signal's time domain to its frequency domain, can be used to show a spectrum on a computer screen. A spectrum essentially depicts the frequency domain manifestation of the time-domain signal of an audio input [28].

Using mathematics, the discrete Fourier transform (DFT) converts a constrained sequence of uniformly spaced function samples into a sequence of equally spaced samples of the discrete-time Fourier transform (DTFT), which is a complex-valued function of frequency. The DFT can be written as [29], which transforms a sequence of N complex numbers into another sequence of complex numbers.

$$\hat{x}(k) = \sum_{n=0}^{N-1} x(n) e^{-2\pi i k n/N}$$

$$\text{for } k = 0,1,\ldots, N-1 \qquad (5)$$

Since DFT operates on a limited amount of data, it can be executed on computer devices using numerical algorithms or specialized hardware [30]. The effective Fast Fourier Transform (FFT) techniques are frequently used in these tasks. The terms "FFT" and "DFT" are frequently used interchangeably. The abbreviation "FFT" may have also been used to refer to the ambiguous word "Finite Fourier Transform" before its present use [31] [32].

Since the mathematical procedure known as the Fast Fourier Transform (FFT) allows for the transfer of signals from the time domain to the frequency domain, by applying the FFT to each frame, we can obtain the magnitude frequency of the signal. Thus, the output of the FFT process results in either a Periodogram or a Spectrum, as stated in reference [33]. So, this process is critical in signal processing and provides valuable insights into the characteristics of the signal.

Fig. 5 describes the application of FFT on saxophone signals, enabling the conversion of frequency information into a magnitude-based domain.

5) Triangular bandpass filter: A bandpass filter is an electronic filter that permits only a specific range of frequencies to pass through while suppressing or obstructing frequencies outside that range. It is engineered to transmit signals within a designated bandwidth while impeding signals that are beyond it. Bandpass filters are frequently employed in a wide range of applications such as audio processing, medical equipment, and wireless communication systems [34] [35]. These filters can be constructed using different methods, including passive RC filters, active filters, and digital filters. The center frequency, bandwidth, and quality factor are crucial design parameters that govern the filter's selectivity, gain, and noise performance.

To obtain a smooth magnitude spectrum for our research, which significantly shrunk the feature size, we used 20 triangle bandpass filters. We need to note that Hertz is represented by f in this context. The linear scale frequency is converted to Mel scale frequency using Eq. (6), which is defined as,

$$\text{Mel(f)} = 2595 \log_{10}\left(1 + \frac{f}{700}\right) \qquad (6)$$

Spectral envelop extraction is achieved by utilizing triangular bandpass filters, as described in reference [36]. Mel frequency filters are constructed using triangular bandpass filters that are dispersed unevenly along the Mel frequency axis. In other words, the low-frequency axis has a higher density of filters, whereas the high-frequency area has a lower density of filters. References [37] and [38] are used to support this, which is shown in Fig. 6 (for 26 filters).

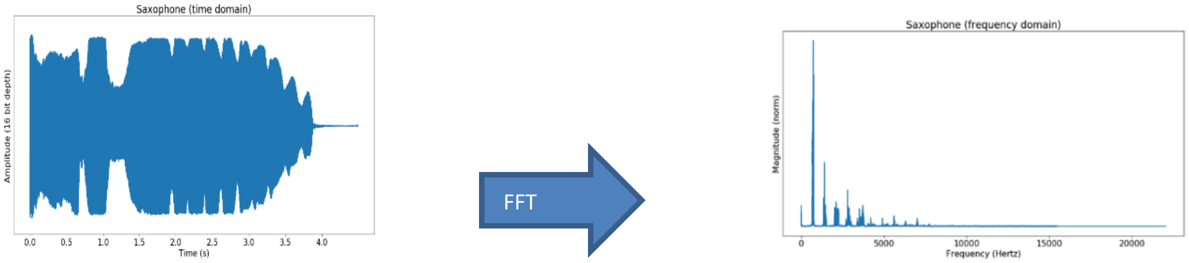

Fig. 5. FFT transformation.

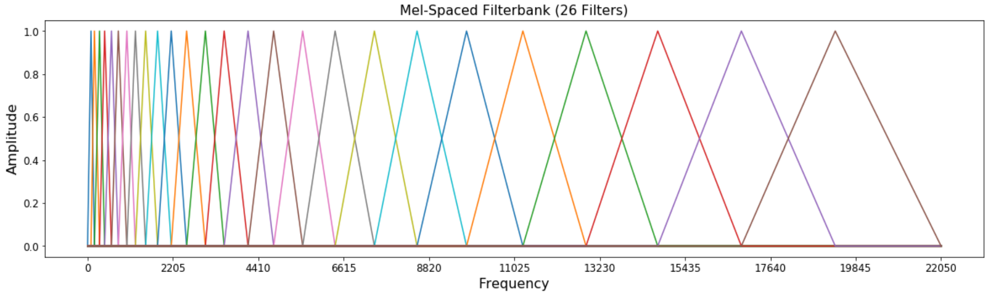

Fig. 6. Filter bank.

In order to create a filter bank, Eq. (6) is employed, which is visible in Fig. 6. The equation is defined as follows:

$$Hm(k) = \begin{cases} 0 & k < f(m-1) \\ \frac{k-f(m-1)}{f(m)-f(m-1)} & f(m-1) \leq k \leq f(m) \\ \frac{f(m+1)-k}{f(m+1)-f(m)} & f(m) \leq k \leq f(m+1) \\ 0 & k > f(m+1) \end{cases} \quad (7)$$

In this case, the letters "M" stand for the total number of filters used (26 in Fig. 6), while the letters "f()" stand for a list of M+2 Mel-spaced frequencies. The plots of the 26 filters cross over, each filter bank having a different pattern. The first filter starts at the first point, peaks at the second point, and then resets to zero at the third. The continuation of this pattern for succeeding filter banks results in an orderly evolution that improves the accuracy and thoroughness of our study.

Overall, a significant step in lowering feature size and obtaining spectral envelop extraction is the use of Mel frequency filters and triangular bandpass filters. These filters work by applying a non-uniform distribution along the Mel frequency axis, so more filters are found in the low-frequency zone and fewer in the high-frequency region. A filter bank that can be utilized for several purposes can be made using this process.

6) The filter's energy logarithm: The logarithm of filter energy is a commonly employed technique in audio classification, which entails computing the energy of an audio signal in particular frequency bands, followed by taking the logarithm of those energies.

This approach generally reduces the dimensionality of the feature space by transforming the raw energy values into logarithmic values, which are less sensitive to small fluctuations in signal amplitude. This is crucial since audio signals can exhibit a wide range of amplitudes, and the logarithmic transformation helps to normalize energy values across different signals. Moreover, the logarithm of filter energy can capture both high- and low-energy components of a signal, rendering it valuable for classification tasks such as music genre classification or speech recognition. The technique enables the extraction of pertinent features from an audio signal, such as energy distribution across different frequency bands, which can differentiate between various audio signals.

Our study uses Eq. (8) to calculate log-energy by adding the filtered components from each filter. This process offers insightful information about the data.

$$S(m) = \log_{10}[\sum_{K=0}^{N-1} |X(k)|^2 . Hm(k)] \quad 0 \leq m \leq M \; (8)$$

We determine the log-energy, denoted as S(m), by taking the base-10 logarithm of the spectral magnitude weighted sum within the filter bank's channel. Specifically, the sum of the squared magnitudes of the discrete Fourier transform (DFT) coefficients in each frequency bin is multiplied by the corresponding filter weights (Hm(k)). This calculation is performed for each filter bank channel, resulting in a log-energy value for each bin per frame of filter.

Overall, the logarithm of filter energy is a potent tool in audio classification, often combined with other techniques such as Mel Frequency Cepstral Coefficients (MFCCs) to achieve high classification accuracy. Recent studies have shown that combining the logarithm of filter energy with deep learning approaches can significantly enhance the performance of audio classification systems [39] [40] [41].

7) DCT (Discrete Cosine Transform): A widely used mathematical technique for evaluating and processing various sorts of signals, including audio signals, is the discrete cosine transform (DCT). In the realm of audio classification, the DCT is frequently utilized to alter an audio signal from the time domain to the frequency domain, thereby making it possible to efficiently analyze and extract essential features.

The DCT mainly breaks down a signal into a collection of cosine functions of differing frequencies, with each function having its own amplitude. The output frequency coefficients represent the contribution of each frequency component to the original signal. These coefficients can then be deployed as features for audio classification.

Several variations of DCT are available, with DCT Type II being the most commonly used version, often referred to as the "standard" DCT. This version is employed in the widely popular audio compression format, MP3. So we can say that DCT is an immensely powerful tool for audio analysis and classification. By capturing vital frequency information that is not immediately evident in the time domain, the DCT greatly enhances the accuracy and efficiency of audio classification [42] [43].

We applied the Discrete Cosine Transform (DCT) to transform the Mel frequency domain, which characterizes the logarithmic power spectrum of an audio signal, back into the time domain [44]. This crucial step yields Mel Cepstral Coefficients as the output. The Mel Frequency Cepstral Coefficient (MFCC) was the final preprocessing step, as described in a paper [45]. The MFCC version produces a more condensed image compared to the Mel filterbank. It achieves decorrelation of many energies from the prior energy band using the DCT, a compression method utilized for audio and image files. By converting higher frequencies to lower frequencies, the DCT principle compresses audio and image data, allowing different sounds to have distinct visual representations. This completes the data preprocessing stage.

IV. Dataset Overview

Our final objective was to increase our model's accuracy, even when it was trained on a modestly sized dataset. This was accomplished using a portion of the Freesound Dataset Kaggle 2018 ("FSD Kaggle 2018") dataset, a considerably larger dataset than the one we utilized. The total dataset is many gigabytes in size and consists of forty-two audio classes. More information about the dataset can be found at [46] [47].

We also experimented with a seemingly more extensive dataset compared to FSD, namely ESC-50, having a sample rate of 44100 KHz and a substantial size of approximately 2 gigabytes. This dataset encompasses 50 distinct classes and comprises a total of 2000 audio files. To further amplify its scale, we applied augmentation techniques.

Upon our rigorous customization of the dataset, we have taken the initiative to share it on Kaggle, ensuring it serves as a substantial resource for future researchers. The concise FSD-Kaggle dataset as well as the CSV file can be found at https://www.kaggle.com/datasets/jewelmd/subset-of-fsd-kaggle-2018, while the augmented variant is available at this link: https://www.kaggle.com/datasets/jewelmd/augmented-esc-50-441-khz.

Through a combination of careful dataset selection and model construction, we were able to achieve our target of higher accuracy, even with a limited dataset. Our results demonstrate the effectiveness of our approach, as well as the importance of careful dataset selection and model construction in achieving accurate and reliable results.

A. *Contents of Our Dataset*

From the Kaggle competition, we have specifically chosen ten diverse classes pertaining to musical instruments where we have 300 audio files (30 audio files per class). We will also be working with a CSV file that will help us associate the audio files' obscure names with the respective musical instrument classes. The ten instrument classes we are working with are 'Acoustic_guitar', 'Bass_drum', 'Cello', 'Clarinet', 'Double_bass', 'Flute', 'Hi-hat', 'Saxophone', 'Snare_drum', and 'Violin_or_fiddle'. We will employ advanced analytical techniques to classify these instruments based on the data we have gathered.

The ESC-50 dataset initially comprised 50 distinct classes, 40 files per class, total (40 x 50) 2000 audio files. Through augmentation, the dataset underwent a sixfold expansion, yielding a total of 12000 audio files. Detailed explanations of this augmentation process are provided in the dedicated Section IV on data augmentation.

B. *Employing Data Augmentation Techniques*

In our endeavors with the ESC-50 dataset, we diligently applied data augmentation methods. Given our focus on audio data, we navigated through a plethora of techniques tailored specifically for enhancing this type of information. Audio data augmentation has emerged as a pivotal practice within the domain of machine learning, particularly in tasks pertaining to audio processing. This practice involves artificially amplifying the diversity of a dataset by subjecting original audio samples to an array of transformations. The overarching objective is to equip machine learning models with the capacity to adeptly handle a wider range of real-world scenarios. Notably, recent years have seen the advent of seminal research papers [48][49][50] that have propelled advancements in this domain. Below, we outline the detailed steps taken to implement data augmentation on the ESC-50 dataset in Fig. 7.

1) Initialization and directory definitions: In the initialization phase, necessary packages were imported. Following this, paths for both the original and augmented dataset directories were established. Then this module verifies if the augmented dataset directory already exists; if not, it creates it. This step ensures the availability of essential directories for seamless data processing.

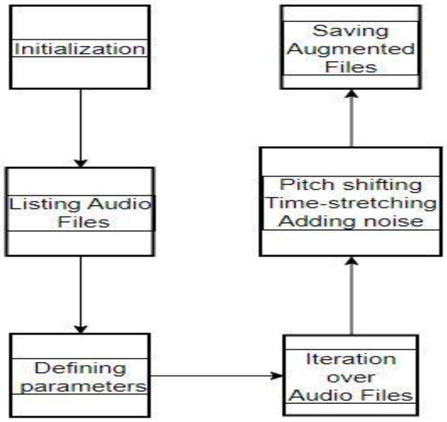

Fig. 7. Data augmentation steps.

2) List audio files: This step involves obtaining a list of audio files from the designated original dataset directory.

Parameter definitions

In this step, key parameters for data augmentation are established. These include pitch shift steps, time stretch factors, and noise levels, which are essential for modifying the audio data.

Below are the parameters we applied to the audio files, visible in Table I.

TABLE I. AUGMENTATION TYPES AND FACTORS

Augmentation type	1st factor	2nd factor
Pitch shift step	-2	2
Time stretch factor	0.8	1.2
Noise level	0.001	0.01

3) Iteration over audio files: This step involves a loop that iterates through each audio file in the list. For each file, it performs two tasks: extracts the class label from the file name and loads the audio file.

4) Data augmentation: In the data augmentation phase, an empty list named augmented_audios is initialized to store modified versions of the audio. Pitch shifting is applied for each specified pitch shift step, and the augmented audio is appended to the list. Similarly, time stretching is implemented for designated factors, and the altered audio is added to augmented_audios. Additionally, background noise is introduced by generating random noise and combining it with the audio. This augmented audio is then included in the augmented_audios list, completing the data augmentation process.

5) Saving augmented files: In this step, each augmented audio file from the list augmented_audios undergoes a two-part process: first, a unique file name is generated, and then the augmented audio is saved to the designated augmented dataset directory. This ensures that the augmented versions are properly stored for future use.

We derived six additional files from a single audio recording. Initially, the ESC-50 dataset comprised 2000 audio files. After implementing data augmentation, this number multiplied to 12000 (2000 x 6). This expansion is due to the application of three distinct types of data augmentation, each with two contributing factors, resulting in a sixfold increase in dataset size.

a) CSV file generation: With the dataset update resulting in a total of 12000 audio files, it became imperative to also update our CSV file for training purposes. To accomplish this, we developed a script that generated a new CSV file containing all the newly created file names and their respective categories.

To implement the proposed approach for audio data classification, it is necessary to set up a folder (named 'wavfiles') to store all the raw audio files and a corresponding CSV file is required too. This CSV file should consist of at least two columns: one labeled 'filename' containing the names of the audio files, and the other labeled 'category' representing their respective classes.

For instance, if we have an audio file named 'Audio_file_001', it would be associated with the class 'Flute'. While the CSV file may contain additional columns like 'take' or 'length', our primary focus will be on these two columns.

V. DATASET PRE-PROCESSING AND CLEANING

Our whole model, including the pre-processing phases, was conducted within a Python environment (version 3.7) before beginning the analysis. We carefully incorporated crucial libraries like "Python speech features," "Tqdm," "Librosa," and other necessary packages to enable a seamless analysis, establishing a solid platform for a thorough study of the data.

We carried out a thorough analysis of the distribution of all classes in our audio dataset (Fig. 8), which revealed a significant amount of dead space in the audio files. Eliminating these duplicate sections will greatly improve the quality and effectiveness of our study, producing more reliable and significant outcomes.

To prepare an audio dataset for classification, it is needed to remove any dead spots, i.e., the silent parts in the files. This process, known as cleaning, ensures that the data is of high quality and is free of any unnecessary noise. As depicted in Fig. 9, after cleaning the dataset and storing it in a separate directory, the distribution of classes has undergone a transformation, indicating the effectiveness of this approach in enhancing the quality of the data. We performed this cleaning process on all of our datasets, including FSD, ESC-50, and Augmented ESC-50. However, in the Figure, only FSD-Kaggle is depicted.

A. *Plotting and Cleaning*

The first step in the procedure was to create a directory called "Clean" that would be used to store the cleaned audio recordings. We also initialized four dictionaries that were crucial to the task at hand: signals, FFT, Filter bank, and MFCCs. We chose to use 26 filters, 512 FFT, and a signal rate of 16000 for each dictionary. Additionally, with a 25 ms window size, we used the short-term Fourier transformation as well as an 1103 sample per second sampling frequency. The ideal number for our needs was 13, hence the MFCCs were programmed to have 13 Cepstral Coefficients. For both versions of the ESC-50 dataset, we employed a signal rate of 44100, as the data versions we utilized were formatted at this rate.

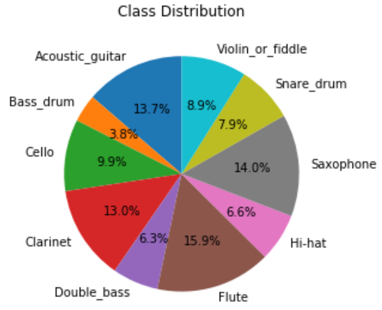

Fig. 8. Before cleaning.

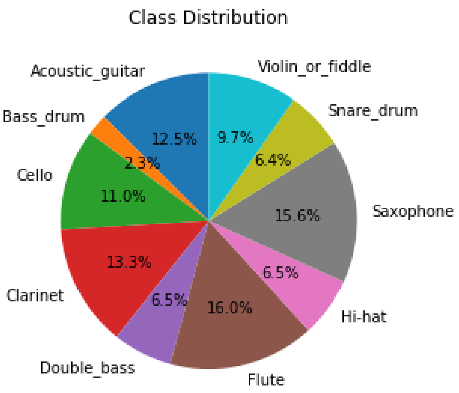

Fig. 9. After cleaning.

1) Removing dead spots: To optimize the quality of the audio signal, we executed a series of steps to prepare our data for effective training. The specific procedures are outlined in Table II.

The process aims to enhance audio data quality for analysis. It begins by smoothing amplitude representation with an envelope calculation. Sample rates are adjusted for compatibility (44100 Hz for ESC-50, 16000 Hz for FSD). A mask generated from the envelope function refines the signal, followed by filtering for data accuracy. Processed audio files are stored in a dedicated "clean" directory for organized analysis.

TABLE II. STEPS TAKEN FOR REMOVING DEAD SPOTS FROM AUDIO FILES

Steps	Description
1. Calculate Envelope	Utilized a window size of 0.1s and a frequency of 1 period/minute to obtain a smooth amplitude representation.
2. Up/Down-Sampling	Adjusted the sample rate to 16000 Hz (for FSD), 44100 Hz (for ESC-50) for compatibility and signal refinement.
3. Generate Mask	Utilized the envelope function to create a mask and applied it at a 0.005 rate after adjusting the sample rate.
4. Apply Filter	Successfully removed redundant or erroneous data using a filter.
5. Create "clean" Directory	Established a directory named "clean" to store processed audio files.

For greater clarity, a specific example of the 'Flute' is presented, illustrating its appearance before being cleaned, which exhibited several dead spots. Following the removal of these dead spots from the audio file, a visual representation of the cleaned Flute can be observed in Fig. 10 and Fig. 11 as it is evident that there are a lot of dead spots.

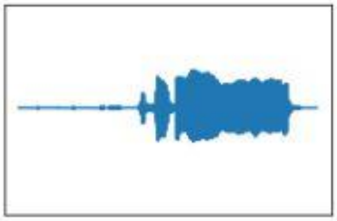

Fig. 10. Before removing dead space.

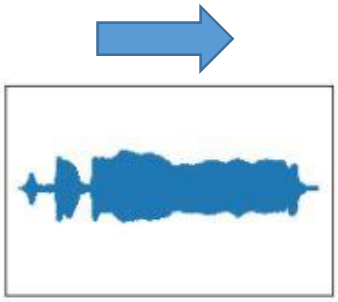

Fig. 11. After removing dead space.

B. Exploratory Data Analysis (EDA)

As part of the preprocessing phase, we created an 'eda.py' file with the following functionalities:

This script is designed to conduct a comprehensive analysis of the audio dataset. It encompasses tasks such as feature extraction, generating visualizations, and potentially deriving insights into the characteristics of the audio files. The visualizations produced by this script serve as valuable aids for informing further analysis or gaining a deeper understanding of the dataset before proceeding with more advanced tasks like machine learning or signal processing.

To begin, we imported required libraries including os, tqdm, pandas, numpy, and matplotlib. Following that, we established several plotting functions to facilitate visual representation and analysis.

Plotting Functions:

1) Plot_signals(signals): This function takes a dictionary of time series signals and plots them in a 2x5 grid, showing the waveforms of different audio samples, visible in Figure 12.

2) Plot_fft(fft): This function takes a dictionary of Fourier Transforms and plots them in a 2x5 grid, displaying the frequency domain representation of different audio samples, visible in Fig. 13.

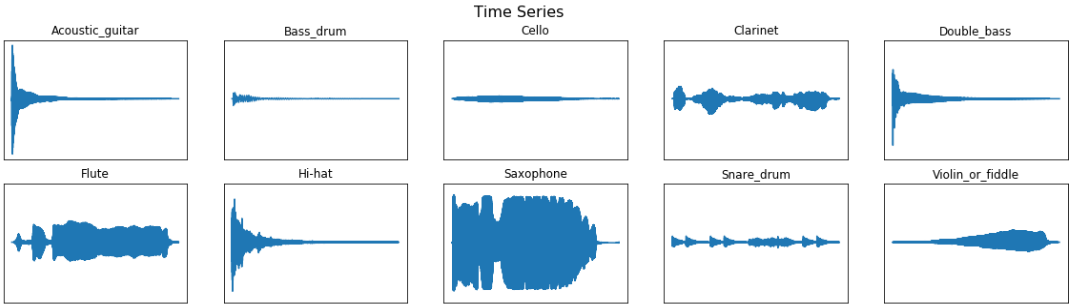

Fig. 12. Time series plot for clean data.

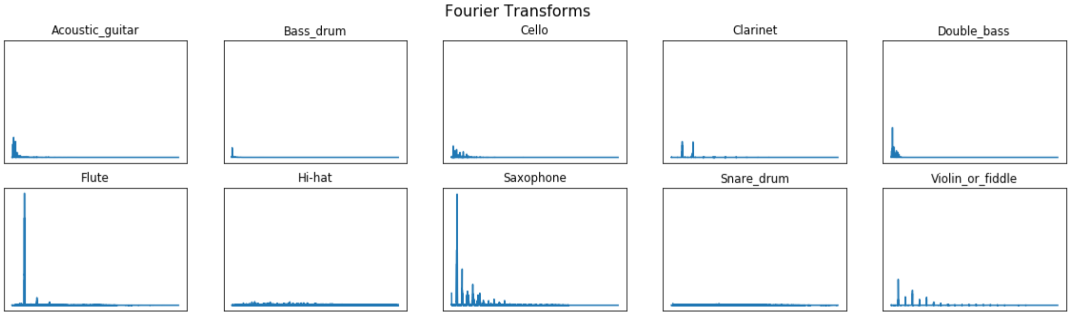

Fig. 13. FFT plot of clean data.

3) Plot_fbank(fbank): This function takes a dictionary of Filter Bank Coefficients and displays them in a 2x5 grid as images, showing the distribution of frequency components, visible in Fig. 14.

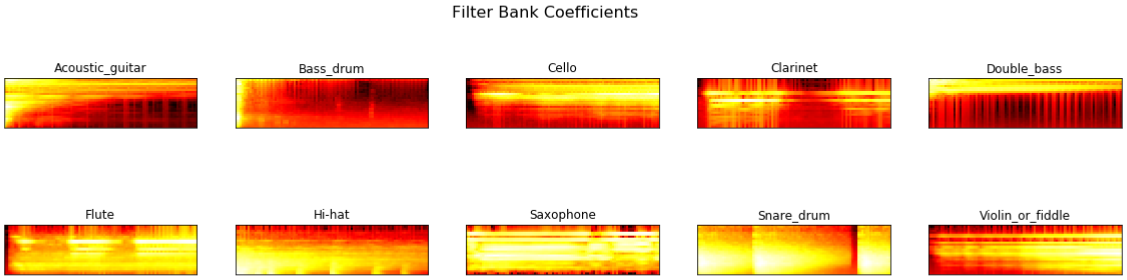

Fig. 14. Filter Bank plot of clean data.

4) Plot_mfccs(mfccs): This function takes a dictionary of Mel Frequency Cepstrum Coefficients and displays them in a 2x5 grid as images, representing the features of audio signals, visible in Fig. 15.

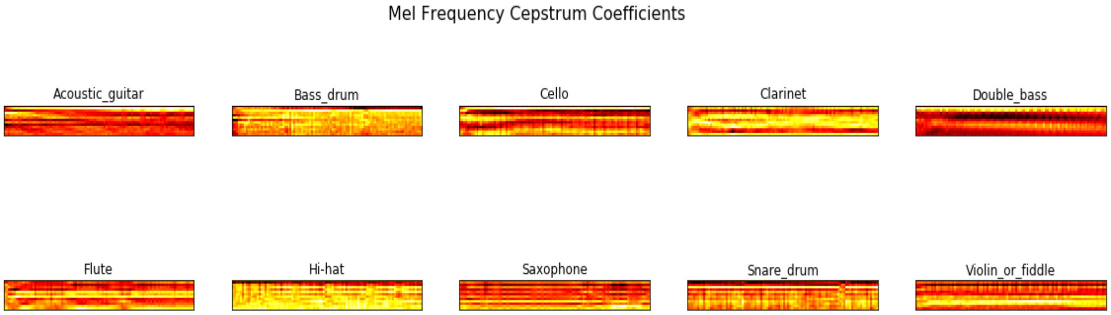

Fig. 15. MFCCs plot of clean data.

We applied these procedures to all three datasets: FSD-Kaggle, ESC-50, and Augmented ESC-50. However, in this demonstration, we are specifically showcasing the plotting for the FSD-Kaggle dataset.

Then we read the CSV file and created a DataFrame (df) to store the data. We also set the index of the DataFrame, which is likely a unique identifier for each audio file.

In the next stage to process the audio files, this script reads the WAV file located in the wavfiles/ directory and computes the sample rate and the signal. It then calculates the length of the audio file in seconds and stores it in the DataFrame under the column 'length'.

So, this script (eda.py) is designed to read and process a dataset of audio files, extracting features like signal length, and generating visualizations to help analyze the audio data. It leverages libraries like Pandas, NumPy, Matplotlib, and others for efficient data handling and visualization

VI. Model Building

A. Model Preparation

To enhance our model, we focused on managing class distribution and balance during training. With a specially designed function, we generated the input (X) and target (Y) matrices, randomly sampling one-second audio chunks, utilizing only a tenth of a second per sample. This data transformation enabled accurate prediction of the target variable Y, significantly improving our analysis.

We also paid close attention to the model's properties, including its sampling rate, window length, step size, and N FFT value. By taking a meticulous approach to model preparation, we were able to optimize our neural network's performance and accuracy. The procedures for building this model were completed by following Seth Adams' guidelines on audio classification [51]. So, we developed a separate script named 'cfg.py' to handle configuration settings. These settings are particularly pertinent to the processing of audio data. Within this script, we constructed a class named 'Config' with the specific purpose of managing these parameters. The 'Config' class not only provides predefined values for certain parameters but also allows for tailored adjustments when an instance of the class is created. The outlined configurations are detailed below in Table III:

TABLE III. Name and Value of the Parameter

Parameter	Property	Default Value (customizable)
mode	A string, indicating the mode	'conv'
nfilt	An integer, representing the number of filters	26
nfeat	An integer, specifying the number of features	13
nfft	An integer, representing the size of the Fast Fourier Transform (FFT)	512
rate	An integer, denoting the sample rate	16000

Due to their customizable nature, we fine-tuned these values to align with our specific needs. For instance, we configured the mode to 'time' when training our model on RNN and adjusted the rate to 44100 Hz for the ESC-50 dataset. We also defined the step size here which is one-tenth of the sample rate. We used it for processing audio data.

B. Convolutional Neural Network (CNN) Model

Audio classification can employ both 1D and 2D Convolutional Neural Networks, based on the input's data representation type. When the audio's time and frequency domains need to be analyzed, a 2D CNN is more appropriate. A 2D CNN was used for both ethnicity recognition and gender classification tasks in [52] but the feature maps extracted from the input images were combined and encoded into a 1D vector to facilitate classification. For tasks that involve the temporal structure of the audio, a 1D CNN is more suitable. Ultimately, the selection of the CNN architecture should be based on the audio data's specific characteristics and the classification task requirements.

During this phase of our project, we have successfully constructed several Convolutional Neural Network (CNN) models. The first step in building this model involved decoding the hot encoded Y matrix and converting it back to its original class form. We utilized the powerful Numpy Argmax function to accomplish this, which allowed us to map the encoded data back to its original column with ease.

The next step involved specifying the input shape for the convolutional layer, a critical aspect in ensuring the model's efficacy in detecting underlying data features. Key parameters, such as batch size, epochs, shuffling (enabled), class weighting (utilized Scikit-learn), and the reserved test data proportion, were defined. Following this, a sequence of convolutional and pooling layers was implemented to compress and stack the data over time, effectively reducing the dimensionality of high-dimensional input spaces. This process enabled the construction of a CNN architecture adept at capturing significant data features. The specific architecture of CNN models is given below in Table IV.

The ESC-50 CNN model consists of 10 layers, including Conv2D layers with varying filter numbers (16, 32, 64, 128) and 3x3 kernels with ReLU activation. It also features MaxPooling, Dropout (0.5), Flatten, and Dense layers with 128 and 64 units, each followed by ReLU activation. The output layer has 50 units with Softmax activation. The model utilizes the Adam optimizer and employs Categorical Crossentropy as the loss function.

TABLE IV. SEQUENTIAL CNN ARCHITECTURE

ESC-50 – CNN model	Augmented ESC-50 – CNN model
Number of Layers: 10	**Number of Layers: 15**

Optimizer: Adam	**Optimizer:** Adam (Learning Rate: 1e-3)
Loss Function: Categorical Crossentropy	**Loss Function:** Categorical Crossentropy
	Additional Techniques: - Learning Rate Scheduling - Early Stopping

The Augmented ESC-50 CNN model has 15 layers, featuring Conv2D layers with varying filters, Batch Normalization, MaxPooling, Flatten, Dense layers, and Dropout for regularization. The output layer has 50 units with Softmax activation. The model uses the Adam optimizer (LR: 1e-3) and Categorical Crossentropy as the loss function. Additional techniques include Learning Rate Scheduling and Early Stopping.

Here are two CNN models designed for the ESC-50 and augmented ESC-50 datasets. The model used for the FSD-Kaggle dataset (with 10 classes) mirrors that of ESC-50, with the only difference being the last dense layer which has 10 units. We implemented various supplementary techniques as outlined below.

1) Learning rate scheduling: Learning Rate Scheduling dynamically adjusts the learning rate during training. We implemented a custom schedule using a function, lr_schedule(epoch), which scales the rate based on epoch thresholds (e.g., 10, 20, 30, 40).

2) Early stopping: Early Stopping prevents overfitting by monitoring validation loss and stopping training after a set number of epochs with no improvement (patience=10). Using restore_best_weights = True ensures the model retains the best state.

3) Batch normalization: Batch Normalization stabilizes training, speeds up convergence, and reduces overfitting by normalizing activations within each layer. This leads to better generalization and enables the use of higher learning rates, ultimately enhancing the model's performance.

C. RNN (Recurrent Neural Network) Model

In our ongoing efforts to optimize machine learning algorithms, we developed RNN models to complement our existing CNN architecture. Unlike CNNs, RNNs employ LSTM (Long Short-Term Memory) units, which excel in processing sequential data due to their long-term memory capabilities. Our RNN model demonstrated exceptional proficiency in learning from such data. Our rigorous training and testing procedures guaranteed that the model would exhibit accuracy and adaptability to new datasets. More detailed descriptions of our RNN model can be found in the Table V:

The FSD-Kaggle RNN model (10 classes) comprises nine layers, including two LSTM layers with 128 units each. It incorporates a Dropout layer (rate: 0.5) for regularization, followed by TimeDistributed Dense layers with varying units (64, 32, 16, and 8) and ReLU activation. The model concludes with a Flatten layer and a Dense layer (10 units, softmax activation), tailored for multi-class classification. It is optimized using Adam with Categorical Crossentropy loss, suiting the classification task's requirements.

The RNN model for ESC-50 and Augmented ESC-50 datasets consists of 13 layers. It includes LSTM units, Batch Normalization, and Dropout layers. TimeDistributed Dense layers with ReLU activation are utilized, followed by Flatten and a final Dense layer for multi-class classification. The model uses Adam optimizer (LR: 0.001) and employs Categorical Crossentropy as the loss function. Additional techniques like Learning Rate Scheduling and Early Stopping are implemented for improved training performance and prevention of overfitting.

TABLE V. SEQUENTIAL RNN ARCHITECTURE

FSD-Kaggle(10 classes) **– RNN model**	**ESC-50 & Augmented ESC-50 – RNN model**
Number of Layers: 9	**Number of Layers: 13**
Layer Types and Details: - LSTM (128 units), return_sequences=True, input_shape=input_shape - LSTM (128 units), return_sequences=True - Dropout (0.5) - TimeDistributed(Dense(64, activation='relu')) - TimeDistributed(Dense(32, activation='relu')) - TimeDistributed(Dense(16, activation='relu')) - TimeDistributed(Dense(8, activation='relu')) - Flatten - Dense (10 units, softmax)	**Layer Types and Details:** - LSTM (256 units), return_sequences=True, input_shape=input_shape - Batch Normalization - Dropout (0.3) or [0.2 for augmented] - LSTM (256 units), return_sequences=True - Batch Normalization - Dropout (0.3) - TimeDistributed(Dense(128, activation='relu')) - Batch Normalization - TimeDistributed(Dense(64, activation='relu')) - Batch Normalization - TimeDistributed(Dense(32, activation='relu')) - Flatten - Dense (50 units, softmax)
Optimizer: Adam	**Optimizer:** Adam (Learning Rate: 0.001)
Loss Function: Categorical Crossentropy	**Loss Function:** Categorical Crossentropy
	Additional Techniques: - Learning Rate Scheduling - Early Stopping

ESC-50 and augmented ESC-50 models were similar, with dropout rates of 0.3 and 0.2 respectively. Additional techniques were applied with adjusted rates compared to the CNN model. Here, *Learning Rate Scheduling* is implemented with an initial constant rate for the first 10 epochs, followed by an exponential decrease. Early Stopping is employed to halt training if no improvement is detected over six consecutive epochs.

D. Comparison of ModeTraining Parameters

For all models, the class weight is consistently set to 'Balanced'. Monitors are configured as 'val_acc' and 'val_accuracy' in 'max' mode, while both 'save_best_only' and 'save_weights_only' are uniformly set to 'True'. The main distinguishing factors emerge in the number of epochs, the allocation for validation split, and the incorporation of class weights alongside a learning rate scheduler, visible in Table VI.

TABLE VI. COMPARISON OF TRAINING CONFIGURATIONS

Parameter	**FSD-Kaggle**		**ESC-50**		**Augmented ESC-50**	
	CNN	**RNN**	**CNN**	**RNN**	**CNN**	**RNN**
Period	1	1	1	1	1	1
Batch Size	32	32	32	32	32	32
Shuffle	True	True	True	True	True	True
Validation Split	0.1	0.1	0.2	0.2	0.2	0.2
Epochs	15	15	100	30	50	30
Learning Rate Scheduler	No	No	No	Yes	Yes	Yes
Early Stopping	No	No	No	Yes	Yes	Yes
Total Files	300		2000		12000	

VII. ANALYSES OF RESULTS

Within this section, we will assess the performance of multiple deep learning models, including Convolutional Neural Networks (CNN) and Recurrent Neural Networks (RNN). The CNN models harnessed convolutional and pooling layers to effectively capture underlying data features, resulting in impressive accuracy rates within relatively short training periods. On the other hand, RNN models, employing LSTM units for sequential data processing, required more time to train due to their computational complexity. After training across various epochs for each respective model, we achieved good accuracy levels. A comparative table (Table VII) detailing the performance of these diverse models is provided below.

TABLE VII. COMPARATIVE TABLE DETAILING THE PERFORMANCE OF THESE DIVERSE MODELS

Model	**Architecture**	**Accuracy (%)**		**Loss (%)**	
		Train	**Test**	**Train**	**Test**
FSD-Kaggle (small dataset)	CNN	96.26	96.52	10.03	9.99
	RNN	87.84	87.88	33.60	34.55
ESC-50	CNN	86.33	88.47	45.02	40.86
	RNN	92.86	92.89	22.70	27.38
Augmented ESC-50	CNN	71.25	76.20	104.41	84.84
	RNN	77.29	79.18	80.90	73.23

In our study, we observe that for smaller datasets, CNNs outperform RNNs. As dataset size increases, RNNs prove superior in learning underlying features. CNNs efficiently capture important data features but may struggle with sequential data. Conversely, RNNs, with LSTM units, excel in processing sequences, but at a higher computational cost and time investment compared to CNNs.

We also observed a performance decrease after applying data augmentation, possibly due to factors like over-augmentation and model sensitivity. Fine-tuning augmentation parameters and exploring alternative techniques may mitigate this. Future research could delve into optimizing augmentation strategies and model configurations for improved performance. In addition, the augmented RNN's accuracy of 79.18% implies a potential for increased robustness in real-world scenarios, given its training on a dataset comprising 12,000 audio files.

A. *Result Visualization and Analysis*

This step involves visualizing the model's performance metrics, such as accuracy and loss, over the training process. By plotting these metrics, it provides a clear overview of how well the model is learning from the data. These visualizations help in understanding the effectiveness and progress of the training process.

1) FSD-kaggle dataset: A peek at the accuracy and loss curves reveals good convergence for both CNN and RNN models after running for 15 epochs. So, we got higher accuracy and lower loss (given in Table VII). We achieved around 96.52% and 87.88% accuracy during testing on the FSD-Kaggle dataset for CNN and RNN models respectively. On the other hand, we had a very lower loss too for both architectures. However, on the FSD-Kaggle dataset, the performance of CNN model was better than RNN model during training and testing on dataset. The visualizations are shown in Figures 16 through 19.

2) ESC-50 dataset: After running 100 epochs for the ESC-50 dataset on the CNN model and 50 epochs on the RNN model, we got 88.47% and 92.89% accuracy on a testing dataset of the CNN and RNN model respectively (given in Table VII). So, here the RNN model outperforms the CNN model. We can see from the graphs that there is a bit of instability at the initial phase of training for the ESC-50 RNN model but after running for 25 epochs it seems to be stable. The visualizations are shown in Fig. 20 through Fig. 23.

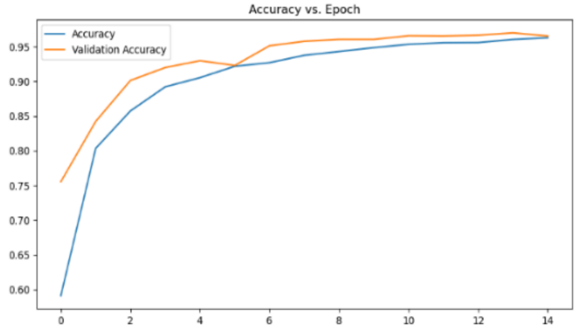

Fig. 16. Accuracy vs. epoch for FSD-Kaggle CNN model.

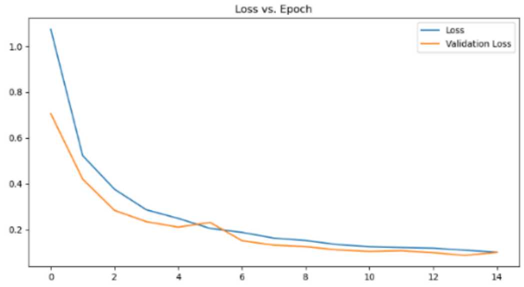

Fig. 17. Loss vs. epoch for FSD-Kaggle CNN model.

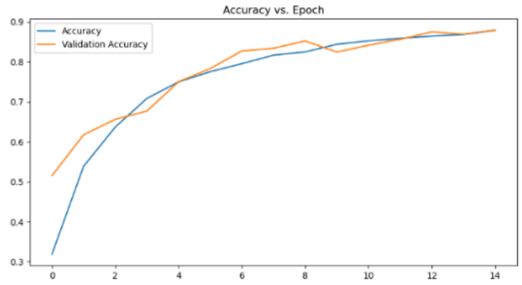

Fig. 18. Accuracy vs. epoch for FSD-Kaggle RNN model.

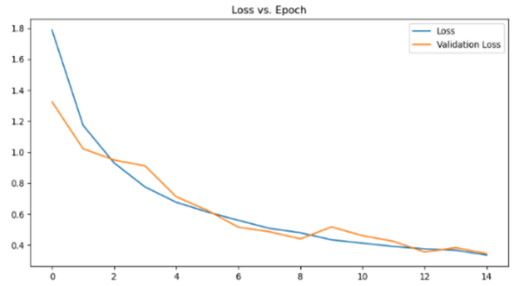

Fig. 19. Loss vs. epoch for FSD-Kaggle RNN model.

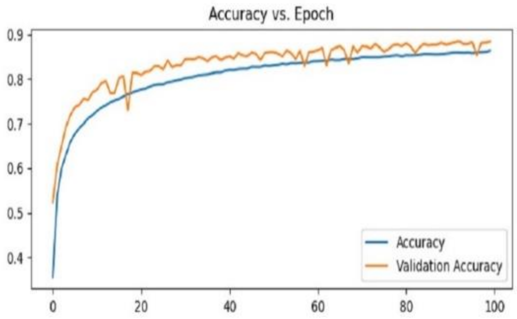

Fig. 20. Accuracy vs. epoch for ESC-50 CNN model.

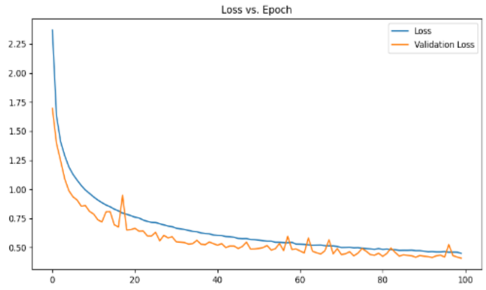

Fig. 21. Loss vs. epoch for ESC-50 CNN model.

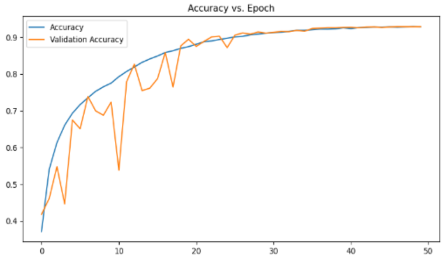

Fig. 22. Accuracy vs. epoch for ESC-50 RNN model.

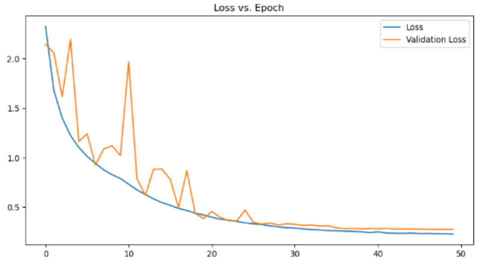

Fig. 23. Loss vs. epoch for ESC-50 RNN model.

3) Augmented ESC-50 dataset: From the accuracy and loss curves of CNN and RNN models on the Augmented ESC-50 dataset, it is clear that the RNN model achieved more accuracy and lower loss during training. We ran around 50 epochs for both of the models and got around 76% and 79% accuracy on testing for CNN and RNN models respectively (given in Table VII). During training, the RNN model took a bit longer time since there were LSTM layers. Probably the reason lies in the fact that LSTM cells can store more information over extended time periods. From the substantial amount of loss, it can be said that the model had difficulties adapting to the augmented features generated by the augmented dataset. This also suggests that RNN outperforms CNN on new data. The visualizations are shown in Fig. 24 through Fig. 27.

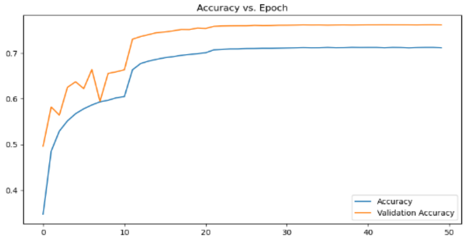

Fig. 24. Accuracy vs epoch for augmented ESC-50 CNN model.

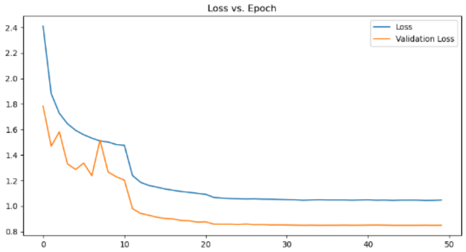

Fig. 25. Loss vs epoch for augmented ESC-50 CNN model.

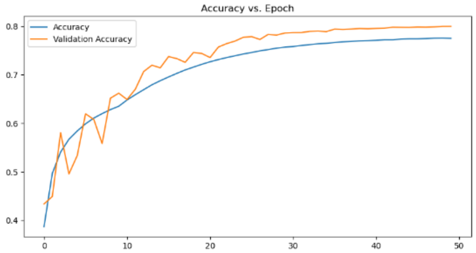

Fig. 26. Accuracy vs. epoch for augmented ESC-50 RNN model.

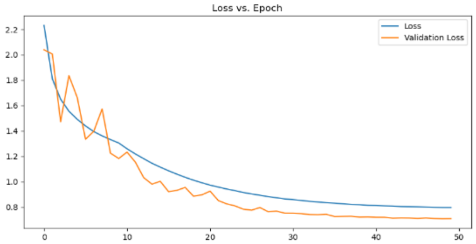

Fig. 27. Loss vs. epoch for augmented ESC-50 RNN model.

So, using different datasets, and testing various models based on CNN and RNN architectures, we have come to a conclusion where we can say that both CNN and RNN models can classify audio but the measurement of accuracy and the convergence of the graph curves depend on numerous factors including the complexity of the dataset and the ability of the model to extract several underlying features. We have also seen that for larger datasets RNN model outperformed the CNN model.

VIII. Conclusions

This study delves into audio classification using CNN and RNN-LSTM models, exploring their performance across different dataset sizes. We found that CNNs excel with smaller datasets, efficiently capturing key features, while RNN-LSTM models better perform with larger datasets, revealing intricate underlying patterns. The impact of data augmentation was also examined, revealing a nuanced balance between augmentation and performance. While augmented models showed improved robustness, some experienced a minor accuracy reduction, highlighting the need for parameter fine-tuning. Our research contributes valuable insights for optimizing audio classification, paving the way for applications in diverse real-world scenarios. Future studies can build upon these findings to further refine these models' capabilities.

Autonomous Robots for Transport Applications

Yang Lu
Department of Electrical & Electronic Engineering, The University of Manchester,
Manchester, United Kingdom, M13 9PL

Abstract—**Even though automation of travel systems is already happening, it's important to know how the introduction of self-driving cars might change people's transportation habits because changes in these choices could have an effect on health as well as the long-term viability and efficiency of transportation systems. For this study to be useful in Australia, it had to fill in this information gap that had been seen. The people who answered gave information about their backgrounds, the ways they currently travel, the importance they thought certain aspects of transportation were, and their feelings about self-driving cars. Then, they read a story that had been shaped by the opinions of experts and that talked about a future where cars would drive themselves. After reading the story, the people who answered picked the types of transportation they would most likely use in that scenario. They used descriptive studies to look at how transport choices have changed and regression models to figure out the factors that would be used to predict how transport options will change in the future. A lot of people who answered said they wanted to use outdoor, shared, and public travel more in the future than they do now. Half as many chances were taken to use private transport. In general, better public transportation, a workable system for active transportation, and fairly cheap shared driverless cars were seen as positive changes in how people planned to use transportation in the imagined situation. In the event that politicians are able to take action to achieve these results, the autonomization of transportation is likely to result in good changes to society.**

***Keywords*—Autonomous vehicles; transport choices; sustainability; health; physical activity; active transport; shared autonomous vehicles; private autonomous vehicles; public transport**

I. Introduction

The thought behind the suggested online terrain learning method comes from long-term tasks where self-driving robots would improve their operational effectiveness while travelling through environments they had not seen before. One way to find tough terrain, like big rocks, is to use a graphic picture of the world that can be seen. These areas of land could be called barriers. The NASA Mars Rover Spirit got stuck in soft sand and did these things [1]. We use the given method to teach a "black box" model to decide if the terrain is suitable for travel in a certain setting based on how it looks [2]. We assume that some terra-mechanical factors are unknown. We recommend that ground models be learned online in small steps [3] as part of long-term deployments and research trips [4]. It is possible that the link between how the land looks and how easy it can be travelled may only work in certain places. You can learn how to do traversability evaluation online, and these robots are a great way to show how useful it is. This new method is different from what has been done before because it considers the different ways the robot moves and lets different terrain-gait movement cost models be found. The suggested exploration method also gives a broad answer [5] that takes into account both the learning of the passage cost models and the discovery of space. This is an important benefit.

The suggested method uses geometric models based on a grid-based elevation map to find the parts of the world that can't be explored [6]. The six-legged walking robot is shown in Fig. 1. The robot trains these models by using the experience it has gained by walking on surfaces that look like the ones it is training on. A type of regressor called Gaussian process (GP) is used in the traversal cost models [7]. Based on how the land looks, these regressors make guesses about how much it will cost to cross. The shape and movement cost models are being made in stages During the rollout, each model will keep giving you a list of exploration goals that you need to meet in order to learn more about and improve the model. The exploration strategy is to figure out the order of the travel goals that need to be visited for each of the possible goal places. People think that this order can help solve the Generalised Travelling Salesman Problem (GTSP) [8] in a way that isn't biassed and takes into account the "TSP distance cost" [9]. The sixth section, we will analyse the advantages and disadvantages of the strategy that has been suggested.

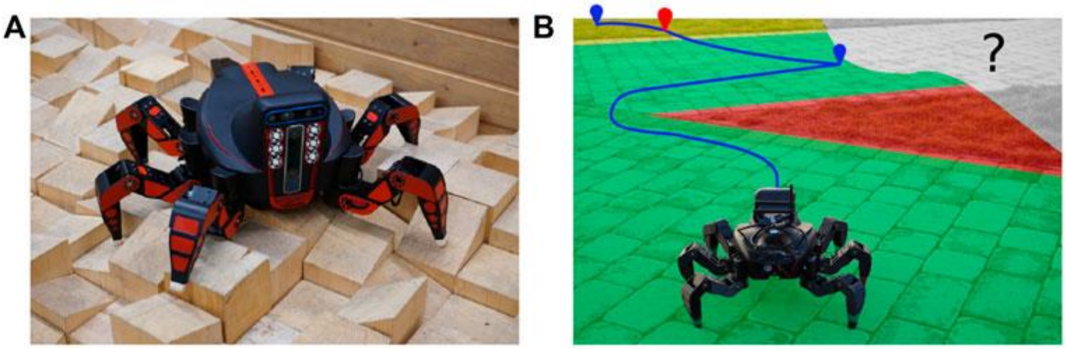

Fig. 1. A six-legged walking robot (Forouhar et al., 2021). (B) A possible way to use it.

A. Research Challenges:

The article points out six issues that need to be fixed before self-driving robots can be made:

1) Coming up with ways to make sure robots can work safely in busy and complicated places while also modelling how robots interact with each other;

2) New methods for self-directed learning need to be thought about in terms of making decisions, then tested and put into action;

3) There is room for improvement in how the fleet is managed, the standard of services, and how well the website works;

4) There needs to be a better way to work when the weather is bad.

5) Methods for evaluating safety need to be checked.

6) Perception and planning need to be closely connected in terms of how doubt spreads directly.

II. Related Work

For the purpose of effectively implementing delivery robots in public settings, it is essential that the delivery robot interacts with the environment in a manner that is both effective and efficient. [10] say that people and traffic need to be ready to deal with the delivery robot when it comes out. In the literature review that is being done to find the mental components, two of the newest parts are included.

A. How Well New Travel Ideas Work

“Performance of new technology is a key measure of the amount of success,” say [11]. This performance may include a lot of different things. The year 2021 by [12] are having problems right now because they need to change to meet their current and future needs. If possible, travel innovations should be able to work with the way things are now. The surroundings may also be changed to fit the new technology in a way that makes sense whenever the areas change or when they are built from scratch. [13] say that it can be hard to make or set up automated systems in public places because it depends on the people, the room, and their habits. It's hard to make or use automatic tools because of this. [14] Fisher put out a set of rules that were meant to help people make automatic apps that can be used in towns. The clean and wonderful nature of cities, their safety and continuity, the ease of movement, the variety, the clarity, and the adaptability of cities are some of the things that make up this group. It is very important that people can move around freely [13]. These fears should not be ignored now that delivery robots are seen in public places. These problems are connected to success factors such as change, speed, and stability. There isn't a lot of research on how a transport robot deals with its surroundings yet. Five things that [10] came up with were used to rate how well swarm robots worked. These factors were linked to: being able to do it, being useful, being acceptable, and being necessary. These things could be used in the situation of transport robots working in a traffic area. "Feasibility" means that the robot's risks and opportunities are real. This means that the delivery robot has to work in a safe way when we talk about its performance. In the second factor, "manageability," the tasks of the computer that can be easily carried out without breaking any rules is what is meant. For delivery robots, this might not be seen as breaking any road rules, which is what the element compliance is.

Because of this, the things that matter only happen when the robot is moving. They don't change how well the delivery service works, like picking up and dropping off goods. The papers are used to figure out what makes this work different. These factors are turned into markers and can be used for evaluation (see Table I).

TABLE I. Measureable Performance Parameters from Literature Study

Source\performance factors	Pace	Continuity	Deviation	Safety	Compliance (number of violated traffic rules)
[10]	Synchronization	Functionality of individual robots robustness	Reliability, robustness	Reliability	Reliability, swarm intelligence
[14]	Ease of movement	Ease of movement, adaptability	Ease of movement		Legislation
[13]	Flow of people must not be adversely affected		Flow of people must not be adversely affected	Flow of people must not be adversely affected	Flow of people must not be adversely affected

B. Social Acceptance of Technology Innovation

In the context of technology breakthroughs that are applied in public spaces, acceptance is an essential component. The only way for the innovation to be successful is for people to engage with it and embrace it [15]. Therefore, [16] says that an idea must first meet the basic requirements for usefulness and be seen as useful in order to be accepted. The main focus of this study is on the innovation that happens in the transportation setting. Because of this, social approval is being looked into. People who are not using the road, like walkers or other road users, are in this group.

Most of the time, models of technology acceptance look at how well the person who will use the technology can accept it [17]. Technology Adoption Model (TAM) is the first and most popular one. Davis says that these two things have an effect on adoption. The good drive to use technology is linked to these things. This is known as a relationship. We accept this model based on how it is used. These parts have an effect on people because of different rules, how useful they are, and how they feel about technology. A lot of different types of people have built on TAM in their own fields. People also know about the Unified Theory of Acceptance and Use of Technology (UTAUT), which is another form of acceptance. It was made in [18]. The two things that come from TAM in this case are known as success expectation and effort expectation. Part of this model is also the thought of social effect. The TAM and UTAUT models are more general and can be used in a lot of different tech settings. There are two more models that can only be used for automation systems. Things like faith, safety, and worry are in these models, which were made to be better than the first ones [19, 20]. There are other models that are used to study robots. guesses what people will do if they are asked to use delivery robots. This plan was made by [21, 22], who looked into how people in Germany actually use transportation robots. To do this, they used a bigger version of the UTAUT model that was already known to work with last-mile transport robots.

Acceptance of sidewalks by people who don't use them is also necessary for people to live together peacefully on streets. Some things that are connected to use, like useful and social contact, look and form, usage, and liberty, may not be important to people who don't use the product, according to [22]. The concept of Existence Acceptance (EA) was presented by them, with the primary emphasis being placed on the acceptance of the delivery robot's existence in a passive manner. Among the factors that are taken into consideration are the degree of skill, curiosity, discomfort, pleasure, as well as the overall recognised usefulness for society and the subjective social standards.

Research conducted on other automated systems, on the other hand, offers some unique perspectives. In [23] talked about whether or not autonomous driving is acceptable. They talk about a two-level category system in their piece. This system says that things that are related to items and things that are related to themes both happen in a certain situation. It is now being thought about how to accept the functional side as part of this study on transport robots. This is the reason why style and privacy aren't thought about. The "perceived features of the technology" and "evaluative attitudes expectations" parts of the two-level category system are the only ones that matter in this case because of this. You can see that these elements are ease, comfort, and excitement, all of which are linked to these traits. Getting robots into public places can be based on how useful the idea is thought to be, how easy it is thought to share the road, and the vehicle's specs. The general usefulness of transport robots, how predictable the robot is, and how big the robot is all connected factors. The acceptance model literature comparison is shown in Table II.

TABLE II. ILLUSTRATES THE ACCEPTANCE MODEL LITERATURE AND ESSENTIAL ELEMENTS

Source	**Factors found**	**Predictability (difference in the expected and the actual behaviour of the robot)**	**Competence (functioning of the robot)**	**Comfort (non-annoyance caused by the robot)**	**Dimension (size of the robot)**
Davis(1989)	Perceived ease of use		×	×	
Venkatesh et al.(2003)	Performance expectancy	×	×	×	
Ghazizadeh et al.(2012)	Compatibility and trust		×	×	
Osswald et al.(2012)	Perceived safety	×	×	×	×
Kapser and abdelrahman (2020)	Perceived risk and price sensitivity	×	×	×	×
Abrams et al.(2012)	Competence and discomfort	×	×	×	×

You can figure out a lot of things that affect how well an idea is accepted by reading about technology acceptance models and how people use tools. Because of this, the following list of important things is made:

- Predictability refers to the degree to which the robot in question behaves differently from what was anticipated of it.
- Ability (the robot's ability to do its functions).
- Convenience (the absence of discomfort brought on by the robot).
- Size of the robot is referred to as its dimensions.

C. Conceptual Model

A survey of the relevant literature formed the basis for the elements that pertain to performance and acceptability that were discussed in the preceding subsections. A conceptual model is developed to illustrate the current linkages between public space, robots, and people. These are converted into the final product. There is a description of the model in Fig. 2. The evaluation process is built on the foundation offered by the components that make up the conceptual model.

With regard to this study, the traffic environment is provided, as can be seen in Fig. 2. This environment has an impact on the functioning of the robot and also on the social acceptability of the robot. The variables that make up the performance are the following: pace, continuity, deviation, safety, and compliance. The state and the degree of roboreadiness are both determined by the combination of both dimensions. It is possible for the delivery robot to be effectively integrated into the public space if the factors have a value that is acceptable and, as a result, guarantee that there is an adequate level of the components.

Table III compares the autonomous transporters in terms of the environment in which they operate as well as the speed and range they can reach. It is highlighted whether these transporters benefit ("✓") or not ("X") from a camera in interpreting the environment.

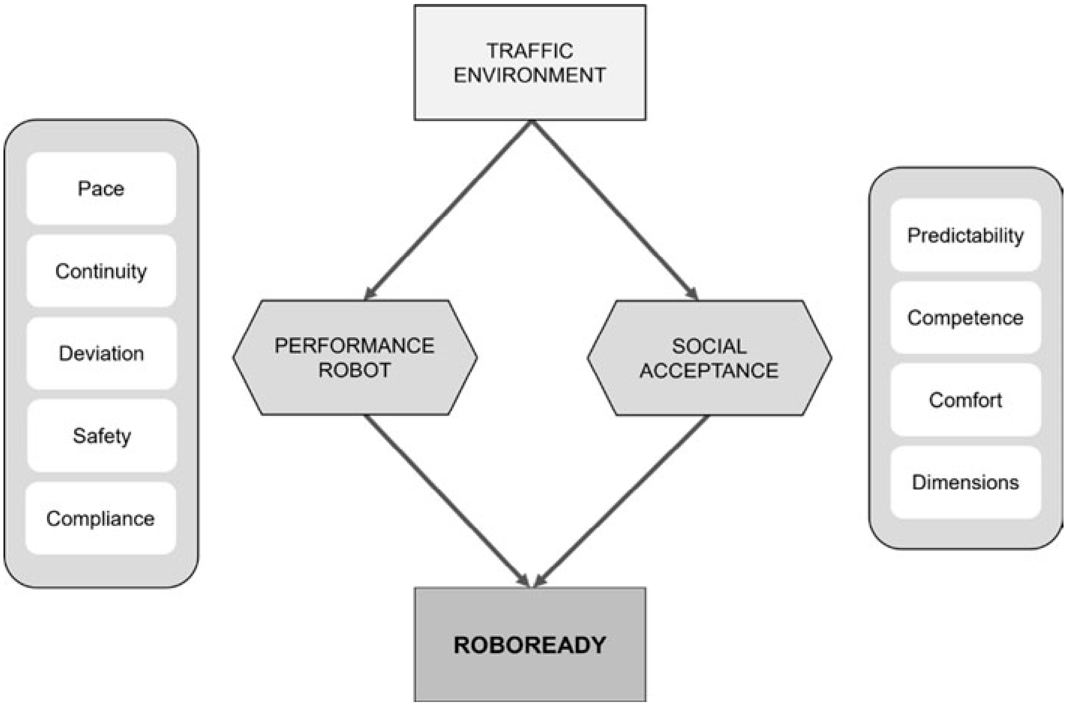

Fig. 2. Conceptual model of robo readiness factors.

TABLE III. COMPARISON OF AUTONOMOUS TRANSPORT SYSTEMS

Range	Environment	Speed	Camera
19.2 Km	Industrial	5 km/h	✓
N/A	Warehouse	5 km/h	N/A
N/A	Industrial	1.2 m/s	N/A
N/A	Industrial	40 m/min	✓
12 day	Industrial	45	X
95.0–137.9 cm	Industrial/home	N/A	✓
7 h	Hospital	1.0 m/s	✓
N/A	Hotel	N/A	✓
1 h	Office	1.0 m/s	✓
N/A	Industrial	N/A	✓

III. METHODOLOGY

When it comes to fully driverless cars, there is no longer any time to play around in the lab. One part of their automation is the addition of a new layer: neural intelligence that is specifically designed for the systems that the cars are built on.

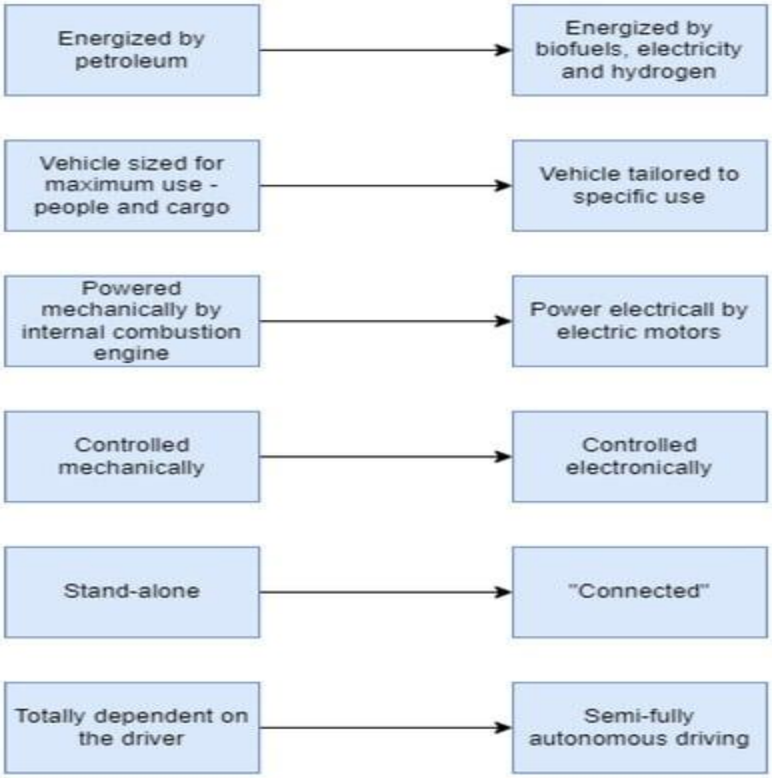
The other hand, a big error could happen and not affect the system at all in other situations. The great degree of complexity that these software systems possess is dictated by the fact that they are extremely non-linear.

In Table IV, some of the things that are linked to self-driving cars are shown. The things that have been said about them so far give us an idea of what they can do.

As shown in Fig. 8, the incorporation of these newly developed characteristics into autonomous vehicles is contingent upon a number of transformations in terms of their development.

TABLE IV. AUTONOMOUS CAR CHARACTERISTICS

Changes	Extended objectives
Energy	Low-cost renewable energy
Emissions	No environmental impact at the tailpipe
Safety	Accident free vehicles
Congestion	Congestion free route. Easier parking
Affordability	Vehicles suitable for any type of luggage or purpose



Energized by petroleum
Energized by biofuels, electricity and hydrogen
Vehicle sized for maximum use - people and cargo
Vehicle tailored to specific use
Powered mechanically by internal combustion engine
Power electricall by electric motors
Controlled mechanically
Controlled electronically
Stand-alone
"Connected"
Totally dependent on the driver
Semi-fully autonomous driving

Fig. 3. Transposition of traits.

From 0 to 5, these levels are available. The completely autonomous cars that are capable of self-control and adaptability in a variety of conditions are included in Level 5, which is similar to the capabilities of human drivers. The transposition of traits is shown in Fig. 3.

Chen describes the coalition principle, which is a concept that refers to the sharing of data between cars for the purpose of receiving the next movements of traffic participants in front of the vehicle. Including disaster management, space missions, military operations, and as machines that are capable of driving themselves among other applications.

Further research and studies are conducted, it will be possible to create automobiles that are superior to those that are already available. In conclusion, the creation of algorithms that are executed on high-performance processors, such to those that Tesla has developed, is strongly tied to the future of autonomous cars. Specifically, the deadly accident that occurred on May 7, 2016, is a moment that demonstrates the greater attention that is being paid to the perceptions of these sensors.

Planning may be hindered by some factors, such as the presence of noise or uncertainty. In order to develop the approach that we prepare as well as the strategy of the far horizon, it is necessary to eliminate the hazards that are involved.

Despite this, the limits that are now in place in cities are a significant barrier to the marketing and implementation of these autonomous vehicles. The following is a list of the qualities that make it difficult to advocate for the marketing of various kinds of automobiles:

It has been difficult to implement them since there is no high-level testing technique or theory available. New technologies need the revision and establishment of regulations that are relevant to autonomous driving. These laws need to be explicit and transparent.

The communication method between cars is currently highly unstable and restricted, with a vast sequence of activities that are not protected being employed in the communication process. As the speed of the vehicle increases, the system becomes more inadequate in terms of the outcomes that are recognised. Another issue that arises is the misunderstanding that occurs between the robot and the driver of the vehicle. This occurs because the robot misinterprets the participation of the traffic participants. Table III provides a comparison of the likelihood of success for one of the autonomous cars that have been examined.

The Scopus database between the years 1970 and 2022. In terms of the amount of papers, the field of self-driving cars took its first big step forward after 2003. Fig. 4 shows the details of literature.

As you can see in Fig. 5, this list is based on the ten places where the articles about the self-driving cars have been seen about the most. Italy came in third place, despite having 87 less publications than Japan.

IV. Discussion

We've discussed in depth about this paper how the production line's material supply works, which is currently done by machines. This makes managing the company's production ability very hard and leads to a lot of confusion, mistakes, and issues. As a result, we talk about two different ways to automate this process in the paper. One idea for controlling the flow of materials along the production line is to use a mobile robot that can move around on its own, has two charge stations, and can move 202 boxes per hour. The second plan also calls for the use of a mobile robot that can move around on its own to feed the production line and pick up empty boxes. This robot would have four charging stations, though.

After looking at the processes that were looked at and the different ways that they could be used—humans, traditional handling technology, or the robot E10—it is possible to figure out how much the proposed solution would save the company in terms of time, money, and efficiency.

The first choice was to send an employee and some handling gear, which included a truck and a delivery rig. After giving a detailed account of the supply process from the warehouse to the production line and back, we calculated the employee's work time to see how long it would take them to complete this process in order to meet the production line's need for eight pallets per hour. Based on the maths, it was found that it would take one worker about 50 minutes to complete the task, which means that person would not be able to meet the production line's demand of eight boxes per hour. Because of this, the business would need to send up to two workers and two tractor-trailers with two transport rigs per shift. The company would need to send up to eight workers to this process because it works on four shifts. Since the average speed of the cleaner and transport platforms is 4.5 km/h, the current state of automatically protected transfer of goods to the production line is not good enough. Other ways of handling tools need to be found. We did a lot of research and found that the worker who pulls the full pallets takes a 504-meter-long blue route to the production line and a 321-meter-long red route with empty pallets. In a four-shift production facility, Table I shows what each worker does in more detail. Putting eight people to work for the company would cost about EUR 120,000 a year, and buying two tractors and eight transport frames would cost another EUR 12,000. The business also expects care costs of about EUR 6,000 per year. The first choice would cost the business a total of EUR 246,000. This choice seems to be less effective, more expensive, and less customisable. One problem is that it would be hard to meet the production line's requirement to deliver eight boxes per hour if employees got sick, took time off or were absent in some other way. It would also be hard to get the needed number of boxes to the production line if a truck or delivery unit broke down, which would slow down production.

The second choice is to use mobile robots that can move themselves from the building to the production line and back again. After going into great detail about the supply method, we had to figure out how long it would take the robot to send eight boxes per hour as needed by the production line. We did the maths and found that the process could be done by one robot in about 24 minutes. This means that one robot could do it twice, which would take 48 minutes. The robot could do half of the work in the last 12 minutes, or it could charge for those 12 minutes. One more box would be moved from the storeroom to the production line if the robot worked for the last 12 minutes. That's half of the process. It would be helpful to do the half process because it would add one more box to the production line every other hour. For this process, the company would use four robots to meet the needs of the production line.

Since the robots can work nonstop for 8 hours, the second choice seems to be the most efficient and flexible. Even if one of the robots broke down, the other three would still be able to send the necessary number of boxes to the production line. It costs more to use robots than to hire people to handle the equipment, but if the company chooses two charging stations, the price difference is only EUR 22,000.

When robots are used, warehouse workers no longer have to use material handling tools to move things automatically from the warehouse to the production line. This is another benefit of robots. When robots are used, the number of direct workers who are needed to make the end product will go down, which could mean that the price of the finished product goes down as well.

It would be possible for the worker to pick up more materials while the robot moved the ones that were already there faster. The company should use robots to manage the process of moving boxes to and from the production line. This will save time and money for the company, as well as make operations run more smoothly and remove mistakes in the inventory and handling process.

Our plan for putting together an independent mobile robot is one of a kind because it can be used in any factory for any material supply task. In the future, work could be done to improve battery life and charge options. When the new robots get worn out, we will need to think about other ways to charge them and the option of using extra robots, since this is what happens in many places when automated guided vehicles are put in place. This paper only talks about putting new mobile robots that can move on their own into service. The batteries are the main issue. So, the production staff should be asked to take apart and put together a new battery. If not, the only easy thing left to do is buy one more robot just in case.

V. Results

Recently, there have been some substantial changes in energy systems that have been developed and documented, and these changes have also had a large influence on the area of conveyors. Because of this technology, many recent improvements have been made to the creation of a programme whose main goal is to make controlling and tracking electric conveyors easier and more efficient. This programme tries to solve the important problem of making mixed systems use the least amount of energy possible. There are some very good industrial transporters on the market right now, like the Kiva System (Fig. 6).

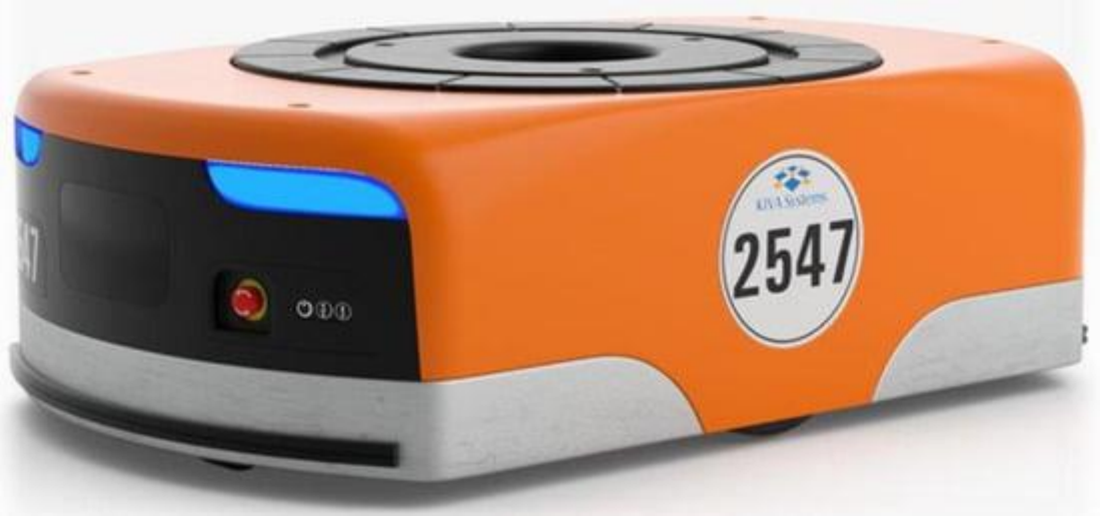

Fig. 6. Carry robot.

Nowadays, accidents in factories mostly happen on conveyor belts that are operated by hand. This is why automation of production is so wanted. In addition to making products much better, these robots also help companies meet safety standards.

Industries that make things need autonomous mobile robots, or AMRs, to speed up some steps in the production process. Comparing the self-driving trucks is shown in Table IV. This table looks at the environments in which they work as well as their top speeds and longest ranges. It's important to find out if these carriers get any benefits ("X") from having a camera around in order to understand their surroundings.

A staged study from 1931 to the end of 2022 was used to make Fig. 7. It shows how interest in this growth area changed over time. The number of writings on this topic changed a lot because of this.

Fig. 8 shows a score that comes from information in the Scopus library. Across the rest of the list, interest is steadily and steadily going down in all of the areas.

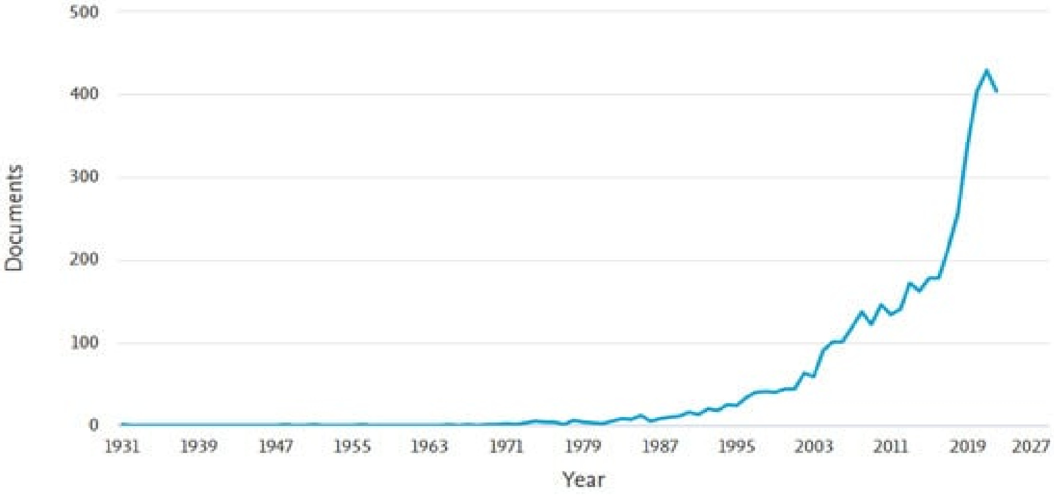

Fig. 7. Autonomous carrier scientific literature volume trend.

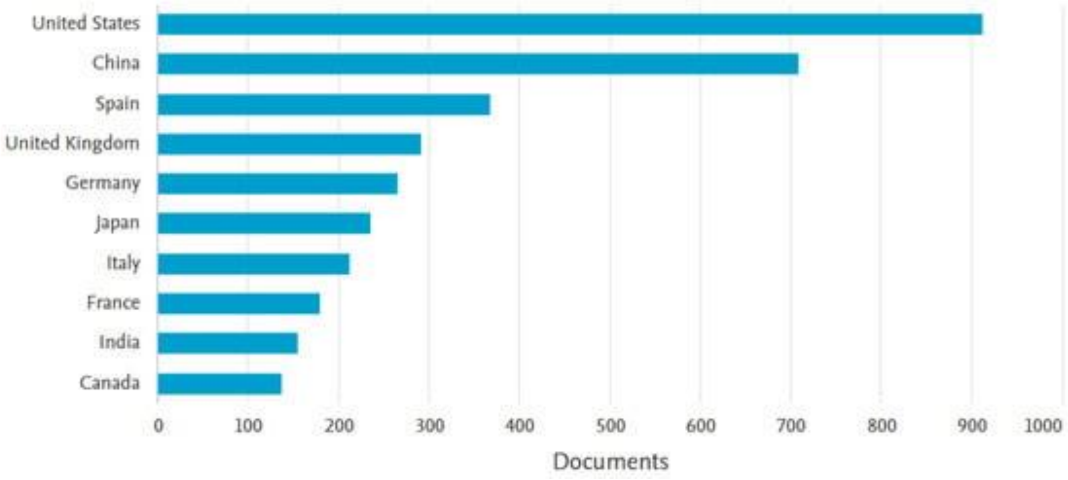

Fig. 8. Country categorization of autonomous carrier scientific interest.

VI. Conclusion

Based on what we've learned here, it looks like the arrival of self-driving cars (AVs) could not be bad, but rather helpful for many reasons. Even though this is a positive viewpoint, if policymakers try to create a future similar to the one presented to the participants in this study, people may be more likely to use more environmentally friendly and healthy modes of transportation, thereby improving the transportation system. It's possible that public education campaigns that stress the benefits of busy and shared transport networks could help make this future come true. The introduction of self-driving cars (AVs) could be a watershed moment in changing people's mobility behaviours for the better by focusing on creating surroundings that support positive decisions. However, such a scenario is extremely unlikely to occur by itself. To make this happen, the government must ensure that effective rules are in place to encourage people to utilise alternative modes of transportation rather than privately owned self-driving vehicles. According to the study's findings, there appears to be plenty of opportunity for greater scientific and technological advancements and progress in a variety of research areas. These include (i) developing and integrating artificial intelligence techniques into these devices to improve their decision-making, movement planning, and interaction with people; (ii) increasingly integrating sensors, with an eye towards the additional functions that higher levels of sensor integration may allow; and, in the case of drones, (iii) developing better techniques for controlling them.

VII. Future Work

A. System Expansion and Optimization

1) 6G Network: Using 6G networks will allow contact with very low delay, which will greatly cut the time it takes for data to be sent between robots and edge computers. Also, 6G networks depend on satellite communication. To make sure that EDRP can work in rural or ignored areas, future study will focus on finding ways to use this feature. This could be especially helpful for watching the environment, responding to disasters, and security efforts. By using 6G's features, the suggested system might be able to keep connection strong and constant, which could ensure that data is sent reliably and operations run smoothly no matter where they are.

2) 5G Specialized Network: The 5G network environment is good for controlling robots in rural areas where regular networks can't reach or in military and industrial settings where safety is very important. The 5G specialised network offers a separate communication space, making sure that links are stable and that the suggested system can be used in a safe setting. In the future, researchers will look into how to add 5G specialised networks to the suggested system to make it more stable and safe.

B. Applicability

Search and rescue robots can quickly handle different situations at disaster sites by using the suggested system to process data in real time. This helps keep people alive and fix the damage caused by disasters. Robots can work for longer periods of time, which lets them explore larger areas and do rescue operations. This makes work more efficient by letting people share data and work together in real time.

The suggested method can also be used to watch and direct robots in public places. Edge sharing makes it easy to do complex AI jobs that robots can't do, like those needed by large language models (LLMs), without having to upgrade the robot's computing power. It is believed that this will make it possible to provide more services, such as user reaction and policing using LLMs.

Abstract—**In India, regional languages play an important role in government-to-public, public-to-citizen rights, weather forecasting and farming. Depending on the state the language also changes accordingly. But in the case of remote areas, the understanding level becomes complex since everything nowadays is presented in the English Language. In such conditions, the regional language manual translation consumes more time to provide services to the common people. The automatic translation of one language to another by maintaining the meaning of the given input sentence there by producing the exact meaning in the output language is carried out through Machine Translation. In this work, we proposed a Memory Based Neural Network for Translation (MBNNT) model on simple, compound and complex sentences for English to Telugu language translation. We used BLEU and WER metrics for identifying the translation quality. On applying these metrics over different type of sentences LSTM showed promising results over Statistical Machine Translation and Recurrent Neural Networks in terms of the quality and performance.**

Keywords—Machine translation; English-Telugu translation; RNN; LSTM

I. INTRODUCTION

India is considered as the world's second highest number of languages. In India there are various regions based on their traditions and culture. These regions use their regional languages [1]. The main aim is that the Language translation system which is used in translation of different type of languages. This process makes it easy for people to communicate in their regional language [2]. The form of communicating among people is done through various sources like interchanging their thoughts, exchanging their ideas etc. Telugu language is considered as one of the ancient regional languages in India that is being used from centuries. Most of the southern states of India use Telugu as a commonly spoken language [3].

In English language, general conversations play an important role in understanding the language. Usually there are three type of sentences that are commonly used in these conversations, namely: simple, complex and compound sentences [4]. The simple sentences are those in which every other sentence is constructed upon them. These have only single independent clause that completes the sentence and hence called as simple sentences [5]. During translation to desired language the simple sentence can be easily translated since it has a single clause. In case of complex and compound sentences, they have two different independent clauses [6].

A. Compound Sentences

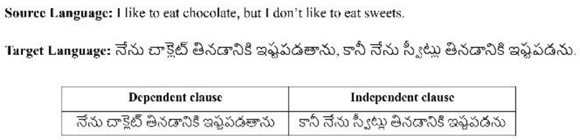
The compound sentences are constructed from the simple sentences, but have two independent clauses. This explains that each clause in compound sentence can be explained itself completely irrespective of the second clause [7]. The two clauses can be linked together by coordinating conjunctions. Those are FOR, AND, NOR, BUT, OR, YET, and SO which are explained below with an example each in Table I.

TABLE I. Conjunction words in compound sentences

English Sentence	**Conjunction**	**Explanation**	**Telugu Connection**
Arun doesn't speak Telugu, for he is from United States	For	Here both sentences are complete	కోసం
He lives in Ontario, and his friend's lives in Dubai.	And	Both the sentences are given equal importance	మరియు
I don't watch television, nor do I like movies.	Nor	Both are speaking negatively	లేదా
He is a professor, but his brother is a doctor.	But	Here the usage of 'but' is opposite	కాని
You can play cricket, or you can go for shopping.	Or	This clause shows an option	లేదా
They were not hungry, yet they went out for lunch	Yet	It refers that they have done something even they do not have to	ఇంకా
Sheetal was not well, so he visited the doctor.	So	First clause is the result of the second	కాబట్టి
English Sentence	Conjunction	Explanation	Telugu Connection

B. Complex Sentences

The complex sentences that are frequently used in the conversations also have two different clauses, where one is independent referring that it is a complete clause and the other is dependent clause [8]. This depends completely on one clause without the other the sentence cannot be completely understood. In complex sentences these two clauses are linked together through subordinating conjunctions [9]. There are six types of these subordinating conjunctions namely: contrast, cause, condition, time, place and relative pronouns [10]. During translation into Telugu Language, the subordinate clause always comes at the beginning of complex sentence [11]. The independent clause is always followed by a dependent clause as shown in Fig. 1.



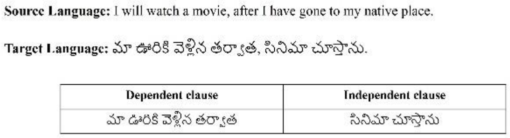
Source Language: I like to eat chocolate, but I don't like to eat sweets.

Target Language: నేను చాక్లెట్ తినడానికి ఇష్టపడతాను, కానీ నేను స్వీట్లు తినడానికి ఇష్టపడను.

Dependent clause	Independent clause
నేను చాక్లెట్ తినడానికి ఇష్టపడతాను	కానీ నేను స్వీట్లు తినడానికి ఇష్టపడను

Fig. 1. Category 1 - Complex sentence in Telugu language.

In Telugu, the subordinate conjunction that appears in the dependent clause always comes at the end of the subordinate clause. Fig. 2 shows how the clauses are rearranged while translating.



Source Language: I will watch a movie, after I have gone to my native place.

Target Language: మా ఊరికి వెళ్లిన తర్వాత, సినిమా చూస్తాను.

Dependent clause	Independent clause
మా ఊరికి వెళ్లిన తర్వాత	సినిమా చూస్తాను

Fig. 2. Category 2 - Complex sentence in Telugu language.

C. Types of Conjunctions

Conjunctions are represented as parts of speech that connect the clauses, words and phrases in a sentence [12]. These conjunctions are divided into four types, namely coordinating, correlative, subordinating and conjunctive adverb. A few examples explaining the type of conjunctions are mentioned in Table II.

TABLE II. CONJUNCTION WORDS IN COMPOUND SENTENCES

English Sentence	Conjunction	Explanation	Telugu Connection
Arun doesn't speak Telugu, for he is from United States	For	Here both sentences are complete	కోసం
He lives in Ontario, and his friend's lives in Dubai.	And	Both the sentences are given equal importance	మరియు
I don't watch television, nor do I like movies.	Nor	Both are speaking negatively	లేదా
He is a professor, but his brother is a doctor.	But	Here the usage of 'but' is opposite	కాని

In this work, we consider Machine Translation (MT) for handling simple, compound and complex sentences from English language to Telugu Language [13-14]. The main aim of this translation is to generate the meaningful sentence without any grammatical errors obtained from source to desired target language. MT is a major study in the field of natural language processing (NLP) which is used in the translation of regional languages technically [15]. Form the past few years, neural machine translation (NMT) gained success and became the major part in applied MT. This mechanism depends on the availability of large corpus data and memory-based methods which gather verbal details through sequence-to-sequence information [16].

NLP is a language translation approach that supports in understanding the grammar and verbals of a language with its accuracy in analyzing the language. It is related to the advancement of methods that automatically strive to translate a language. Also, support in utilizing this language for conveyance among common people. This approach needs some information while translating and also needs some data related to the language including its grammar [17].

There are various methods which are developed to attain greater accuracy in translations namely: Statistical Machine Translation (SMT), Knowledge, Rule, and Corpus. These methods individually have their advantages and disadvantages. Of them, SMT is a sub-field of corpus translation and is commonly utilized. Since it shows good results when compared with other methodologies [18]. In recent days one of the popular methods called neural networks in MT is used all over the World. This has become a unique method of MT with the help of these neural nodes commonly termed NMT. The process of NMT to convert the source language to the target language is shown in Fig. 3.

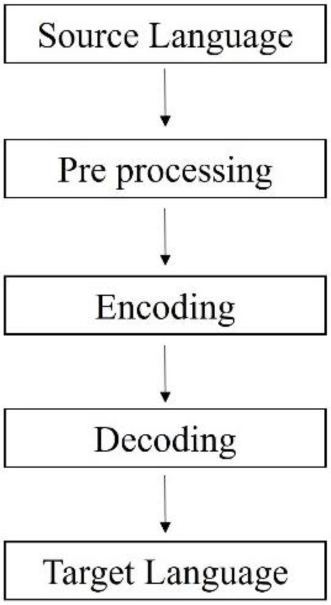


Fig. 3. Work flow of neural machine translation.

In this research work, we used a memory based neural machine translation models such as Recurrent Neural Network (RNN) and Long Short-term Memory (LSTM) for translation of English language to Telugu Language. The objectives of this work are arranged as follows:

- The given input English language sentence is divided into phrases and clauses.
- The generated phrases are identified depending upon the type of sentence.
- The type of sentence is identified at the pre-processing phase.
- Based on the type of sentence, the phrases are rearranged.
- These rearranged phrases are given to memory-based Neural Machine Translation to obtain the target Telugu language.

The remaining sections of this work are organized as follows: Section II discusses Related Works considered for this study, Section III discusses the methodology of this work, Section IV deals with the results and performance evaluation metrics, and Section V describes the conclusion and link to future work.

II. Related Work

An automated grading model for English translation based on NLP is created in order to decrease the burden of conventional grading and increase the effectiveness of scoring. It is suggested to use an attention LSTM of the English MT model. Initially, an English MT model based on LSTM focus encoding is defined; the framework level of the translation evaluation system is developed. This is done in accordance with the properties of the basic LSTM network, which uses resolved layered vectors to demonstrate phrases in the modelling phase [19].

The posterior distribution of a specific phrase or word combination in the translation process is statistically intended by using the defined linguistic structure of the language translation for calculating scores. The outcomes demonstrate that, when comparison to English MT models built using existing NN such as standard LSTM and RNN models, the LSTM focus embedding-based model developed in this study can improve the recognition of the input language relevant information and increase the accuracy of the English MT model and the reliability of the translation [19].

Researchers now understand the value of data with the need to examine this large amount of data according to the expanding digital environment. In required to conduct content analysis, it is necessary to classify a sizable volume of multilingual textual information. In this case, NMT is used to suggest a labelling with the use of annotated English sample, which is available in plenty. Labeling data for multilingual character recognition is difficult to retrieve [20]. In order to create context and categorize text into positive and negative sentiments groups, the proposed method would use vectors as embedding that are given to RNN and LSTM. The system for labelling texts that is utilized to collect tagged bilingual textual information is the main selling point. This model can categorize content analysis part of the text [20].

The effectiveness and desirability of English MT in application areas are both constrained by linguistic diversity, the restricted capacity to represent semantic features, and the scarcity of parallel corpus data. Due to highly parallel computing computational capability, which shortens the model training and enables it to record the lexical significance of all phrases in the sentence, the self-attention method has drawn a lot of interest in English MT. Moreover, because the self-attention process disregards the location and information about the structure among word vectors, its effectiveness is different from that of RNN. In order to exploit location information among phrases, the English MT model focused on self-process encode the actual location data of words [21].

An English translation system prototype has been created for mapping English and Chinese phrases through knowledge vectors, and it leverages RNN for both encodings. It is examined how well the activation function-based model performs. According to the study results, the decoding layers of the activation function and the encoder layers both exhibit the best result. According to the effectiveness of the LSTM and GRU stages, the GRU layer performs better. The nonlinear activation functions are used to set the attention layers [22].

Unlike the classic SMT, this neural machine translation focuses at developing a single neural model which can be collaboratively modified to maximize the translation quality. With the help of the LSTM approach, 47 multilingual food recipes from Spanish to English and English to Spanish language translation. This work produced new insights and useful guidance for developing and improving NMT. The BLEU metric is used to evaluate this model. According to the comparison results, the conversion of food recipes into English to Spanish has achieved a value of 0.998426 for BLEU with a ratio of 70% and 30% [23].

The complete LSTM analysis of the previous state is necessary for the subsequent LSTM phase. For a series of n nodes, this needs to be calculated ‘n’ times. The main cost components in this are the linear transforms needed for the LSTM gates and condition calculations. This approach comprehensive LSTM contextual analysis by calculating hidden layers and gates with an input signal and a straightforward bag-of-words encoding of the previous tokens contexts in order to allow sequential parallel computation of LSTMs. As a result, we can effectively measure each information step in comparison rather than the previously expensive sequenced linear functions. Then, using computationally affordable element wise procedures, we link the results of each concurrent phase [24].

In order to represent the semantic relationship between distant phrases in a text, a tree-based conversion models are used. However, it has issues with costly manual annotating costs and inaccurate automated annotations. This research focused on how to encode an input text language into a matrix in an un-supervised way to decode the target language. A Gumbel Tree-LSTM can learn to create tree hierarchies to attain sequence-to-sequence model by using both spoken media corpora [25].

By studying and refining real datasets, the SCN-LSTM (Skip Convolutional Network and Long Short Term Memory) language translation model is developed. In order to provide conceptual foundation for the study and use of the SCN-LSTM require similar in English instruction, the performing viability, translating accuracy, and scalability of the model are examined. To be more precise, the rate of translated ambiguity is reduced by 39.21% relative to LSTM model, and the scalability is 0.4 times of the N-tuple prototype in the SCN-LSTM language conversion [26].

From the research works [19-26], it can be concluded that while translating a sentence from one language to another the importance of grammar like finding the clauses, and maintaining the subject is mainly essential. Whereas, the above-mentioned works only highlighted the normal translation process using various neural network models. Based on this limitation, the aim of this work is to design a memory-based neural network by maintaining the quality of the sentence during translation.

III. METHODOLOGY

This section deals with the memory-based neural models for translation of English to Telugu language of simple, compound and complex sentences.

A. *Preprocessing*

During this phase, the type of the sentence is identified. The given input sentence may contain subject, verbs, main clause, conjunctions and punctuations. In order to identify the sentence, the main clause and conjunctions are stored in a memory for easy translation of a sentence. Usually, a simple sentence can be identified easily since it has only a single independent clause. In similar to it, the compound sentence can be identified by two main clauses. In the case of complex sentences, the main clause is combined together by one or more dependent clauses. In such cases the conjunctions come into the picture in joining a complex sentence. The memory associated with the networks acts as a connecting bridge in retrieving the information in translating such complex sentences.

B. *Dataset*

The data set used in this research work is collected from “Indian-Parallel-Corpa” [27], which contains 1263 English and Telugu sentences. For model validation purpose along with this dataset we have also created our own synthesized dataset which includes simple, compound and complex type of sentences. The synthesized dataset contains 150 simple, 480 compound and 970 complex sentences. The summary of the datasets used in this work is given in Table III. Based on the benchmark and synthesized data we have a total of 2,863 sentences making our model to achieve the high translation quality.

C. *Neural Machine Translation*

Neural Machine Translation (NMT) is commonly used in language translations to attain meaningful sentences by maintaining the quality. This uses only a small amount of memory like Statistical Machine Translation (SMT) approach. For extending the performance of translation every node is connected directly to the previous nodes in the entire neural network.

This neural network structure contains three basic layers namely: input, hidden and output as shown in Fig. 4. The English sentence is divided into words or phrases and is given to input layer. Each word in input layer is connected to different nodes within the neural network. These nodes are interconnected with each other in the hidden layer. This traditional network provides good translation quality while translating word-to-word or phrase-to-phrase in case of simple sentences.

The language translation not only depends on word to word translation but also re-ordering of the translated words in a particular language is also to be maintained correctly for a meaningful sentence. For example, the English sentence “I like watching movies” is translated into Telugu sentence as “నాకు సినిమాలు చూడటం ఇష్టం” . The word ‘like’ appeared as the second word in the English sentence and after translation, this word appeared at the last position in the Telugu language. For translating such simple sentences small amount of memory is required that do not make the network complex. In case of compound and complex sentences the amount of memory is to be increased depending on the complexity of the sentence by using Recurrent Neural Network (RNN) and Long-short Term Memory (LSTM).

TABLE III. SUMMARY OF DATASET

Type of dataset	Number of sentences	Type of sentence		
		Simple	Compound	Complex
Benchmark [27]	1263	253	379	631
Synthesized	1600	150	480	970

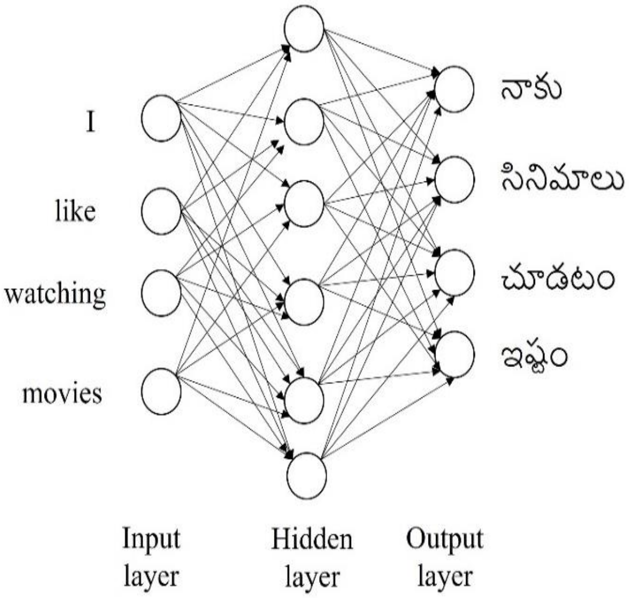

Fig. 4. Neural network for translation with hidden layers.

D. Proposed Model

From Fig. 5, our proposed model takes English sentence as input language. Based on the length of the sentence the number of phrases or words are identified. Depending on the clauses and type of conjunctions the input sentence is categorized into simple, compound and complex. If it is a simple sentence, the memory-based neural networks directly inputs the sentence and produce the desired translated sentence. If the given sentence is compound, the type of conjunction is identified and rearranged the sentence based on the conjunction and then given to memory-based neural network to produce the required output. If the given sentence is a complex sentence, the dependent and independent clauses are verified. Here the sentence is reordered to maintain the meaning of the language and the resultant sentence is given to memory-based neural network to attain the required translated sentence.

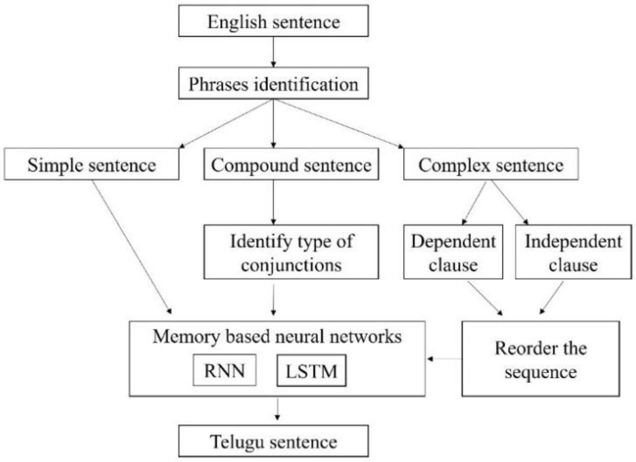

Fig. 5. Proposed model for a memory-based neural network for translation.

E. Recurrent Neural Network

A neural network is a differential function that maps one type of variable to another type of variable. Addressing the problem of predicting the type of event which is going to happen at every certain point is explained through Recurrent Neural Networks (RNN). These RNNs have loop like structures within them, which allow the information to pass. In RNNs the same weight is carried out in the entire recurrent unit. The RNNs have short-term memory that can store only limited amount of data. During translation process these RNNs use only nearby words that come in sequence. In this we use NLP task for completing the sentence formation.

In this work both the input and output sentences are sequences. The input is a certain word in a sentence and output is to predict the next word in the sequence with the help of proper training models. These are used in generating the sentence on its own. The sequence to sequence model had equal size of inputs and output, where most of them don’t have such equal sequences. For instance, consider a 10 word sentence in English language as input. The final output may not have the 10 word sentence in Telugu Language. While at the time of texturization the input is a set of sentences, during translation process the training is carried out by the definition of the sentence given and is summarized to a group of sentences. In such cases, the encoder-decoder architecture is used in translating and producing the meaningful Telugu sentence.

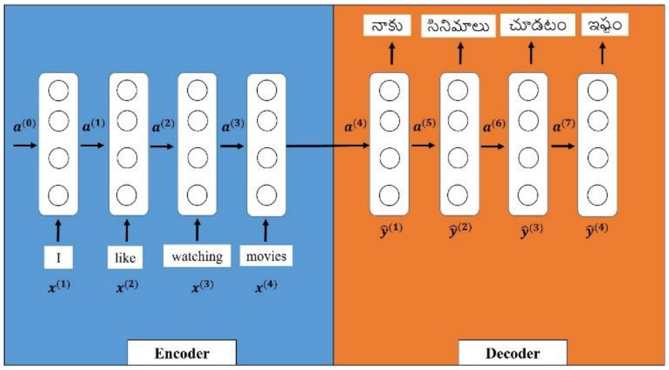

Fig. 6. Encoder and Decode in RNN.

Fig. 6, represents the encoder-decoder process for conversion of the sequence into a vector done by encoder whereas; the conversion of the vector into a sequence is done by the decoder. It takes the English sentence as input and converts it into its internal representation. This form of representation is a vector that holds the meaning of the English sentence. The decoder now takes this meaning of the vector and converts it into a sequence which is a Telugu sentence. The input is represented as $x^{(n)}$, the output is given by $\widehat{y^{(n)}}$ and the activation function is represented by $a^{(n)}$.

Internally when a sentence is passed as input every word is individually taken as node separately. The translation process is initiated only after the entire sequence of words is completed as shown in Fig. 7.

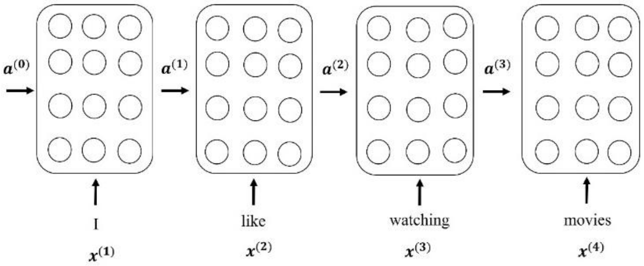

Fig. 7. Internal nodes of the hidden layer.

The sequence of the sentence can vary from 0 to infinity depending upon the sentence given. This is represented in Eq. (1) as follows:

$$x^{(n)} = W^n x^{(0)} \tag{1}$$

In the recurrent network having n units, initially $x^{(0)}$ is a scalar vector at a rate W. After n iteration units its value would be $x^{(n)}$. Since this is a dynamical system, we represent it in the form of Eq. (2).

$$W^n\, x^{(0)} \rightarrow \{\infty; W > 1 | 0; W < 1\} \tag{2}$$

For every n value the $x^{(n)}$ for $W > 1$ the value $W^n\, x^{(0)}$ explodes and for $W < 1$ value $W^n\, x^{(0)}$ becomes 0 or vanishes. If this happens, it leads to loss of the information which is given as input depending on their weights. This problem is called as vanishing gradient problem. The loss of information in these cases can be prevented in four ways.

- The usage of skip connections is required to eliminate the loss.
- By actively removing the connections having Length as 1 and replace them with longer connections. These force the network to move along in a modified path.
- Using the Leaky Recurrent Units, by adding a constant as shown in Fig. 8, over every edge that joins the network. This constant regulates the amount of information that the network which it has to remember over a certain period of time. If this constant is closer to value 1, more the memory is retained and if this is closer the value 0, memory of the previous state gets erased or vanishes.
- An enhancement to leaky recurrent network is the usage of Gated Recurrent Neural Networks (GRNN).

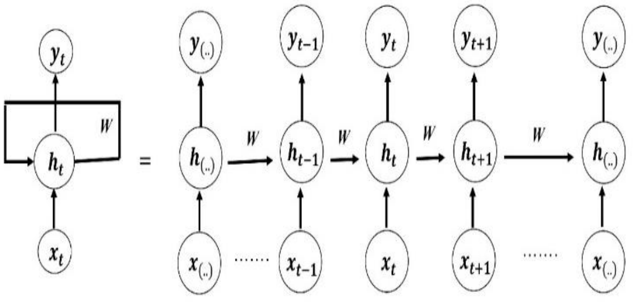

Fig. 8. Leaky RNN.

The expanded hidden layers of leaky RNN are represented in Eq. (3) which identifies any leakage or missing words within the network.

$$h^{(t+1)} = f(h^{(t)}, x^{(t+1)}) \tag{3}$$

Instead of assigning a constant value, we introduce a set of parameters one for every time lapse. Based on this, the network itself decides which sequence is to be remembered and what is to be erased. These set of parameters act as gates at every state of the network. In RNNs based on the beginning of any word, the ending of the sentence is predicted. These do not remember what appeared at the beginning of the sentence. They are fed with each word in the sentence depending on the weight's activation action is performed. It contains only a single layer, and relies on the time interval or time axis. In predicting the further words in a sentence, the initial words of the sentence are to be remembered. While in RNN, it is a short-term memory and hence is not recommended for auto completion of a sentence. One of the commonly used GRNN architecture is used in maintaining the memory of words for auto completion of a sentence that is Long Short Term Memory (LSTM). This is determined as the upgraded version of RNN which solve the problem of short term memory.

F. *Long-short Term Memory (LSTM)*

The name itself refers to extended memory during translation process called as LSTM. In this model we introduce a new state called long term memory along with short term memory in RNN. Every hidden layer is replaced with the LSTM or memory cell along with another connection for every cell called as cell state as shown in Fig. 9. Since there are many parameters in the layer, to avoid this we also use two gates namely 'update' and 'reset' gates.

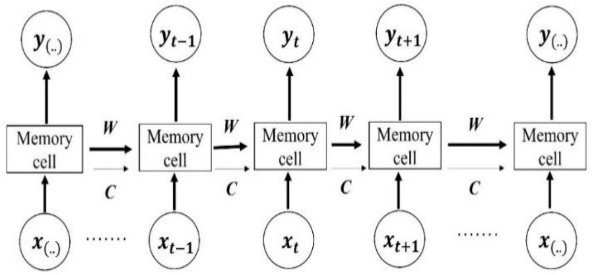

Fig. 9. Memory Cell Representation of LSTM.

The key words and main words in a given sentence are stored in long term memory for predicting the end words for auto completion of a sentence. These are stored until it finds the next keyword in the sequence. Depending on the current sentence certain keywords are added and previous sentence keywords are erased or deleted in auto completion process. This entire process is carried out in the training phase of the RNN. In training phase, the group of words is given to understand the structure in RNN based on which words are to be discarded and which words are to be stored.

LSTM contains three gates namely input gate, forget gate and output gate as shown in Fig. 10. The input gate control whether the memory cell is updated and is represented by Eq. (4).

$$i_t = \sigma(W_i * [h_{t-1}, x_t] + b_i) \tag{4}$$

The forget gate controls if the memory cell is set to 0 and is represented by Eq. (5). The output gate controls whether the information of the current cell state is made visible and is given by Eq. (6). Since RNN structure contains loops, to overcome this and to constitute the smooth curves in the range 0 to 1 the sigmoid function is used. Apart from these gates there is Vector $\bar{C}$ ', which modifies the cell state at the time of sigmoid activation as shown in Eq. (7). The 'tanh' has a 0 centered range performs sum operation is given by Eq. (8). This distributes the gradients equally among them. It also allows the cell state information to flow longer without erasing or exploding until the requirement of the certain keyword.

$$f_t = \sigma(W_f * [h_{t-1}, x_t] + b_f) \tag{5}$$

$$o_t = \sigma(W_o * [h_{t-1}, x_t] + b_o) \tag{6}$$

$$\bar{C}_t = tanh(W_c * [h_{t-1}, x_t] + b_c) \tag{7}$$

$$h_t = o_t * \tanh(C_t) \tag{8}$$

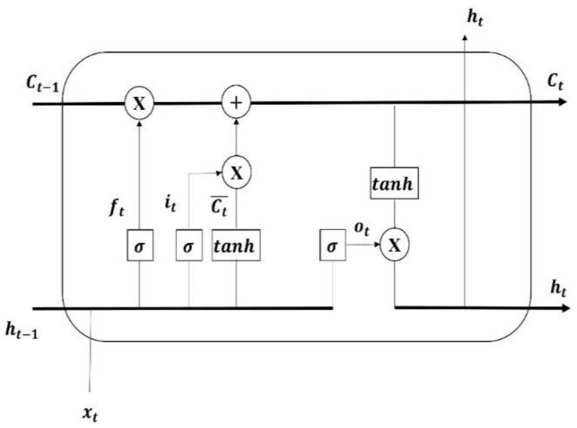

Fig. 10. Internal structure of LSTM memory cell.

It contains a previous hidden state current word by restricting the numbers between 0 and 1 during input. The restriction is maintained to discard the previous memory and gives a vector as output which has all the 0 and near to 0's. X defines the previous memory cell state that will be 0 and is determined by the forget gate. Every state has some weights attached while the sequence of words is given as input. Finally, the output is obtained by Eq. (9) which combines the sigmoid function along with the 'tanh' function and is given by the short-term memory.

$$C_t = f_t * C_{t-1} + i_t * \bar{C}_t \quad (9)$$

IV. Results and Discussion

This section represents the outcome of memory-based neural models for translation on simple, compound and complex sentences with BLEU and WER metrics.

A. Bilingual Evaluation Understudy Metric (BLEU)

The BLEU metric is used in analyzing the standard of the sentence which is translated through a machine from one language to another language. The term standard is determined as the reference between the output given by the machine with that of human translation. The BLEU scores are evaluated for each translated phrase by comparing them with a group of standard quality translation references available in the corpus is represented by Eq. (10). This score always represents a number between 0 and 1. The values which are closer to '1' represent the more common similar context between source and target language.

$$BLEU = \min\left(1, \frac{output\ context}{reference\ context}\right) * \prod_{i=2}^{4} precision_i \quad (10)$$

Where i ranges from 2 to 4, that represents the number of words such as 2-gram, 3-gram and 4-gram, $precision$represents the number of phrases in the given input sentence occurring in the reference sentence to total number of phrases in the input sentence.

B. Word Error Rate (WER)

The WER metric is also considered as one of the common metrics in evaluating the performance of Machine Translation models. It is used for distinguishing various systems and also for analyzing enhancements in one particular system. This is attained by arranging all the observed sequence of words with the reference sentence through dynamic sequence alignment. This can be calculated by Eq. (11).

$$WER = \frac{count(substitutions \cup deletions \cup insertions)}{Total\ number\ of\ words\ in\ the\ reference} \quad (11)$$

C. Performance of Proposed Model

The count of words in a sentence are represented as n-gram. In this work, the translation quality is measured on simple, compound and complex sentences of 2-gram, 3-gram and 4-grams. From Tables IV to VI, represents the translation quality on simple, compound and complex sentences among memory based neural networks and statistical model under BLEU and WER metrics. The visualization of these metric outcomes as shown in Fig. 11.

From Table IV, it can be observed that for a simple sentence the BLUE score for LSTM for all 2-gram, 3-gram and 4-gram is 0.89, 0.79 and 0.76 respectively. The BLEU score is higher for the LSTM model in all considered grams when compared with SMT and RNN. The rate of error obtained by LSTM is lesser with the values of 0.23, 0.21 and 0.20 when compared with other models. The model SMT doesn't have stored memory and obtained more error rate and lesser BLEU scores when compared to memory-based models like RNN and LSTM. Even though RNN and LSTM are memory-based models, with the help of our proposed model we can analyze similar outcomes between them in the case of simple sentences.

TABLE IV. Translation Quality of Simple Sentence

Model	2-gram		3-gram		4-gram	
	BLEU	WER	BLEU	WER	BLEU	WER
SMT	0.71	0.43	0.68	0.38	0.62	0.32
RNN	0.83	0.31	0.75	0.26	0.71	0.24
LSTM	0.89	0.23	0.79	0.21	0.76	0.20

Table V, represents the translation quality measures on 2-gram, 3-gram and 4-gram which are applied on compound sentences. On all these grams, the performance of the LTSM model is better performed with higher BLEU and lesser WER scores such as 0.91, 0.89, 0.82 and 0.14, 0.19, 0.20 respectively. This shows that LSTM considers every minute change of 0.01 in the given sentence and is calculated by showing better results when compared to RNN.

TABLE V. Translation Quality of Compound Sentence

Model	2-gram		3-gram		4-gram	
	BLEU	WER	BLEU	WER	BLEU	WER
SMT	0.76	0.41	0.71	0.33	0.68	0.35
RNN	0.87	0.25	0.82	0.23	0.74	0.21
LSTM	0.91	0.14	0.89	0.19	0.82	0.20

Finally in case of complex sentence results shown in Table VI, it can be clearly examined that using the memory based LSTM model is very advantageous for obtaining the best results when compared to that of other models.

TABLE VI. TRANSLATION QUALITY OF COMPLEX SENTENCE

Model	2-gram		3-gram		4-gram	
	BLEU	**WER**	**BLEU**	**WER**	**BLEU**	**WER**
SMT	0.79	0.37	0.75	0.31	0.71	0.26
RNN	0.89	0.23	0.82	0.17	0.85	0.14
LSTM	0.94	0.19	0.89	0.14	0.92	0.11

On comparison of translation quality of different types of sentences, memory cell based neural network model LSTM attained higher BLEU metric score and least WER metric scores on 2-gram, 3-gram and 4-gram sentences from English to Telugu language translation. The visualization of neural network models performance based on BLEU and WER metrics as shown in Fig. 11.

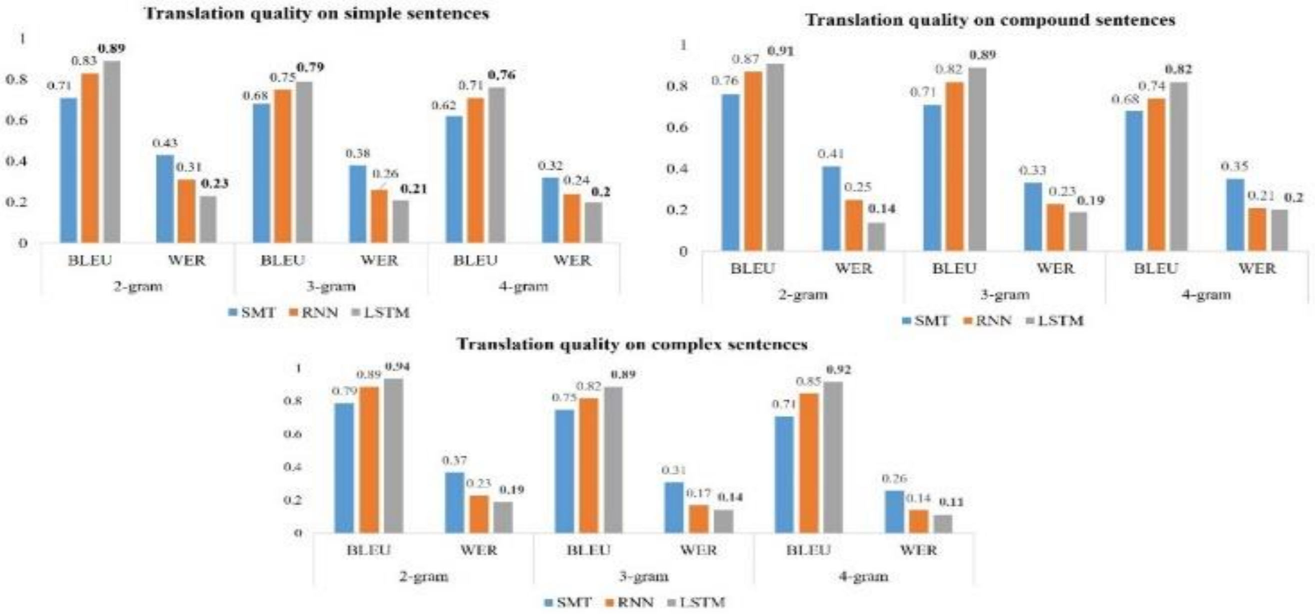

Fig. 11. Translation quality performance of neural network models.

V. CONCLUSION AND FUTURE SCOPE

This work is carried out on English to Telugu Language translation, since Telugu language is one of the fifth most common spoken language across India. During this process of translation, the word to word mapping becomes complex because this requires various reordering mechanisms and large corpus data. In SMT approach, the phrase to phrase mappings from input to output becomes complex due to the absence of memory cell and also the need for reordering becomes high. To overcome this limitation a memory based neural network is required to maintain proper syntax and semantics among source and target language. In this proposed work, based on the phrases the type of sentence is identified whether it is simple, compound or complex sentence. Depending on the type of sentence, the independent and dependent phrases are rearranged to obtain decent translation quality. In future work, there is a scope to reuse the existing memory cell for every word instead of creating a new memory every time. By using this approach, the complexity of designing the model becomes easier to handle any type of sentence.

***Abstract*—The study investigates the performance of hybrid security systems under different personnel training and artificial intelligence (AI) assistance conditions. The aim is to understand the system's impact on different scenarios that involve human operators and AI and to develop a predictive model for optimizing system performance. A human security information model was built to predict the performance of hybrid security systems. The system's performance metrics (response time, hits, misses, mistakes), cognitive load, visual discrimination, trust, and confidence were measured under different training and assistance conditions. Participants were divided into trained and non-trained groups, and each group performed surveillance tasks with and without AI assistance. Predictive modeling was performed using Linear Regression. The training significantly improved performance by reducing misses and mistakes and increasing hits, both with and without AI assistance. In the non-trained group, AI assistance boosted speed and hit accuracy but led to more mistakes. AI assessment reduced response time and misses for the trained group while increasing hits without affecting the mistake rate. Trust and confidence were higher with AI in the non-trained group, while AI reduced cognitive load in the trained group. The findings highlight the interactions between human operators, AI assistance, and training in hybrid surveillance systems. The predictive model can guide the design and implementation of these systems to optimize performance. Future studies should focus on strategies to enhance operator trust in AI-assisted systems and confidence, further optimizing the collaborative potential of hybrid surveillance frameworks.**

Keywords*—*Hybrid surveillance systems; human-AI interaction; operator training; predictive modeling; linear regression

I. Introduction

The delicate balance between human judgment and artificial intelligence (AI) in surveillance is critical. While AI-powered automated systems have demonstrated remarkable capabilities in enhancing the efficiency and effectiveness of monitoring tasks, their inherent limitations necessitate the continued involvement of human operators [1]. Extensive research has demonstrated that deploying monitoring and surveillance devices, such as cameras and sensor-operated security systems, is crucial in reducing crime rates [2]. The demand for security services has evolved beyond monitoring criminal activities to encompass detecting and tracking abnormal behaviors [3]. Such behaviors, mainly in crowded or densely populated areas, can pose significant risks. These gatherings, often driven by religious, cultural, or social events, necessitate heightened security measures due to their importance and potential disruptions. The need for advanced security surveillance cameras has never been more critical. Integrating intelligent surveillance systems capable of identifying suspicious or abnormal behaviors is indispensable. Moreover, the effectiveness of these systems is greatly enhanced by the presence of qualified and trained personnel who can operate and interpret the data from these devices, thereby completing the security framework [4]. Ensuring public safety and security is paramount, surpassing all other considerations. In the absence of security, the fundamental components of life disintegrate. Motivated by this imperative, our project aims to elevate the quality of security surveillance systems by enhancing their ability to detect abnormal behaviors and assist personnel in their duties [5]. This approach provides crucial guidance and optimizes efforts, ensuring a more secure environment.

A. Surveillance Systems Evolution

Traditional security surveillance systems have evolved significantly, transitioning from basic physical security measures to sophisticated technological solutions. Initially, security systems primarily involved visual monitoring, which was adequate but limited by human capabilities and response times. Technology became essential as the need for more efficient and reliable security solutions grew. This evolution introduced electronic surveillance systems, which have become a cornerstone of modern security strategies. Among these advancements, Closed-Circuit Television (CCTV) systems emerged as a supportive technology, providing real-time monitoring capabilities and enhancing the overall effectiveness of security operations.

In the 1940s, CCTV first appeared, primarily gaining traction within security contexts. Germany pioneered installing the world's inaugural CCTV system [6] [7]. Subsequently, British law enforcement deployed CCTV during political demonstrations in central London. However, this early adoption faced significant challenges due to costs [8]. Since these initial implementations, CCTV technology has undergone substantial advancements. Improvements have encompassed enhanced visual quality, data storage, remote accessibility, and the integration of automated detection systems powered by artificial intelligence.

B. Automated Surveillance Technologies Implications on Security

Artificial Intelligence (AI) technologies significantly enhance Closed-Circuit Television (CCTV) systems by introducing advanced features such as facial recognition, behavior analysis, and real-time threat detection. These capabilities allow for proactive surveillance, expanding the effectiveness of traditional CCTV setups. Automated surveillance can quickly and accurately analyze large amounts of data, identifying potential security threats that might be missed by human operators. This reduces the high cognitive load level on CCTV operators, allowing them to focus on critical incidents that require human judgment [9]. Thereby increasing their productivity and reducing the number of personnel needed simultaneously [10].

Despite the advancements and positive impacts of AI on surveillance systems, the human element remains crucial [9]. While AI can support routine monitoring tasks, it cannot entirely replace human intuition and expertise. Comprehensive training programs for CCTV operators are essential, focusing on how to handle various aspects of their work environment, job roles, skills and competencies, and the nature of the places they monitor [11]. Effective training ensures that operators can manage tasks, understand their responsibilities clearly, and develop the necessary competencies to perform their tasks efficiently [12]. By being well-prepared to deal with the complexities of the environments they oversee, operators can leverage both human intuition and advanced AI technologies to enhance their monitoring capabilities and respond more effectively to security threats.

C. Hybrid Security Systems

Hybrid surveillance systems offer numerous benefits by combining AI's precision and speed with human oversight's contextual understanding, positively affecting performance. These systems enhance accuracy and reduce false alarms by automating routine tasks and analyzing vast amounts of data in real-time, which lowers the workload on human operators and allows them to focus on more complex tasks, thereby improving overall performance [13]. The reduced cognitive load enables operators to maintain higher levels of alertness and efficiency [14]. Enhanced visual discrimination is achieved as AI quickly identifies patterns and anomalies, assisting human operators in detecting subtle differences that might be missed otherwise. This collaboration fosters greater confidence and trust in the system as operators can rely on AI to provide accurate initial assessments, ensuring quicker, more accurate, and contextually appropriate responses [15]. Ultimately, these improvements contribute to a more effective and reliable surveillance operation.

II. OMAR Framework

In this study, we test a new framework that will positively affect the security system. The Operator Machine Augmentation Resource (OMAR) framework is a comprehensive system designed to enhance the efficiency and effectiveness of CCTV surveillance operations. OMAR integrates advanced technologies such as a Computer Vision model, human training techniques, and alert triggers to address limitations in traditional surveillance systems. The framework improves the productivity of surveillance by facilitating operator tasks and reducing human effort, ultimately enhancing the quality of security. It includes components like a detection model using the YOLO (You Only Look Once) object detection system, which efficiently analyzes live video feeds for real-time object detection and annotation. OMAR training sessions are designed to cultivate a broad set of skills and competencies, thereby equipping CCTV operators with the necessary knowledge and expertise to effectively monitor and manage surveillance environments [16]. The rationale behind OMAR is to create a hybrid system that leverages both AI and human oversight, combining the strengths of each to achieve better accuracy, reduce false alarms, and improve overall surveillance efficacy.

III. Literature Review

It has become evident that the use of surveillance systems has increased dramatically in the past decade, mainly due to the computerization of some of these techniques to fight terrorism and other activities that lead to increased crime rates. These systems play critical roles in guaranteeing security and detecting and managing large crowds in different settings. Monitoring systems are generally categorized into two types: Vision-based and non-vision-based.

A. Monitoring System

1) Vision-based systems: Vision-based systems mainly rely on cameras, leveraging advanced image-processing technologies and computer vision models to ensure safety and security. These systems are extensively deployed in urban areas, business districts, commercial hubs, and transportation centers, aiming to mitigate insecurity and enhance public safety [17]. The integration of computer vision within these systems enables sophisticated functionalities such as facial recognition, behavior analysis, and anomaly detection, significantly improving their efficacy and reliability. By incorporating these elements, AI-driven monitoring systems provide a robust framework for proactive and reactive security measures, facilitating real-time monitoring and prompt response to potential threats.

2) Non-Vision-based systems: Other forms of monitoring mechanisms rely on other means to detect and observe parts of the physical space where vision-based surveillance is challenging or cannot be applied. These systems are particularly useful, especially when issues such as the absence of light or something obstructing sight make using cameras less effective. Popular non-vision-based system tools include Wi-Fi, Bluetooth, Radio frequency identification, RFID, and cellular networks [18]. Bluetooth is a short-range and low-cost wireless technology designed with features similar to Wi-Fi sets but with less coverage range [19]. It is commonly used in premises monitoring to track a person's or object's slow movement. Bluetooth technology, however, uses personal devices to track the movement and location of Bluetooth-enabled devices compared to Wi-Fi technology, which uses access points to monitor the movement and location of Wi-Fi devices. This technology can be used particularly well in crowded areas that are difficult to maintain order within, such as airports, malls, and stadiums. RFID, or Radio Frequency Identification Technology, is the system of using radio frequencies to verify the identity of an individual and or object tagged [19]. RFID systems can be of two types: one type does not have energy resources, and the second has energy resources inbuilt in them and can have better signal transmission and sound range than the first ones, known as RFID tag passive or active accordingly [20]. Cellular network monitoring involves transmitting information between mobile devices and cells. This technology is crucial for tracking the location and movement of mobile users over vast geographical areas. Effective utilization of cellular networks for surveillance purposes requires the cooperation of multiple mobile network operators to ensure seamless data transmission and coverage [18] [21]. Additionally, advancements in 5G technology promise to further enhance the capabilities of cellular-based surveillance systems by providing higher data rates, lower latency, and more reliable connections.

Non-vision-based surveillance technologies require optimal conditions to function effectively. Moreover, the receivers associated with these systems are susceptible to deliberate interference and manipulation by individuals. Based on the facts presented, although both vision and non-vision systems are essential components of modern security systems, the vision-mode systems possess certain advantages noteworthy on the significance of real-time controls, and additional capabilities originating from AI technologies. With these capabilities, vision-based surveillance systems are more suitable for most applications, especially in areas where detailed monitoring is required and prompt action is sensitive, as in urban and highly crowded regions.

B. Automated Systems

To fully leverage the vision-based monitoring system technologies, it is crucial to integrate these systems with advanced artificial intelligence (AI), machine learning (ML), and deep learning (DL) methodologies. Recent advancements in AI have led to the development and deployment of various sophisticated techniques, each evaluated based on their efficacy in identifying anomalous behavior. This comparative analysis has revealed significant improvements in surveillance capabilities, underscoring AI's critical role in enhancing modern surveillance systems' accuracy and reliability. In recent years, a diverse exhibition of models and techniques has been extensively tested, including Generative Adversarial Networks (GANs), Convolutional Neural Networks (CNNs), Long Short Term Memory (LSTM) networks, Gaussian Mixture Models (GMMs), Support Vector Machines (SVMs), and Random Forests (RF) [22]. Numerous studies have employed these techniques to identify behaviors that could potentially disrupt crowds. In our research, we drew upon prior work that has categorized actions such as standing, sitting, sleeping, running, moving in opposite or different crowd directions, and non-pedestrian movements such as cars and wheelchairs as abnormal behaviors that could compromise the safety and flow of moving crowds [23] [24]. Although these methodologies have been proven effective in their respective functions, their effectiveness nevertheless has its drawbacks. These gaps imply that human oversight is still very relevant in order to come up with results that can meet all the parameters of precision [9]. Despite the critical role played by CCTV operators, humans need to improve their ability to monitor large crowds over extended periods effectively. This limitation arises from human cognitive capacity constraints, which deteriorate under prolonged monitoring tasks, leading to lowered performance. Consequently, there is a pressing need for an auxiliary element, such as AI, to augment human capabilities. AI can significantly enhance the efficiency and ease of surveillance operations, improving overall performance. Notably, while AI provides substantial support, it is not intended to replace the human presence but rather to complement and optimize human efforts in surveillance tasks.

Research on the training of CCTV operators is notably lacking, primarily focusing on applying general psychological theories. One notable study suggests that an individual's situational awareness significantly enhances operational performance [25]. Existing literature predominantly aims at improving the efficiency of CCTV operators while concurrently minimizing their cognitive load [26].

IV. Methodology

A. Participants

This study recruited 30 participants, aged between 20 and 49, through flyers that provided detailed information about the research. These flyers were distributed to both Iowa State University students and residents. All participants gave informed consent prior to their involvement in the study. The research procedures adhered to ethical guidelines and were approved by the Human Institutional Review Board (IRB) at Iowa State University. To qualify for the experiment, participants needed to be physically and mentally capable of meeting the study's demands. It included being physically present for the entire duration of the study sessions and being able to handle the physical requirements without experiencing excessive fatigue or discomfort. Participants had to be mentally prepared to manage any potential stress or discomfort associated with the study. Furthermore, normal visual acuity was a prerequisite for participation.

B. Experimental Design

The main objective of this study was to evaluate and enhance the performance, visual discriminations, cognitive load, trust, and confidence for both trained and non-trained groups. The design was adopted to evaluate two independent variables: personnel and system. One-way ANOVA and T-test were performed, and all participants were distributed randomly between two groups. The study spanned 18 days, with participants returning for a second visit four days after the first visit and a third visit two weeks after the second visit to evaluate their performance. Each observation session lasted 20 minutes. The first group had a training session, and the second group had no training, but both groups were tested with an assisted and no assisted system.

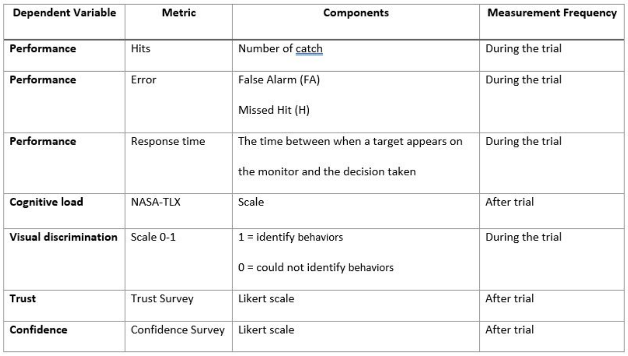
In this study, we employed an experimental design incorporating two independent variables. The first independent variable is the level of personnel training, which is categorized into two groups: trained personnel and untrained personnel. Personnel variables are essential in assessing the impact of professional training on the study's outcomes. The second independent variable is system. The system variable is similarly divided into two levels: the non-assisted system and the assisted system. Both independent variables are critical to our investigation, enabling a comprehensive analysis of the interplay between human training and technological support see Fig. 1.

			System	
			Non-assisted system	Assisted system
		Levels	**1**	**2**
Personnel	Non-trained personnel	**1**	Y11	Y12
	Trained personnel	**2**	Y21	Y22

Fig. 1. Factors, levels, and treatment combination yields.

C. Measurements

This study encompasses five dependent variables: performance, cognitive load, visual discrimination, trust, and confidence. Performance is assessed through response time, the number of hits, errors, and misses. Cognitive load is quantified using the NASA-TLX scale [27], [28]. Visual discrimination is evaluated by categorizing participants' responses on a point scale, awarding one point for each correctly identified abnormal behavior and zero points for failures to recognize abnormal behaviors. Trust is scaled on a continuum from 0 (no trust in the system) to 100 (complete trust in the system). Confidence is measured on a similar scale, ranging from 0 (no confidence in decisions) to 100 (complete confidence in decisions) see Fig. 2.



Dependent Variable	Metric	Components	Measurement Frequency
Performance	Hits	Number of catch	During the trial
Performance	Error	False Alarm (FA) Missed Hit (H)	During the trial
Performance	Response time	The time between when a target appears on the monitor and the decision taken	During the trial
Cognitive load	NASA-TLX	Scale	After trial
Visual discrimination	Scale 0-1	1 = identify behaviors 0 = could not identify behaviors	During the trial
Trust	Trust Survey	Likert scale	After trial
Confidence	Confidence Survey	Likert scale	After trial

Fig. 2. Description of dependent variable metrics, units, and frequencies.

D. Procedure

Detailed information about the research objectives and study procedures was presented to participants to ensure clarity and understanding and eliminate any potential bias before commencing the study. The study lasted 18 days weeks to determine factors that can influence the performance of the participants. The protocol will include having the participant randomly assigned to one of two groups of getting security training or not (between subject). Then each participant in each group (trained or not trained) will be tested under two conditions of system monitoring (AI Assistant system and no AI Assistant system) (within subjects) see Fig. 3.

1) Visit 1: Participants' visual acuity was assessed using the Snellen eye chart test, while their dominant eye was determined through the Porta Test, a sighting test designed for this purpose [29]. Additionally, their color vision was evaluated using a series of plates, each featuring a circle filled with numerous small colored dots that form numbers. Those in the trained group experienced a dedicated training session to enhance their performance. Upon completion of these examinations and training, participants completed a survey see Fig. 4.

Fig. 4. Study procedure.

2) Visit 2: To mitigate immediate recall bias, participants returned to perform the experiment four days after the initial visit. Participants from both groups were asked to watch the 20 minutes long video and indicate any observed abnormal behaviors within the crowd by moving the cursor to the target and providing detailed explanations of their observations. Additionally, participants were instructed to describe any abnormal behaviors that could disturb the walking crowd verbally. The collected verbal protocol data was utilized for analysis. Following the video task, participants completed a survey to assess their overall experience and the effectiveness of the experiment see Fig. 4.

3) Visit 3: We applied our algorithm to the video to detect abnormal behaviors. Participants from both groups watched the 20 minutes long video, identified abnormal behaviors that could disturb the walking crowd by moving the cursor to the target, and described the specifics of their observations. Verbal protocols were used. Following the video task, participants completed a survey to assess their overall experience and the experiment's effectiveness see Fig. 4.

V. Result

All data were analyzed using SPSS 28. We used One-way ANOVA to assess mean differences between trained and non-trained groups with and with no AI assistants in monitoring abnormal behavior in terms of performance (response time, miss, hit, and mistake) and measuring the trust, confidence, cognitive load, and visual discrimination level. Also, a Paired-Sample T-test was needed to discover the efficiency of AI assistance compared to no AI assistance for each group separately to distinguish the individual differences in performance (response time, miss, hit, and mistake) and measure the trust, confidence, cognitive load, and visual discrimination level.

A. Trained and Non-Trained Groups with AI Assistant (Between-subject)

1) Performance: H1: While monitoring abnormal behaviors through CCTV, there will be a significant difference in performance (response time, miss, hit, and mistake) between trained and no trained groups with AI assistants.

The ANOVA test comparing the performance of trained and non-trained groups with AI assists in response time, misses, hits, and mistakes. The trained group did not show a significant difference in the response time (F (1, 28) = 0.059, p = 0.810) compared to the non-trained group. On the other hand, the trained group significantly had fewer missed incidents (mean difference = 29.34, F (1, 28) = 30.838, p ¡ 0.001) compared to the non-trained group. Also, the trained group significantly had fewer mistakes in catching incidents (mean difference 19.47, F (1, 28) = 48.532, p ¡ 0.001) compared to the non-trained group. Moreover, the trained group had significantly more incident hits (mean difference = 29.34, F (1, 28) = 30.838, p ¡ 0.001) compared to the non-trained group. Therefore, these results suggest that training significantly improves performance by reducing misses and mistakes and increasing hits, as shown in Fig. 5.

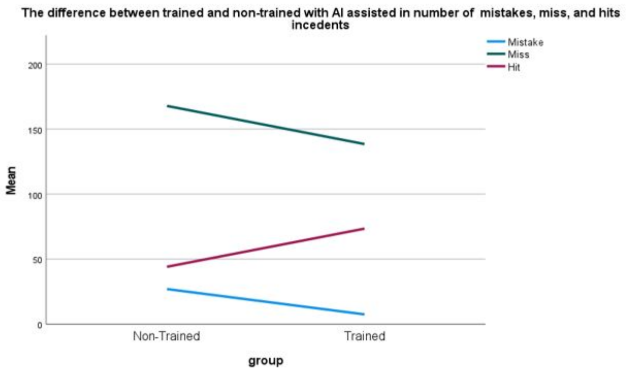

Fig. 5. The average of the trained and non-trained groups with AI assistants in a number of mistakes misses, and hits.

2) Trust, Confidence, Cognitive Load, and Visual Discrimination: H2: While monitoring abnormal behaviors through CCTV, trust level will be significantly different between trained and no trained groups with AI assistance.

H3: While monitoring abnormal behaviors through CCTV, confidence levels will significantly differ between trained and non-trained groups with AI assistance.

H4: While monitoring abnormal behaviors through CCTV, there will be a significant difference in cognitive load between trained and non-trained groups with AI assistance.

H5: While monitoring abnormal behaviors through CCTV, there will be a significant reduction in visual discrimination between trained and non-trained groups with AI assistance.

The ANOVA test compares the performance of trained and non-trained groups with AI assistants in terms of the trust, confidence, cognitive load, and visual discrimination. The trust score between non-trained and trained groups is not statistically significant (p = 0.445). Also, there was no significant difference between trained and non-trained in the level of confidence (p = 0.125). Cognitive load, the non-trained group also shows no significant difference compared to the trained group (p = 0.30). However, visual discrimination shows a near-significant difference; the trained had a high (mean difference of 0.025 F (1, 28) = 3.758, p = 0.063) compared to the non-trained group. These findings suggest that training does not significantly impact trust, confidence, or cognitive load but may have a marginal effect on improving visual discrimination.

B. Trained and Non-Trained Group with no AI Assistant (Between-Subject)

1) Performance: H6: While monitoring abnormal behaviors through CCTV, there will be a significant difference in performance (response time, miss, hit, and mistake) between trained and non-trained groups with no AI assistant.

The ANOVA test compares the performance of trained and non-trained groups with no AI assistant regarding response time, misses, hits, and mistakes. There is no significant difference in response time between the non-trained and trained with no AI assistant (p = 0.512). However, the trained group had significantly fewer missed incidents (mean difference = 25.53, F (1, 28) = 19.735, p ¡ 0.001) compared to the non-trained group. Moreover, the trained group had significantly more hit incidents (mean difference: 25.53, F (1, 28) = 19.735, p ¡ 0.001) compared to the non-trained group. Also, the trained group had significantly fewer mistakes in catching incidents (mean difference = 12.47, F (1, 28) = 22.783, p ¡ 0.001) compared to the non-trained group. Therefore, these results suggest that training significantly improves performance by reducing misses and mistakes and increasing hits, as shown in Fig. 6.

2) Trust, Confidence, Cognitive Load, and Visual Discrimination: H7: While monitoring abnormal behaviors through CCTV, there will be a significant difference in trust level between trained and non-trained groups with no AI assistance.

H8: While monitoring abnormal behaviors through CCTV, there will be a significant difference in confidence levels between trained and non-trained groups with no AI assistance.

H9: While monitoring abnormal behaviors through CCTV, there will be a significant difference in cognitive load between trained and non-trained groups with no AI assistance.

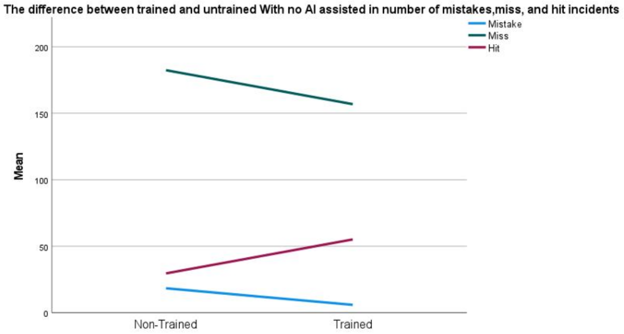

Fig. 6. The average of the trained and non-trained groups with no AI assistant in a number of mistakes, misses, and hits.

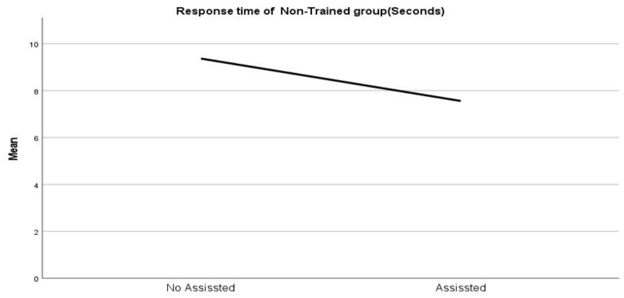

Fig. 7. The response time average of the non-trained group with AI and no AI assistants.

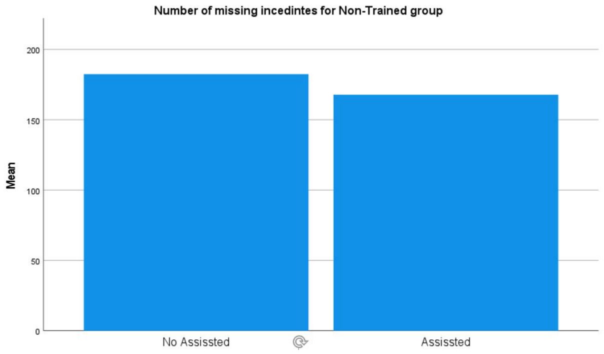

Fig. 8. The missing incidents average of the non-trained group with AI and with no AI assistant.

H10: While monitoring abnormal behaviors through CCTV, there will be a significant reduction in visual discrimination between trained and non-trained groups with no AI assistance.

The ANOVA test compares the performance of trained and non-trained groups with no AI assistant regarding trust, confidence, cognitive load, and visual discrimination. The trust score between non-trained and trained groups is not statistically significant (p = 0.397). Also, the confidence level was not significantly different between trained and non-trained (p = 0.320). However, cognitive load shows a near-significant difference, with the trained group experiencing a higher cognitive load than the non-trained group (mean difference: 10.89, F (1, 28) = 3.218, p = 0.084). Finally, visual discrimination did not show a statistically significant difference between the groups (mean difference (p = 0.303). Therefore, these results did not significantly impact trust, confidence, or visual discrimination but may increase cognitive load.

C. Non-Trained Group (Within-Subject)

1) *Performance:* The results of the paired t-tests reveal significant reduction in response times for AI (mean difference = 1.81 seconds, t = 2.409, p = .030) compared to no AI assistant, see Fig. 7, and number of misses (mean difference = 14.53, t = 6.200, p ¡.001). See Fig. 8, indicating that AI assistance is significantly enhance the user's performance in both time consuming to catch incidents and number of missed incidents compared to no AI assistance. Also, the number of hits of AI assistants is significantly increased (mean difference = -14.53, t= -6.200, p ¡ .001) compared to no AI assistants, see Fig. 9. However, this improvement in hits is accompanied by a significant increase in the number of mistakes (mean difference = -8.60, t= -5.644, p¡.001) see Fig. 10. Therefore, these results suggest that AI assistance boosts performance speed and hit accuracy, but it leads to a higher mistake rate.

2) *Trust, Confidence, Cognitive Load, and Visual discrimination:* The results of the paired t-tests reveal significant differences between the non-trained group with AI assistance and those with no AI assistance across four aspects: trust, confidence, cognitive load, and visual discrimination. The user's trust level with AI assistance is significantly higher (mean difference = -15.667, t = -3.063, p = .008) than with no AI assistance. Also, the user's confidence level is highly significant with AI assistance (mean difference = -22, t = -4.069, p = .001). However, cognitive load results were not statistically significant (p = .100), and AI assistance did not significantly affect visual discrimination (p = .718) compared to no AI assistance see Fig. 11.

Trained Group (Within- subject)

3) *Performance:* The paired t-test results revealed significant differences in the performance of the trained group with an AI assistant and no AI assistant. Participants with AI assistants spent significantly less time catching incidents (Mean difference 1.12 seconds, t = 2.221, p = .043) than no AI assistant see Fig. 12. Also, participants with AI assistants had significantly fewer miss incidents (mean difference 18.33, t = 6.510, p ¡ .001) compared to the no AI assistant see Fig. 13. Moreover, participants with AI assistant significantly had higher hits incidents (mean difference = 18.33 hits, t = -6.510, p ¡ .001) compared to the no AI assistant see Fig. 14. However, there is no significant difference in the number of mistakes in catching incidents between AI assistance and no AI assistance (p = .164) see Fig. 15.

4) *Trust, Confidence, Cognitive Load, and Visual discrimination:* The paired t-test results revealed a significant difference between AI and no AI assistant in cognitive load; however, there was no significant difference between the others. The participants with AI assistance had a significantly less cognitive load (mean difference = 15.94, t = 2.151, p = .049) than the no AI assistant see Fig. 16. However, there was no significant difference in trust level (p = .946). Similarly, there was no significant difference in confidence level (p= 1.00). Lastly, visual discrimination also showed no significant difference (p = .455).

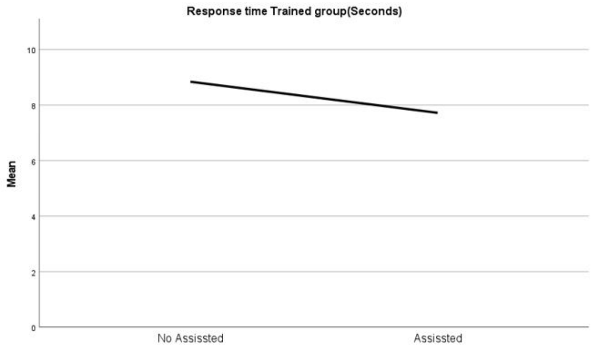

Fig. 12. The response time average of the trained group with AI and no AI assistants.

VI. Modeling

A. Data Preprocessing

Data preprocessing was completed. it transformed the data into a meaningful, efficient format, ready for machine learning models. This study focuses on two categorical variables: personal and system. These categorical variables were transformed using the one-hot encoding method. One-hot encoding involves converting each unique category within a categorical variable into a separate binary feature in a new column. Consequently, for each observation, a binary indicator of 1 is assigned to the feature corresponding to its original category, while all other features receive a binary value of 0. This method generates a new binary feature for each possible category, improving the model accuracy and predictive analysis.

B. Multicollinearity

The Variance Inflation Factor (VIF) method was utilized to quantify the degree of multicollinearity among the regression variables. Multicollinearity occurs when two or more predictors exhibit a high degree of correlation simultaneously, potentially reducing the statistical significance of individual independent variables [30]. The Variance Inflation Factor (VIF) values will uniformly be 1 in procedures with no correlated predictors. VIF values exceeding five indicate multicollinearity and may consider further investigation or removal from the model (see Table I). The VIF is calculated using the following formula:

$$\mathrm{VIF}_j = \frac{1}{1 - R_J^2} \tag{1}$$

TABLE I. Variance Inflation Factors for Features

Feature	VIF
Trust	2.458356
Confidence	2.088327
Mental	2.927619
Physical	1.284067
Temporal	2.227160
Performance	1.855252
Effort	3.794435
Frustration	2.163868
Training-Non-trained	∞
AIassisstance_AI_Assisstance	∞
AIassisstance_No_AI_Assisstance	∞

C. Model Development

This study employed linear regression to predict performance. Linear regression is a statistical approach used for modeling the association between a dependent variable and independent variables by providing a linear equation to observed data. The purpose of linear regression

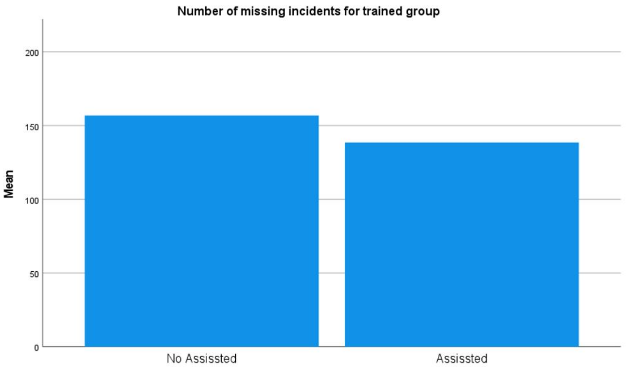

Fig. 13. The missing incidents average of the trained group with AI and with no AI assistant.

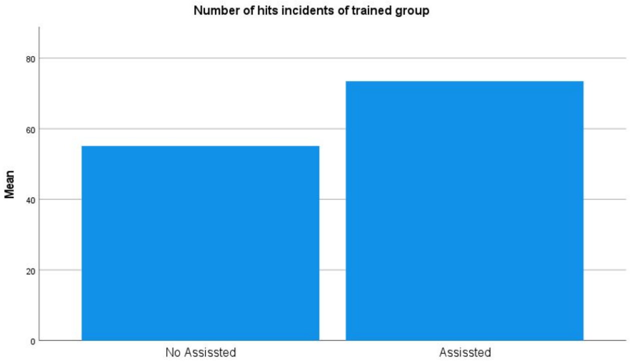

Fig. 14. The hits incidents average of the trained group with AI and with no AI assistant.

is to predict the dependent variable based on the values of the independent variables [31]. This method is favored for its simplicity, interpretability, and efficiency in modeling linear relationships, making it widely applicable in various fields such as predictive study, elucidating variable relationships, and data sciences. Linear regression is particularly valued for its ability to provide clear insights into the strength and direction of relationships between variables and for its utility in predictive analytics.

D. Performance Metrics

In our study, we assessed the performance of our predictive models using Mean Absolute Error (MAE) and Root Mean Square Error (RMSE). They are widely utilized metrics for assessing models [32]. Both metrics are essential for evaluating the accuracy of our models and quantifying the deviation from the actual values. MAE is the mean of the gap between the anticipated values and the actual values of the target variable (see Eq. 2). RMSE, on the other hand, is calculated as the square root of the average of the squared errors (see Eq. 3). These metrics enabled us to rigorously evaluate the precision of the models and facilitate comparative performance analysis. MAE and RMSE deliver a comprehensive study of model error.

$$\text{MAE} = \frac{1}{n}\sum_{i=1}^{n}|y_i - \hat{y}_i| \qquad (2)$$

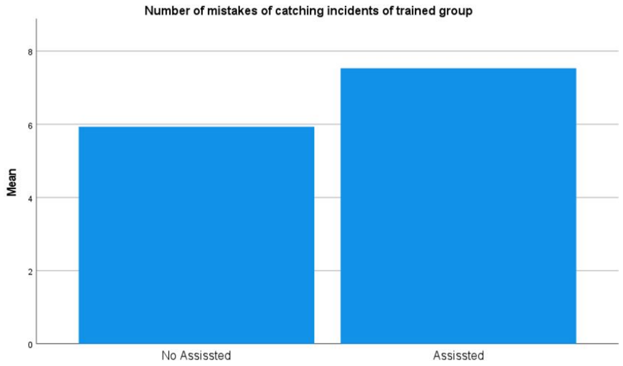

Fig. 15. No significant difference in the number of mistakes in catching incidents between AI and no AI assistance.

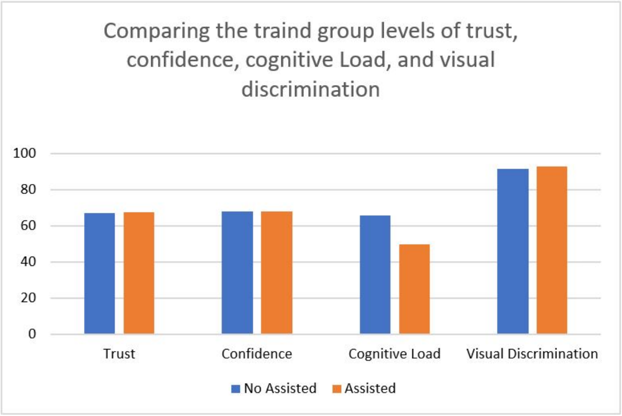

Fig. 16. The average of trust, confidence, cognitive load, and visual discrimination for a trained group with and with no AI assistance.

$$\text{RMSE} = \sqrt{\frac{1}{n}\sum_{i=1}^{n}(y_i - \hat{y}_i)^2} \qquad (3)$$

E. Prediction Results

TABLE II. Performance Analysis for Different Models on Test Data

Metrics	**LR**
RMSE	17.247 (3.05)
MAE	14.031 (2.67)

The performance was assessed using the test metrics MAE and RMSE (Table II). Fig. 17 compares actual versus predicted values using scatter plots for the Linear Regression model. The scatter plot for the LR model shows a wide dispersion of data points, indicating the prediction error of the model. This analysis demonstrates that the Linear Regression model provides a reasonably accurate prediction with a lower MAE and RMSE.

VII. Discussion

This study explored the effectiveness of hybrid security systems that integrate human oversight with automated

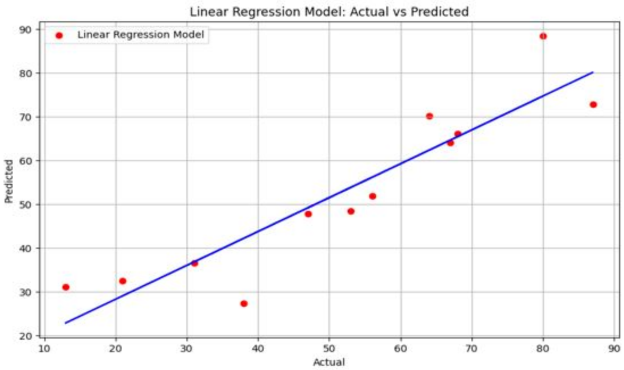

Fig. 17. Comparison of actual vs. predicted values for linear regression.

surveillance powered by advanced AI technologies. The findings emphasize the critical interplay between human operators and AI systems in enhancing the overall performance of surveillance operations. Our results demonstrate that AI-assisted surveillance systems significantly improve the detection of abnormal behaviors compared to systems solely reliant on human operators. These automated capabilities allow for proactive monitoring, reducing the cognitive load on human operators and enabling them to focus on critical incidents requiring human judgment and expertise. The study revealed that trained personnel significantly outperformed untrained personnel in identifying incidents, both with and without AI assistance. Specifically, the trained group exhibited fewer missed incidents and mistakes and more behavior identification incidents. In addition, it highlights the importance of comprehensive training for CCTV operators, ensuring they can effectively collaborate with AI systems to enhance surveillance efficacy. The performance metrics assessed included response time, number of hits, misses, and mistakes. AI assistance notably reduced response times and increased the number of hits for both trained and untrained groups. However, it also led to increased mistakes among the non-trained group, suggesting that while AI enhances performance, it requires the human operator's expertise to mitigate errors effectively [33]. The cognitive load, measured using the NASA-TLX scale, showed mixed results. For the non-trained group, AI assistance did not significantly impact cognitive load, while on the contrary, for the trained group, AI assistance resulted in a significantly lower cognitive load. The result indicates that trained personnel can better leverage AI capabilities to reduce mental strain, enhancing their performance and efficiency. The study also examined trust, confidence, and visual discrimination. While AI assistance did not significantly impact trust and confidence levels for either group, it could marginally improve visual discrimination among trained personnel. Also, operators can benefit from AI assistance to enhance their ability to discern subtle differences and abnormalities in monitoring footage when adequately trained. Our modeling efforts involved linear regression to predict performance metrics based on various factors. The feature importance analysis revealed that factors such as training level and AI assistance were significant predictors of surveillance efficacy. These findings emphasize surveillance performance's multifaceted nature, where human and technological factors interplay to determine overall effectiveness.

The integration of AI technologies in surveillance systems significantly enhances their effectiveness, particularly when complemented by well-trained human operators. The findings underscore the necessity for continuous training and support for CCTV operators, ensuring they can leverage AI capabilities to their full potential. Furthermore, the hybrid approach of combining AI precision with human contextual understanding offers a balanced solution that maximizes the strengths of both elements.

VIII. Future Work

While the study highlights the benefits of integrating AI with human oversight in surveillance systems, future research can explore the gamification of these systems to boost participant motivation and interaction [34].

Gamification uses game-design elements in non-game settings to improve engagement and motivation [35]. In hybrid surveillance systems, gamification can:

- Enhance Training: Gamified training sessions with points, badges, and leaderboards can make learning enjoyable and effective.
- Provide Real-time Feedback: Scoring systems and instant rewards can reinforce positive behaviors and enhance attentiveness.
- Boost Cognitive Engagement: Challenges and missions can reduce monotony and cognitive fatigue, making tasks more engaging.
- Foster Collaboration: Team-based challenges can improve teamwork and collective performance in large operations.

Gamifying hybrid surveillance systems can enhance operator engagement and performance, leveraging the full potential of both human and AI capabilities for more effective surveillance operations [36].

Another area for exploration is the inclusion of more advanced machine learning models such as Random Forest, which has shown promise in predicting surveillance performance metrics. Random Forest, known for its robustness and versatility, can handle complex interactions between features and offer unique insights. However, Random Forest models might be promising but require larger studies to assess their performance adequately. Hyperparameter tuning, such as optimizing the number of trees, maximum depth, and other parameters, can improve the model's performance. Investigating the importance of different features in the Random Forest model can also provide deeper insights into the factors that significantly impact surveillance performance.

IX. Conclusion

The study provides evidence that hybrid surveillance systems, which integrate AI with human oversight, enhance detection capabilities, reduce cognitive load, and improve overall performance. Future research should focus on strategies to enhance operator trust in AI-assisted systems and confidence, further optimizing the collaborative potential of hybrid surveillance frameworks. This approach will ensure safer and more secure environments in increasingly urbanized and densely populated areas.

Towards Secure Internet of Things-Enabled Intelligent Transportation Systems: A Comprehensive Review

Changxia Lu[1]*, Fengyun Wang[2]
Heze Vocational College, Heze 274000, Shandong, China[1]
Heze Engineering Technician College, Heze 274000, Shandong, China[2]

***Abstract*—The Internet of Things (IoT) constitutes a technological evolution capable of influencing the establishment of smart cities in a wide range of fields, including transportation. Intelligent Transportation Systems (ITS) represent a prominent IoT-enabled solution designed to enhance the efficiency, safety, and sustainability of transport networks. However, integrating IoT with ITS introduces significant security challenges that need to be addressed to ensure the reliability of these systems. This research aims to critically analyze the current state of IoT-integrated ITS, identify security threats and vulnerabilities, and evaluate existing security measures to propose robust solutions. Utilizing a comprehensive review methodology that includes literature analysis and expert interviews, we identify key achievements and pinpoint critical security gaps. Our findings indicate that while substantial progress has been made in securing ITS, significant challenges remain, particularly regarding scalability, interoperability, and real-time data processing. The study proposes enhanced security protocols and methods to mitigate these risks, contributing to the development of more secure and resilient IoT-enabled ITS.**

***Keywords*—Internet of Things; intelligent transportation; security; logistics**

I. Introduction

The Internet of Things (IoT) seamlessly transforms real-world objects, vehicles, home appliances, etc., into digital ones [1]. With IoT, ordinary things can instantly collect, share, and analyze data by integrating sensors, actuators, and communication technologies [2]. These gadgets, commonly known as intelligent things, can connect to each other independently or through centralized platforms, creating an ever-changing and widespread ecosystem [3]. The main goal of IoT is to optimize productivity, streamline processes, and provide practical information by leveraging the uninterrupted data stream from these connected devices [4]. The IoT has a far-reaching impact on various areas, including smart homes, cities, industrial applications, and healthcare systems [5]. It can revolutionize our interactions with the natural world and bring improvements by enabling continuous communication and cognitive analysis of data [6].

Intelligent Transportation System (ITS) combines multiple technologies to improve transport networks' effectiveness, safety, and environmental friendliness [7]. ITS uses information and communications technology to enhance the effectiveness and control of various transportation methods [8]. This includes multiple transport networks such as highways, trains, airlines, and sea connections [9]. ITS covers multiple applications, including real-time traffic monitoring, the operation of traffic signals that adapt to changing conditions, automated vehicle systems, and services that provide information to travelers [10, 11]. ITS strives to combat congestion, minimize travel times, improve safety through accident prevention systems, and advocate for environmentally friendly behavior through data-driven solutions. The integration of sensors, communication networks, and intelligent algorithms promotes a responsive and adaptable transport infrastructure [12].

The IoT is essential to ITS as it can completely transform and boost transportation networks' efficiency, safety, and utility [13]. The IoT combines physical objects, sensors, and communication technologies, enabling instant data collection and exploration [14]. In the ITS context, this connectivity allows for unprecedented levels of automation and responsiveness [15]. IoT empowers vehicles and infrastructure components to communicate, providing real-time traffic management, proactive maintenance, and flexible control systems [16]. Real-time monitoring to monitor traffic conditions, infrastructure health, and vehicle behavior increases decision-making accuracy, reduces congestion, and improves safety [17]. Furthermore, the IoT facilitates the development of intelligent transport networks, where data-driven analytics empower authorities and users to make informed decisions and ultimately promote sustainable and resilient urban mobility. Integrating IoT technology into ITS improves operation effectiveness [18].

Deploying IoT-enabled ITS poses numerous challenges, particularly in terms of security. The interconnection of IoT devices in transport networks introduces a variety of potential vulnerabilities that different types of attacks can exploit [19]. Unauthorized access, data breaches, and cyber-physical attacks can jeopardize transport infrastructure security and reliability. Privacy concerns also arise from IoT devices, which generate sensitive data such as location information and travel history [20]. Keeping this data confidential and secure is crucial. In addition, the wide range of devices in ITS leads to difficulties in compatibility and standardization. This makes building consistent security procedures more complex. As transportation systems become increasingly dependent on the IoT, it is critical to prioritize security concerns. This is necessary to maintain public trust, protect critical infrastructure, and promote advanced and connected transport networks [21].

The present study aims to achieve several key objectives to enhance the understanding and advancement of ITS enabled by IoT technology. The study's primary goal is to comprehensively analyze the current status of IoT applications in the transportation industry, focusing on their contribution to intelligent logistics and improved mobility. In addition, the study identifies and examines the security barriers associated with IoT integration in transportation, with a particular focus on risks, weaknesses, and privacy issues. Third, it aims to explore and evaluate the security mechanisms and protocols developed to address these difficulties and provide insights into the most effective methods for ensuring IoT-powered ITS reliability and strength. The survey also presents successful schemes and practical applications, giving an overview of the practical elements of implementing secure IoT solutions in transportation. The study achieves these goals by providing a comprehensive resource for determining the future of safe and efficient ITS.

The remainder of the paper is arranged in the following manner. Section II describes the IoT environment in the ITS context and outlines an overview of critical elements and functions. Section III provides a thorough analysis of IoT-enabled ITS security challenges. Section IV examines a range of security methods and protocols, covering intrusion detection, encryption, and authentication systems. Section V focuses on forecasting future advances and outlines future research directions for IoT-secure applications in transportation. Section VI concludes the paper.

II. Background

The IoT ecosystem in ITS represents a complex integration of interconnected components and technologies to transform the transportation industry. This ecosystem consists of intelligent vehicles, infrastructure components, communication networks, and central control systems, all working together to make transport networks more efficient, safe, and sustainable [22]. Intelligent vehicles are critical components of the IoT-based ITS ecosystem. These vehicles are equipped with multiple sensors, including GPS, accelerometers, and cameras, that constantly collect and send real-time data about their condition, location, and environment. The voluminous data received is the key to making well-founded decisions and adapting the transport system flexibly [23].

The infrastructure components in the IoT environment consist of a network of intelligent traffic lights, road sensors, and monitoring systems. These components are strategically placed throughout the transport network. These components collect and examine data about vehicle movement, road conditions, and hazards. The smooth integration of these components enables a comprehensive understanding of the traffic ecosystem and allows authorities to proactively address dynamic circumstances, optimize traffic signals, and improve overall traffic management. Communication networks are critical for connecting the many components of the IoT ecosystem and facilitating information transfer between automated vehicles and infrastructure. Efficient and reliable communication is crucial for the immediate coordination and synchronization of various components within the transport system. Central control systems serve as a cognitive operations center, analyzing incoming data, formulating intelligent judgments, and issuing instructions to improve performance, minimize congestion, and optimize traffic flow [24].

A. *IoT-Enabled ITS Architecture*

When implementing an IoT-based ITS, it is necessary to consider a wide range of transportation infrastructures, vehicles, and objects. This approach focuses exclusively on advancing particular business requirements, altering current transportation networks, integrating shared information resources, and simultaneously transforming unique company demands. To incorporate the IoT into ITS, it is crucial to establish a well-designed architecture for an ITS inside the IoT framework. The IoT-based intelligent transportation architecture consists of three layers: identification, network, and application, as depicted in Fig. 1.

The primary role of the identification layer is to gather precise traffic data promptly. The use of various sensors and communication networks primarily determines traffic information. These include video capture tools, ultrasonic detectors, microwave radar sensors, temperature measurement devices, and pressure sensors. Upon the transmission of sensor data across Wireless Sensor Networks (WSNs), the process of data aggregation is eventually finalized [25].

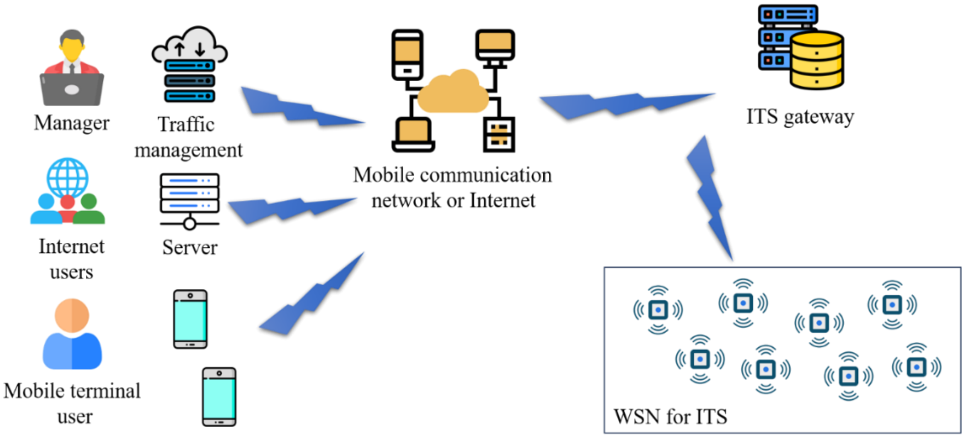

Fig. 1. Architecture of IoT-based ITS.

The primary objective of the network layer is to guarantee traffic data transmission with a significant degree of dependability and protection. The network layer must be able to create a link between application and sensor layers [26]. Communication networks with significant capacity are necessary for effective and reliable information transfer. There are two kinds of communication networks: wireless and wired access networks. Wireless access networks incorporate traditional cell phone networks and Wireless Local Area Network (WLAN) systems that may be used with mobile sensing devices. Wired access networks rely on telephone lines and Ethernet channels, which are well-suited to facilitating tools like traffic junction cameras and subterranean detecting coils.

The application layer processes, analyzes, and uses traffic data gathered by traffic-aware networks and provides diverse intelligent traffic services [27]. The application layer encompasses several systems, such as illustrations, including prototype systems for government and social applications and industrial and corporate applications. Common uses encompass sophisticated traffic management systems and live traffic data services. A system may consist of an advanced electronic toll-collecting system, a public transit management system, and a cutting-edge car.

WSNs are self-organizing networks designed explicitly for ITS tasks. These networks generally include sensor nodes deployed within a designated area for environmental tracking. These nodes are equipped with indicators, inbuilt processing units, and radio transmitters, allowing them to carry out activities such as collecting traffic information, analyzing data, and forwarding it [28]. These nodes establish a network to oversee and analyze environmental data or traffic items inside the designated detection region by utilizing wireless connection and self-organization. Subsequently, the gathered data and information are transferred to the convergence node to carry out specific monitoring duties as specified. The ITS gateway is the intermediary between two separate networks, granting connectivity to general and traffic-aware networks.

Moreover, it facilitates the transformation of communication protocols and the management of networks between the two networks. Once traffic data gathered by the monitoring system is sent to the public network via the gateway, it becomes accessible to the traffic control system that processes data, evaluation, preservation, and reaction actions.

B. Architectural Design of Vehicle Communication Networks

Mobile communication networks typically encompass communication between vehicles and roadside facilities. Roadside facilities include fixed nodes like petrol pumps, comfort service locations, and speed control signs, which are considered a specific type of mobile node. In terms of overall network architecture, there is no fundamental distinction [29]. Mobile Ad-hoc Networks (MANETs) are transient networks consisting of mobile devices sharing the same service set, lacking an Access Point (AP) to connect them. This type of network emphasizes self-organization, distributed, mobile, wireless, and multi-hop communication without using base station equipment. The network's dynamic links allow free movement, resulting in a topology that changes quickly and unpredictably. MANETs function as standalone networks or connect to the broader Internet.

MANETs comprise mobile nodes, which can function as main routers or ordinary nodes distributed across various platforms such as aircraft, aircraft, vessels, buses, cars, people, etc. [30]. This results in the following attributes: 1) Restrictions on connectivity and bandwidth, primarily arising from the constrained wireless channel compared to wired channels; 2) A constantly evolving network structure due to the continuous movement of vehicles; 3) Energy constraints on mobile terminals necessitate energy conservation and reliable energy supply considerations; 4) Poor network security, attributed to public and distributed wireless networks, makes them highly susceptible to interception attempts. The application of mobile self-organizing networks extends across both civilian and military sectors. In the military, troops, vessels, aircraft, and other elements may create decentralized networks utilizing mobile node technology, which improves dependability by distributing the network's functions. MANETs are versatile and have a self-organizing character, making them useful in many civilian settings such as vehicle communication networks, private local networks, emergency rescue services, and workplace meetings.

In the current network protocol architecture, two widely recognized models are the standard Open Systems Interconnection (OSI) protocol and the TCP/IP model widely applied to computer networks. In MANETs, each mobile node establishes its wireless network, introducing distinctions from wired networks operating over the TCP/IP protocol. While the Vehicular Ad Hoc Network (VANET) falls under the category of MANET, the protocol settings at each layer exhibit notable differences. VANET emphasizes the predictability of vehicular trajectories and the impact of obstacles in urban environments. Fig. 2 compares the architecture of the OSI, TCP/IP, VANET, and MANET protocols. Network protocol design for vehicle communication is built upon the TCP/IP model. Subsequent discussions discuss the structure, properties, and current studies on the different tiers within vehicle communication systems.

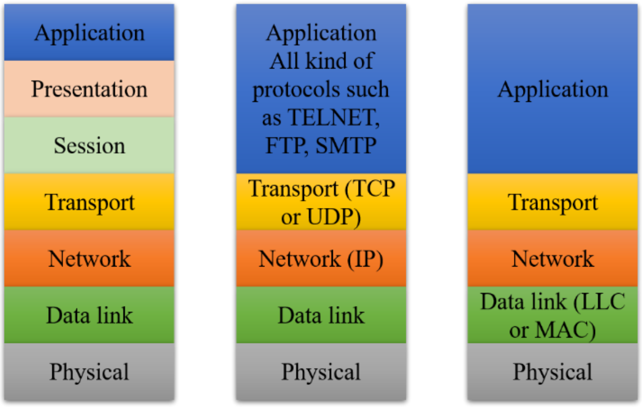

Fig. 2. OSI, TCP/IP, MANET, and VANET architectures.

In VANETs, the physical and Medium Access Control (MAC) layers are commonly grouped and referred to as a PHY/MAC layer. Various frequency bands, such as high-frequency, microwave, millimeter, and infrared wavelengths, are employed in vehicular communications. The Federal

Communications Commission (FCC) in the United States has assigned a specific frequency range of 75MHz, called Dedicated Short-Range Communication (DSRC), for vehicular connection. This frequency range spans from 5.850GHz to 5.925GHz. Similar allocations have been made in Europe and Japan. The PHY/MAC layer in in-vehicle communication networks encounters several challenges. These challenges encompass maintaining reliable communication among vehicles, efficiently allocating broadcast spectrum, adjusting to variations in node density, and ensuring Quality of Service (QoS) for emergency applications within a wireless environment.

The network layer of VANETs focuses on routing protocols, drawing inspiration from MANETs research but incorporating features suitable for traffic communication scenarios. VANETs are characterized by linear networks, fast-moving nodes with predictable trajectories, and the ability to obtain node positions using GPS. Rapid changes in network topology due to high-speed movement pose challenges in establishing and maintaining communication links. There are several types of routing protocols, including location-based (GPSR, MDDV), multicast (MAODV, MOLSR), and unicast (DSR, AODV).

The VANET network protocol design follows the TCP/IP paradigm; however, modifications are required to address the constraints of conventional TCP protocols in wireless networks. Studies have shown that TCP protocols may not be suitable for VANETs, especially when there is a lot of network congestion. Although some enhanced TCP protocols apply to VANETs, most studies focus on User Datagram Protocol (UDP) connections. The security of VANETs is of utmost importance due to their direct influence on the well-being of individuals. The security usages of VANET protocols are subject to stringent requirements that prioritize dependability, confidentiality, and authenticity of sent data throughout communication.

C. Integration of Mobile Model and Network Simulation Software

For VANETs to utilize vehicle movement models, compatibility with network simulation software is essential. Most historical and contemporary mobile models employed by research institutions fall into this category, as illustrated in Fig. 3. Simulation software generates different scenes before simulation, analyzing them according to predetermined path formats. The motion scenes remain unmodifiable, leading to a lack of interaction between the network and mobility domains. In recent years, increased demands for interaction, driven by specialized applications in vehicle communication, have fostered improved collaboration between these domains.

The embedded technique addresses the absence of protocols by facilitating collaboration between networks and movement domains, as shown in Fig. 4. This solution features a straightforward and effective interface between the network and mobile models, leveraging validated driving patterns and carefully following established protocols. Vehicle self-organizing network simulation has emerged as an essential area of study.

Fig. 5 depicts incorporating conventional network simulation software into mobile applications or specialized traffic simulation software via standardized interfaces. The increasing integration of simulation software results in novel applications, including safe transportation solutions. Initially, application simulations in the early stages were mostly centered around the network. However, as vehicle self-organizing network applications have progressed, there has been a change in emphasis towards simulating vehicle mobility in these applications. Although research is now moving towards the integration and interplay of different approaches, the three methodologies, namely isolated, blended, and embedded, persist in simultaneous existence. The isolated technique is preferred for its broad applicability and simplicity, especially in traffic management and safety, where scholars tend to prefer combining and integrating methods.

III. Security Challenges in IoT-Enabled ITS

This section covers the complex security concerns in the context of IoT-enabled ITS. As illustrated in Fig. 6, incorporating IoT technology into transportation infrastructure has several prospects for enhanced efficiency and innovation while simultaneously introducing new possibilities for malicious activities and vulnerabilities. As connectivity between vehicles, sensors, and infrastructure rises, protecting these systems from unscrupulous individuals and illegal entry becomes more complex. The security difficulties in IoT-powered ITS present numerous challenges, including maintaining data transmission integrity and defending against cyber-physical attacks. These concerns are constantly changing and need constant attention. Through analyzing these challenges and examining possible methods to reduce their impact, our objective is to provide valuable knowledge on strengthening the capacity of IoT-enabled transportation networks to cope with and maintain their functionality in the presence of ever-changing cyber threats.

A. Vulnerabilities in Connected Devices

The widespread adoption of IoT devices in the ITS sector exposes various vulnerabilities. Intelligent automobiles, road infrastructure, and communication networks are susceptible to cyber assaults. Device setups that are not secure, delayed software upgrades, and inadequate authentication techniques can create vulnerabilities that allow hostile actors to undermine the integrity and performance of connected transportation components. Resolving these vulnerabilities is crucial for enhancing the overall security of transportation systems driven by IoT technology.

Urban traffic congestion is a significant issue in modern cities, and ITS is being researched to address this issue. Zhang and Lu [11] used OPNET Modeler software to develop a vehicle tracking scheme, analyzing vehicle communication networks in an IoT-based system. Simulation experiments showed that low-speed vehicles can improve wireless network coverage, especially when roadside units are kept between 500m and 600m away. The AODV protocol proved more appropriate for network communication requirements than the DSR protocol, improving overall performance.

Anand, et al. [31] presented a threat architecture for IoT devices, concentrating vulnerabilities in a three-layer baseline design. They investigate weaknesses taken advantage of in different assault areas and assess the difficulties in measuring them. The research also examines ITS and secure energy management in smart grids, specifically emphasizing IoVT applications. Implementing the suggested framework into current apps raises concerns among developers over potential security risks inside the system, underscoring the need to address these weaknesses in IoT devices.

Supply chain vulnerabilities

Fig. 6. Security challenges in IoT-enabled ITS.

Ribeiro, et al. [32] have proposed a deep-learning algorithm for enhancing traffic behavior security. They present a policy gradient approach to identifying vehicular misuse, using a triple network replay method to maximize convergence rates. The model is tested on accurate urban maps with 5G or 6G communications, cellular networks, and VANET in a software-defined network. Compared to related studies, the results show improved accuracy prediction, cumulative reward, and convergence rate. The proposed deep learning algorithm improves ITS by increasing the accuracy of predictions, reducing communication delays, and adjusting traffic paths to accommodate congestion.

Alladi, et al. [33] developed a set of deep learning-based misbehavior classification approaches for intrusion detection in IoV networks using LSTM and CNNs. The DCLEs, deployed on vehicular edge servers, identify 18 behaviors with higher F1-scores. The proposed classifiers were compared with existing studies on edge server simulation testbeds. Rani and Sharma [34] propose an ITS framework for IoT-based vehicular network traffic in smart cities using tree-based decision trees, random forests, extra trees, and XGBoost machine learning models. Simulation results show a high level of detection accuracy and low computational requirements.

B. *Data Privacy and Confidentiality Concerns*

The significant volume of sensitive data collected by IoT devices in the transportation industry, including real-time location information and driving behavior, raises important concerns regarding data privacy and confidentiality. Unauthorized access to this data can lead to identity theft, illegal spying, and misuse of personal information [35]. Utilizing robust encryption techniques and implementing stringent access controls are crucial to safeguard user privacy and instill confidence in the secure deployment of IoT in transportation.

Belhadi, et al. [36] have developed a secure and scalable system for detecting knowledge from urban traffic data using blockchain learning technology and a threaded GPU. The system uses optimizations and a reinforcement deep learning algorithm to merge local knowledge into global knowledge. Experiments on well-known data show the framework outperforms baseline solutions for outlier detection. Tang, et al. [37] presented a flexible and privacy-preserving query protocol for ITS, utilizing matrix decomposition techniques for flexible route organization and ciphertext state operation for route protection. The scheme improves computational and communication overhead, making it suitable for resource-constrained vehicles.

Das, et al. [38] propose blockchain-based identity generation and management methods to deal with security concerns in ITS applications. The solution ensures the validity of Personal Identification Information (PII) and the application's usability, making it suitable for vehicle administration in ITS. Thapliyal, et al. [39] developed SAKP-ITS, a secure authentication protocol for IoV-enabled ITS, demonstrating resistance to potential threats and outperforming competitors in communication, computation, and security metrics. The protocol's practical implementation is also presented to test its effect on critical performance attributes.

C. *Network Security Risks*

The interconnectivity of IoT devices is primarily dependent on communication networks. Nevertheless, this mutual dependency gives rise to network security vulnerabilities, such as denial-of-service (DoS) assaults, man-in-the-middle attacks, and eavesdropping. Implementing encryption, intrusion detection, and prevention tools can be crucial steps to limit risks and ensure the robustness of the transportation network. Bi, et al. [40] utilized the cryptographic-integrated steganography methodology for secure communication on an IoT-enabled cloud platform for urban transportation. The algorithm produces code for privacy, converts data into a specific format, and uses encryption keys to protect confidential data. The findings demonstrate efficient and secure data sharing.

The development of ITS has led to the development of communication frameworks for addressing security concerns related to intelligent sensors. Rawashdeh, et al. [41] proposed an efficient query-as-a-service communication scheme that incorporates fog computing concepts, communication standards that ensure data integrity and security evaluation tailored to mobile vehicles in ITS applications. The data-driven approach allows entities to share data structures instead of data itself, reducing the communication burden and allowing misinformation tolerance. Experiments have shown superior performance concerning data granularity, detection rate, false-detection rate, and probability of query failure, overcoming traditional cloud-based models' limitations. Table I shows summary of security measures and protocols in IoT-enabled ITS.

TABLE I. SUMMARY OF SECURITY MEASURES AND PROTOCOLS IN IOT-ENABLED ITS

Security measure	Advantages	Limitations
Authentication	Enhances user and device identity verification	Implementation complexity and potential for false positives
Encryption	Secures data in transit and at rest	Computational overhead and potential compatibility issues
IDPS	Continuous monitoring and threat detection	False positives/negatives and resource-intensive
Secure communication protocol	Lightweight and secure data exchange	Protocol compatibility and potential latency issues
Firmware updates and patch management	Addresses vulnerabilities promptly	Operational disruptions during updates and user compliance
RBAC	Granular control over user and device access	Complexity in role assignment and potential misconfigurations

Shen, et al. [42] propose the IoT-assisted Innovative Data Integrity Verification Scheme (IoT-IDIVS) to integrate transportation system data and exchange information effectively. The system aligns GPS data with passenger and schedule information to maintain reliability. The IoT-IDIVS has improved measurement costs and coordination costs, with experimental results showing a packet loss rate of 21.3%, average service delay of 26.9%, data transmission ratio of 95.5%, throughput bit of 92.3%, traffic congestion ratio of 92.6%, error rate of 17.9%, successful delivery rate of 92.57%, and energy optimization of 97.12%.

Altaf, et al. [43] investigate the Beacon Non-Transmission (BNT) attack in ITS, where the attacker is a source vehicle. They propose two lightweight techniques to detect BNT attacks: one based on beacon loss distribution and loss due to channel error and another using autocorrelation function (ACF) to identify shortish and longish attacks. They also propose a random inspection model to balance detection accuracy with limited computational resources. Extensive simulations show the lightweight nature of both techniques and the effectiveness of ACF-based techniques.

D. *Lack of Standardization and Interoperability*

The lack of established security protocols and interoperability standards across various IoT devices in transportation limits the development of unified security solutions. Implementing universal security measures can be problematic in heterogeneous systems due to the varied degrees of protection [44]. Developing universal standards and protocols that provide secure communication, authentication, and data integrity is crucial for building a robust security framework for IoT-enabled mobility.

Baker, et al. [45] propose a lightweight framework for smart transportation systems, integrating blockchain for authentication and fog computing for efficient and secure transportation. They consider future technologies of 5G and Beyond 5G (B5G) and argue that integrating these technologies, federated learning, blockchain, and edge computing provides the perfect platform for an intelligent transportation system. The framework is evaluated by comparing it to the current cloud-based approach in iFogSim, and the blockchain-based authentication is estimated using a customized implementation. The simulation results show superior security, latency, and energy consumption performance.

Smart cities, particularly in China, are rapidly developing globally, with over 1000 cities undergoing development as of 2017. However, there is a lack of uniform understanding of these systems, potentially affecting their evaluation and planning. Self-organizing system theory can help explain these cities. Yan, et al. [46] conducted qualitative data analyses and developed a comprehensive system framework for smart cities, focusing on smart devices, Information and Communications Technology (ICT), and developmental mechanisms. They used China's smart transportation systems as a case study.

Singh, et al. [47] highlighted the importance of digitalization in highways for a sustainable environment. It categorizes digitalization into five subcomponents: bright highway lighting, traffic and emergency management, renewable energy sources, bright display, and AI. The study proposes an architecture for intelligent highway lighting, traffic, and emergency management, integrating AI for road safety and recommending innovative reflectors, renewable energy adoption, vehicle-to-vehicle communication, and intelligent lampposts for highway implementation.

Dahooie, et al. [48] developed a portfolio matrix to identify IoT applications in urban transportation based on sustainable development and feasibility. They used a hybrid multi-criteria approach, identifying seventeen applications and evaluating their impact on sustainable development. The results showed bike and car sharing as the top priorities for investment in developing countries.

E. *Physical Security and Cyber-Physical Threats*

In addition to virtual threats, IoT-enabled transportation systems have physical security problems. The manipulation of sensors or disruption of communication between automated vehicles presents a concrete danger in the form of cyber-physical assaults. To strengthen the overall resilience of IoT-enabled transportation infrastructure, it is crucial to ensure the physical security of IoT equipment, including tamper-resistant designs and installing redundant systems. These methods help to prevent cyber-physical threats. To tackle these complex security concerns, a comprehensive solution is needed that integrates technical breakthroughs, regulatory frameworks, and collaborative efforts among companies in the sector.

Traditional risk assessment processes often overlook the importance of physical and cyberspace in IoT-enabled transportation infrastructure. Ntafloukas, et al. [49] propose a new approach for cyber-physical attacks against IoT-based wireless sensor networks. This involves identifying novel cyber-physical characteristics such as threat source, vulnerability, and types of physical impacts. Monte Carlo simulations and sensitivity analysis show that 76.6% of simulated cases have high-risk scenarios and control barriers can reduce cyber-physical risk by 71.8%. The approach is beneficial for stakeholders who are incorporating the cyber domain into risk assessment procedures.

Ntafloukas, et al. [50] propose a new vulnerability assessment approach for transportation networks, combining physical and cyberspace. They use a Bayesian network attack graph and a probability indicator to model vulnerability states. The approach measures network efficiency after removing the highest probability-based nodes. Monte Carlo simulations and sensitivity analysis show vulnerability depends on successfully exploiting vulnerabilities in both cyber and physical spaces. The approach is helpful for stakeholders incorporating cyber domains into vulnerability assessment procedures.

Rajawat, et al. [51] explored the possibility of using a blockchain-based security assurance architecture to protect intelligent roadways and autonomous vehicles within the framework of ITS. The suggested model adopts a semi-distributed approach in deploying blockchain to provide a decent IoV service while maintaining appropriate security measures. The intelligent roads and innovative parking management experiments demonstrate that the suggested model accomplishes efficient data transmission and decreased latency. This opens up possibilities for using blockchain technology in the IoV for a reliable and trustworthy ITS.

F. Supply Chain Vulnerabilities

The complex supply chain that produces IoT devices for transportation systems presents additional security obstacles. Adversaries might take advantage of weaknesses in the manufacturing process to introduce corrupted components or firmware into devices. To maintain the integrity of the supply chain in IoT-enabled transportation, it is crucial to implement strict quality assurance measures, secure sourcing processes, and ensure transparency. This is necessary to prevent the inclusion of compromised parts that might potentially jeopardize the entire security of the system.

Abizar, et al. [52] developed an innovative energy-based SESLPP technique for sustainable urban city roads, preserving source location privacy while maintaining an accurate reputation based on trust, speed, distance, and acceleration. The method uses an analytical network process for optimal phantom node selection, considering intersections, and provides an optimal platform for smart city communication networks.

The internet has profoundly affected the demand and supply of materials, increasing competition in the industrial industries. Using Industrial IoT (IIoT) in intelligent manufacturing and logistics is crucial for advancing Industry 5.0. It aims to reduce time and cost, enhance customer happiness, and boost organizational profitability. Bhargava, et al. [53] presented an IoT model incorporating intelligent logistics and transportation management to enhance logistics efficiency, improve customer experience, and save costs. The methodology significantly enhanced overall performance by 77% to 98%, resulting in heightened customer satisfaction, increased process efficiency, and reduced operational expenses. The novel IIoT-based architecture provides enhanced energy efficiency and minimal latency performance.

G. Resource Constraints

Most IoT devices used in transportation operate with constrained processing capacity, memory, and energy resources. These limitations may prevent the installation of resilient security solutions. Achieving a harmonious equilibrium between efficient resource utilization and adequate security measures is essential. To effectively tackle security concerns in resource-limited IoT devices, it is crucial to develop lightweight security protocols, minimize resource utilization, and integrate energy-efficient encryption techniques.

Rehman, et al. [54] proposed an intelligent vehicular algorithm using an IoT system (SVA-IoT) to improve transportation systems. The algorithm ensures reliability, reduces device overhead, optimizes routes, and increases intelligence. It also establishes a secure communication structure by identifying authentic devices. The technique was tested through simulated experiments, showing significant improvement over existing work in route optimization and data privacy.

Gadekallu, et al. [55] developed a Moth-Flame Optimization-based ensemble machine learning model for classifying the IDS dataset in ITS. The model uses standard-scaler method normalization and optimal features, trained using linear regression, random forest, and XGBoost algorithms.

The increasing number of vehicles on roads leads to congestion and safety issues. WSN can help address these issues by reducing communication overhead. Gaber, et al. [56] introduced a bio-inspired, trust-based cluster head selection approach for WSN in ITS. The model is energy-efficient, achieves a more extended network lifetime, and has a high average trust value under different malicious node percentages (30% and 50%).

H. Human Factors and user Awareness

Human factors heavily influence the security concerns in IoT-enabled mobility. User actions, such as using easily guessable passwords or vulnerability to deceptive phishing attacks, can potentially undermine the system's overall security. To tackle security concerns connected to humans in the IoT context, promoting user awareness, offering training on cybersecurity best practices, and creating user-friendly security interfaces are crucial.

Din, et al. [57] developed a Context-Aware Cognitive Memory Trust Management System (CACMTM) for ICPTS, utilizing game theory to model trust interactions. The system combines evaluation, decision, update, and knowledge modules to provide a reliable trust management solution for Customer-Centric Communication and Networked Control for ICPTS (CNC-ICTS). The system uses a multi-dimensional trust evaluation model that considers historical behavior, reputation, and contextual information. The system also incorporates a blockchain-secured logging mechanism for security, transparency, and accountability.

Karthikeyan and Usha [58] propose a secure IoT-ITS framework using cognitive science to address risks in the IoT-ITS environment. The framework aims to differentiate legitimate users from malicious ones and perform real-time data analysis. The study aims to resolve security demands without compromise, utilizing cognitive science to distinguish legitimate users from malicious ones.

Strimovskaya and Bochkarev [59] proposed a model for total transportation time (TTT) estimation, considering factors like customer satisfaction, sustainable development, and social aspects. This model enhances transportation system flexibility and planning. The research emphasizes the importance of considering multiple factors in integrated transportation systems planning and control. The model's numerical example for multimodal international conveyance demonstrates its role in information management and control in multi-object systems.

I. Regulatory Compliance and Legal Frameworks

Deploying safe IoT-enabled transportation systems is difficult due to the intricate nature of regulatory compliance and legal frameworks. Uncertainties over jurisdiction, differing regulatory norms, and the absence of a unified legal framework might impede endeavors to implement consistent security measures. Partnerships between industry players and politicians are crucial to establishing precise and enforceable laws that tackle the distinct security problems linked to IoT in transportation while promoting innovation and interoperability.

He, et al. [60] propose a risk prediction-based access control mechanism using a Wasserstein Distance-based Combined Generative Adversarial Network (WCGAN). The model solves gradient disappearance and pattern collapse problems, with a prediction accuracy of 86.3% when training with 5000 nodes. This model improves pattern collapse accuracy and can be used in IoT-based ITS to control access rights, ensure information resource security, and reduce communication delays. The research provides a reference for safe IoV communication.

Even though current solutions for IoT security intended for ITS applications exhibit significant progress, they do not come without drawbacks. These solutions might not be easily scalable to suit a rapidly evolving business. With numerous connection solutions, it becomes hard to have strong security measures to handle the constant flow of connected devices. Recent alternatives are inadequate for optimization as the structure grows, and this is where weaknesses occur as the structure rises. For instance, many lightweight cryptographic algorithms are helpful for IoT devices due to limited resources, and they are not as efficient in scaling up in large numbers. To cope with such scalability problems, security solutions need to be more elastic and resilient.

Another essential attribute that remains a weakness in most IoT models is the compatibility of security protocols between different IoT devices and systems. The absence of unified security measures entails each manufacturer developing their devices with varying security measures, creating a weakness in the whole system’s security. The security policies facing these environments are heterogenic and do not allow a comprehensive defense, which creates difficulties in achieving uniformity of the necessary level of protection. However, the requirements for real-time data processing in ITS are as follows: Improving security can sometimes compromise response time and thus has considerable drawbacks, especially for safety-critical applications such as self-driving cars and real-time traffic control. The question of achieving the right level of security while meeting the prerequisites for real-time and high-speed processing is still one of the most challenging in the field.

IV. Discussion

The study outlined and discussed several security issues associated with IoT-based ITS systems. In the transportation system, IoT poses several risks, including outsiders' access, threats to internal data, and other malicious cyber-physical threats. These threats primarily stem from the enhanced interconnection between cars, on-board sensors, and road systems that provide more opportunities for an adversary. This research underscores the importance of more frequent scans and changes to IT security measures to deal with such threats.

Authentication is crucial for ensuring the security of IoT-enabled ITS. By implementing robust authentication techniques, the network may be accessed only by authorized devices and users. Typical authentication methods encompass biometrics, cryptographic certificates, and multi-factor authentication. Biometric techniques, such as fingerprint or facial recognition, may enhance user-specific authentication, while cryptographic certificates provide a secure means of identifying devices inside the IoT network.

Ensuring data security while being transmitted and stored is paramount in IoT-enabled ITS. Encryption methods, such as Transport Layer Security (TLS) for communication channels and Advanced Encryption Standard (AES) for data storage, protect against interception and unwanted entry. By employing robust encryption techniques, the transportation network guarantees the secrecy and reliability of sensitive data shared among devices and systems.

Symmetric key encryption, also known as secret-key cryptography, utilizes an identical key for both encryption and decryption. This technique guarantees the protection of sensitive information by transforming the original text into an encrypted form that can only be decrypted with a mutually agreed-upon key. Nevertheless, the difficulty is in safely disseminating and monitoring the confidential keys. Popular algorithms like AES employ symmetric key encryption to secure sensitive data, files, and communications.

Intrusion Detection and Prevention Systems (IDPS) are vital in identifying and mitigating security threats inside the IoT ecosystem. These systems continually track network traffic and device activity, detecting abnormalities or malicious behaviors. Once detected, the IDPS can promptly generate warnings or autonomously implement preventative measures, protecting against unauthorized entry, data breaches, and other security breaches.

Selecting and implementing secure communication protocols is crucial for preserving data integrity and preventing cyber-attacks. Protocols like MQTT and CoAP provide efficient and secure communication between IoT devices and infrastructure. These protocols include encryption and authentication elements, guaranteeing the secrecy and legitimacy of data sent inside the transportation system.

Transport Layer Security (TLS) and its precursor, Secure Sockets Layer (SSL), are cryptographic protocols created to ensure communication security across a computer network. The TLS and SSL protocols guarantee the secrecy and accuracy of information sent between apps. By encrypting the communication channel, they prevent unauthorized access and eavesdropping, ensuring that sensitive information remains protected during transmission.

Maintaining regular updates to device firmware and effectively managing patches are crucial security practices for reducing vulnerabilities. Implementing up-to-date security patches and firmware upgrades for IoT devices is essential for mitigating vulnerabilities and strengthening the overall resilience of the transportation system. A reliable patch-tracking system is critical for upholding the security of the many devices in the IoT-enabled ITS.

Role-Based Access Control (RBAC) provides a crucial security solution for managing and controlling user rights and privileges in the IoT environment. RBAC ensures that only authorized entities can perform certain activities by giving individuals and devices unique roles and access levels. The ability to have precise control over access helps mitigate the danger of unauthorized entry, minimize the potential for harmful actions, and bolster the overall security of ITS.

V. Recommendations and Future Directions

The section presents suggestions for improving security, privacy, and system efficiency in IoT-enabled ITS networks. We provide comprehensive strategies to enhance resilience against cyber-attacks and assure the safety, intelligence, and interconnectedness of transportation systems. The suggestions include improving security standards and adopting cutting-edge technology, which will provide the groundwork for a forward-thinking conversation about the future of ITS.

Integrating blockchain into IoT-enabled transportation systems faces challenges related to scalability, high energy consumption, and the need for consensus mechanisms. These challenges must be addressed to ensure the feasibility and efficiency of blockchain implementation. IoT-specific blockchain architectures should be explored to develop scalable and energy-efficient consensus algorithms. Blockchain integration can be enhanced by optimizing smart contracts and exploring hybrid solutions that utilize centralized and decentralized elements.

Security concerns arise from the distributed nature of edge computing, where devices process data locally. Critical challenges are ensuring secure communication, access control, and protection against edge device compromise. The development of security frameworks and encryption techniques for edge computing requires further study in the future. Developing intrusion detection systems appropriate for edge environments and implementing effective access control mechanisms can strengthen security.

Machine learning-based anomaly detection systems may face challenges related to false positives, adaptability to dynamic environments, and the need for large labeled datasets. Anomaly detection algorithms should be improved in accuracy and adaptability. Machine learning can be enhanced by leveraging unsupervised learning approaches, exploring transfer learning methods, and developing techniques to handle evolving threats.

The emergence of quantum computing challenges conventional cryptography methods, requiring creating and incorporating cryptographic solutions that can withstand quantum attacks. The future of cryptography should focus on designing and implementing quantum-safe algorithms. Several promising areas for developing quantum-resistant algorithms include post-quantum cryptography, lattice-based cryptography, and hash-based cryptography.

Physical attacks on IoT devices, such as tampering with sensors or communication links, pose significant challenges to maintaining the stability and security of transportation systems. Researchers should investigate mechanisms for preventing physical attacks, such as tamper-resistant hardware, secure bootstrapping, and physical layer security solutions. IoT-enabled transport systems can be more resilient by implementing robust authentication and encryption techniques.

IoT devices often function with restricted processing capacity and power sources, making it difficult to apply security measures requiring significant resources. Research efforts should be directed towards developing lightweight and energy-efficient security protocols. Resource constraints can be addressed while maintaining robust security measures by utilizing efficient key management strategies, optimizing cryptographic algorithms, and leveraging hardware-based security mechanisms.

Ensuring privacy in the collection, storage, and processing of sensitive data within IoT-enabled transportation systems presents challenges related to data anonymization, secure data sharing, and compliance with privacy regulations. The development of advanced privacy-preserving data management techniques, such as homomorphic encryption, differential privacy, and federated learning, should be explored in research. Data privacy can be protected, and data utility can be maximized by implementing secure data-sharing frameworks with granular consent mechanisms.

Traditional authentication methods may be susceptible to identity theft and credential-based attacks, necessitating more secure and user-friendly authentication solutions. User authentication should incorporate behavioral biometrics, such as keystroke dynamics and gait analysis. Authenticating users with these biometric factors provides seamless, non-intrusive experiences that enhance security.

Developing a one-size-fits-all security solution for the diverse range of IoT-enabled devices and applications in transportation is challenging due to varied operational requirements and resource constraints. Hybrid security models that combine centralized and decentralized approaches should be explored in future research. Security measures tailored to the characteristics of each IoT device or application can optimize security without adding unnecessary overhead to resource-constrained devices.

The ethical implications of security measures, such as surveillance and data collection, must be carefully considered to avoid unintended consequences and potential misuse. Security solutions should be designed with ethical considerations in mind. Data collection and usage can be controlled transparently and accountable based on user preferences to address moral concerns and promote responsible IoT-enabled transportation.

VI. Conclusion

The incorporation of IoT technology into ITS offers significant opportunities for improving efficiency, safety, and sustainability in urban and highway transportation. Nevertheless, IoT technology's considerable capacity for change is accompanied by noteworthy security obstacles that desire efficient solutions to guarantee the dependability and durability of IoT-enabled transportation networks. By examining security measures such as authentication mechanisms, encryption mechanisms, intrusion detection and prevention systems, secure communication protocols, device firmware updates and patch management, role-based access control, and other strategies, we have emphasized the significance of thorough and proactive security strategies. Participants might implement robust security measures and follow strict standards to limit the dangers of cyber threats, unauthorized access, data breaches, and cyber-physical attacks. This can assist in establishing trust and confidence in IoT-based transportation systems. Moreover, it is essential to cooperate among policymakers, industry stakeholders, researchers, and cybersecurity specialists to formulate uniform security frameworks, facilitate information sharing, and develop a culture of awareness about cybersecurity. To maximize the benefits of intelligent transportation in the digital era, it is crucial to prioritize ongoing research and innovation in cybersecurity technologies and processes. This is necessary to protect IoT-enabled ITS networks.

Hybrid Machine Learning Models Based on CATBoost Classifier for Assessing Students' Academic Performance

Ding Hao*, Yang Xiaoqi, Qi Taoyu
School of Educational Science, Anhui Normal University, Wuhu, Anhui 241000, China

***Abstract*—This study addresses the imperative task of predicting and evaluating students' academic performance by amalgamating qualitative and quantitative factors, crucial in light of the persisting challenges undergraduates encounter in completing their degrees. Educational institutions wield significant influence in prognosticating student outcomes, necessitating the application of data mining (DM) techniques such as classification, clustering, and regression to discern and forecast student study behaviors. Through this research, the potential of deriving demonstrates valuable insights from educational data, empowering educational stakeholders with enhanced decision-making capabilities and facilitating improved student outcomes. Employing a hybrid approach, models developed within the realm of educational DM, leveraging the CATBoost Classifier (CATC) in conjunction with two cutting-edge optimization algorithms: Victoria Amazonica Optimization (VAO) and Artificial Rabbits Optimization (ARO). Initially, the models undergo partitioning into training and testing sets for performance evaluation utilizing statistical metrics. After classifying 649 students according to their final scores, VAO outperformed ARO in terms of maximizing CATC's classification ability, resulting in an approximate 6% enhancement in accuracy and precision. Moreover, the VAO model adeptly categorizes 606 out of 649 students accurately. This research furnishes invaluable predictive models for educators, researchers, and policymakers endeavoring to enrich students' educational journeys and foster academic success.**

Keywords*—Academic performance; hybridization; CATBoost classifier; meta-heuristic algorithms; educational institutions

Nomenclature

CATC	CATBoost classifier	ARO	Artificial Rabbits Optimization
VAO	Victoria Amazonica Optimization	CAAR	CAT+ARO
CAVA	CAT+VAO	DM	Data Mining
AUC	Area Under the Receiver Operating Characteristic Curve	MCC	Matthews Correlation Coefficient
Pstatus	Parents' Cohabitation Status	Medu	mother's education
Mjob	Mother's employment	Fedu	Father's Education
Fedu	Father's employment	G3	Grade 3

I. Introduction

The educational processes generate vast quantities of data, including information related to academic grades, enrollment, and student performance. The increasing volume of this data has prompted consideration of its utilization beyond mere accountability, aiming to extract valuable insights and facilitate informed decision-making within the academic domain, ultimately fostering advancements in the educational sector [1–3].

In order to extract useful information from students, a broad variety of student variables may be analyzed in the quickly developing scientific subject of educational DM [4,5]. In this context, numerous predictive algorithms have been effectively employed in educational settings for various purposes, utilizing diverse data sets and student records. A comprehensive review outlines two primary application purposes within academic contexts: predictors and early warning systems [6].

The purpose of predictors is to foresee how a course or degree will turn out, based on specific input data, while early warning systems not only perform this predictive function and report their findings to teachers or students at an early stage, enabling preemptive actions to prevent or lessen possible adverse consequences. Common forecast objectives in this context include assessing the risk of course failure, predicting dropout rates, estimating grades (focusing exclusively on college performance [7,8], or substituting individual course grades with semester-based course averages such as Grade Point Average (GPA) per semester or cumulative GPA at the time of prediction [9,10]), and forecasting graduation rates.

Predicting academic performance is a highly noteworthy objective; for example, at the time of graduation, it has multiple vital purposes, including assisting educational institutions in identifying at-risk students for specialized help to lower failure rates and providing information to admissions committees about candidates likely to finish their program, recognizing high-achieving students to guide their career development, and assessing key factors to enhance the quality of education continuously. When examining the existing literature on predicting students' academic performance, it becomes evident that these studies predominantly rely on four categories of student information: demographic and socioeconomic information, statistics from high school, records of college enrollment, and data on academic achievement up to the time of projection [11].

Frequently used predictive factors in academic performance include demographics like sex [12] and household income [13], along with high-school data such as GPA and admission test scores [12,14]. College-related information encompasses major, full-time, or part-time status and scholarship availability

[12,15,16]. Additionally, academic performance is usually represented by past course grades, except for predictive models used during admission [17,18].

In recent years, wide-ranging research has been conducted to analyze the factors influencing student performance, encompassing the direct and indirect attributes that affect academic outcomes. Some studies focus solely on attributive analysis, while others employ machine learning (ML) algorithms, particularly AI techniques [19], like ANN, random forests (RF), and Bayesian classifiers, to forecast student performance according to these attributes. Specific examples include the application of the Naive Bayesian DM technique to predict student performance based on 19 attributes such as gender, family status, and students' grades [20].

Support Vector Machines (SVM) have demonstrated significant improvements in predicting students' problem-solving performance using Bayesian Knowledge Tracing (BKT) compared to the standard BKT method [21]. Various feature selection techniques, decision tree (DT) algorithms, particle swarm optimization, and ensemble methods have also been employed for student performance prediction [22]. Socio-economic factors and entrance examination results have been utilized to predict cumulative grade point averages, and multiple techniques have been explored for forecasting students' academic success and choice of majors, with the Random Forest Classifier proving particularly effective [23, 24]. Additionally, hybrid models combining generative and discriminative models have been employed, and fuzzy logic, Adaptive Neuro-Fuzzy Inference System (ANFIS), and fuzzy ANFIS have been used for ratings and predictions in the educational context [25,26].

II. Related Work

Many academics have painstakingly examined the many aspects impacting students' achievement at different levels of education [27,28]. Numerous research in this field has used DM techniques, namely classification algorithms, to forecast student performance and boost the total effectiveness of higher education institutions. This section provides a summary of several relevant studies, paying special focus to those that address DT and classification methods in evaluating students' academic achievement [29–32].

For instance, Mustafa et al. [33] analyzed student data from C++ classes using the Cross Industry Standard Process for DM (CRISP) framework. She compared the performance of many classifiers, including Iterative Dichotomize 3 ($ID3$), C4.5 DT, and Naive Bayes (NB). With its improved performance, the C4.5 DT provided valuable insights into the variables affecting student success. Using classification and clustering methods, Sunita and LOBO L.M.R.J. The research in [34] were able to predict student performance and categorize students according to that performance, demonstrating the usefulness of DM in education. Classification models were created by Bichkar and R. R. Kabra [35] with the intention of detecting vulnerable first-year engineering students.

Table I shows the overview of published papers.

TABLE I. Overview of Published Papers

Ref.	Carried out works	Advantage	Disadvantage
Cortez and Silva [36]	This study analyzes educational trends in Portugal, focusing on high student failure rates in core subjects. It utilizes Business Intelligence/Data Mining (BI/DM) techniques to address achievement issues, collecting recent real-world data via school reports and questionnaires. Mathematics and Portuguese subjects are modelled using classification and regression tasks.	- Addresses pressing education issues. - Utilizes advanced BI/DM techniques. - Incorporates recent real-world data. - Comprehensive evaluation of models and methods. - Identifies key factors influencing achievement. - Provides actionable insights for tool development.	- Reliance on retrospective data. - Limited focus on specific subjects. - Potential effectiveness variations. - Biases or limitations in data collection. - Lack of consideration for external factors.
Hasib et al. [37]	5 classification algorithms were utilized in the development of a prediction model for secondary school student success: XGBoost, Naive Bayes, K-Nearest Neighbors (KNN), and Logistic Regression. 2 Portuguese school reports and surveys provided the data, which was then used to model the mathematics and Portuguese language disciplines using binary/5-level classification tasks. To address dataset imbalance, K-Means SMOTE was employed. Additionally, interpretable LIME models were trained for all classifiers, enhancing model transparency and interpretability.	- provides a model that uses sophisticated classification algorithms to predict student achievement - Utilizes real-world data from Portuguese school reports and surveys. - Addresses imbalanced dataset issue with K-Means SMOTE. - Achieves high accuracy (96.89%) with Support Vector Machine (SVM). - Enhances model interpretability with LIME, providing confidence and transparency in predictions.	- Reliance on specific classification algorithms may limit the exploration of other potential models. The generalizability of findings may be limited to the Portuguese education context. - Interpretability may vary depending on the complexity of underlying processes.
Asselman et al. [38]	Focus on enhancing the Performance Factors Analysis (PFA) approach, a crucial component of Knowledge Tracing (KT) in adaptive educational hypermedia systems. Introduction of Ensemble Learning methods, specifically Random Forest, AdaBoost, and XGBoost, to improve predictive accuracy of student performance. Evaluation of the proposed models on 3 different datasets.	- Addresses the need for improved prediction accuracy in educational hypermedia systems. - Introduces Ensemble Learning methods to enhance technical aspects of PFA. - Evaluation of multiple datasets enhances the generalizability of findings. - Demonstrates a substantial improvement in performance prediction compared to the original PFA algorithm, particularly with XGBoost.	- Focus on technical enhancements may overlook pedagogical considerations. - Limited discussion on potential challenges or limitations of the proposed approach. - Generalizability of findings may be restricted to specific datasets or educational contexts.

Shreem et al. [39]	introduced a wrapper feature selection technique for student performance prediction systems using an extended binary genetic algorithm (EBGA). A new hybrid selection process that combines the electromagnetic-like (EM) approach with k-means clustering is proposed. Using EBGA in conjunction with five classifiers (KNN, DT, NB, SVM, and Linear Discriminant Analysis) in a hybrid ML technique. Assessment of the suggested methodology using two actual case studies from the UCI ML Repository.	- Introduction of an enhanced feature selection method tailored for student performance prediction systems. - Novel hybrid selection mechanism improves predictive accuracy. - Utilization of a hybrid ML approach enhances model performance. - Evaluation of real case studies enhances the practical applicability of findings. - Demonstrates an improvement in the performance of binary genetic algorithms and classifiers by 1% to 11%.	- Limited discussion on potential challenges or limitations of the proposed approach. - Generalizability of findings may be restricted to specific datasets or educational contexts. - Lack of comparison with existing feature selection or hybrid ML methods.
Sarwat et al. [40]	To predict student success through in-class and at-home tutoring, a deep-layer support vector machine (SVM) and an enhanced conditional generative adversarial network (CGAN) is proposed. Creating artificial data samples in order to deal with tiny dataset sizes. Model performance is assessed both with and without CGAN. Examination of several kernel-based methods for deep SVM, such as polynomial, sigmoid, radial, and linear functions. Performance comparison of the suggested model with the current solutions.	- Effectively addresses small dataset size with synthetic data generation. - Demonstrates improved prediction accuracy with combined school and home tutoring. - Extensive evaluation of multiple kernel-based approaches for deep SVM. - Outperforms existing solutions in sensitivity, specificity, and AUC.	- Limited discussion on potential challenges or limitations of the proposed approach. - Complexity of the model may hinder replication or generalization. - Comparative analyses may overlook nuances in different educational contexts.
Mehdi and Nachouki [41]	created an explanatory and prediction model utilizing ANFIS to forecast the grade point average (GPA) of graduates in Ajman University's computer technology program. Use of high school GPA (HSGPA) and grades in foundational and introductory IT courses as predictors. Sensitivity analysis to ascertain each predictor's relative importance. ANFIS methodology is compared to popular methods like multilinear regression.	- Effective use of ANFIS methodology for predicting GPA. - Identification of key predictors and their significance in influencing graduation GPA. - High predictive accuracy, with 77% of predicted values within one root mean square error of actual GPA. - Demonstrates ANFIS's superiority over commonly used techniques like multilinear regression. - Provides actionable insights for improving IT education programs.	- Focused on a single academic program at one institution, which may limit generalizability. - Limited discussion on potential challenges or limitations of the ANFIS methodology. - Results may vary in different educational contexts or with different datasets.

Despite the numerous models used for classifying student performance, none have incorporated the CATBoost classifier (CATC) until this point. With the aim of bridging this gap, the primary objective of this study was to advance a CATC-based model for forecasting student performance in language courses, using trustworthy data sources. The selection of the CATC was informed by its recognized robustness and efficacy in handling categorical features, a prevalent characteristic in student performance prediction tasks. CATBoost's track record of superior performance across diverse domains made it a compelling choice for this study, where accurate prediction of student outcomes is paramount. Moreover, the integration of VAO and ARO was driven by their specific strengths in optimization tasks. VAO, inspired by the adaptive behavior of the VA plant, excels in dynamic optimization problems, thereby offering an edge in scenarios with evolving parameters or data dynamics. Similarly, ARO, which mimics the foraging behavior of rabbits in search of optimal solutions, shows promise in fine-tuning model parameters and improving overall model performance. The study's goal was to increase the predictive model's precision and accuracy by combining CATBoost with VAO and ARO in a way that maximizes their complementary strengths. This approach would also help to strengthen and improve the forecasting framework for language course student performance.

In the following sections, related work is given in Section II, the dataset description and processing are detailed in Section III. Section IV provides an in-depth explanation of the presented model, while Section V discusses the meta-heuristic algorithms used. Section VI outlines the metrics employed to assess the performance of the developed models. Convergence analysis is given in Section VII. Results and discussion is given in Section VIII and Section IX respectively. Finally, Section X concludes the paper.

III. Data Selection and Processing

This study uses data collected from previous literature [36,42]. Despite some governmental investments in Information Technology, most public schools still rely on paper-based information systems. Consequently, the database may be constructed from two sources: school reports (containing final grades and school absences) or questionnaires (covering demographic, social/emotional, and school-related variables expected to influence student performance).

The study's database contains the following variables: the student's school, gender, age, home address (rural or urban), parents' cohabitation status (Pstatus), the mother's and father's degree and occupation (Medu, Fedu, Mjob, and Fjob), the reason the student chose this particular school (e.g., proximity to home, school reputation, course preference, or other), the student's guardian (mother, father, or other), the number of previous academic failures, extracurricular activities, paid instruction, attendance at nursery school, desire for further education, desire for further education, home Internet connection, romantic relationship, and family quality Any displayed input variable may be binary, numeric, or nominal.

G3 and the number of school absences (absences) were selected as model outputs. $G3$ is the final grade of students obtained from school reports, with values between zero (the lowest grade) and 20 (the highest grade). Finally, by classifying reported grades, students were divided into four categories: Poor ($G3$ of $0-12$), Acceptable ($G3$ of $12-14$), Good ($G3$ of $14-16$), and Excellent ($G3$ of $16-20$).

The correlation matrix for each new input and output variable is shown in Fig. 1. The parents' education had the highest positive effect on the grade obtained by the student, while the father's job was not as effective as the mother's. As expected, study time positively affected outcomes, and the influence of previous failures of the student was revealed to be highly negative. The positive impact of internet accessibility and students' willingness to continue higher education and, in contrast, the negative consequences of alcohol consumption were noticeable. Also, the main variables influencing the number of absences from school were age, failures, and the amount of alcohol consumed on a daily and weekly basis.

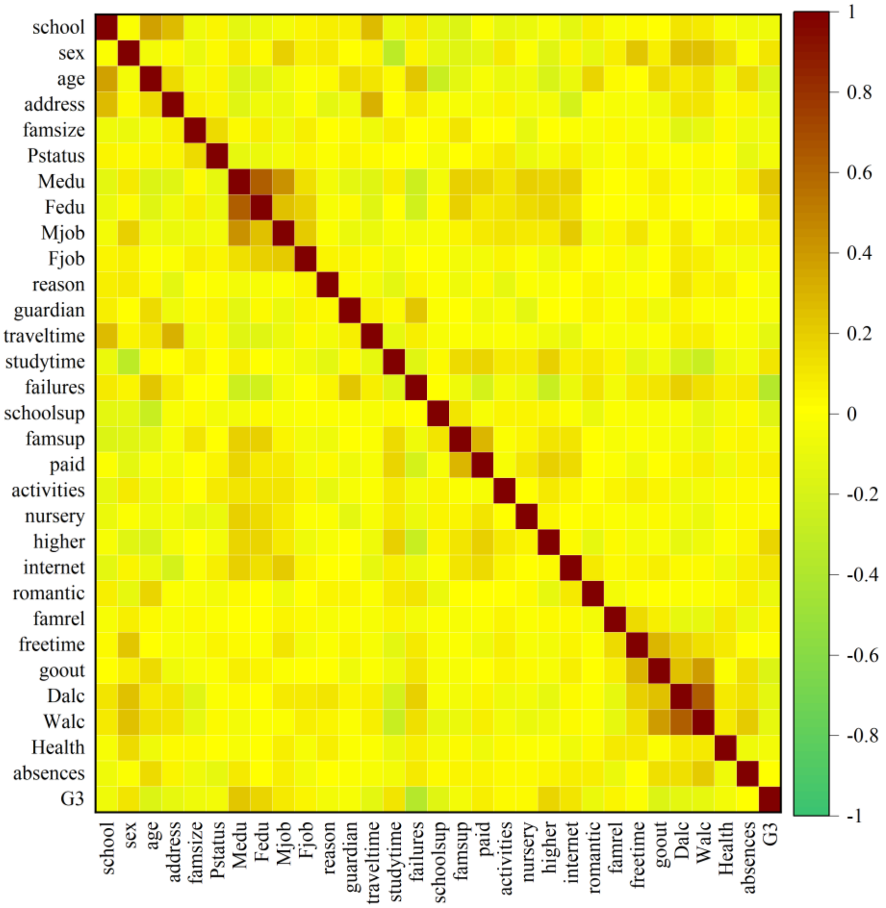

Fig. 1. Correlation matrix for the input and output variables.

IV. CatBoost Classifier (CATC)

A proficient ML algorithm for forecasting categorical attributes is the CatBoost classifier. CatBoost employs gradient boosting and utilizes binary DT as foundational predictors [43]. Let's consider a dataset comprising samples $D = \{(X_j, y_j)\}$, $j = 1, \ldots, m$, where in $X_j = (x_{j}^{1}, x_{j}^{2}, \ldots, x_{j}^{n})$, $y_j \in$ R, the response feature, and a vector of n characteristics. The answer feature might be numerical (0 or 1) or binary (yes or no). The samples (X_j, y_j) have the same independent distribution according to some unknown distribution $p(.,.)$. To train a function H : R^n $\rightarrow$ R that lowers the predicted loss as given by Eq. (1) is the aim of the knowledge problem.

$X_j = (x_{j}^{1}, x_{j}^{2}, \ldots, x_{j}^{n})$ denotes a vector of n characteristics and the response feature $y_j \in$ R, which can be expressed as a numerical feature (0 or 1) or as binary (i.e., yes or no). The samples (X_j, y_j) have the same independent distribution according to some unknown distribution $p(.,.)$. To train a function H : R^n $\rightarrow$ R that lowers the predicted loss as given by Eq. (1) is the aim of the knowledge problem.

$$\mathcal{L}(H) := \mathbb{E}L(y, H(X)) \qquad (1)$$

Where (X, y) indicates testing data selected from training data D, and $L(.,.)$ is a smooth loss function.

The gradient boosting procedure [44] incrementally builds a series of approximations $H^t : R^m \rightarrow R, t = 0, 1, ..$ in a greedy manner. Starting from the previous approximation H^{t-1}, each new approximation H^t is obtained through an additive process, where $H^t = H^{t-1} + \alpha g^t$. Here, α represents the step size and the function $g^t: R^n \rightarrow R$, which serves as a base predictor, is chosen from a set of functions G to minimize or reduce the expected loss defined in Eq. (2):

$$\begin{aligned} g^t &= \arg\min_{g \in G} \mathcal{L}(H^{t-1} + g^t) \\ &= \arg\min_{g \in G} \mathbb{E}L(y, H^{t-1}(X) + g(X)) \end{aligned} \qquad (2)$$

Frequently, the Newton approach is used for the minimization issue, using a second-order approximation of $\mathcal{L}(H^{t-1} + g^t)$ at H^{t-1}, or by taking a (negative) gradient step. Both approaches, Newton's method and gradient descent, are utilized [45,46]. For additional details on the CatBoost algorithm, please refer to [43].

V. Meta-heuristic Optimization Algorithms

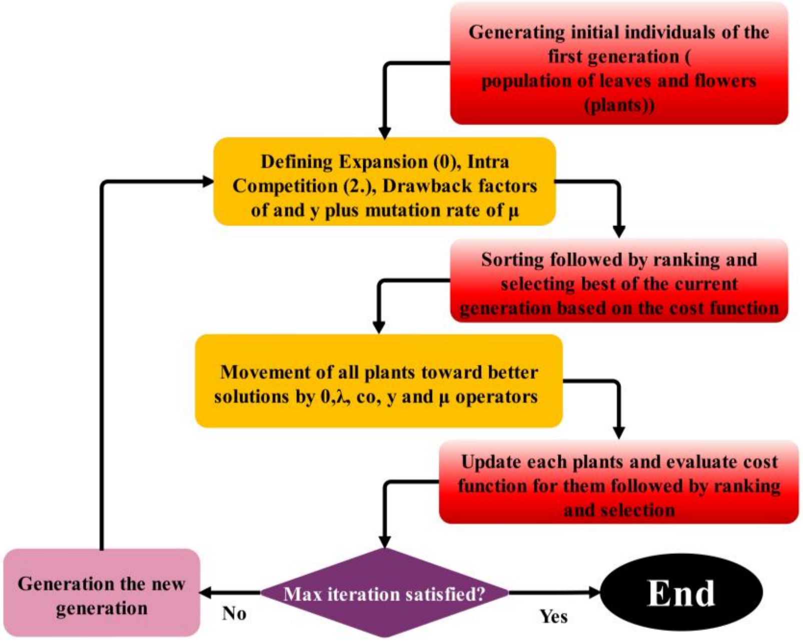
A. *Victoria Amazonica Optimization*

The distribution of the initial population, which is made up of two parts—Leaves and Flowers—and their corresponding capacities to spread over the surface are the main foci of the VAO algorithm [47]. This algorithm predominantly functions as a metaheuristic and uses swarm local search techniques. Its main drawback lies in the potential of getting trapped in local optima. However, it is noteworthy for its swiftness and resilience in handling a wide range of optimization tasks. In the context of this research, the scientific representation of diameter $\varnothing$ is employed to illustrate how entities grow circularly. This growth includes their ability to occupy space, which is achieved through the forceful displacement of one another as they gain strength and spines. This competitive interaction is called intra-competition or denoted as λ for formulation.

Three common challenges affecting plant growth are beetle mortality, inadequate pollination, and temperature drops, collectively referred to as ω. A higher ω value indicates weaker plant growth. Plant pests, like water lily Aphids, represented as μ, can damage leaves. A lower μ value implies better situations for a plant’s growing.

Lastly, the mutation occurs when pond beetles cross-pollinate a water lily flower with a different type, Hybrid Mutation, represented by the symbol ρ. As mentioned earlier, this mutation can result in negative and positive changes, each with a 0.2% frequency per generation. The healthiest and most robust leaf is identified as the optimal or α. The VAO method's flowchart is presented in Fig. 2.

$$VAO = \sum_{i=1}^{n} \sum_{j=1}^{n} (x_{ij}[\varnothing_{ij},\ \lambda_{ij}] +\ \mu + \omega) * (\rho) \tag{3}$$



Generating initial individuals of the first generation (population of leaves and flowers (plants))
Defining Expansion (0), Intra Competition (2.), Drawback factors of and y plus mutation rate of μ
Sorting followed by ranking and selecting best of the current generation based on the cost function
Movement of all plants toward better solutions by 0,λ, co, y and μ operators
Update each plants and evaluate cost function for them followed by ranking and selection
Generation the new generation
Max iteration satisfied?
No
Yes
End

Fig. 2. Flowchart of the proposed VAO.

B. *Artificial Rabbits Optimization*

The ARO idea is derived from the survival techniques used by rabbits in their natural environment, which are designed to confuse predators and guarantee their ability to avoid being tracked. ARO encompasses integrating rabbits' approaches related to foraging, concealing, and managing energy resources, allowing for a seamless transition between these strategic behaviors [48].

1) Detour foraging: Rabbits use a detour foraging strategy when they forage for food, focusing on far-off food sources and often ignoring closer ones. Imagine an environment where a number of rabbits, each with its region complete with burrows and grass, are contained inside the ARO framework. These bunnies often stumble into one other's foraging spots at random. The mathematical model to describe the deviation search behavior of rabbits is as follows:

$$\begin{aligned}\vec{B}_i(t+1) = x_j(t) + S \times (x_i(t) - x_j(t)) + w(0.5 \\ \times (0.05 + r_1)) \times m_1, \\ i,j = 1, \dots, n\ and\ j \neq 1\end{aligned} \tag{4}$$

$$S = M \times v \tag{5}$$

$$M = (e - e^{\left(\frac{t-1}{I}\right)^2}) \times \sin(2\pi r_2) \tag{6}$$

$$v(y) = \begin{cases} 1 & if \quad y = f(1) \\ 0 & else \end{cases} \quad k = 1, \dots, d\ and\ l \\ = 1, \dots, \lceil r_3 \times d \rceil \tag{7}$$

$$f = p(d) \tag{8}$$

$$m_1 = N(0,1) \tag{9}$$

In all equations above:

n: The population's total number of rabbits

d: The scope of the issue

$\vec{B}_i(t+1)$: The $i-th$ rabbit's location at time $t + 1$,

n_1: Based on the conventional normal distribution distribution model.

T: The maximum number of iterations,

$x_i(t)$: The position of the $i-th$ rabbit at time t.

p: produces a random permutation, or rearrangement, of numbers between 1 and d.

w: An algorithmic mapping tool that makes it easier to choose components at random from the explorer to provide diversity to the search procedure.

r_1, r_2, and r_3: Random values in the interval $[0, 1)$.

S: During detour foraging, the run length indicates the pace of movement.

2) Random hiding: To enhance their survival chances, rabbits are likely to select one of their caves at random as a shelter. The mathematical model that represents this stochastic shelter-seeking behavior is expressed through the following equations. The $j-th$ burrow of the $i-th$ rabbit's formulation is as follows:

$$\vec{B}_i(t+1) = x_i(t) + N \times f \times \vec{x}_i(t), \; i,j = 1, \dots, n \; and \; j \neq 1 \tag{10}$$

$$D = \frac{I-t+1}{I} \times r_4 \tag{11}$$

$$m_2 = N(0,1) \tag{12}$$

$$f(y) = \begin{cases} 1 & if \quad y = g(1) \\ 0 & \quad else \end{cases} \quad k = 1, \dots, d \tag{13}$$

$$\vec{R}_{i,r}(t) = \vec{x}_i(t) + N \times f \times \vec{x}_i(t) \tag{14}$$

The parameter N, which represents the hiding capability, gradually decreases linearly during the iteration process, starting at 1 and decreasing to $1/I$, with the addition of random perturbations.

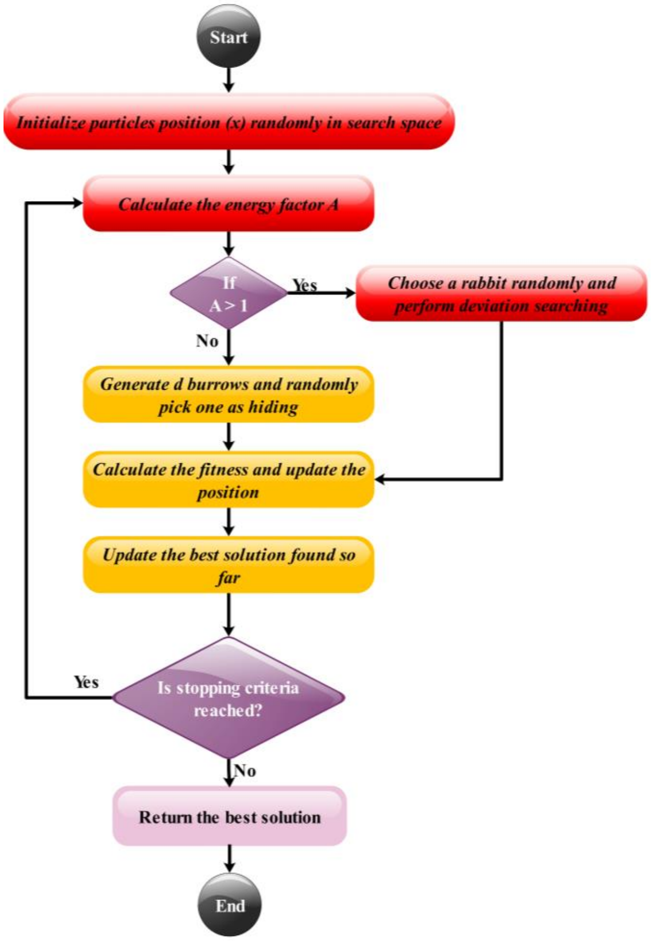
Finally, whether the random hiding or detour foraging tactics are used, the update of the $i-th$ rabbit's position follows the formula provided in Eq. (15):

$$\vec{x}_i(t+1) = \begin{cases} \vec{x}_i(t) & g(\vec{x}_i(t)) \leq g\left(\vec{B}_i(t+1)\right) \\ \vec{B}_i(t+1) & g(\vec{x}_i(t)) > g\left(\vec{B}_i(t+1)\right) \end{cases} \tag{15}$$

3) Energy shrink: The rabbits' energy levels steadily decline as a result of their frequent cycles of haphazard concealment and diversionary foraging. Consequently, an energy component must be included in the ARO framework:

$$E(t) = 4\left(1 - \frac{t}{I}\right) ln \frac{1}{r} \tag{16}$$

Fig. 3 displays the ARO flowchart.



Start
Initialize particles position (x) randomly in search space
Calculate the energy factor A
If A > 1
Yes
Choose a rabbit randomly and perform deviation searching
No
Generate d burrows and randomly pick one as hiding
Calculate the fitness and update the position
Update the best solution found so far
Yes
Is stopping criteria reached?
No
Return the best solution
End

Fig. 3. Flowchart of ARO.

VI. Evaluation Metrics

The most frequently employed metric in a classification problem like the one addressed in this study is Accuracy. In defining the Accuracy, True positives, or TPs, are situations in which the model's predictions came true. Instances that were also accurately anticipated are known as true negatives (TN). False negatives (FN) indicate cases that were incorrectly predicted, while false positives (FP) indicate cases that were incorrectly anticipated.

Nevertheless, five other metrics (Precision, F1-score, Recall, MCC, and AUC) have been chosen because the Accuracy metric has limitations and may not accurately reflect the situation when dealing with imbalanced data, because it usually benefits the dominant class. Precision measures how well positive predictions work, which is important for reducing false positives, while recall shows how well a model can locate all relevant instances within a class. Furthermore, by taking into account both the minority and majority classes, the F1-score enables us to evaluate and correct for uneven data [49]. Evaluation parameters are defined in Eq. (17) to Eq. (21):

$$Precision = \frac{TP}{TP+FP} \quad (17)$$

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \quad (18)$$

$$F1\_score \;= \frac{2\times Recall \times Precision}{Recall+Precision} \quad (19)$$

$$Recall = TPR = \frac{TP}{P} = \frac{TP}{TP+FN} \quad (20)$$

$$MCC \;= \frac{(TP*TN)-(FP+FN)}{\sqrt{(TP+FP)(TP+FN)(TN+FP)(TN+FN)}} \quad (21)$$

VII. Convergence Analysis

VAO and ARO are two distinct metaheuristic optimization algorithms that have shown promise in enhancing the performance of ML models. This study applied them to optimize CATC development CAVA and CAAR hybrid models. These optimizers work to fine-tune the model's hyperparameters and improve its predictive accuracy.

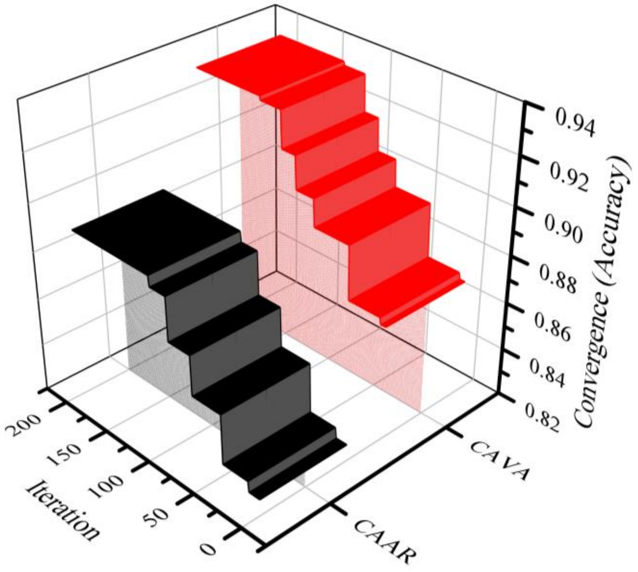


Fig. 4. Convergence curve of hybrid models.

An efficient method for assessing the convergence of these optimizers is by employing a convergence curve depicted in Fig. 4, which is based on the measure of accuracy through 200 iterations. This curve provides a graphic illustration of how the model's accuracy evolves with each iteration, enabling us to determine whether the optimizer is progressing toward an optimal solution and with which rate this convergence is occurring. As evident in Fig. 4, CAVA and CAAR have similar convergence rates, but CAVA starts its operation with about 5% higher accuracy than CAAR, and it reaches a better ultimate value. It is important to highlight that in both models, the trend line exhibited a linear pattern at around 120 iterations, indicating that this point represents the optimal level of computational efficiency.

VIII. Results

This project incorporates a wide range of student data, with a focus on their final grades ($G3$), in an effort to predict future academic success in language courses by using ML techniques. The three models—CATC, CAAR, and CAVA—that are based on the CATBoost Classifier (CATC) are trained and evaluated in large part using this dataset. This section contains the study's methodical computation of performance measures for each prediction step, including *Accuracy*, *Recall*, *Precision*, *F1-score*, MCC, and AUC. With the goal of identifying the best prediction model, this careful investigation provides insightful information that may be used to improve students' academic performance. Every pertinent measure value for testing, training, and model performance is listed in Table II and shown in Fig. 5. When it comes to the G3 prediction results, $CAVA$ and $CATC$ have the best and lowest prediction performances, respectively, with maximum and minimum accuracy scores of 0.9449 and 0.8744. The highest values that $CAVA$ was able to obtain were $0.9453, 0.9449, 0.9449, 0.9192$, and 0.944 for Precision, Recall, F1-score, and AUC, respectively. These results demonstrate the excellent accuracy of CAVA's exact predictions. Conversely, the performance of the other hybrid model (CAAR) was lower than that of CAVA in the prediction processes, experiencing weaker performance across all metric values.

TABLE II. Outcomes of the Models Presented

Model	*Phase*	*Index values*					
		Accuracy	*Precision*	*Recall*	*F1 _score*	*MCC*	*AUC*
CATC	*Train*	0.8744	0.8786	0.8744	0.8759	0.8183	0.909
	Test	0.8872	0.8892	0.8872	0.8871	0.8350	
	All	0.8783	0.8800	0.8800	0.8800	0.8230	
CAAR	*Train*	0.9053	0.9066	0.9053	0.9045	0.8603	0.904
	Test	0.8564	0.8548	0.8564	0.8519	0.7876	
	All	0.8906	0.8900	0.8900	0.8900	0.8384	
CAVA	*Train*	0.9449	0.9453	0.9449	0.9449	0.9192	0.944
	Test	0.9077	0.9065	0.9077	0.9063	0.8641	
	All	0.9337	0.9300	0.9300	0.9300	0.9026	

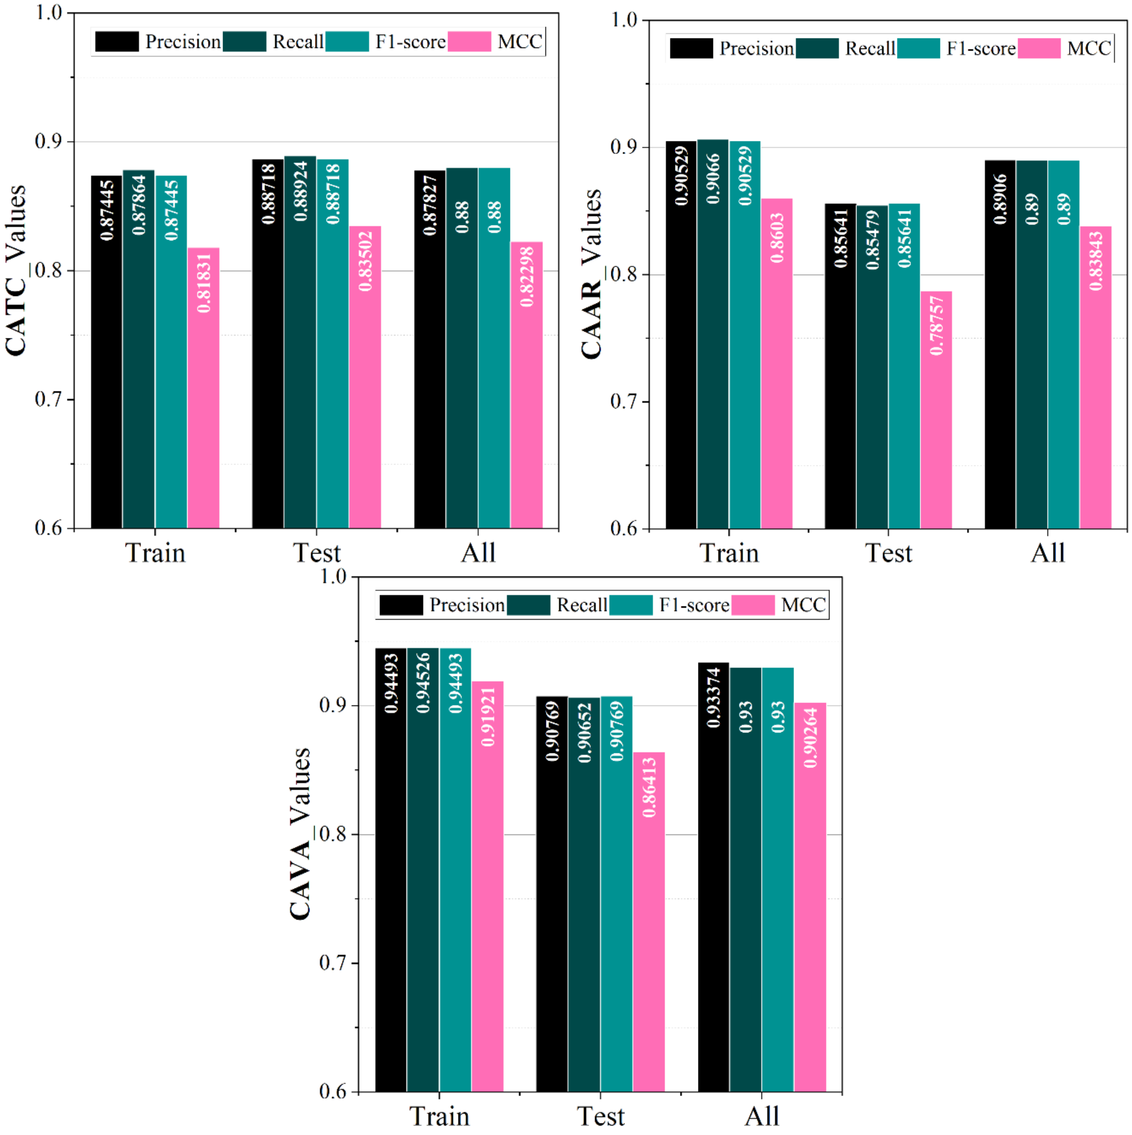

Fig. 5. Bar charts for evaluation results related to hybrid models.

After data processing and examining the classification capability of models in both training and testing phases, to discuss in detail, a total of 649 students based on test results (G3 values) divided into four categories: Poor (G3 of 0–12), Acceptable (G3 of 12–14), Good (G3 of 14–20), and Excellent (G3 of 16–20). Based on categorizing results, 82, 112, 154, and 301 students were located in Excellent, Good, Acceptable, and Poor classes. It revealed that most students (46.38%) performed poorly, while 23.73%, 17.26%, and 12.63% achieved acceptable, good, and excellent educational performance, correspondingly. Table III shows the accuracy, recall, and F1-score index values to assess how well the constructed model's categorization performance across various student groups. Each of the three Index values has been taken into consideration in the comparative study that follows:

1) Precision: A thorough examination of two optimized models presented that, when categorizing students across various categories, the CAVA model exhibited the highest level of precision in all cases, except for the Excellent grade category, where the CAAR model achieved a max $Precision$ value of 0.99. For students classified as Poor and Excellent, the CAVA model demonstrated a Precision value of 0.96 for both categories. Notably, the classification performance of all three models was least precise when dealing with students in the Good grade category, with the lowest precision values observed as 0.78, 0.83, and 0.88 for CATC, CAAR, and CAVA, respectively.

2) Recall: Considering recall values, CAVA performed better in identifying all relevant instances within a class with 0.89, 0.88, 0.9, and 0.98 of the Recall for Excellent, Good, Acceptable, and Poor categories, respectively. Of course, there was an exception in the case of poorly graded students, where CAAR with a marginally higher Recall value was better than CAVA. Similar to those obtained in Precision values comparison, all models performed poorly in classifying students in the Good grade category.

3) F1-score: Compared to the Precision and Recall, the F1-score offers a more comprehensive and nuanced basis for comparative analysis. This metric is bounded between 0 and 1, with higher values signifying superior model performance. A higher F1 score indicates that the model achieves a balance between recalling all true positive instances and precisely recognizing positive cases (precision and recall). The $CAVA$ shows itself to be the most accurate when taking into account all student categories, producing F1-scores of $0.92, 0.88, 0.9$, and 0.97 for students rated as *Excellent*, *Good*, *Acceptable*, and *Poor*. In the second position, concerning the classification of Poor and Excellent students, CAAR displayed greater accuracy than the individual model, whereas their performance was identical for Good students. For Acceptable students, CATC outperformed CAAR.

4) MCC: The Matthews Correlation Coefficient (MCC) results show that $CAVA$ performed well in finding all relevant occurrences in each class. *Excellent*, *Good*, *Acceptable*, and *Poor* categories received scores of $0.95, 0.87, 0.85$, and 0.91, respectively. This indicates a high degree of accuracy in predicting student performance across various grade levels. It's noteworthy to mention that, akin to the findings in the comparison of Precision values, all models exhibited weaker performance in accurately classifying students within the Good grade category.

In general, Table III shows the results of the developed models in detail.

Fig. 6 provides chances for visual comparison by displaying the frequency of students in each category based on metrics and conclusions from the categorization model. It is evident that the students who fell into the categories of bad, acceptable, good, and exceptional were, in fact,$301, 154, 112$, and 82. The CAVA model demonstrated the max accuracy in correctly identifying the categorization of students across different categories, with one exception in the Poor category, where CAAR classified a higher number of students correctly (298 students). In contrast, considering all other grades of students, CAAR was the weakest classifier, especially in the case of Good grades, where only 77.68% of students classified correctly.

The confusion matrix in Fig. 7 demonstrates the number of students accurately assigned to their respective grades and those misclassified into incorrect categories. Considering CAVA, 73, 99, 138, 196 (cumulative number of 606), students were categorized correctly in Excellent, Good, Acceptable, and Poor classes, and just 49 were in the wrong grade. In contrast, the number of students whom CAAR and CATC misclassified was 71 and 79. For two optimized models, misclassification occurred mostly between neighborhood categories, for instance, 9 and 15 students in the case of CAVA and CAAR instead of coming in the $Excellent$ category positioned in the $Good$ grade category. On the other hand, in the instance of the single CATC model, seven students with a minimum score difference of four points in their G3 scores were wrongly placed in the Poor group instead of the Excellent category. Overall, CAVA outperformed 2 other models capable of predicting students' academic performance in the future more precisely.

TABLE III. GRADE-BASED PERFORMANCE EVALUATION INDICES FOR THE CREATED MODELS

$Model$	$Grade$	$Index\ values$			
		$Precision$	$Recall$	$F1-score$	MCC
$CATC$	$Excellent$	0.85	0.86	0.85	0.88
	$Good$	0.83	0.83	0.83	0.81
	$Acceptable$	0.78	0.83	0.80	0.76
	$Poor$	0.95	0.92	0.93	0.80
$CAAR$	$Excellent$	0.82	0.82	0.82	0.92
	$Good$	0.99	0.80	0.89	0.77
	$Acceptable$	0.83	0.78	0.80	0.76
	$Poor$	0.92	0.99	0.96	0.88
$CAVA$	$Excellent$	0.91	0.90	0.90	0.95
	$Good$	0.96	0.89	0.92	0.87
	$Acceptable$	0.88	0.88	0.88	0.85
	$Poor$	0.96	0.98	0.97	0.91

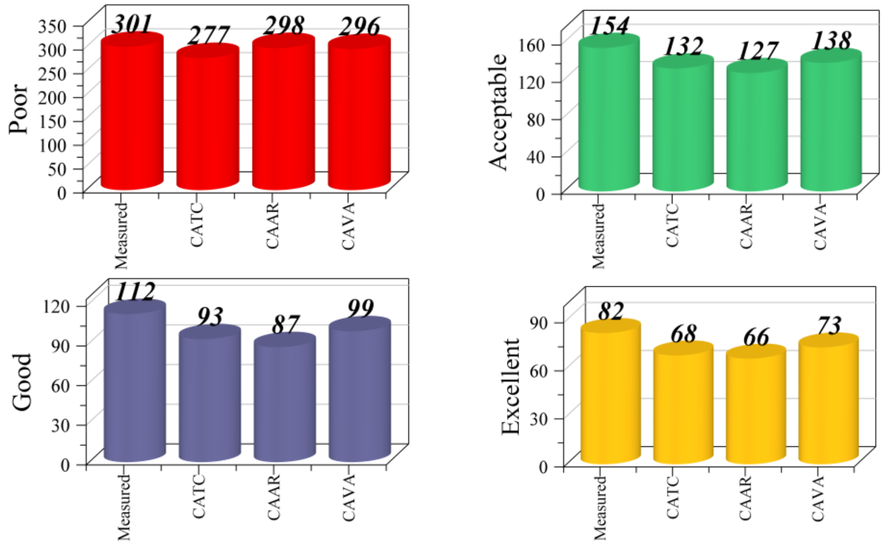

Fig. 6. Based on measurements and the results of categorization models, the number of pupils in each category.

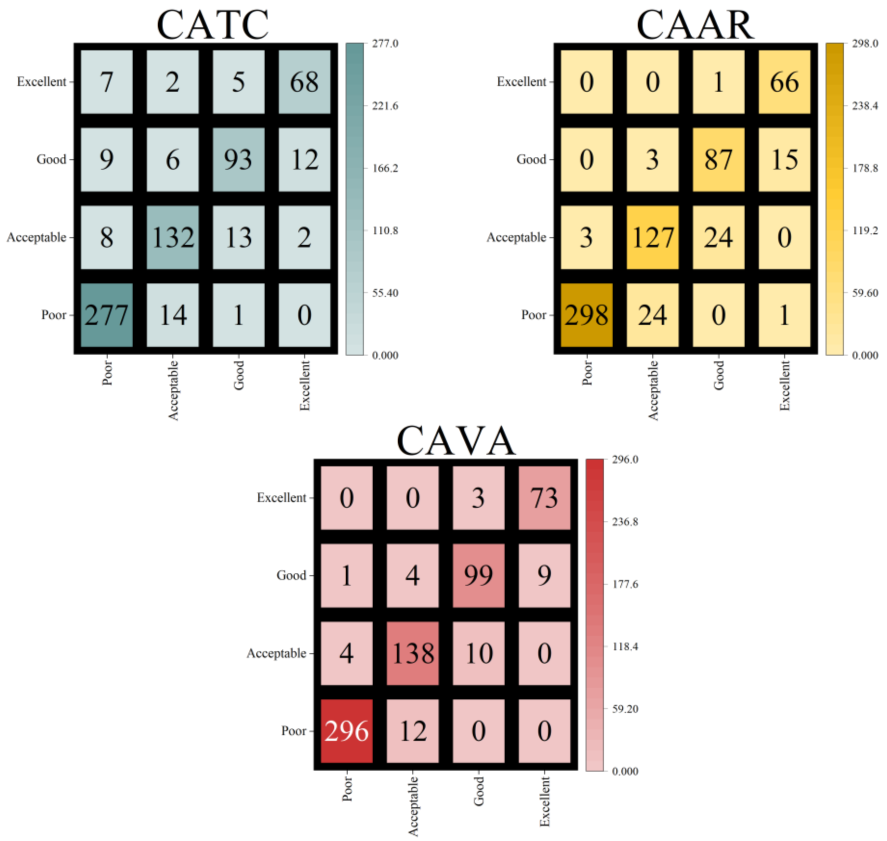

Fig. 7. Confusion matrix showing the accuracy of each model's categorization.

The analysis makes use of the Receiver Operating Characteristic (ROC) curve to achieve equilibrium between True Positive (TP) and False Positive (FP) rates, gauged by the Area Under the ROC Curve (AUC). A higher AUC signifies better control over the FP rate relative to the TP rate. An ideal discriminatory test is marked by an ROC plot converging towards the upper-left corner, indicative of 100% sensitivity and specificity. As depicted in Fig. 8, which presents ROC curves for the CATC, CAAR, and CAVA models in G3 score classification, it is evident that the AUC for the CAVA model (0.944) surpasses that of other categories, underscoring its robust discriminatory capability. The discernible inclination of the curve towards the upper-left corner underscores the model's effectiveness in distinguishing between various classes with precision.

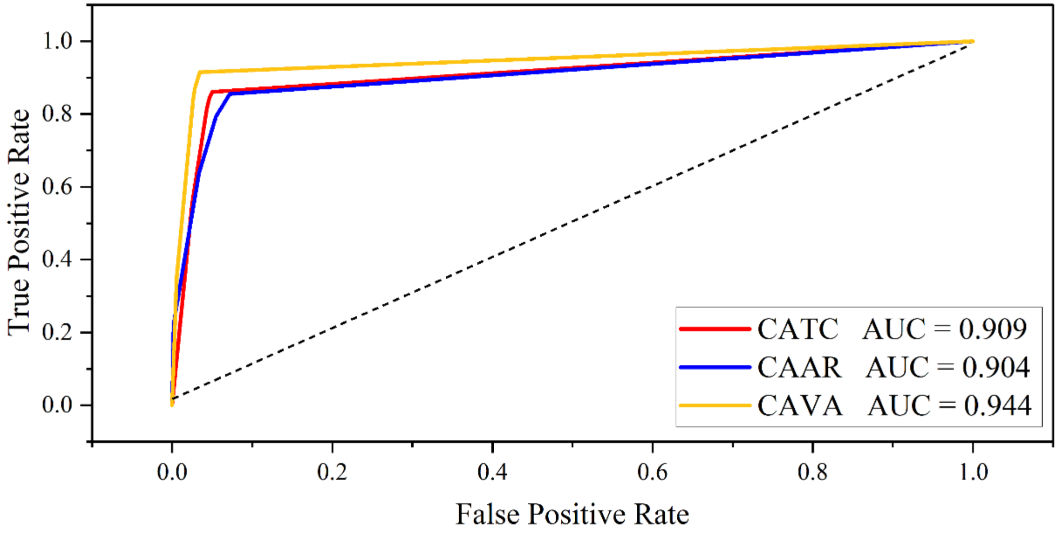

Fig. 8. The result of the ROC curve.

IX. Discussion

Since a particular dataset was used for the study, it is acknowledged that the findings might not apply to different educational settings. Nevertheless, the strategy proposed, which combines the CATC model with optimization algorithms, is believed to have the potential for generalization to other settings under specific conditions:

1) Sufficient and representative data: The dataset needs to be sufficiently big and representative of the intended audience. It must have pertinent characteristics that may record the elements impacting pupils' academic achievement. Additionally, rigorous preprocessing and cleaning are essential to guarantee data quality and validity.

2) Tuning of optimization algorithms: The tuning and adaptation of the optimization algorithms to the properties of the data is required. This involves adjusting parameters and initial conditions to optimize the objective function effectively.

While optimization algorithms are powerful tools for enhancing predictive models, they also possess certain limitations and potential drawbacks:

1) Dependence on data quality and quantity: Optimization algorithms rely on the quality and quantity of data for learning and optimizing the objective function. Issues like overfitting, underfitting, or bias in the optimization findings may arise from insufficient, erroneous, or unrepresentative data.

2) Computational resources: Optimization algorithms' iterative procedures sometimes need large amounts of memory and processing power, especially when dealing with high-dimensional and nonlinear issues. Due to this, they might not be as helpful or successful in real-world scenarios where time and distance are crucial factors.

3) Sensitivity to parameters and initial conditions: Optimization algorithms typically involve specifying or tuning multiple parameters and initial conditions. Selecting these factors can have a big influence on the optimization solutions' quality, stability, and convergence, making it difficult to adapt to other situations or datasets.

4) Lack of guarantees and robustness: Despite their effectiveness, optimization algorithms may lack guarantees and robustness in certain situations. Variability in convergence, stability, and quality of results may occur, making it challenging to ensure consistent performance across diverse contexts.

Awareness of these limitations is essential when employing optimization algorithms in practical applications, necessitating careful consideration and validation to mitigate potential drawbacks and optimize their utility effectively.

B. Comparison with Published Papers

Table IV shows that the CAVA model in the present study achieves an accuracy of 93.37%, significantly outperforming other models such as the DTC and NBC used in previous studies. The superior performance of the CAVA model is attributed to its advanced optimization techniques, which improve parameter tuning and feature selection. This highlights the potential of using sophisticated optimization algorithms to address challenges in educational DM, leading to better predictive performance. The findings suggest that robust models like CAVA can enhance decision-making and support systems in educational settings, ultimately improving student outcomes.

TABLE IV. Extensive Study Results Compared to the Current Work

Author (*s*)	*Models*	*Accuracy*
Present study	*CAVA*	93.37%
Kabakchieva [50]	*DTC*	72.74%
Bichkar and R.R. Kabra [35]	*DTC*	69.94%
Nguyen and Peter [51]	*DTC*	82%
Edin Osmanbegovic et al. [52]	*NBC*	76.65%

X. Conclusion

This inquiry is primarily concerned with the utilization of data-driven prediction models within educational settings, highlighting the critical integration of qualitative and quantitative components to forecast and assess students' academic success in language classes. Regression, classification, and clustering are 3 examples of DM techniques that show promise in addressing a variety of issues faced by undergraduate students. The knowledge gained from this study provides lawmakers, academic institutions, and students with important direction for improving future academic achievement. Additionally, the study introduces a pioneering approach by combining the VAO and ARO methods with the CATBoost classifier (CATC) model. This creative combination shows how ML methods and optimization algorithms may improve the accuracy and performance of prediction models. The resultant toolbox equips stakeholders to navigate the evolving complexities encountered throughout students' academic journeys. Through meticulous analysis, including model partitioning into training and testing sets, the study emphasizes how important it is for hybrid models to improve the CATC model's classification performance. Substantial improvements in Matthews Correlation Coefficient (MCC), Accuracy, and Precision attest to this progress. Detailed scrutiny of the data underscores the growing recognition of hybrid models for substantially refining the CATC model's categorization abilities. Particularly noteworthy is the exceptional performance of the VAO in boosting classification accuracy. Notably, the CAVA model demonstrates an impressive ability to accurately identify 93.37% of students, outperforming CAAR and CATC. Ultimately, this work propels predictive modeling in education forward, offering avenues to augment the precision and efficacy of academic performance evaluations. These findings underscore the favorable impact data-driven strategies can have on undergraduate students' academic trajectories. Future work in this field should focus on expanding the dataset to include a more diverse student population and a broader range of academic disciplines to validate the generalizability of the models. Additionally, exploring the integration of other advanced optimization algorithms and ML techniques could further enhance model performance. Investigating the real-time application of these models in educational settings and their impact on student interventions and support strategies would also be valuable.

Exploring the Impact of Time Management Skills on Academic Achievement with an XGBC Model and Metaheuristic Algorithm

Songyang Li
Police Skills and Tactics Training Department, Criminal Investigation Police University of China,
Shenyang 110035, Liaoning, China

***Abstract*—Estimating a student's academic performance is a crucial aspect of learning preparation. In order to predict understudy academic performance, this consideration uses a few Machine Learning (ML) models and Time Administration Aptitudes data from the Time Structure Questionnaire (TSQ). While a number of other useful characteristics have been used to forecast academic achievement, TSQ findings, which directly evaluate students' time management skills, have never been included. This oversight is surprising, as time management skills likely play a significant role in academic success. Time administration may be an ability that may impact the student's academic accomplishment. The purpose of this research is to look at the connection between college students' academic success and their ability to manage their time well. The Extreme Gradient Boosting Classification (XGBC) model has been utilized in this study to forecast academic student performance. To enhance the prediction accuracy of the XGBC model, this study employed three optimizers: Giant Trevally Optimizer (GTO), Bald Eagle Search Optimization (BESO), and Seagull Optimization Algorithm (SOA). Impartial performance evaluators were employed in this study to assess the models' predictions, minimizing potential biases. The findings showcase the success of this approach in developing an accurate predictive model for student academic performance. Notably, the XGBE surpassed other models, achieving impressive accuracy and precision values of 0.920 and 0.923 during the training phase.**

Keywords*—Student academic performance; time management; machine learning; extreme gradient boosting classification; metaheuristic algorithm

I. Introduction

A. Background

Student academic execution could be an exceptionally vital perspective for colleges and schools since it speaks to how healthy they teach their understudies [1]. As early as possible, it is important to predict a student's academic success so that universities may take appropriate action [2]. For illustration, if an understudy is demonstrated to have a terrible review, the teacher can give extra fabric or a session for the understudy [3]. A few things have been conducted to anticipate student academic execution utilizing different highlights. Highlight choice is a critical viewpoint in making forecasts [4]. Numerous highlights have been utilized, extending from social, statistical, behavioral, individual, and academic information. Among those elements, the academic elements continue to be the most persuasive factor when choosing how to implement academically [5].

However, another consideration [6] appeared curious: that time administration aptitude is related to academic execution. A student with a tall review point normally tends to have solid time administration aptitude [7]. Nevertheless, few tests have been conducted utilizing time administration aptitudes, including anticipating understudy execution. In this way, a ponder must be approved out by attempting to use time administration ability information as a highlight to form forecasts [8]. ML points to forming machines that can do their jobs skillfully by utilizing clever computer programs [9], [10]. ML has the potential to shed light on many topics, including categorization problems. The process of dividing input vectors into a finite number of distinct, specified categories or classes is known as classification [11], [12].

B. Literature Review

A ponder in 2008 [13] employments understudy foundation (sexual orientation, age, family, etc.), understudy social exercises (week after week think about time, free time after school, extra−curricular exercises, etc.), and coursework result (to begin with a period review and moment period review) as highlights for doing classification. Five diverse calculations are utilized to decide the most excellent calculations. They are NB, SVM, NN, DT, and RF. As a result, 93% exactness is accomplished for twofold classification and 78.5% precision for $five$ −level classification. The most important aspect of categorization, it was discovered, is coursework. Utilizing the same dataset as [13], another study in 2018 [14] appears comparative comes about. Even Nevertheless, the most notable aspect of classifying coursework is its outcome. Another consideration [15] conducted in Jordanian utilized $three$ distinctive include categories: individual data (sex, family status, age, etc.), instructive data (tall school stream, tall school review, college sort, etc.), and geographic information (travel time and transportation sort). By utilizing $NN,$ 97% precision can be obtained for $four$ −level classification. At the same time, $DT,$ as it were, gets approximately 66% precision. Instructive data is the foremost important and noteworthy highlight within the classification. Focusing on scholastic variables, another thinks about [16] connecting straight regression (LR), numerous regression (MR), and NN to anticipate students' GPA. This ponders centered on scholastic components. As the result, 83% precision is gotten through NN.

Curious discoveries were made in study [17]. 43 diverse highlights have been created to anticipate understudy scholarly execution in arithmetic. They consider employments seven distinctive calculations: forward-thinking Auxiliary Condition Modeling $(pSEM)$, Multilayer Perceptron (MLP) $NN, C5.0$ of DT, Calculated Relapse $(LoR$, Successful Negligible Optimization (SMO) of SVM, and RF. The accuracy may go up to 93.52%. This analysis has also made an effort to identify the most compelling features when classifying. The three most insightful points, therefore, have to do with managing time. These include the repetition of thinking through and preparing for assessments and examinations, the quantity of time dedicated to independent study, and the repetition of completing homework and clarifying mathematical problems [18].

Claessens et al. [18] describe time management practices as actions that lead to making effective use of time while carrying out certain goal-directed tasks. Since time management is a talent, it can be quantified. Using a Time Management Questionnaire or Time Structure Questionnaire (TSQ) is one method of measuring time management skills (TMS). Quill and Bond introduced TSQ in 1983 [19], including seventeen items about time management. A 1 to 7 scale with the labels "Yes, continuously" and "No, never" was used to rank each item. The answers to the preexisting items were included to get the total score. An individual's ability to manage their time improves with increasing score. As seen in the study [20], by deleting one item and adding ten more, TSQ improved upon Quill and Bond's 1988 efforts, making a total of 26 unique items available. According to studies [20] and [21], there was a sign that understudies with great TMS tend to have great scholastic execution as well. Other than that, it found that understudies who had a great TMS score essentially detailed more prominent work and life fulfilment [20]. Moreover, individuals with organized and Intentional time management are associated with high levels of confidence and depressive symptoms [22].

Malykh et al.'s study [23] complements existing literature by demonstrating that the format of non-symbolic comparison tasks significantly affects children's numerosity estimation, with homogeneous formats enhancing the congruency effect and heterogeneous formats reducing it. This aligns with previous research indicating that visual properties can either aid or hinder numerical processing, depending on the context. Their findings suggest that younger children, in particular, are prone to relying on visual cues, which can skew their numerical estimations. As children age, their ability to process numerical information independently of these cues improves, highlighting the importance of developmental considerations in educational assessments.

C. Objective

This study utilizes ML, specifically Extreme Gradient Boosting (XGB), to predict student performance based on their time management skills. In an effort to improve the single model's performance, three metaheuristic algorithms are employed: Giant Trevally Optimizer (GTO), Bald Eagle Search Optimization (BESO), and Seagull Optimization Algorithm (SOA). This study assessed the performance of ML models in evaluating student performance, ensuring fairness through performance evaluators like accuracy and precision. Pre-processing techniques helped create a clean and effective training dataset, while feature selection identified the most relevant input factors. This approach provides a novel overview of ML in student performance evaluation, potentially aiding institutions in optimizing their strategies and analyzing their students more effectively. However, it is important to acknowledge that even with these measures, the potential for bias in the data or chosen algorithms cannot be eliminated. This study makes several key contributions: it integrates TSQ data, which evaluates students' time management skills, into predictive models—a novel approach not previously utilized in predicting academic performance. The study also ensures fairness and minimizes potential biases through the use of impartial performance evaluators. Finally, the findings offer valuable insights that can help educational institutions improve their strategies and analyze student performance more effectively, potentially leading to more effective academic interventions and support systems. Acknowledging the potential for bias in data and algorithms, the study raises awareness about the limitations and ethical considerations of using ML for educational purposes. This awareness can lead to more cautious and responsible application of these technologies in educational psychology.

D. Research Organization

The introduction of this study is divided into four key sections: background, related work, objectives, and research organization. The subsequent structure of the paper is as follows: Section II provides detailed overviews of various machine learning techniques, including models and optimization algorithms, along with a brief description of the evaluation metrics used. Section III examines the dataset, highlighting the correlation between input and output variables and the feature selection processes. Section IV presents comparative results based on metric values to assess the performance of the models. Section V, titled "Discussion," discusses the study's limitations and potential directions for future research. Finally, Section VI summarizes the key findings and conclusions derived from the study.

II. Methodology

A. Extreme Gradient Boosting Classification (XGBC)

Comparable with angle boosting, XGBoost [24] combines a frail base classifier into a more grounded classifier. At each emphasis of the preparing handle, the remaining base classifier is utilized within the following classifier for optimizing the objective work. Assume the base classifiers are trees with a number of K [25], [26]. For an input test xi, the yield is calculated by:

$$\hat{y}_i = \sum_{i=1}^{k} f_k(x_i), f_k \in F \tag{1}$$

where, $f_k(x_i)$ is the yield of the k_{th} trees and F is the space of all relapse trees. Based on angle boosting, XGBoost makes a few enhancements by regularizing the objective work [27]:

$$L = \sum_i l(y_i, \hat{y}_i) + \sum_k \Omega(f_k) \tag{2}$$

Where the previous term could be a misfortune work that measures the contrast between the forecast $\hat{y}_i$ and label y_i. The last-mentioned term could be a regularization term that measures the complexity of the trees [28].

The total objective work cannot be optimized straightforwardly. Instep, added substance way is considered [29]. Let $\hat{y}_i(t)$ be the expectation of the i_{th} test at the t_{th} emphasis, the objective work is composed as:

$$L^{(t)} = \sum_{i=1}^{n} l\left(y_i, \hat{y}_i{}^{(t-1)} + f_t(x_i)\right) + \Omega(f_t) \simeq \sum_{i=1}^{n}\left[l\left(y_i, \hat{y}_i{}^{(t-1)}\right) + g_i f_t(x_i) + \frac{1}{2} h_i f_t{}^2(x_i)\right] + \Omega(f_t) \tag{3}$$

Where, gi is the primary arranged fractional subsidiary of the misfortune work and hi is the moment arranged halfway subsidiary of the misfortune work. Subsequently, the misfortune work must be twice differentiable. The steady terms of Eq. (3) are evacuated, and the objective work is disentangled as follows:

$$\tilde{L}^{(t)} = \sum_{i=1}^{n}\left[g_i f_t(x_i) + \frac{1}{2} h_i f_t^2(x_i)\right] + \Omega(f_t) \tag{4}$$

The regularized term is characterized by

$$\Omega(f) = \gamma T + \frac{1}{2}\lambda \|w\|^2 \tag{5}$$

where, T is the number of takes off within the tree. ω is the T-dimension vector of scores on take off. γ and λ» are steady coefficients speaking to the complexity of clears out and scale of punishment. The space of trees is characterized as $F = \{f(x) = \omega_{q(x)}.q(x)$ could be an outline relegating the test to the comparing leaf. The occurrence set of leaf j is I_j. Thus, Eq. (4) can be expanded as follows:

$$\tilde{L}^{(t)} = \sum_{i=1}^{n}\left[g_i f_i(x_i) + \frac{1}{2} h_i f_t^2(x_i)\right] + \gamma T + \frac{1}{2}\lambda \sum_{j=1}^{T} \omega_j^2 = \sum_{j=1}^{T}\left[\left(\sum_{i\in I_j} g_i\right)\omega_j + \frac{1}{2}\left(\sum_{i\in I_j} h_i + \lambda\right)\omega_j^2\right] + \gamma T \tag{6}$$

Eq. (6) can be encouraged compressed by characterizing $G_j = \sum_{i\in I_j} g_j$ and $H_j = \sum_{i\in I_j} h_i$. Expecting the structure of the tree to be settled, the ideal esteem of all left can be calculated by Eq. (7). And the comparing esteem of objective work can be obtained utilizing Eq. (8).

$$\omega_j^* = -\frac{G_j}{H_i + \lambda} \tag{7}$$

$$\tilde{L}^{(t)}(q) = -\frac{1}{2}\sum_{j=1}^{T}\frac{G_j^2}{H_i + \lambda} + \gamma T \tag{8}$$

As the structures of trees can be assessed, an estimation for the part hubs is characterized in Eq. (9). Characterize IL and IR as the occurrence sets after the part.

$$Gain = \frac{1}{2}\left[\frac{G_L^2}{H_L+\lambda} + \frac{G_R^2}{H_R+\lambda} - \frac{(G_L+G_r)^2}{H_L+H_R+\lambda}\right] - \gamma \tag{9}$$

B. Giant Trevally Optimizer (GTO)

The GTO approach was chosen to address the $P-OPF$ issue over different scenarios. The GTO strategy could be a metaheuristic calculation that determines motivation from the chasing behaviors of the monster trevally [30], [31]. The giant trevally employments procedures that include designed scavenging developments, choice of an ideal chasing locale, and jumping out of the water to capture prey [32]. The GTO calculation duplicates these procedures into a $3-$ step preparation: broad look, determination of zone, and assault.

1) Extensive search: The GTO method recreates the long separations mammoth trevallies travel to find nourishment employing a numerical show based on Exact flights, a shape of arbitrary walk. This stage progresses the algorithm's investigation capability and helps in maintaining a strategic distance from nearby optima. The condition utilized in this stage can be outlined as delineated below:

$$X(t+1) = Best_p \times R + (Maximum - Minimum) \times R + Minimum \times Levy(Dim) \tag{10}$$

where, the location vector of the enormous trevally in the subsequent iteration is denoted by $X(t + 1)$, $Best_p$ speaks to the leading position gotten, R speaks to an arbitrary number extending from 1, and $Levy\ (Dim)$ speaks to the Require flight.

2) Choosing area: In this stage, the calculation finds the ideal chasing locale based on nourishment accessibility interior of the look space. The taking after condition is utilized to reproduce this behavior numerically:

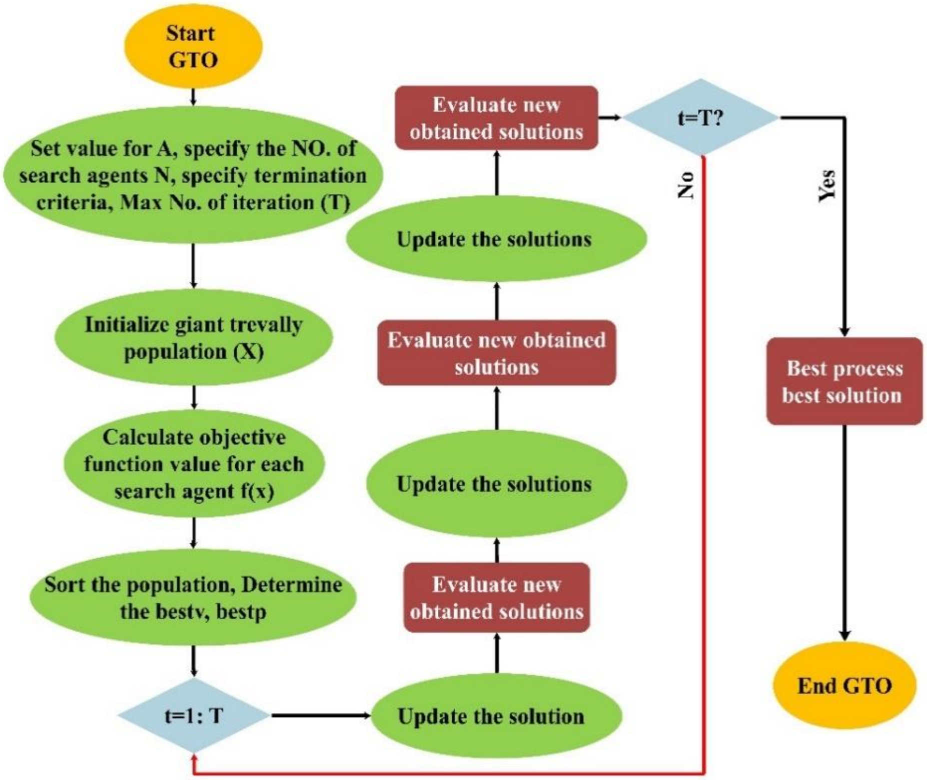
$$X(t+1) = Best_p \times \mathcal{A} \times R + Mean_{Info} - Xi(t) \times R \tag{11}$$

where, A may be a parameter that controls position alters, $Xi(t)$ denotes the current position, and R may be an arbitrary number. The successful utilization of all information gotten from earlier areas is suggested by the term Mean Info for these giant trevallies.

3) Attacking: The last arrangement of the algorithm mimics the trevally's attack on its victim. The trevally's behavior is affected by light refraction, which affects its ability to see. In order to replicate this behavior, the computation first uses Snell's equation to compute the visual twisting V. Next, it uses the following to simulate the trevally attack:

$$X(t+1) = \mathcal{L} + \mathcal{V} + \mathcal{H} \tag{12}$$

where, $X(t + 1)$ signifies another position, $\mathcal{L}$ is the dispatch speed, $\mathcal{V}$ is the visual mutilation, and $\mathcal{H}$ is the jumping incline work, in this manner permitting the calculation to move from the stage of investigation to the stage of misuse. Fig. 1 presents the process of the GTO.



Start GTO
Set value for A, specify the NO. of search agents N, specify termination criteria, Max No. of iteration (T)
Initialize giant trevally population (X)
Calculate objective function value for each search agent f(x)
Sort the population, Determine the bestv, bestp

End GTO

Fig. 1. The process of the GTO.

C. Bald Eagle Search Optimization (BESO)

It's possible that the BES computation is a subsequent meta-heuristic optimization computation that was suggested in 2020. Bald eagles (BE) are ranked highest in the food chain according to their measurement. They are unintentional hunters. They can eat any straightforward, easily available food that is high in protein [33], [34]. They choose an angle, especially salmon, dead or alive, as their primary food source. Because eagles have extraordinary eyesight and can simultaneously look in two different orientations, they can locate angles from a great distance. The main source of inspiration for BES was their cunning social conduct with regard to their pursuing device. Three phases make up the chasing component of BE [35], [36]. These phases include swooping, gazing in space, and choosing a spot. The eagle selects the area with the greatest concentration of prey during the selecting-the-space phase. The eagle starts hunting for prey within the selected space during the searching-in-the-space phase.

Finally, during the swooping phase, the falcon starts to swoop from its optimal position from the previous phase. At that moment, it is chosen which point is optimum to pursue. All of the eagle's subsequent developments are directed toward this goal.

1) Mathematical Model: The numerical definition of the chasing component of BE is characterized by the taking after:

Selecting−space stage. The BE, in this stage, decides the ideal zone based on the sum of nourishment. This behavior is numerically characterized as:

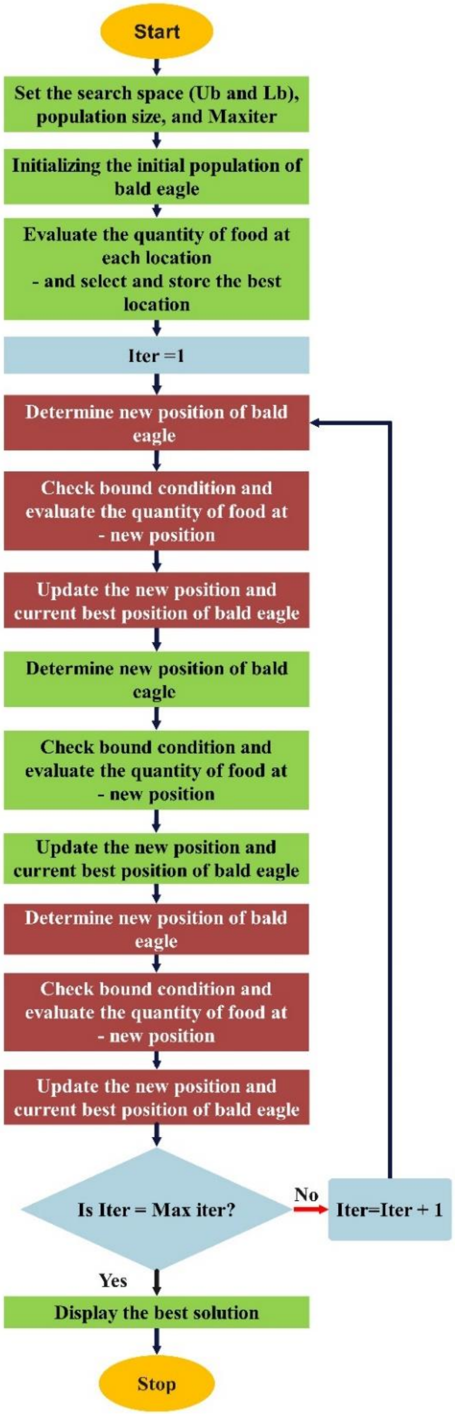
$$X_{new} = X_{best} + \alpha \times r(X_{mean} - X_i) \tag{13}$$

Where X_{best} is the chosen look space based on the finest eagle's position, X_{mean} is the harsh division between each of the bare hawks' postures (cruel of the populace), Xi is the present hawk position, r could be an arbitrary parameter produced in [0-1], and α may be a consistent parameter.

Phase of searching in space. In this step, the BE moves entirely various headings within the selected spiral zone from the previous stage in search of prey. Additionally, a decision is made on who would lead the pursuit and swooping of prey. The following numerical description of this behavior:

$$\begin{gathered} X_{new} = X_i + z(i) \times (X_i - X_{i+1}) + p(i) \\ \times (X_i - X_{mean}) \\ p(i) = \frac{pr(i)}{max|pr|}, z(i) = \frac{zr(i)}{max|zr|} \\ pr(i) = r(i) \times \cos(\theta(i)), zr(i) \\ = r(i) \times \sin(\theta(i)) \\ \theta(i) = \alpha \times \pi \times r1 \\ r(i) = \theta(i) + R \times r2 \end{gathered} \tag{14}$$

where, $r1$ and $r2$ are two random parameters, R is another constant parameter with a value between 0.5 and 2, and α is a constant parameter with a value in the range $[0.5, 2]$. Fig. 2 presents the flowchart of the $BESO$.



Start

D. *Seagull Optimization Algorithm (SOA)*

Around the world, gulls, or more accurately, the seagull family, are seabirds. Seagulls come in a variety of varieties, each with unique bulk and length. Being omnivores, seagulls provide support to squirrels, angels, reptiles, terrestrial and aquatic animals, and night crawlers. The majority of gulls are protected by white plumes [37], [38], [39]. Gulls are exceptionally intelligent feathered creatures. They utilize breadcrumbs to pull in angle and make the sound of rain on their feet to draw in night crawlers covering up underground. Numerical models of predator relocation and assault are examined. The computation recreated the movement of a group of gulls from one area to another during the relocation. The requirements a seagull must fulfill are as follows:

An extra variable, A, is used to calculate the unused look operator area, thereby preventing collisions between adjoining look specialists.

$$C_s = A \times P_s \tag{15}$$

Where Cs speaks to the position of look specialist, which does not collide with other look specialists, Ps speaks to the current position of look operator, x demonstrates the current emphasis, and A speaks to the development behavior of look specialist in a given look space.

$$A = f_c - (x \times ({}^{f_c}/_{Max_{iteration}})) \tag{16}$$

Where fc is presented to control the recurrence of utilizing variable A, which is straightly diminished from fc to 0.

After maintaining a strategic distance from the collision between neighbors, the look specialists move toward the heading of best neighbor.

$$M_s = B \times (P_{bs}(x) - P_s(x)) \tag{17}$$

Where MS speaks to the positions of look operator Ps towards the leading fit look specialist P_{bs}. Because B behaves randomly, it may be trusted to balance proper amounts of abuse and investigation. The calculation for B is:

$$B = 2 \times A^2 \times rd \tag{18}$$

Where rd could be an arbitrary number that lies within the extent of [0,1]. Finally, the look specialist can overhaul its position with regard to the best look specialist by:

$$D_s = |C_s + M_s| \tag{19}$$

Where Ds speaks to the removal between the look operator and best-fit look specialist.

The purpose of this enhancement is to capitalize on the engagement and history of the look preparation. Attacking prey causes the spiraling activity to occur inside the discussion. This behavior is represented as follows in the x, y, and z planes:

$$\acute{x} = r \times \cos(k) \tag{20}$$

$$\acute{y} = r \times \sin(k) \tag{21}$$

$$\acute{z} = r \times k \tag{22}$$

$$r = u \times e^{kv} \tag{23}$$

Where r is the span of each turn of the winding, k may be an irregular number in extend $[\,0 \le k \le 2\pi\,]$. u and v are constants to characterize the winding shape, and e is the base of the common logarithm. The overhauled position of the look operator is calculated utilizing Eq. (19) to Eq. (22).

$$P_s(x) = (D_s \times \acute{x} \times \acute{y} \times \acute{z}) + P_{bs}(x) \tag{24}$$

Where Ps spares the leading arrangement and overhauls the position of other look operators.

E. Evaluation Criteria

To see on the off chance that a classifier is sweet, distinctive ways of judging it are utilized. Precision may be a common way to determine how numerous forecasts are right. Accuracy, review, and precision are vital measures that are regularly utilized together. Accuracy measures how exact a test is at finding positive cases, while recall looks at finding all the genuine positive cases. The f1-score could be a combined degree of exactness and review.

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \tag{25}$$

$$Precision = \frac{TP}{TP+FP} \tag{26}$$

$$Recall = TPR = \frac{TP}{P} = \frac{TP}{TP+FN} \tag{27}$$

$$F1\ score\ = \frac{2 \times Recall \times Precision}{Recall + Precision} \tag{28}$$

These conditions utilize TP for accurately distinguishing a positive case, FP for wrongly anticipating a positive case, TN for accurately foreseeing a negative case, and FN for wrongly foreseeing a negative case.

III. Description of Dataset

As part of continuous research at Nottingham Trent International College, data was collected using a questionnaire [40]. The objective of this research is to elucidate the many elements that impact the time management skills of 125 students. The dataset contains various demographic data on students, including age, gender, nationality, study programs (Foundation, International Year One, Pre-Master's, and Language Only), academic performance indicators, language course achievements, and attendance records. The dataset further includes the responses provided by students on their proficiency in managing their time. Fig. 3 illustrates the connection between the input and output variables, with the respective magnitudes shown on the right side using distinct color coding. The questions are as follows:

Questionnaire:

1. Do you often have a sense of aimlessness in your life without a clear and specific goal?
2. Do you always find it easy to manage your tasks?
3. Once you begin an activity, do you persist with it until you finish it?
4. Do you occasionally feel a sense of insignificance towards the tasks you must do during the day?
5. Do you organize your activities on a daily basis?
6. Do you tend to procrastinate?
7. Do you have a tendency to transition haphazardly from one task to another during the day?
8. Do you abandon your planned activities just because your friend refuses?
9. Do you believe that you adequately use your time?
10. Do you have a tendency to get easily bored with your daily tasks?
11. Do your significant interests and activities in life have a tendency to shift often?
12. Are you aware of the exact amount of time you dedicate to each of your homework assignments?

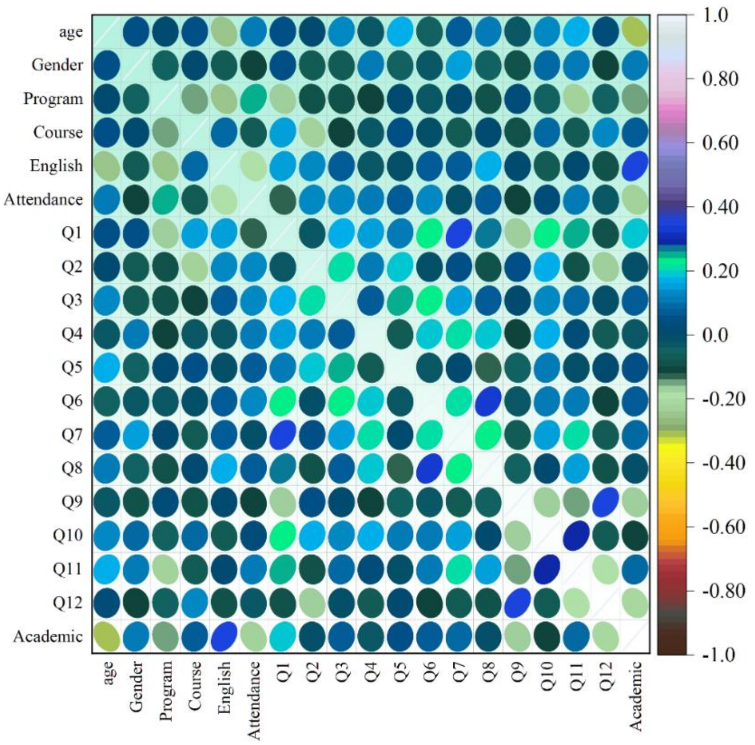

Fig. 3. The relationships between input and output variables by utilizing the correlation matrix.

A. Feature Selection

In ML, feature selection plays a critical role in building efficient and accurate models. Among various techniques, f-classification, a supervised technique utilizing the F-statistic from analysis of variance (ANOVA), offers valuable insights into feature relevance. Fig. 4 displays a bar chart summarizing the results of the feature selection process using f-classification for the input variables. Notably, the average score achieved by this method is 0.35. Features exceeding this average score, highlighted in the chart, were selected for inclusion in the model training process.

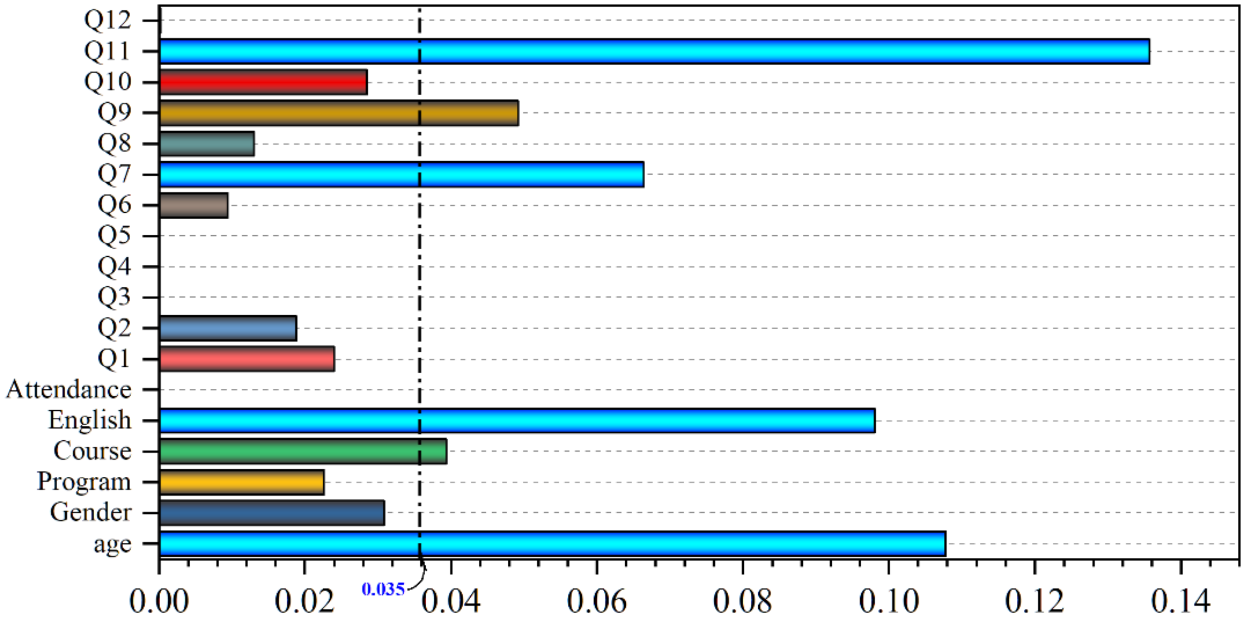

Fig. 4. The bar plot for the result of the feature selection method.

IV. Results

A. Convergence Curve

The headway of an iterative optimization strategy over time is spoken to graphically by the meeting bend that appeared in Fig. 5. It shows the changes within the objective work esteem of the calculation with each emphasis, showing that the calculation is getting near a perfect arrangement. When an algorithm approach joining within the setting of optimization issues, it implies that it consistently minimizes or maximizes the objective work until it comes to a point at which extra emphasis results in minor advancements.

The plot shows that the XGBE model reliably beats the XGGT and XGSO models, accomplishing a top exactness of 0.86 after 120 iterations, showing its predominant execution. Be that as it may, even though the XGGT and XGSO model's precision appeared to be a discernible increment after 110 iterations, it still might not outperform the execution of the XGBE model.

B. Comparative Analysis for Predicted Models Based on Metrics' Results

Table I shows the outcomes of both the single and hybrid models and Fig. 6 visualizes these differences. There are four models, and each model has been compared in four different metric values and two different Sections. The metrics are (Accuracy, Recall, Precision, and F1-score) and the Sections are Train and Test. The model performs best if the number of values gets close to one. Among the evaluated models, XGBE exhibited the highest accuracy in the training section. In terms of precision, XGSO ranked second, followed by XGGT. Conversely, XGBC demonstrated the weakest recall performance during training.

During testing, XGSO achieved the highest F1 score, demonstrating overall solid performance. XGBE and XGSO excelled in the recall, showcasing their ability to identify true positives, with XGGT following closely behind in second place. XGBE took the lead for precision, with XGSO again securing the second-best position.

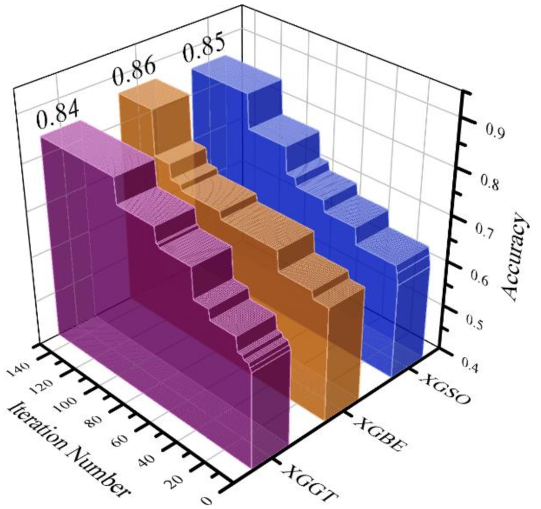

Fig. 5. Convergence curve for hybrid models.

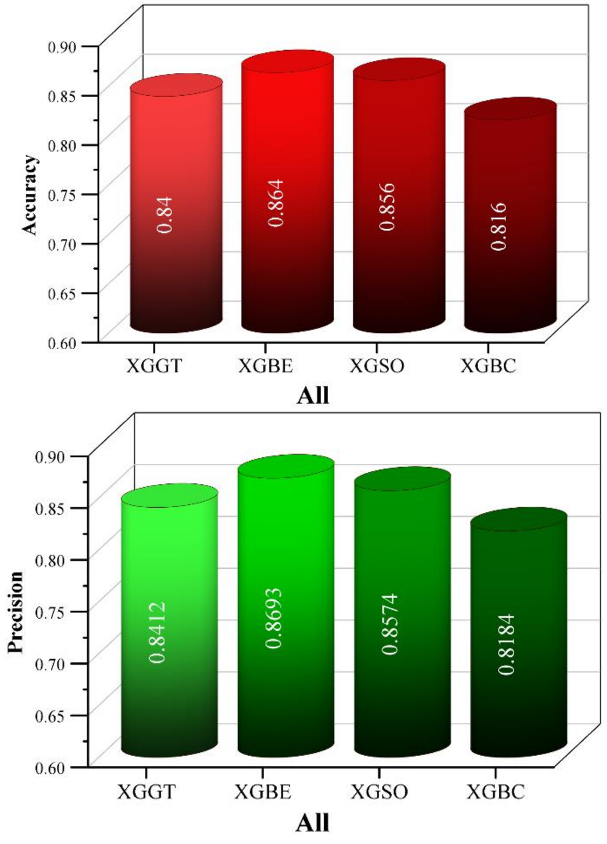
TABLE I. THE OUTCOMES OF BOTH THE SINGLE AND HYBRID MODELS ARE SHOWCASED IN THE PRESENTATION

Section	Metric	Model			
		XGGT	*XGBE*	*XGSO*	*XGBC*
Train	*Accuracy*	0.897	0.920	0.908	0.885
	Precision	0.896	0.923	0.909	0.886
	Recall	0.897	0.920	0.908	0.885
	F1 _Score	0.896	0.920	0.908	0.885
Test	*Accuracy*	0.711	0.737	0.737	0.658
	Precision	0.710	0.749	0.737	0.653
	Recall	0.711	0.737	0.737	0.658
	F1 _Score	0.703	0.733	0.735	0.634
All	*Accuracy*	0.840	0.864	0.856	0.816
	Precision	0.841	0.869	0.857	0.818
	Recall	0.840	0.864	0.856	0.816
	F1 _Score	0.840	0.864	0.856	0.815

Table II presents a comprehensive performance evaluation of four individual and hybrid models across different conditions and metrics. The evaluation leverages four grading criteria (Poor, Acceptable, Good, Excellent) and three key metrics (Precision, Recall, F1-score) to compare model performance comprehensively. Interestingly, both XGBE and XGBC models exhibit peak precision in the "Poor" condition, while both XGGT and XGSO models share the second-best performance. However, under the "Acceptable" condition, XGBE takes the lead in precision, with XGBC exhibiting the weakest performance.



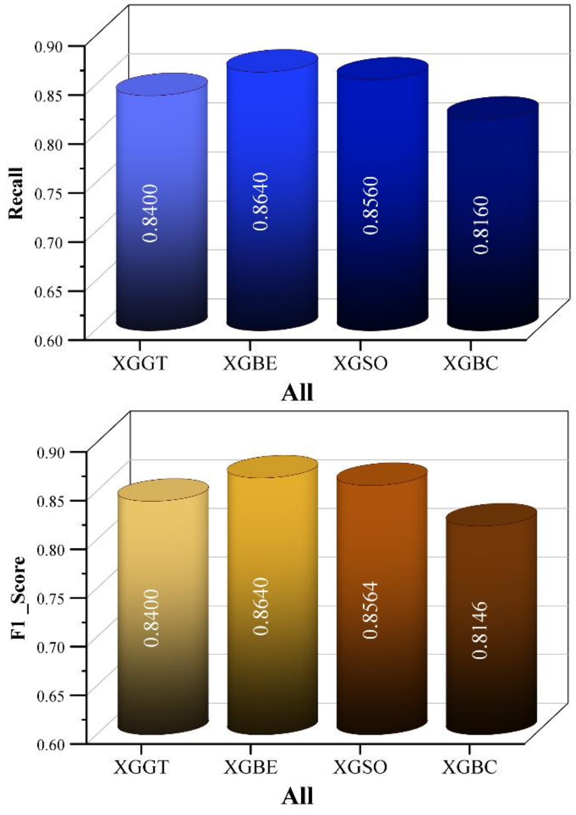


Fig. 6. A 3D bar plot indicating the difference between the measured and predicted values.

This detailed analysis, presented in Table II, allows for a thorough understanding of how different models perform under varying conditions and based on crucial evaluation metrics.

In Recall value at Good condition, three of the models have the same and the best performance. The XGGT, XGBE, XGSO, and XGBC models have the lowest and weakest performance. In excellent condition at the Recall value, the XGBE, XGSO, and XGBC have the highest performance, and the XGGT model has the weakest performance.

TABLE II. MODELS ACHIEVED RESULTS IN THE DIFFERENT PRESENTED CONDITIONS

Metric	Condition	Model			
		XGGT	*XGBE*	*XGSO*	*XGBC*
precision	Poor	0.857	0.923	0.857	0.923
	Acceptable	0.857	0.896	0.840	0.774
	Good	0.850	0.872	0.810	0.811
	Excellent	0.773	0.760	1.000	0.864
recall	Poor	0.800	0.800	0.800	0.800
	Acceptable	0.875	0.896	0.875	0.854
	Good	0.810	0.810	0.810	0.714
	Excellent	0.850	0.950	0.950	0.950
f1-Score	Poor	0.828	0.857	0.828	0.857
	Acceptable	0.866	0.896	0.857	0.812
	Good	0.829	0.840	0.810	0.760
	Excellent	0.810	0.844	0.974	0.905

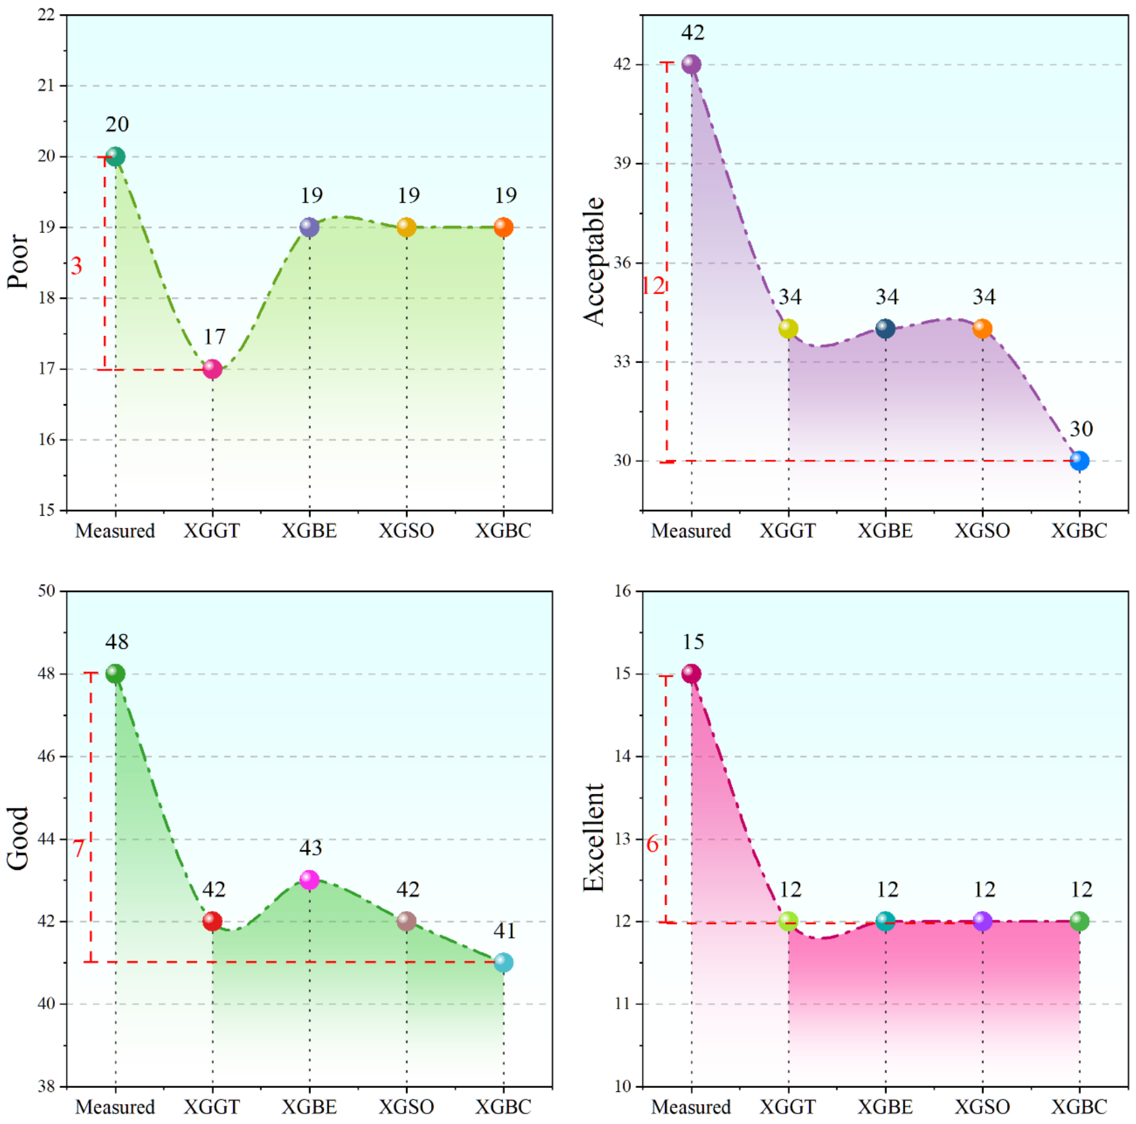

Fig. 7. Line-symbol plot for the visual evaluation of the models' performance.

Fig. 7 presents a line-symbol plot visualizing the performance of different models under varying conditions. In this plot, smaller differences between a model's prediction and the actual measured value indicate better performance for that specific condition.

Acceptable Condition: With a measured value of 42, three models – XGGT, XGBE, and XGSO – exhibited predictions close to the actual value, indicating strong performance in this condition.

Good Condition: For the measured value of 48, XGBE outperformed the others with the closest prediction. Both XGGT and XGSO also predicted close to the measured value, demonstrating good performance.

Excellent Condition: All models achieved the same prediction and performance for the measured value of 15 in this condition.

Fig. 8 presents confusion matrices to evaluate the accuracy of each model across various conditions. For example, in the Poor condition, the XGGT model accurately predicted 17 out of 20 samples, achieving an 85% accuracy rate. Notably, all misclassified samples belonged to the Acceptable category (3 samples). Similarly, in the Acceptable condition, the XGGT model maintained good performance, correctly classifying 34 out of 42 samples (81% accuracy). However, misclassifications occurred in both the Good (5 samples) and Poor (3 samples) categories.

In the evaluation of predictive models, the XGBE model exhibited commendable performance. Among the 48 items categorized as being in Good condition, the XGBE model accurately predicted 43 of them while misclassifying five. Notably, two of the misclassified items were erroneously labeled as Poor condition, two as Acceptable condition, and one as Excellent condition. Moreover, when assessing the 15 items categorized as Excellent condition, the XGBE model demonstrated substantial predictive accuracy by correctly identifying 12 of them. However, it did misclassify three items, with two categorized as Acceptable condition and one as Poor condition. Furthermore, in the assessment of 48 items initially classified as Good condition, the XGSO model accurately predicted 42 of them. However, it misclassified six items, with five categorized as Acceptable condition and one as Excellent condition.

Fig. 9 depicts the Receiver Operating Characteristic (ROC) curves generated to assess the effectiveness of the most proficient hybrid models. The ROC curve serves as a widely utilized visual aid for evaluating a model's performance and illustrating the balance between sensitivity and specificity in binary classification tasks. Sensitivity, also known as the true positive rate or recall, gauges a model's ability to detect positive cases accurately. Conversely, specificity denotes the true negative rate and indicates how well the model can identify negative cases. The ROC curve plots the true positive rate against the false positive rate at various thresholds for the assessed probabilities of the model.

Fig. 9 unmistakably illustrates that the XGBE model exhibits the highest and most consistent performance in identifying cases classified as Poor. It consistently achieves the highest true positive rate (TPR) while maintaining the lowest false positive rate (FPR), underscoring its reliability.

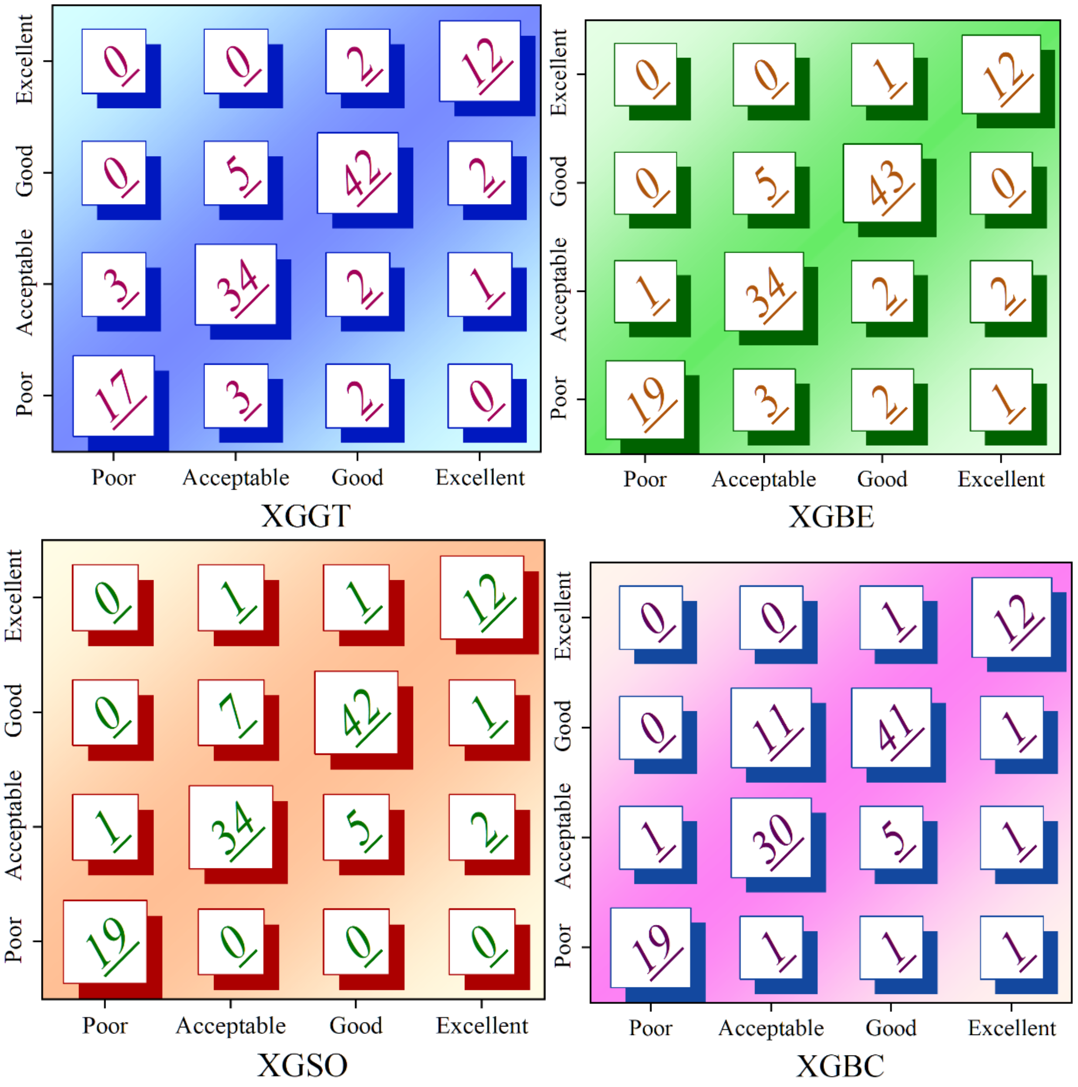

Fig. 8. Confusion matrix for the correctly classified and misclassified values of the models.

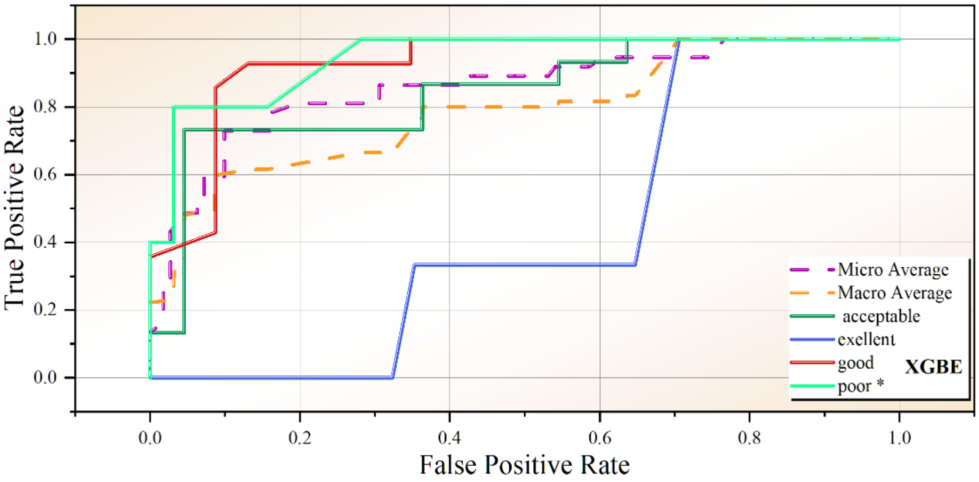

Fig. 9. Line plot for the ROC curve of the best-performed hybrid model.

V. Discussion

A. Limitations of the Study

The study acknowledges several limitations, including the possibility that the dataset used may not fully capture all relevant variables influencing academic performance, suggesting the presence of unmeasured factors. While the predictive models showed promising accuracy, there remains room for improvement, as alternative optimization techniques not explored could enhance performance. Additionally, the generalizability of the findings may be limited to the specific context and population studied, meaning the results might not apply to different educational settings or student groups. These limitations highlight areas for further research and potential enhancements in future studies.

B. Implications of the Study

The study's implications and significances are notable in several areas. Firstly, it underscores the importance of time management skills in predicting academic performance, highlighting a previously underexplored factor in educational outcomes. By integrating ML models with data from the TSQ, the research offers a novel approach to understanding and forecasting student success. The findings suggest that educational institutions can leverage these models to identify at-risk students early, allowing for timely interventions that could reduce dropout rates and foster a more supportive learning environment. Furthermore, the study demonstrates the effectiveness of using advanced optimization algorithms, such as the Bald Eagle Optimizer, in enhancing model accuracy, thereby contributing to the broader field of educational data mining and predictive analytics. These insights pave the way for future research and the development of more comprehensive and accurate predictive tools in education.

C. Future Works

Future work in predicting academic performance using ML and time management skills could explore incorporating a broader range of variables, such as psychological factors and extracurricular activities, to create more comprehensive models. Researchers could experiment with additional optimization techniques to improve model accuracy and conduct longitudinal studies to track performance over time. Validating these models across diverse educational settings and student populations would help assess their generalizability. Developing and evaluating intervention strategies based on these models could enhance their practical utility, while integrating them into real-world educational systems could support timely interventions and reduce dropout rates. Additionally, creating user-friendly tools for educators and addressing ethical considerations related to privacy and data security will be crucial for the responsible implementation of these technologies.

VI. Conclusion

The investigation into predicting academic students' performance has yielded valuable new insights into the intricate interplay among the myriad factors influencing educational outcomes. These factors encompass socioeconomic backgrounds, study habits, and prior academic achievements. A comprehensive examination of these factors has helped elucidate these relationships. Furthermore, this study has concentrated on analyzing a dataset that encompasses students' time management skills and their influence on academic performance. Despite the valuable insights gained, it is important to acknowledge some limitations of this study. Firstly, the dataset used may not fully capture all relevant variables influencing academic performance, and there may be other unmeasured factors at play. Additionally, the predictive models developed in this study, while demonstrating promising accuracy in forecasting academic performance, may still have room for improvement. The integration of three optimizers (BESO, SAO, and GTO) with the base model XGBoost Classifier (XGBC) aimed to enhance performance, but there could be alternative optimization techniques that were not explored. Moreover, the generalizability of the findings may be limited to the specific context and population studied. Despite these limitations, as the education sector evolves, there is a clear opportunity to integrate these models into school systems to identify at-risk students early and provide them with timely support. Such proactive measures can significantly reduce dropout rates and foster a more supportive learning environment. The models underwent differentiation across various stages, scenarios, and metrics. Among them, the XGBoost with Bald Eagle Optimizer (XGBE) emerges as particularly robust in this analysis compared to the XGBoost with Giant trevally Optimizer (XGGT), XGBoost with Seagull Optimization Algorithm (XGSO), and XGBoost Classifier (XGBC) models. The XGBE model demonstrated superior performance, boasting high precision and accuracy values of 0.920 and 0.923, respectively, during the training phase, surpassing both the XGSO, XGGT, and XGBC models.

Deep Hybrid Learning Approaches for COVID-19 Virus Detection Using Chest X-ray Images

Mansor Alohali
Applied College, Imam Mohammad Ibn Saud Islamic University (IMSIU), Riyadh, Saudi Arabia

***Abstract*—This paper introduces a novel deep learning framework for highly accurate COVID-19 detection using chest X-ray images. The proposed model tackles the challenge by combining stacked Convolutional Neural Network models for superior feature extraction to potentially enhance interpretability. The proposed model achieved a high accuracy in distinguishing COVID-19 from healthy cases. The study demonstrates the potential of deep hybrid learning for accurate COVID-19 detection, paving the way for its application in real-world settings. Future research directions could explore methods to further refine the model's capabilities. Overall, this work contributes significantly to the development of robust deep-learning methods for COVID-19 detection with the potential for broader use in medical image analysis.**

Keywords—COVID-19 detection; deep learning; deep hybrid learning; chest X-ray analysis; machine learning classifiers; medical image analysis; convolutional networks

I. Introduction

The emergence of Severe Acute Respiratory Syndrome Coronavirus 2 (SARS-CoV-2) in 2019, causing the highly contagious COVID-19 disease, significantly impacted global health [1]. Coronaviruses, like SARS-CoV-2, cause respiratory illnesses ranging from mild to severe. COVID-19 primarily affects the respiratory system, with common symptoms including fever, cough, fatigue, and shortness of breath. To control the spread of the virus, preventative measures like social distancing and mask-wearing were implemented [2].

Polymerase Chain Reaction (PCR) testing is the standard method for diagnosing COVID-19, but it can be time-consuming and have limitations in accuracy. X-rays, a well-established imaging modality, offer a more accurate alternative for detection. X-ray imaging is used to assess the extent of lung infection, guide treatment decisions, and monitor patients after hospitalization [3]. In addition, recent advancements in technology allow for faster and potentially accurate diagnosis of COVID-19 using chest X-rays, compared to traditional methods.

This work proposes Deep Learning (DL) models for COVID-19 detection using chest X-rays, addressing the limitations of PCR testing by enabling faster diagnosis. DL models have shown good performance in image analysis tasks compared to traditional methods [4]. We propose a novel framework, Deep Hybrid Learning (DHL1) that leverages DL for feature extraction from X-ray images. This framework utilizes stacked Convolutional Neural Network (CNN) models to generate informative feature spaces, which are then fed into separate classifiers for COVID-19 diagnosis. Additionally, we propose a separate RENet model that employs region-based and edge-based operations to extract features. The RENet model incorporates transfer learning (TL) to further enhance COVID-19 detection accuracy. The obtained results of our suggested DHL1 model are promising.

This paper is structured as follows. Section II reviews existing COVID-19 detection methods. Section III describes our proposed schemes for COVID-19 detection in detail. Section IV discusses the experimental setup used to evaluate our methods. The results of these experiments are presented and analyzed in Section V. Finally, Section VI concludes the paper by summarizing the key findings and outlining potential future directions.

II. Background

Since the emergence of COVID-19, researchers have actively sought effective detection methods. Therefore, several researchers have examined well-established CNNs that have shown promise in the detection of COVID-19 using X-ray images such as Xception (e.g., [5], inception (e.g., [6] GoogleNet (e.g. [7]. Researchers employed TL which has been suggested to accomplish this task [8, 9].

Overall, several Artificial intelligence (AI) driven detection methods have been utilized in the detection of Covid-19, supervised learning-based, deep learning-based, active learning based, transfer learning-based, and evolutionary learning-based mechanisms [4]. TL is emerging as a dominant paradigm in the realm of medical image analysis for COVID-19 detection [10]. This approach leverages pre-trained CNN models, honed on vast natural image datasets and adapts them for the specific task of COVID-19 classification in medical images, such as chest X-rays and CT scans [10]. This strategy capitalizes on the pre-existing feature extraction capabilities learned from natural images, promoting faster convergence and improved generalization on the often-limited medical image datasets [4].

For example, Researchers such as [11] created their COVID-Net model for the purpose of detecting cases infected with COVID-19 employing X-ray images, their model attained a high percent accuracy and sensitivity. Similarly, Afshar et al. proposed the COVID-CAPS model that reached a 98 percent accuracy and a detection rate of 80 percent [12].

Nevertheless, the above-described models could have a poor detection rate due to a shortage of COVID-19 collected and labeled datasets [13]. Accordingly, TL is now being implemented in the latest models and adjusted on an issue-specific chest X-ray dataset [14]. For instance, a cutting-edge inception model based on TL was used for screening COVID-

19 while having a low accuracy of 89.5 percent [15]. Similarly, a pre-trained ResNet-50 CNN was used mostly on small numbers of instances, and it attained a 98 percent accuracy [16].

Several researchers used approaches that are based on existent CNNs to detect COVID-19 in suspected cases, namely ResNet18 (e.g., [17], DensNet201 (e.g., [18], and squeezeNet [19]. The aforementioned models were fine-tuned on the "COVID-Xray-5k" dataset employing TL and achieved an accuracy of 98 percent [16]. Each of these models was implemented on a SoftMax (SM) classifier in order to screen COVID-19 subjects. Therefore, these models have utilized the merits of empirical risk minimization (ERM).

Likewise, DHL optimized COVID-19 detection function by employing ERM and structural minimization merits [20]. In these related research [21], the features have been generated from the existent Residual Network-50 (ResNet-50) CNN model and then subsequently fed into the ML classifier. The proposed DBHL framework attained a 95 percent detection accuracy [21]. Also, deep features, derived from the pre-trained ResNet-152, that was fine-tuned, have been extracted and then fed into ML classifiers [22]. Accordingly, COVID-19 detection utilizing the eXtreme Gradient Boost (XGBoost) and Random Forest classifiers obtained 97.3 percent and 97.7 per cent accuracy, correspondingly [24]. Despite advancements, existing methods face some key limitations:

First, Existent CNN models were mostly used on a significantly small chest X-ray dataset. This impairs these models' reliability on larger real-life datasets.

Second, these models have all been particularly created for natural images and fine-tuned for the detection of COVID-19. However, chest X-ray images of COVID-19-infected patients are distinguished from natural images by a distinct pattern and texture. Natural images are often big, basic in composition, and unique from one another [23]. COVID-19 viral infection, on the other hand, manifests a distinct pattern and texture, and its severity differs amongst patients. Indeed, the subject having COVID-19 chest infections exhibits reticulation, ground-glass opacity, and consolidation patterns [25]. Therefore, this paper aims to address the limitations of the previous Covid-19 detection DL model to improve their ability to detect Covid-19 cases accurately and effectively.

The remainder of this paper proceeds as follows: the schemes for the detection of COVID-19 are explicated in depth in Section III. The experimental setup is discussed inSection IV. Then, Section V describes the results, and finally, Section VI concludes this research.

III. Suggested COVID-19 Detection Scheme

The present study proposes a novel DL scheme for detecting COVID-19. Our proposal is named DHL approach that aims to detect COVID-19 virus in chest X-ray images (DHL_Covid19). As illustrated in Fig. 1, this proposed scheme consists of four modules: (1) data preprocessing, (2) feature extraction, (3) models training, and (4) the test of the models using the test dataset. Our proposal is based on deep CNN and ML techniques, and it employs three distinct experimental set-ups. Training instances are augmented during experimentation to ameliorate the models' performance. The aforementioned augmented training instances are used to perform the training of the suggested techniques. Fig. 1 depicts the workflow of the schemes for COVID-19 detection.

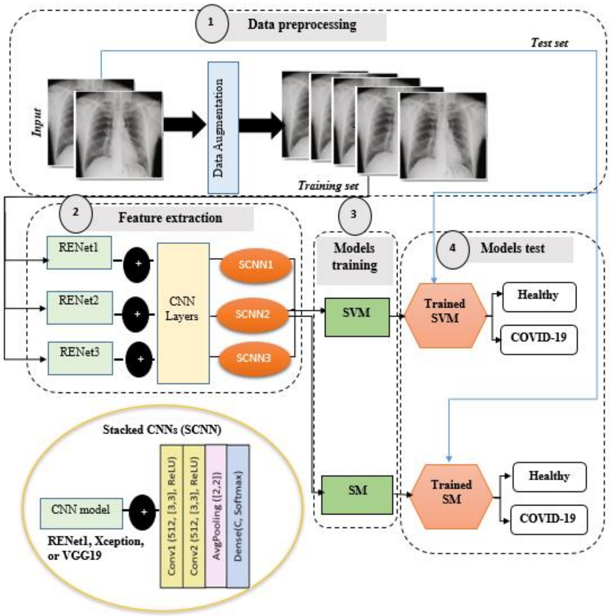

Fig. 1. DHL Covid-19 scheme.

Before exploring the COVID-19 dataset for healthy and COVID-19 classes extraction, the used dataset has to be preprocessed in order to obtain adequate input for the next module. As explained in the following section, this module aims to augment the employed data to ameliorate the ML models' performance.

A. Data Pre-processing

CNN architectures are well-known for their tendency to overfit with limited training data [26]. Large datasets are beneficial for training complex models and improving their performance. One approach to address limited data is data augmentation, a method that expands the number of training samples by applying various transformations to existing data [27]. Table I shows some of the alterations included in our data augmentation method. These transformations, such as rotation, reflection, and scaling, help the model become more robust to slight variations in the input data, mimicking real-world scenarios the model might encounter during deployment. The employed augmentation strategy involves the following operations:

- Rotation: rotate the data with (0,360) degrees.
- Scaling: scale the data with (0.5,1).
- Reflection: reflect the data with X and Y in (-1,1).

TABLE I. DEFINED HYPER-PARAMETERS

Hyper-parameter	Optimizer	Momentum	Learning rate	Weight decay	Loss	Activation function	Epoch	Batch size
value	SGDM	0.95	0.0001	0.0005	Cross-entropy	ReLU	20	16

B. COVID-19 Detection Approaches

In this paper, we propose several experimental frameworks for COVID-19 virus detection using DL. We introduce a novel DHL approach. Here, the deep feature learning potential of the three improved models, RENet1, Xception, and VGG-19, was improved by adding CNN layers. These models incorporate additional CNN layers within modules named stacked CNNs (SCNN1, SCNN2, and SCNN3). The proposed frameworks, DHL1 utilize these SCNN modules separately. DHL1 employs a Support Vector Machine (SVM) classifier, then it is enhanced by utilizing SM classifier for COVID-19 patient diagnosis. Finally, the RENet models are trained using two approaches, from scratch and with TL on chest X-ray datasets.

1) Suggested DHL frameworks: Three well-established CNNs are developed in the present study, namely RENet1, RENet2, and RENet3. In order to ameliorate the feature extraction methods, we proposed to modify the CNN sub-modules and add CNN layers to each one, named Stacked CNNs. Accordingly, three deep feature spaces are generated from these sub-models. Then, they are eventually fed into the SVM, and the SM classifiers as illustrated in Fig. 2. Edge-based and Region-based operations are used methodically in the sub-models to make use of region homogeneity and boundary-related features. Accordingly, we use the average pooling operator and max pooling operator, interlacing convolution operations systematically to achieve efficient learning of the COVID-19 discriminative patterns [29].

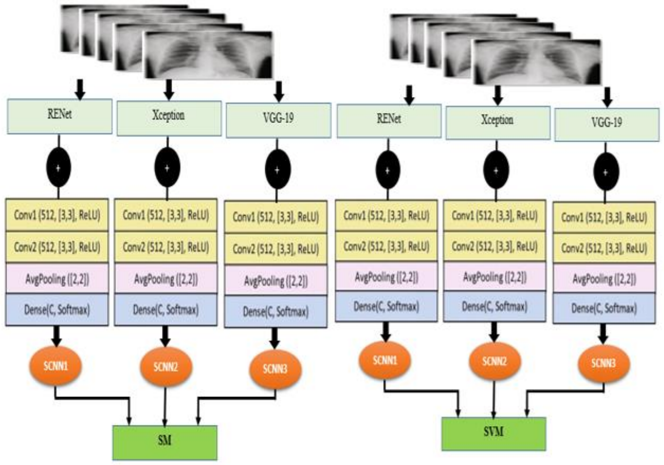

Fig. 2. DHL approach for COVID-19 virus detection.

C. Stacked CNNs (SCNNs)

This work proposes three modifications to established CNN architectures (RENet1, Xception, and VGG-19), named Stacked CNNs (SCNNs). As shown in Fig. 2, the outputs of these SCNNs serve as input for the classifiers. The performance of these classifiers heavily relies on the quality and quantity of extracted features for COVID-19 detection.

The proposed RENet models consist of three feature extraction blocks, each containing ReLU activation functions and convolutional layers. This design leverages spatial correlations by addressing non-linearities in the dataset. To create the SCNNs, we removed the top layers of the base CNNs and added new layers to generate new architectures. Our proposed architecture at the top of the network includes two CNN layers with ReLU activation, a Global Average Pooling layer, a fully connected layer, and a SM layer.

We utilize a deep hybrid learning approach that combines the benefits of ERM and structural risk minimization (SRM) principles to improve COVID-19 detection performance. CNNs excel at learning by minimizing training loss through ERM, which can lead to overfitting [30, 31]. However, SVMs are robust machine learning classifiers known for good classification accuracy. They achieve this by reducing structural risk factors, promoting generalization through widening the margin between classes [32]. In addition to the SVM, we also employ a SM classifier for COVID-19 virus detection. Therefore, our proposed DHL frameworks leverage SCNNs for feature extraction and utilize both SVM and SM classifiers.

2) Detection models' training scheme: Training the proposed SCNN model utilizes chest X-ray data. While the model's parameters are randomly initialized with a uniform distribution, deep CNNs generally require substantial amounts of data for optimal performance. Limited X-ray samples can hinder convergence and consequently impact COVID-19 detection accuracy [30, 31]. To address this challenge, we leverage TL to improve detection performance [34].

TL involves transferring the parameters of pre-trained convolutional layers from a large dataset (e.g., ImageNet) to the target COVID-19 X-ray dataset. This pre-training helps initialize the SCNN parameters effectively. In our hybrid framework, the convolutional layers of the developed TL-based models (RENet1, VGG-19, and Xception) extract COVID-19 image bottleneck features. These features are then fed into the SVM and SM classifiers for training.

IV. EXPERIMENTATIONS

A. Used Dataset

The study presents a chest X-ray dataset encompassing healthy individuals and COVID-19 patients. The new dataset was created by gathering the publicly available X-ray images from repositories like GitHub and Kaggle, which were labeled by radiologists [33-35]. These repositories provide a diverse collection of X-ray images originating from various geographic locations, medical centers, and X-ray equipment. Consequently, the images exhibit variations in patient positions, orientations, and acquisition techniques due to the differences in source institutions and detector panels. As illustrated in Fig. 3, our approach meticulously filters both COVID-19 and healthy instances from these repositories. To ensure balanced representation, we created a dataset containing 3224 X-ray images each from COVID-19 positive and healthy individuals. These images were originally of various dimensions and have all been preprocessed to a uniform size of 224 x 224 pixels.

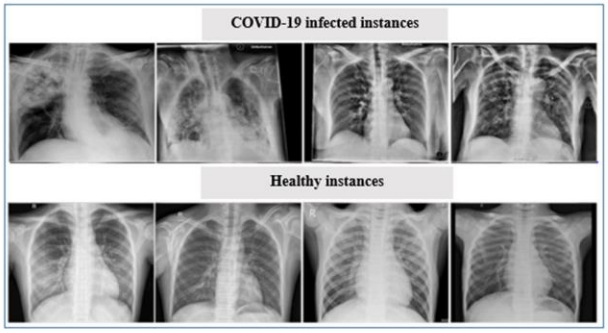

Fig. 3. Dataset instances.

B. Experimentation Process

We employed a hold-out cross-validation approach, splitting the data into an 80% training set (4126 images) and a 20% testing set (1290 images). To address potential class imbalances, stratified sampling was used during the split. The training set was further divided into an 80% inner training set and a 20% validation set (1032 images) for hyperparameter tuning. The CNN models were trained on the inner training set with the optimized.

For evaluating the performance of COVID-19 detection models, we employed conventional metrics including Accuracy (Acc), Sensitivity (Se) or Recall (R), Specificity (Sp), Precision (P), and F1-Score. While accuracy reflects the overall correct predictions, it can be misleading in imbalanced datasets like COVID-19. Therefore, we placed more emphasis on sensitivity and specificity. Sensitivity indicates the model's ability to correctly identify individuals with COVID-19 (low false negative rate), which is crucial to prevent undetected cases. Specificity reflects the model's accuracy in classifying healthy individuals without COVID-19 (low false positive rate), minimizing unnecessary treatments or interventions. The following Equations present the mathematical definitions of these metrics.

Eq. (1), represents accuracy measurement.

$$\mathrm{ACC} = \frac{\mathrm{Detected\ Covid} - 19\ -\ \mathrm{Detected\ Healthy}}{\mathrm{Total}} \times 100$$

Sensitivity is measured using Eq. (2).

$$Sensitivity = \frac{Detected\ Covid - 19}{Total\ Covid - 19} \times 100$$

Specificity metric is measured using Eq. (3).

$$Specifictiy = \frac{Detected\ Healthy}{Total\ Healthy} \times 100$$

Eq. (4) demonstrates the precision.

$$Precision = \frac{Detected\ Covid - 19}{Detected\ Covid - 19\ +\ Wrongly\ Detected\ Covid - 19} \times 100$$

Eq. (5) illustrates the F-score.

$$F - Score = 2 \times \frac{Precision \times Recall}{Precision + Recall} \times 100$$

V. Result and Discussion

In the present paper, a new deep learning-based framework, which is named DHL1, is suggested for detecting COVID-19 using chest X-ray images. As highlighted in Table II. The proposed DHL models achieved high performance in COVID-19 detection using chest X-rays, with all models exceeding 98% accuracy across various metrics. SCNN1-based SVM stood out with the highest sensitivity (99.13%), demonstrating its strength in correctly identifying COVID-19 cases. Conversely, SCNN2-based SVM excelled in specificity (98.00%), minimizing false positives among healthy individuals. For a balanced performance between these two aspects, SCNN1-based SVM achieved the best F1-score (98.56). Overall, these findings highlight the potential of our proposed DHL models for accurate COVID-19 detection with chest X-rays, paving the way for further research on larger and more diverse datasets.

TABLE II. DHLs Performance

	ACC	Se	Sp	P	F1-Score
SCNN1-based SVM	98.33	99.13	98	98	98.56
SCNN2-based SVM	98.19	98.55	97	97	97.79
SCNN3-based SVM	98.26	98.52	97	97	97.75
SCNN1-based SM	98.15	98	98	98	98
SCNN2-based SM	98	97	98	98	97.49
SCNN3-based SM	98.07	97	97	97	97

Many researchers have leveraged DL for robust COVID-19 detection. This study contributes to the growing body of research exploring deep learning techniques for COVID-19 detection in chest X-rays. Our proposed CNN-SVM combination (DHL1) achieved superior performance and potentially addressed limitations observed in some prior works.

Similar to previous studies employing DL for this task [28-36], we leverage the powerful feature extraction capabilities of CNNs. However, we move beyond solely relying on CNNs, which can be susceptible to over-fitting or lack interpretability. We integrate SVMs known for strong generalization ability and potential for improved model interpretability. This combined approach achieved high accuracy and offer insights into the features most discriminative for COVID-19 detection.

Our proposed DHL1 framework extracts deep features from well-established CNN architectures like VGG-19, ResNet-1, and Xception, similar to approaches used by [37], As observed in Table II, DHL1 demonstrates high performance in differentiating COVID-19 from healthy cases.

This combined CNN-SVM approach showcases very competitive performance compared to methods using only CNNs, potentially exceeding the accuracy reported in some prior studies (e.g., [38]). Furthermore, utilizing well-established CNNs provides a solid foundation for feature extraction, building upon their proven effectiveness in image recognition tasks.

The high classification accuracy achieved by DHL1 is particularly promising, especially if the model generalizes well to new data. However, as with some previous works (e.g., [39]). Further validation on larger and more diverse datasets is necessary to ensure the generalizability of our findings and mitigate the potential for overfitting.

Our proposed CNN-SVM approach (DHL1) achieves an accuracy of 98% on our dataset, higher than the 94% accuracy reported by [40]. However, DHL1 also achieves a higher sensitivity (0.98 vs. 0.92) and a comparable specificity (0.97 vs. 0.87), indicating a better balance between precision and recall. This suggests that DHL1 might be less susceptible to misclassification. Furthermore, unlike other researchers such as [41, 42] which focused on binary classification, our approach can be extended to handle multi-class scenarios with additional diseases.

An alternative approach to DL for COVID-19 detection involves TL, where pre-trained models are adapted for the specific task. Several studies in this field explore this technique [43]. Transfer learning offers a balance between accuracy and efficiency by leveraging the power of existing models like VGG-16 or ResNet-18. While chest X-rays are the most common image type used, with studies aiming for multi-class detection (normal, COVID-19, other lung issues), some research also investigates CT scans or ultrasounds with varying classification goals (binary or multi-class). The reported accuracy for transfer learning approaches varies, with some achieving impressive results exceeding 95% (e.g., [44, 45].

While there are a number of AI image detection methods used by researchers to detect Covid-19. Using an individual approach could be challenging as each model has its advantages and disadvantages. For, example, using VGG-16 could lead to faster training time and improved accuracy, but it may be suboptimal for medical images as it is trained on natural images, and it might not be suited for the specific patterns and textures seen in medical images [46].

Our study shows how multiple approaches could be utilized to solve a problem and overcome the limitations of other single approach models. Our CNN-SVM approach (DHL1) offers several potential advantages over other TL techniques. Firstly, it allows for more flexibility in feature extraction by leveraging the power of multiple CNN architectures (VGG-19, ResNet-1, Xception) compared to relying on a single pre-trained model. Secondly, the integration of SVMs potentially improves interpretability, offering insights into the features most discriminative for COVID-19 detection.

However, it's important to acknowledge that both approaches have merit. TL can be a good choice when computational resources or dataset size are limited. Further research is needed to comprehensively compare the performance and generalizability of CNN-SVM combinations like DHL1 against other TL techniques across various datasets and tasks.

VI. Limitations and Future Studies

To prevent the COVID-19 spread, patients must be identified quickly and early. The present paper suggests a new framework, DHL1, for detecting COVID-19 in chest X-ray images successfully. For the purpose of detecting COVID-19 accurately, three stacked CNN models, namely SCNN1, SCNN2, and SCNN3 were adopted for feature extraction. The experimental findings illustrate that our suggested DHL1 framework out-performs existing well-established CNNs combined with the SM classifier.

This study has presented promising deep learning frameworks, DHL1, for COVID-19 detection using chest X-rays. However, to ensure their real-world applicability and further refine their capabilities, it's important to address some limitations and explore future research directions.

One key limitation lies in the generalizability of the findings. The models were evaluated on a relatively limited dataset. To ensure they perform well on unseen data and mitigate potential overfitting, validation on larger and more diverse datasets from various institutions is necessary. Additionally, the dataset used in this study might not perfectly reflect the true prevalence of COVID-19 cases in the real world. Future work could investigate the impact of class imbalance on model performance and explore techniques to address any potential biases arising from imbalanced datasets.

While DHL1 integrates SVMs with the potential for improved interpretability, this aspect requires further investigation. Future work could involve analyzing the SVM weights or decision boundaries to understand the specific features most discriminative for COVID-19 detection. This would not only enhance our understanding of the model's decision-making process but also potentially lead to the development of more interpretable AI models in healthcare.

The current study focused on differentiating between COVID-19 and healthy individuals. Future researchers could extend the models to handle multi-class scenarios, allowing them to distinguish COVID-19 from other lung pathologies. Additionally, collaborations with hospitals or medical institutions could enable testing the models on real-world clinical data. This external validation would provide valuable insights into the practical applicability of these models in a clinical setting.

Furthermore, exploring techniques for optimizing the models for computational efficiency is important. This could involve reducing the computational resources required for training and inference. Such optimizations would be particularly relevant for deploying these models in resource-constrained settings with limited computing power. Finally, a comprehensive comparison between DHL1 and other TL approaches on various datasets and tasks would be valuable. This comparison would provide insights into their relative strengths and weaknesses, guiding the selection of the most suitable approach for different scenarios.

By addressing these limitations and pursuing the suggested future work directions, this research can significantly contribute to the development of robust and reliable deep learning methods for COVID-19 detection and potentially pave the way for their application in other medical image analysis tasks.

Having Deep Investigation on Predicting Unconfined Compressive Strength by Decision Tree in Hybrid and Individual Approaches

Qingqing Zhang, Lei Wang*, Hongmei Gu
Information Technology and Cultural Management Institute,
Hebei Institute of Communications, Shijiazhuang 051430, Hebei, China

***Abstract*—In the field of geotechnical engineering Rocks' unconfined compressive strength (UCS) is an important variable that plays a significant part in civil engineering projects like foundation design, mining, and tunneling. These projects' stability and safety depend on how accurately UCS predicts the future. In this study, machine learning (ML) techniques are applied to forecast UCS for soil-stabilizer combinations. This study aims to build complex and highly accurate predictive models using the robust Decision Tree (DT) as a primary ML tool. These models show relationships between UCS considering a variety of intrinsic soil properties, including dispersion, plasticity, linear particle size shrinkage, and the kind of and number of stabilizing additives. Furthermore, this paper integrates two meta-heuristic algorithms: the Population-based vortex search algorithm (PVS) and the Arithmetic optimizer algorithm (AOA) to enhance the precision of models. These algorithms work in tandem to bolster the accuracy of predictive models. This study has subjected models to rigorous validation by analyzing UCS samples from different soil types, drawing from historical stabilization test results. This study unveils three noteworthy models: DTAO, DTPB, and an independent DT model. Each model provides invaluable insights that support the meticulous projection of UCS for soil-stabilizer blends. Notably, the DTAO model stands out with exceptional performance metrics. With an R^2 value of 0.998 and an impressively low RMSE of 1.242, it showcases precision and reliability. These findings not only underscore the accuracy of the DTAO model but also emphasize its effectiveness in predicting soil stabilization outcomes.**

Keywords—Unconfined compressive strength; machine learning; decision tree; population-based vortex search algorithm; arithmetic optimizer algorithm

I. Introduction

Geotechnical Engineering (GE) is no exception to the widespread adoption of ML techniques in several industries. Applications of ML at GE cover a broad variety of responsibilities, from landslip from detection to prediction of material properties. Creating predictive models for GE issues has demonstrated astounding success and cutting-edge technology. It is becoming increasingly clear that there is a growing need for more accurate predictive models to address various geotechnical challenges in various domains. Continuous improvement and advancement are necessary to enable the wide-scale adoption of such models, providing more precise and practical answers to various geotechnical problems [1], [2], [3].

Compaction of loose soils is a critical component of engineering projects because it increases the weight per unit area of engineering structures like earth dams and highway embankments. This compaction process improves soil endurance, boosts load-bearing capacity, and stabilizes embankment slopes to prevent settlement problems, going beyond merely increasing soil strength [4], [5]. Additionally, compaction has various advantages, including increases in density, volume, permeability, waterproofing, and porosity. Together, these improvements raise the soil's general quality and increase its capacity to support structural loads. UCS is a critical component of geomechanical modeling, particularly in investigating mechanical rock behavior [6]. The ultimate compressive stress, or UCS, that a rock can withstand when subjected to controlled, uniaxial loading before undergoing failure. Rock mechanics, which combines theoretical concepts with real-world applications, illuminates how rocks respond to various stress situations [7], [8]. In areas like the production of solid materials and wellbore stability, particularly in the petroleum operations context, the effects of rock failure have wide-ranging effects. In drilling operations, guiding bit hydraulics, determining the ideal mud weight, controlling costs, and improving drilling efficiency overall, the availability of UCS data from subsurface formations is of utmost importance [9], [10], [11]. Due to its crucial role in resolving geotechnical issues, the assessment of UCS is a fundamental pillar in rock engineering [12]. Direct UCS measurement is performed using the Unconfined Compression Test (UCT), a standardised procedure that has the support of both the American Society for Testing and Substances ($ASTM$) and the International Society for Rock Mechanics ($ISRM$) [13]. However, performing UCS tests in a lab requires carefully prepared core samples in addition to time and resources. When collaborating with brittle, thinly bedded, or severely fractured rock formations, it can be challenging to meet these requirements. Many researchers recommend indirect approaches for UCS prediction in response to these difficulties. These techniques, which include the Brazilian tensile strength test (BTS), the point load index test ($Is(50)$), and the ultrasonic test (Vp), provide quick, affordable, and transportable substitutes for UCS testing. Combined with engineering knowledge, these correlated index tests offer applicable initial UCS evaluations. Direct mechanical rock property evaluation is based on experiments performed on extracted core samples, which offer insights into actual stress conditions and mechanical characteristics. These tests use various techniques, including point load tests, scratch tests, Schmidt hammer tests, and uniaxial and triaxial compressive strength tests. Together, these methods create the benchmark for identifying property [14], [15], [16]. To secure representative core samples, however, obtaining a continuous UCS profile along wellbores presents difficulties that include high costs and labor-intensive procedures. Indirect approaches have been developed to get around this restriction, bridging the gap by proving relationships between petrophysical well-log data and rock characteristics. UCS has significantly impacted foundation design, slope stability analysis, and structural integrity. Its significance extends beyond rocks to encompass a variety of materials, including industrial wastes and soils. In stabilized materials, UCS is crucial, impacting both the aesthetics and performance of pavements [17]. However, determining a material's UCS requires takconsidering several factors, including physicochemical characteristics, the kind of cementitious admixtures used, and curing time. These factors call for carefully thought-out laboratory experiments and specialized tools. The pursuit of accuracy, reflected in the specimens' sizes, makes these tests reliable [18], [19].

This study centers around predicting critical soil properties, precisely the UCS outcomes, using a ML approach. Given the challenges in obtaining experimental data, this study focuses on improving the DT algorithm's performance. To overcome this challenge, a combination of two algorithms is employed, including the PVS and the AOA. The research highlights the significant positive impact of optimizing the planning and building of UCS buildings for the infrastructure industry. Through the compilation of a large-scale UCS dataset, this study enables comparison analyses to evaluate the efficacy of the suggested framework. The study's conclusions provide useful insights into accurately predicting UCS in civil engineering projects. This approach revolves around forecasting UCS by incorporating the DT algorithm into the ML strategy. This addresses the complexity of acquiring empirical UCS data by optimizing the DT model's parameters through the integration of PVS and AOA algorithms. In essence, this research provides practical guidance and essential information for tackling UCS prediction, a crucial aspect of soil behavior in civil engineering.

II. Literature Review

The aforementioned challenges with the fundamental sample preparation required for standard testing and the limitations of statistical models may be addressed with the help of certain predictive ML models. Meulenkamp and Grima [20], for example, used Artificial Neural Networks (ANN) to predict UCS and discovered that ANN in 194 rock samples had better generalization than statistical models. Sonmez et al. [21] used regression and fuzzy inference systems (FIS) to predict UCS and elasticity modulus simultaneously, observing that regression performed better for elasticity modulus and that FIS had a good prediction accuracy for UCS. Regression and fuzzy models were used by Gokceoglu and Zorlu [22] to forecast the elasticity modulus and UCS in difficult rocks. Regression and a neural network were used by Dehghan et al. [23] to predict these values; regression was not as successful as the neural network. To estimate UCS for three different rock types, Mishra and Basu [24] employed multiple regression and FIS, proving the superiority of these methods over simple regression. The predicted accuracy of the UCS estimate has been substantially enhanced by several groundbreaking research.

III. Materials and Methodology

A. Data Gathering

In order to ensure the accuracy of predicting the UCS of rocks, it is crucial to compile a comprehensive dataset that includes relevant input variables. This endeavor involves carefully considering various factors and has been undertaken with unwavering commitment. As part of this pursuit, the data is meticulously divided into 70% as the training set, 15% as the validation set, and 15% as the testing set. It has been repeatedly demonstrated and scientifically verified that this allocation improves the performance of prediction models [25]. The prediction of UCS is accomplished using a DT model, which effectively leverages the predictive capabilities inherent in the aforementioned variables. These input parameters, accompanied by their detailed definitions and measurement units, serve as critical components in developing predictive models [26]. The subsequent section delineates the process of collecting data, providing an in-depth overview of each input variable:

1) Bulk Density (BD): Bulk Density quantifies the mass of a rock specimen per unit volume, measured in kilograms per cubic meter (kg/m^3). This parameter offers valuable insights into the rock's density and compactness.

2) Brazilian Tensile Strength (BTS): Brazilian Tensile Strength (BTS) evaluates a rock's resistance to tensile forces, expressed in megapascals (MPa). It is determined through the Brazilian Tensile Strength Test, wherein a rock specimen undergoes diametrical compression until failure occurs.

3) Dry Density (DD): Dry Density signifies the mass of a rock specimen per unit volume when completely dry, akin to Bulk Density. It is also measured in kilograms per cubic meter (kg/m^3) and characterizes the rock's density under dry conditions.

4) P-Wave Velocity (Vp): P-Wave Velocity (Vp) gauges the speed at which compressional ($P - wave$) seismic waves propagate through a rock specimen, expressed in meters per second (m/s). This parameter provides valuable insights into the rock's elastic properties and structural integrity.

5) Saturated Rock name (SRn): Saturated Rock Name (SRn) denotes a rock's compressive strength when saturated with water, measured in megapascals (MPa). Understanding how water impacts a rock's strength characteristics is essential, and SRn plays a vital role in this context.

6) Point load index (Is (50)): Point Load Index (Is (50)) is determined through the Point Load Index Test, which assesses a rock's strength under concentrated loads. It is quantified in megapascals (MPa) and provides insights into the rock's durability [27].

UCS represents the ultimate objective within this dataset. It signifies the maximum axial load a rock specimen can endure without lateral confinement, and it serves as the variable to be predicted using the other input parameters [28]. The successful prediction of UCS in rocks is contingent upon the quality and comprehensiveness of the dataset, encompassing the input variables outlined in Table I. Diligent data collection and preprocessing are indispensable stages in constructing accurate predictive models, which contribute significantly to both rock mechanics and geotechnical engineering. Fig. 1 visually portrays the distribution relationship between the input variables and UCS, facilitating the assessment of how changes in one input parameter positively or negatively affect UCS concerning the other inputs [29].

TABLE I. DATA PROPERTIES OF UCS AND INPUT

Features	Dataset Components						
	BD (kg/m3)	***BTS (MPa)***	***DD (kg/m3)***	***Vp (m/s)***	***SRn (MPa)***	***Is(50) (MPa)***	***UCS (MPa)***
Min	0.00	0.00	0.00	1247.00	0.00	0.10	5.50
Max	3.54	4.20	3011.00	6440.00	45.40	6.07	108.68
Mean	0.97	0.83	1669.73	4092.11	23.75	2.51	47.93
St.Dev.	1.276067	1.226962	1308.101	1722.211	18.84653	1.568194	26.84946

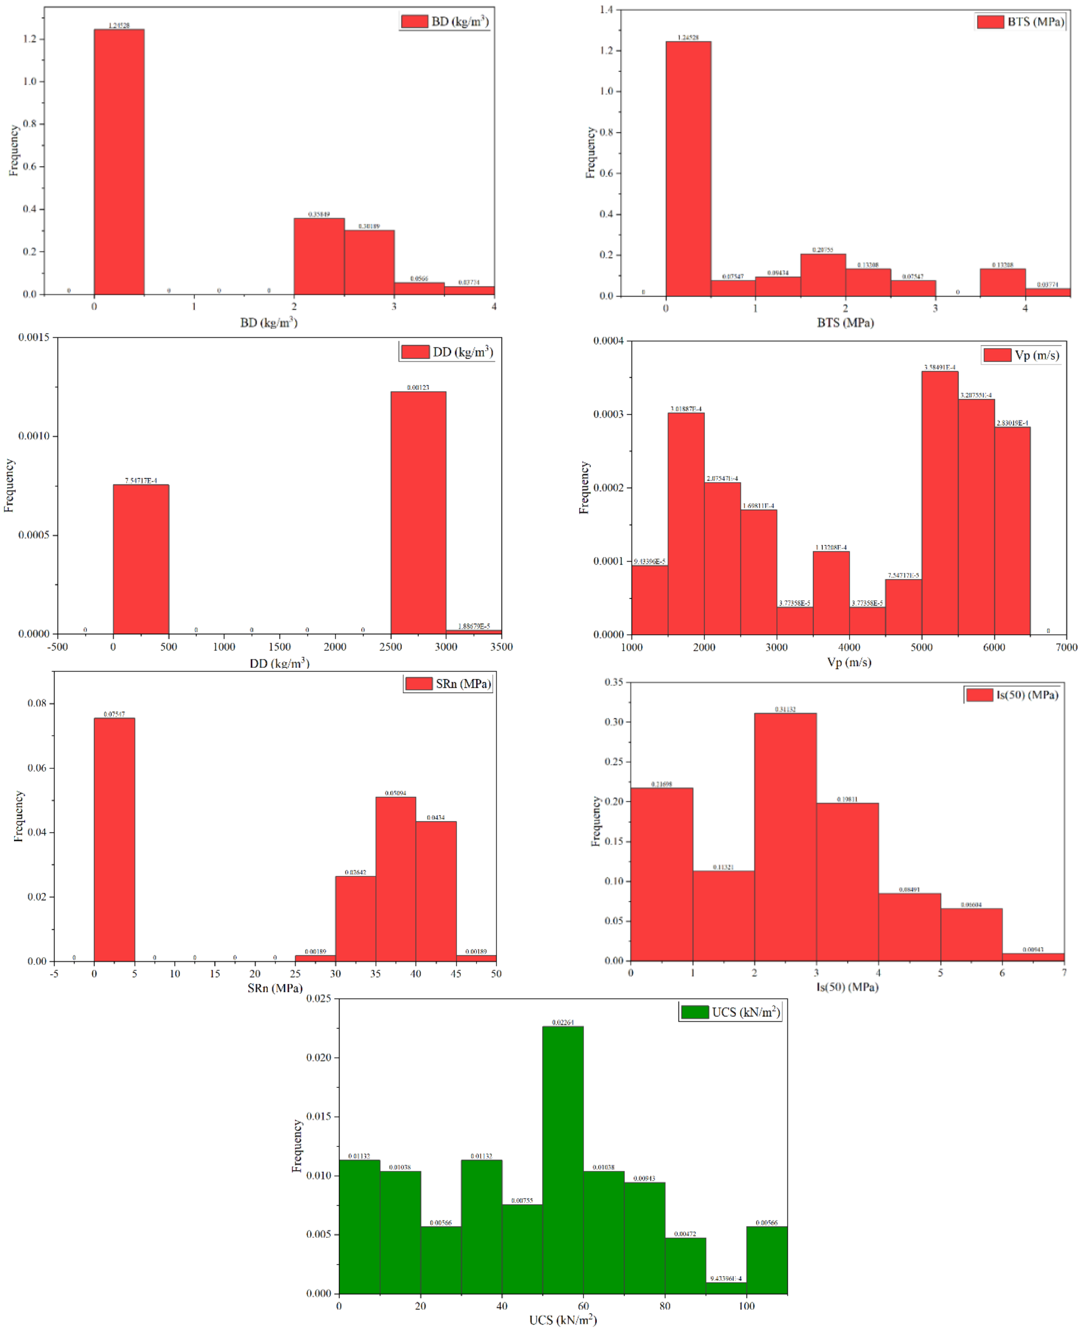

Fig. 1. The input and output distribution plot.

B. Decision Tree (DT)

The DT is a popular supervised learning method for handling regression and classification problems. Because of the tree's split structure or hierarchy, regression analysis may still be used to forecast the expected outcome based on independent variables in cases when a precise category grouping or classification is lacking [30], [31]. The model in Fig. 2 illustrates a basic DT with two continuous variables, x_1 and x_2, whose values are all between 0 and 1, and one binary target variable, Y, with values that are either 0 or 1. Additionally, as Fig. 3 illustrates, the structure may be seen as a segmented geographic region. Dividing the sample space into distinct, well-defined, and comprehensive subspaces is a typical analytical paradigm. Each of these sections is linked to a particular leaf node, which denotes the result of a series of subsequent decision-making processes. In a DT, each record has a single segment that acts as its home, known as a leaf node. The main objective of utilizing DTs for analysis is to find the most effective model that can precisely divide all available data into discrete segments [32].

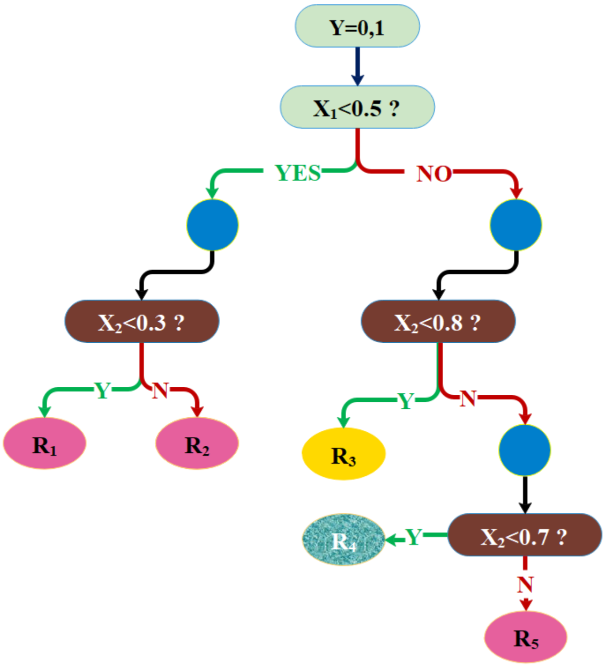

Fig. 2. Y is a binary target variable used in this example DT [33].

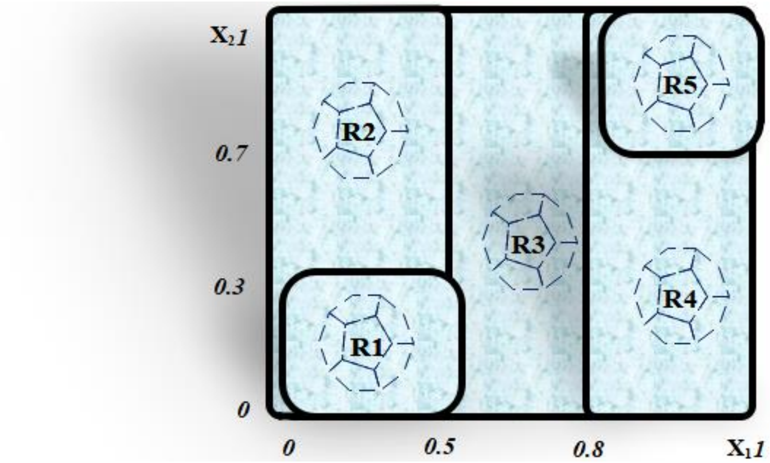

Fig. 3. Sample space view with DT [33].

Nodes and branches are the basic components of a DT model, and splitting, stopping, and pruning are essential steps in its development [34].

C. Population-Based Vortex Search Algorithm (PVS)

As a metaheuristic relying on a solitary explanation, the Vortex Search algorithm demonstrates effective exploitation capabilities, allowing it to execute rapidly [35]. The Gaussian distribution centered on a single point is used by the Vortex Search (VS) method to produce fresh candidate solutions. Nevertheless, despite attempts to promote variety in the search area, this may result in early convergence in some situations. On the other hand, population-based tactics perform better during the search space's exploration stage, when it's necessary to conduct a detailed analysis of unknown regions. These methods create new points based on the understanding gained from each iteration's previous points [36]. A community-driven VS algorithm known as PVS is presented in this study. There are 3 stages to the algorithm: a) initialization, b) the primary phase, and c) another phase.

1) Initializing: Control parameters including population size ($psize$), vortex size ($vsize$), termination condition, and likelihood of mutation (η_m) are specified during the algorithm's initialization phase. The entire quantity of potential fixes generated in a single iteration is represented by the value of $psize$, which is divided equally by halved to produce the value of $vsize$, which is equal to $psize/2$. The value of $vsize$ determines how many candidate solutions (CS) are generated in the initial stage and the subsequent stage generates the remaining CSs from ($vsize + 1$) to $psize$ [37]. The maximum number of function evaluations ($maxFEs$) serves as the method's halting criterion, and the polynomial mutation used in the second phase of the procedure utilizes the probability value η_m. Additionally, μ_0 and q_0 are calculated using, respectively, Eq. (1) and Eq. (2).

$$\mu_0^i = \frac{upper_i + lower_i}{2} \tag{1}$$

$$q_0^i = \sigma_0^i = \frac{\max(upper_i) - \min(lower_i)}{2} \tag{2}$$

2) First phase: The first iteration of this phase involves randomly generating the entire population of size $p$size. Merely 50% of the population ($vsize$) is created at random in the subsequent iterations. After this phase, updating the focal point (μ) is the optimal course of action. In this phase, the Gaussian distribution is used to generate half of the inhabitants, in accordance with Eq. (3) from the original VS algorithm. A population-based technique with selection pressure is used to update half of the population, while the other half is subjected to the best-center-oriented exploitation procedure. Overflowing solutions are recast into the designated range by applying Eq. (4).

$$s_i^t(x_i^t \left| \mu_t, v) = ((2\pi)^d |v|)^{-\left(\frac{1}{2}\right)} e^{\left(-1/2\left(x_i^t - \mu_t\right)^T v^{-1}(x_i^t - \mu_t)\right)} \right. \tag{3}$$

$$\begin{aligned} s_i(lower_i \vee s_i)upper_i \rightarrow s_i \\ = rand \times (upper_i - lower_i) \\ + lower_i \end{aligned} \tag{4}$$

Although it is not explicitly specified, the starting population is generated by using the starting centering point (μ_0) in the original VS algorithm. The midpoints of the population are selected at random after the initial population. This is where a modification to the VS algorithm is proposed, leading to variations of the PVS method. PVS_a designates the version in which μ_0 was present in the starting population, whereas PVS_b designates the version in which it was absent. The computed center point μ_0 is used as the initial potential fix POP (1) in the population during the first iteration of PVS_a, and the remainder $psize - 1$ candidate solutions POP (2: $psize$) are created at random. On the other hand, $psize$ candidate solutions POP (1: $psize$) are generated at random to form the initial population of PVS_b.

3) Second phase: By relying on interactions between potential solutions throughout the course of iterations to modify their locations during the search, population-based algorithms vary from single-solution-based algorithms. The basic strategy involves expressing the local or global experiences of potential solutions in a vector format to enable information sharing, while the updating method may differ based on the specific algorithm employed. Potential solutions are matched by the PVS algorithm using a proportional selection mechanism. This approach incorporates the ABC algorithm's onlooker bee phase's location update procedure, with some modifications made specifically to address minimization issues. Eq. (5) is employed to calculate the selection pb for each candidate solution.

$$\begin{gathered} pb_i = csum_i / csum_{psize} \\ csum_i = \sum_{j=1}^{i} normp_i \ \ and \\ normp_i = p_i / \sum_{i=1}^{psize} p_i \ \ and \\ p_i = 0.9 \times \left(max\{\vec{f}\} - f_i\right) + 0.1 \end{gathered} \tag{5}$$

f symbolizes the suitability value of the ith solution and $max\{\vec{f}\}$ p_i signifies the $ith's$ scaled fitness value solution for minimization, which was achieved by converting the values of the objective function, which range from maximization to minimization. denotes the population's greatest fitness value at this time. The function $normp$ is used to calculate the probability values obtained by normalizing the p values in the $0.5\text{–}1$ range. The cumulative sum vector of norm p values is denoted by $csum$. The remaining 50% of the populace, for each solution CS_i where i ranges from $vsize + 1$ to $psize$, using the prob vector, an arbitrary neighbor solution is chosen from each of the population's solutions. To produce a new solution (CS_{new}), the amount of a randomly chosen dimension is updated using Eq. (6). The acquired dimension value is next subjected to an Eq. (7) check for limit exceedance.

$$\begin{aligned} CS_{new} = CS_{current} \ then \ CS_{new}^i \\ = CS_{current}^i + (CS_{current}^i \\ - CS_{neigbour}^i) \times (r - 0.5) \times 2 \end{aligned} \tag{6}$$

$$CS_{new} = \begin{cases} lower_i, & CS_{new}^i < lower_i \\ CS_{new}^i, & lower_i \le CS_{new}^i \le upper_i \\ upper_i, & CS_{new}^i > upper_i \end{cases} \tag{7}$$

The usefulness of the new solution CS_{new} is calculated with a random number r ranging from 0.5 to 1, and subsequently contrasted with the current solution's fitness value $CS_{current}$. If the If CS_{new} has a higher fitness level than $CS_{current}$, the former takes the place of the latter. On the other hand, a mutant solution

CS_{mutant} is produced by the polynomial mutation in accordance with Eq. (8) if CS_{new} is not superior to $CS_{current}$.

$$CS_{mutant} = CS_{current} + \delta_q \times (upper - lower)$$

$$\delta_q = \begin{cases} \left[\frac{2r+(1-2r)}{(1-\delta_1)^{\eta_m+1}}\right]^{\frac{1}{\eta_m+1}}, & if \ \ r \leq 0.5 \\ 1 - \left[\frac{2(1-r)+2(r-0.5)}{(1-\delta_2)^{\eta_m+1}}\right]^{\frac{1}{\eta_m+1}}, & otherwise \end{cases} \tag{8}$$

$$\delta_1 = \frac{CS_{current} - lower}{upper - lower}$$

$$\delta_2 = \frac{upper - CS_{current}}{upper - lower}$$

In this instance, a random number rnd is created for each dimension between 0.5 and 1. Further processing is applied if rnd is less than the η_m value, which is calculated in this section by dividing 1 by the dimensionality of the problem. The research suggests that the polynomial mutation operator is the best method for overcoming the problem of preventing local peaks and maintaining variety in the search space, which is a major roadblock for metaheuristics. After the answer is warped using a polynomial probability distribution, the polynomial mutation operator generates a perturbation effect. Next, a contrast is drawn between $CS_{current}$ and CS_{mutant} using a greedy selection process. After completing this process, the best option discovered is applied to update the center point (μ).

After the current generation is finished, the radius size for the following generation is decreased by calculating Eq. (9). As long as the PVS algorithm completes the greatest number of function evaluations, it keeps running. First, $vsize$ solutions inside the lowered radius are repeated, and in the second phase, random data is added to the answers, which comprise the remaining 50% of the population.

$$\begin{gathered} r_t = \sigma_0 \times \frac{1}{x} \times \Gamma(x, a_t) \\ where \ \ a_t = \frac{(MaxFEs - Fes)}{MaxFEs} \\ then \ \ if \ \ (a_t \leq 0) a_t = 0.1 \end{gathered} \tag{9}$$

D. Arithmetic Optimizer Algorithm (AOA)

This algorithm was proposed by Abualigah, employing some mathematical operators and formulas in 2020 [38]. The AOA algorithm begins with a random population of solutions. At each iteration, the objective value for each solution is computed. This algorithm has two control parameters called M and \, which need to be updated before updating the solution position in the following:

$$M(i) = Min + i \times \left(\frac{Max - Min}{I}\right) \tag{10}$$

The function's value at the current iteration is shown by $M(i)$, the maximum iteration is shown by I, and the $minimum$ and $maximum$ values for the bounds of M are shown by Min and Max.

$$P(i) = 1 - \left(\frac{i}{I}\right)^{\frac{1}{c}} \tag{11}$$

Here, the coefficient of the mathematical optimizer probability (P) determines the function's value at the ith iteration. After updating the P and M, it also generates a random number called r_3 to switch between exploitation and exploration. The search makes use of Eq. (12).

$$x_{i,,j}(t+1) =$$

$$\begin{cases} \frac{best(x_j)}{(P+\alpha)} \times (ub_j - lb_j) \times M + lb_j \ \ if \ \ r_1 < 0.5 \ (a) \\ best(x_j) \times P \times (ub_j - lb_j) \times M + lb_j \ \ if \ \ otherwise \ (b) \end{cases} \tag{12}$$

Furthermore, Eq. (13) is utilized for exploitation:

$$x_{i,,j}(t+1) =$$

$$\begin{cases} best(x_j) - P \times (ub_j - lb_j) \times M + lb_j \ \ if \ \ r_2 < 0.5 \ (a) \\ best(x_j) + P \times (ub_j - lb_j) \times M + lb_j \ \ if \ \ otherwise \ (b) \end{cases} \tag{13}$$

It should be noted that section 2.3 mentions the AOA parameters, which are the same as $DAOA's$. Additionally, the AOA flowchart is shown in Fig. 4.

E. Performance Evaluation Methods

This article assesses the models using several metrics, such as the previously stated Mean Absolute Relative Error ($MARE$), Correlation Coefficient (R^2), Mean Square Error (MSE), Normalized Root Mean Squared Error ($NRMSE$), and Root Mean Square Error ($RMSE$). Excellent performance of the algorithm during the phases of training, validation, and testing is indicated by a high R^2 value. On the other hand, lower $RMSE$ and MSE values are preferable because they exhibit reduced model inaccuracy. Eq. (14) to (18) are used to calculate these metrics.

Coefficient of Correlation

$$R^2 = \left(\frac{\sum_{i=1}^{W}(h_i - \bar{h})(q_i - \bar{q})}{\sqrt{[\sum_{i=1}^{W}(h_i - h)^2][\sum_{i=1}^{W}(q_i - \bar{q})^2]}}\right)^2 \tag{14}$$

Root Mean Square Error

$$RMSE = \sqrt{\frac{1}{W}\sum_{i=1}^{W}(q_i - h_i)^2} \tag{15}$$

Mean Square Error

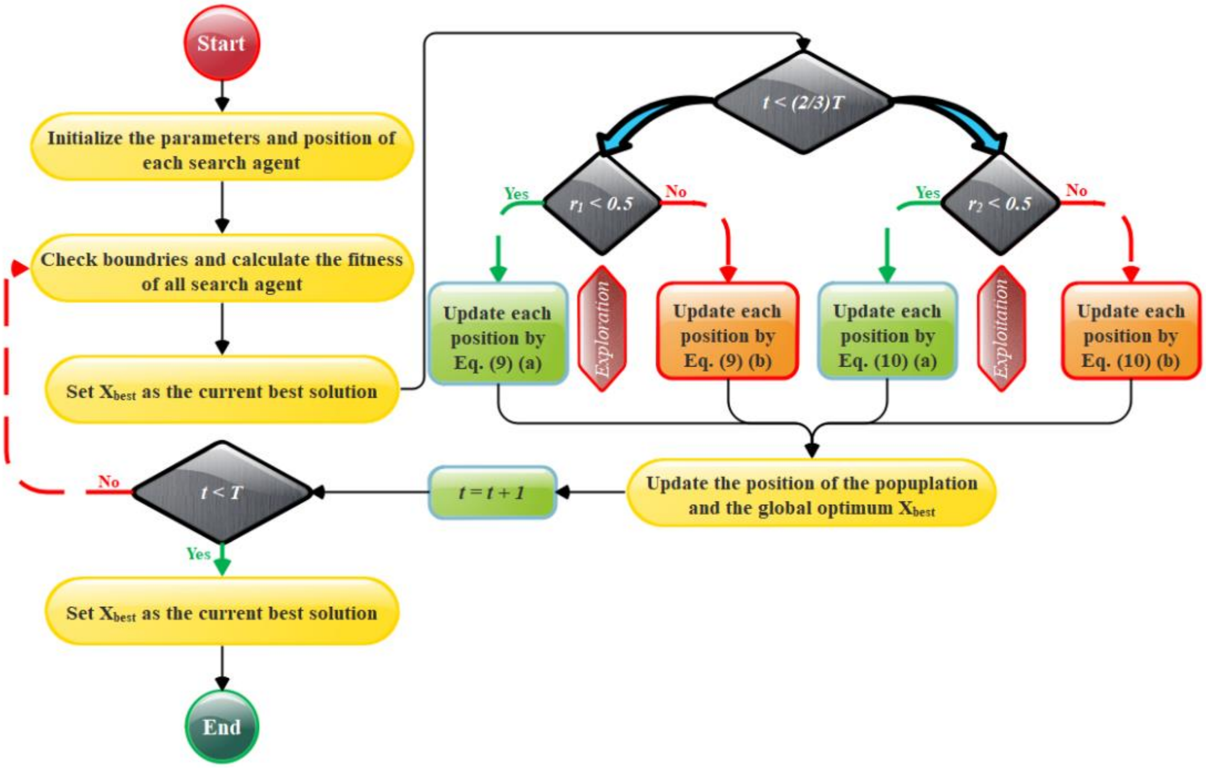
$$MSE = \frac{1}{W}\sum_{i=1}^{w} q_i^2 \tag{16}$$

Mean Absolute Relative Error

$$MARE = \frac{1}{W}\sum_{i}^{w} \frac{|q_i - h_i|}{|\bar{q} - \bar{h}|} \tag{17}$$

Normalized Root Mean Squared Error

$$NRMSE = \frac{RMSE}{q_i - \bar{q}} \tag{18}$$



Start
Initialize the parameters and position of each search agent

Fig. 4. The flowchart of AOA.

The anticipated and experimental values are denoted by the variables h_i and q_i in these equations, respectively. The mean values of the expected and experimental samples are denoted by the symbols $\bar{h}$ and $\bar{q}$, respectively. Alternatively, W indicates how many samples are being examined.

The study employed three models, namely DT, $DTAO$, and $DTPB$, for the prediction of UCS. These models underwent evaluation using experimental measurements in Table II, with the evaluation process divided into four phases: training (70%), validation (15%), testing (15%), and overall assessment (100%), ensuring an unbiased evaluation. To comprehensively assess and compare the algorithms, five statistical metrics were utilized, including $NRMSE$, MSE, R^2, $RMSE$, and $MARE$. The primary metric for assessing model performance was R^2, indicating how effectively the independent variable accounts for variance in the dependent variable.

TABLE II. THE OUTCOME OF THE MODELS CREATED FOR DT

Model	*Phase*	Index values				
		RMSE	*R^2*	*MSE*	*NRMSE*	*MARE*
DT	*Train*	3.537	0.984	12.518	0.048	0.121
	Validation	5.375	0.958	28.887	0.336	0.095
	Test	5.841	0.972	34.122	0.365	0.103
	All	4.271	0.975	18.250	0.040	0.114
DTAO	*Train*	1.242	0.998	1.543	0.017	0.020
	Validation	3.715	0.988	13.802	0.232	0.052
	Test	4.299	0.989	18.480	0.269	0.072
	All	2.439	0.993	5.950	0.023	0.032
DTPB	*Train*	2.444	0.992	5.971	0.033	0.044
	Validation	5.254	0.985	27.605	0.328	0.066
	Test	5.382	0.981	28.965	0.336	0.085
	All	3.565	0.987	12.708	0.034	0.053

The $DTAO$ model demonstrated superior performance during the training phase, boasting the highest R^2 value (0.998) among all models. In contrast, the DT model exhibited slightly lower training-phase R^2 values at 0.984. Additionally, $RMSE$, an error indicator, was evaluated in the study, with a range of 1.242 to 5.841. The DT model had the largest RMSE, while the $DTAO$ model showcased the lowest. In the training phase, the DT model had the highest $NRMSE$ value (0.048), whereas the $DTAO$ model had the lowest (0.017). The $DTAO$ model also excelled in terms of $MARE$, with a value of 0.020, while the DT model had the highest MSE among the models evaluated, with a value of 12.518. Overall, the findings showed that in certain phases, the $DTAO$ model performed better than the DT and $DTPB$ models. But when choosing a model for practical applications, other aspects including computational effectiveness, model complexity, and simplicity of implementation should also be taken into account. However, the results indicate that AOA modification improved the DT model's prediction of UCS substantially.

The performance of hybrid models is efficiently compared using a scatter plot in Fig. 5, which considers two important parameters: R^2 and $RMSE$. R^2 is a robust indicator of agreement, while $RMSE$ quantifies the extent of deviation. The plot's central axis acts as a reference point, and the proximity of individual data points to this axis reveals the precision of the models. Notably, the $DTAO$ model stands out as a model of exceptional accuracy, as indicated by its data points closely clustering around the central axis, highlighting minimal divergence. In contrast, the $DTPB$ and DT models exhibit similar performance levels, with their respective data points scattered widely, indicating significant variability.

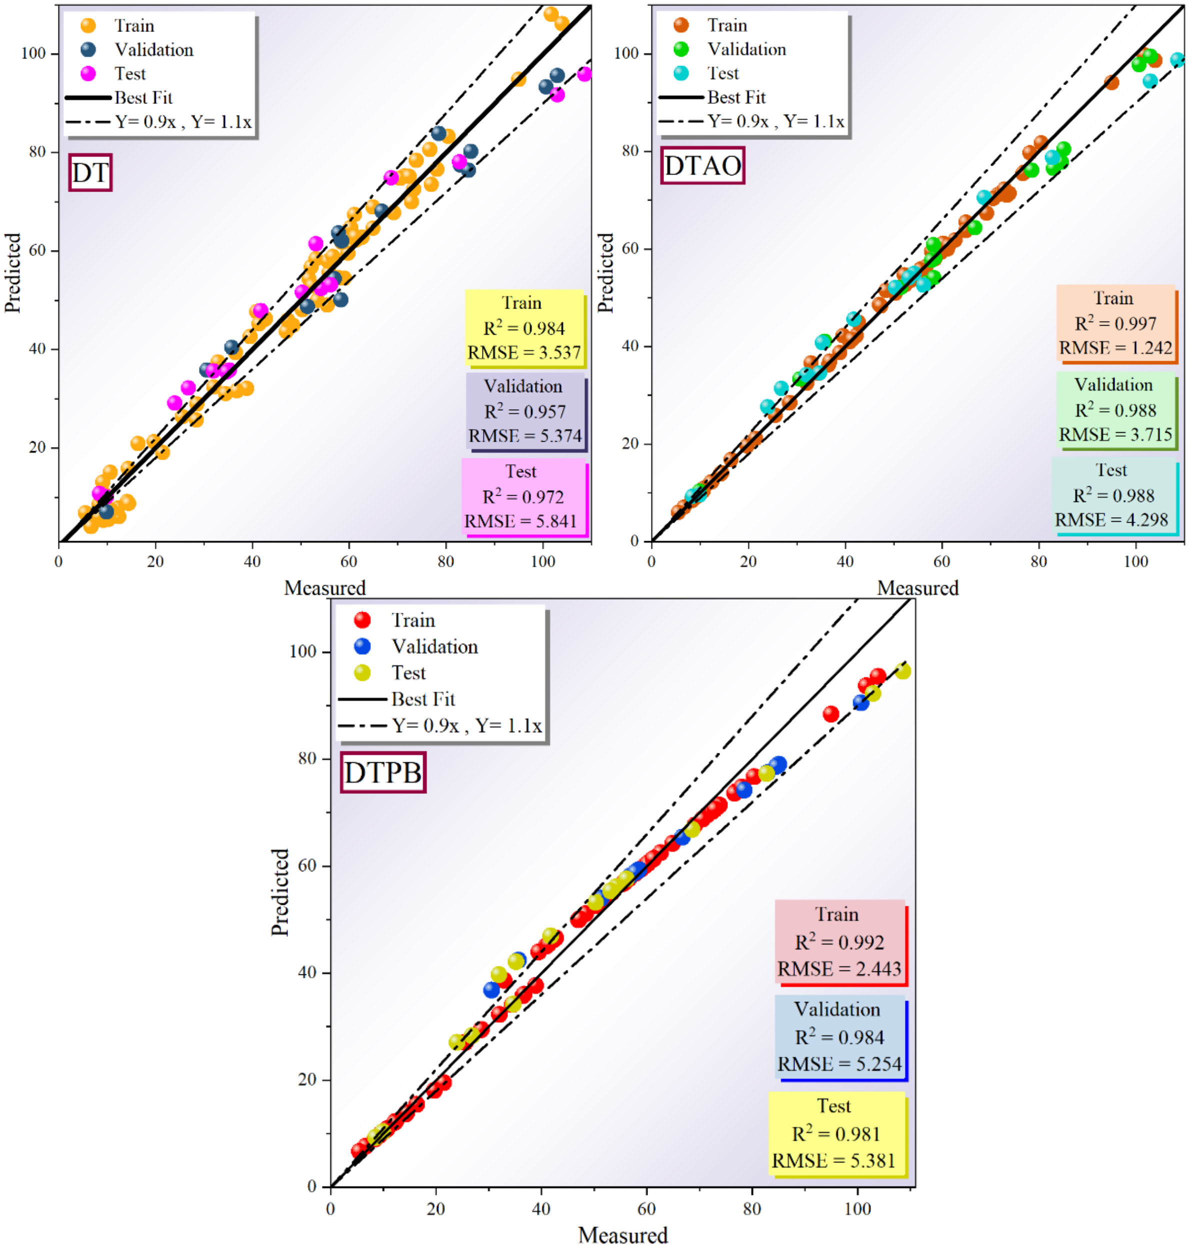

Fig. 5. The hybrid model's produced scatter plot.

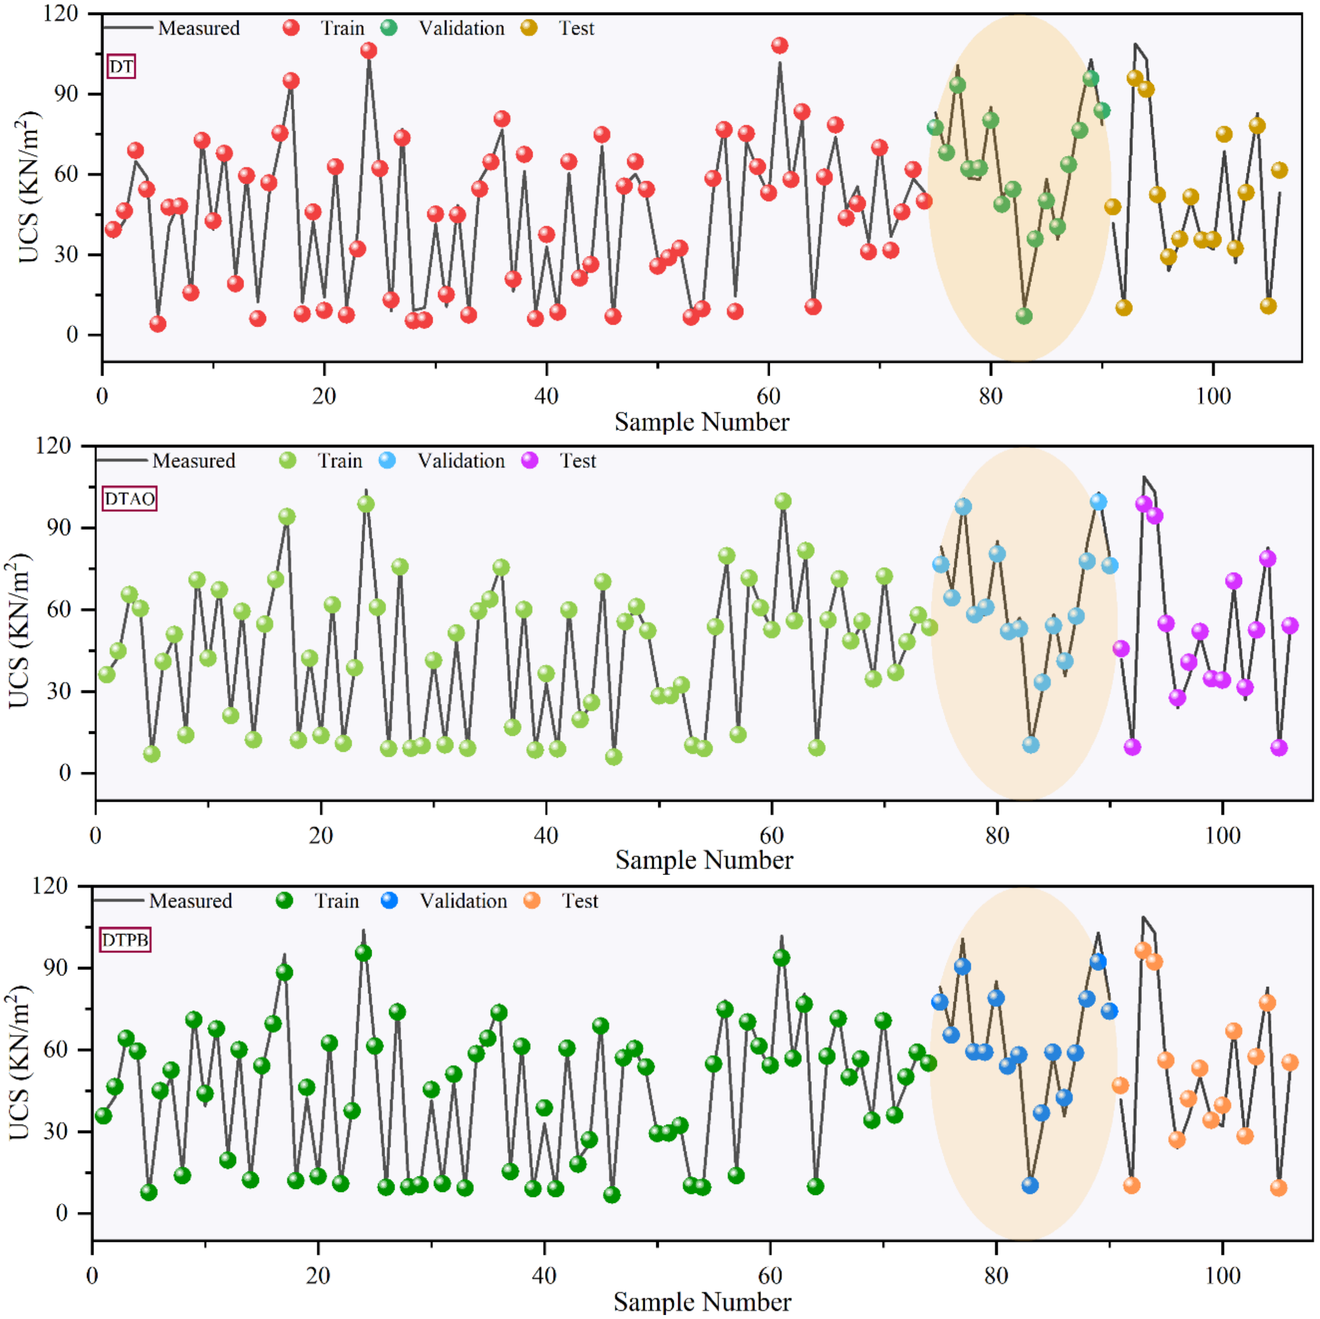

Fig. 6. Comparison between measured and expected values.

Fig. 6 depicts a thorough comparison between expected results and actual measurements, neatly broken down into stages of testing, validation, and training. The best state can be found using these expected outcomes as a guide. Examining the $DTAO$ model's behavior reveals a slight discrepancy between measured values obtained during the training and testing phases, with the latter typically exhibiting relatively higher values. Similar to the $DTAO$ model's projected points, the $DTPB$ model's projected points also deviate slightly from the measurements taken, though not as significantly. The DT model, in contrast, reveals a more pronounced level of variance and exhibits comparatively diminished efficacy in comparison to the other two models.

Fig. 7 shows a line plot of the error % of the created models. $DTAO$ has the lowest error rate, as seen by the graph, with the majority of values falling within the 17% range. More values above 43% and a wider range of error percentages are present for DT and $DTPB$. The DT and $DTPB$ distributions are notably tilted to the right, suggesting that certain data points have notably larger error percentages. This illustrates both the improved accuracy of the $DTAO$ and the way the graphs of the generated models' error percentage distributions are shown.

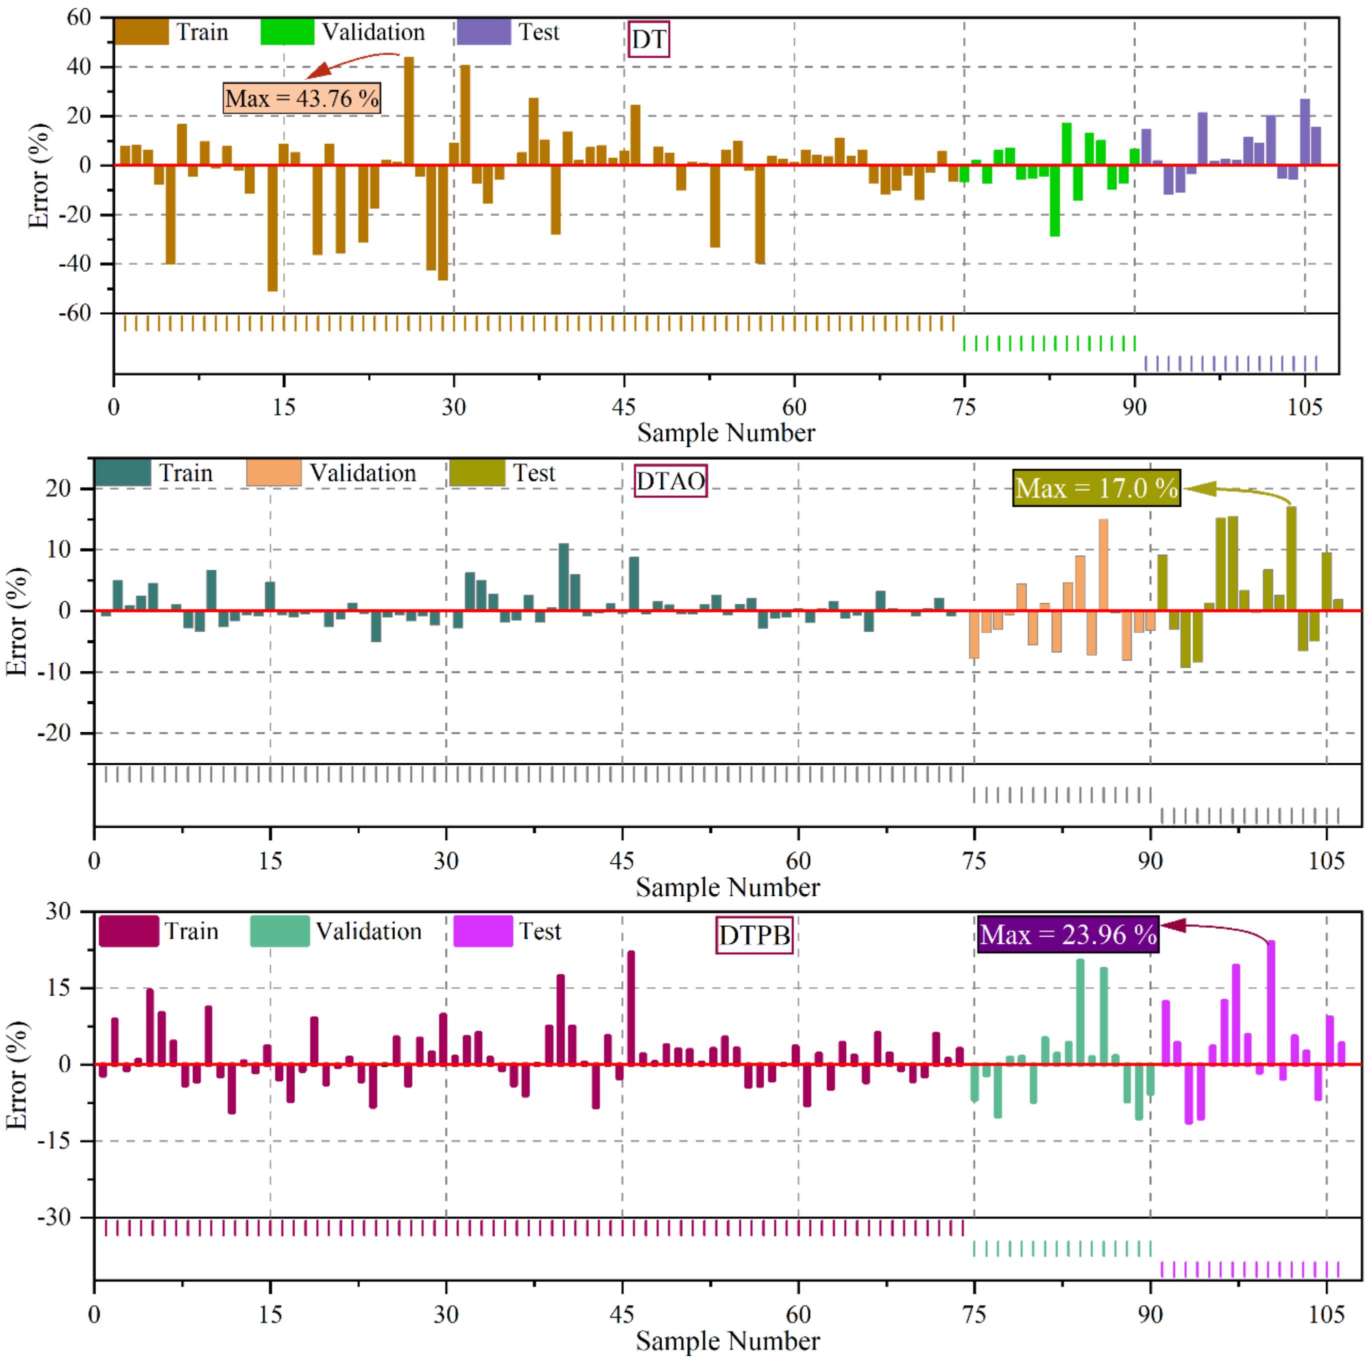

Fig. 7. The line plot determines the error rate percentage for the line models.

Fig. 8 displays an interval map that illustrates the error percentages of the models that were employed in this study. Throughout the training phase, the $DTAO$ model demonstrated remarkable performance, maintaining errors below the 20% threshold with a consistent mean error rate of 0%. There was minimal dispersion in the data's normal distribution. The DT model, on the other hand, demonstrated dispersion in all phases and a very symmetrical and homogenous normal distribution, despite the error rate being below 20%. On the other hand, out of the three models, the DTPB model showed the most substantial and diversified inconsistencies. An uncommon event in statistical analysis occurred during the assessment step when one outlier data point accounted for more than 20% of the dataset. In contrast to the other two models, the DT model's Gaussian distribution showed better dispersion and a lower frequency of occurrences close to 0.

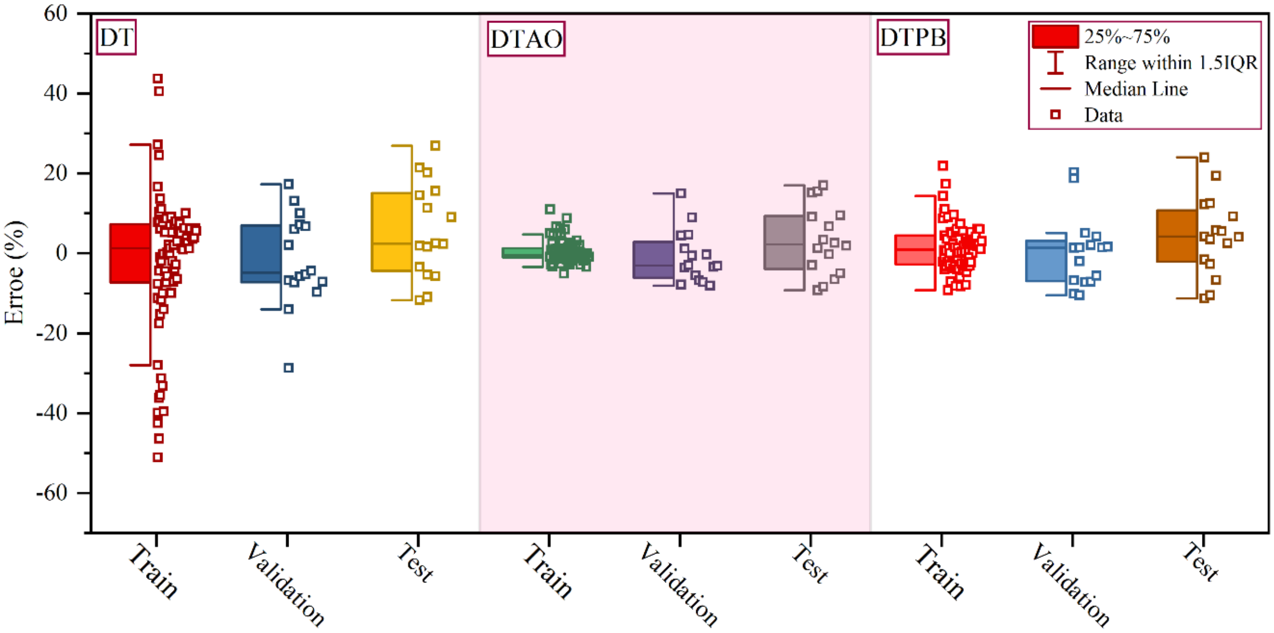

Fig. 8. The normal supply of errors between the intermission plot models.

IV. Discussion

Table III provides a comparative summary of various published articles on the prediction of UCS using different datasets, variables, models, and evaluators, including R² and RMSE metrics. Narendra et al. [39] utilized a dataset of 186 samples with variables such as curing period, clay water-cement ratio, cement content, liquid limit, liquidity index, water content, pH, and Na+. They applied a Genetic Programming (GP) model, reaching an R² of 0.988 and an RMSE of 1.135. Ceryan et al. [40] worked with a smaller dataset of 56 samples, using variables like Clt, Cly, Fld, Qrz, Qq, Bi, n, ne, Id, Vp, and Vm. Their model of regression (REG) yielded an R² of 0.883 and an RMSE of 1.108. A dataset of 93 samples was employed by Majdi and Rezaei [41] and Rezaei et al. [42]. The variables included rock type, Schmidt hardness, density, and porosity. While Rezaei et al. employed a Mamdani fuzzy model and produced an R² of 0.943 and an RMSE of 3.2, Majdi and Rezaei utilized an ANN model and obtained an R² of 0.972 and an RMSE of 1.113. Mohamad et al. [43] analyzed 160 samples with variables such as rock type, weathering grade, BD, BTS, Is(50), and Vp. Their ANN-PSO model demonstrated high accuracy with an R² of 0.982 and an RMSE of 0.077. The present study involved 106 samples and variables including BD, BTS, DD, Vp, SRn, and Is. Using the Decision Tree-Arithmetic Optimizer (DTAO) model, this study achieved a striking R² of 0.988 and an RMSE of 1.242, demonstrating comparable accuracy to the best-performing models reviewed.

1) Limitation: While this study demonstrates significant advancements in predicting UCS for soil-stabilizer combinations using ML techniques, several limitations must be acknowledged. Firstly, the dataset size, though reasonably substantial, may still limit the generalizability of the models. A larger and more diverse dataset encompassing a wider range of soil types and conditions would enhance the robustness and applicability of the models. Secondly, the models developed are highly specific to the input variables used in this study. Variables such as particle size distribution, plasticity, and stabilizer type are crucial, but other potentially influential factors like temperature, humidity, and long-term aging effects were not considered. Including these factors could further improve model accuracy and reliability. Thirdly, the study's reliance on historical data means that any inaccuracies or biases in the original data could propagate through the models, affecting their predictions. Rigorous data validation and cleaning procedures are essential to mitigate this risk. Additionally, the integration of meta-heuristic algorithms like the PVS and the AOA, while enhancing model precision, introduces complexity. This complexity may pose challenges for practical implementation and computational efficiency, particularly for large-scale projects. Lastly, the models, though validated against historical data, require further testing in real-world scenarios to confirm their practical effectiveness and reliability in diverse geotechnical applications.

2) Future study: A potential future study stemming from this research could delve into the application of advanced ML techniques beyond DTs for predicting UCS in soil-stabilizer combinations. One avenue could involve exploring ensemble methods such as Random Forests, Gradient Boosting Machines, or Neural Networks to compare their predictive performance with the DT-based models developed in this study. This comparative analysis would provide a more comprehensive understanding of which ML algorithms are most effective for this specific prediction task. Moreover, considering the integration of meta-heuristic algorithms like the PVS and the AOA, a future study could focus on optimizing the parameters and configurations of these meta-heuristic algorithms. This optimization process could enhance the precision and efficiency of the predictive models, leading to even more accurate UCS forecasts for various soil-stabilizer combinations. Additionally, extending the validation process to include real-world field data from ongoing construction projects or geological surveys could strengthen the practical applicability of the predictive models developed. This extension would involve collaborating with industry partners or governmental agencies to access and analyze relevant datasets, ensuring that the models are validated under diverse and realistic conditions.

V. CONCLUSION

By ML techniques, specifically DT algorithms, this study presents an innovative approach to predict UCS values with a high level of accuracy. This method provides an affordable alternative and drastically cuts down on the amount of time needed for UCS prediction. Using DT techniques, a unique ML model serves as the foundation for the main framework for UCS prediction. To enhance precision and reduce errors, 3 models were developed by combining the AOA and PVS meta-heuristic algorithms, namely DT, $DTAO$, and $DTPB$. These models were put through a rigorous validation process that used lab samples from publically accessible sources for the testing, validation, and training phases. In order to thoroughly assess model performance, various metrics such as $RMSE$, MSE , R^2, $NRMSE$, and $MARE$ were employed. These metrics collectively provide a deep insight into the model's ability to predict UCS accurately and its overall effectiveness in estimation. This research significantly advances the field of soil mechanics by improving understanding of the factors influencing UCS through the application of ML techniques. Consequently, it opens up opportunities for more precise and dependable UCS predictions in various engineering applications. In this investigation, it was demonstrated that the $DTAO$ models achieved the highest R^2 values, while the DT model exhibited the lowest R^2 value, albeit with a marginal difference of only 2.1%. Furthermore, the error indicators revealed that the $DTAO$ models outperformed the DT and $DTPB$ models by demonstrating lower error values. Notably, the $DTAO$ models

Consistently exhibited the last $RMSE$ values across all phases, with a significant difference of 96% and 65% when compared to the DT and $DTPB$ models, respectively. This highlights the exceptional accuracy and reliability of the $DTAO$ models in predicting UCS.

Temporal Fusion Transformers for Enhanced Multivariate Time Series Forecasting of Indonesian Stock Prices

Standy Hartanto[1], Alexander Agung Santoso Gunawan[2]
Computer Science Department-Master of Computer Science, Bina Nusantara University, Jakarta 11480, Indonesia[1]
Computer Science Department-School of Computer Science, Bina Nusantara University, Jakarta 11480, Indonesia[2]

Abstract—**The stock market represents the financial pulse of economies and is an important part of the global financial system. It allows people to buy and sell shares in publicly held corporations. It serves as a platform for investors to trade ownership in businesses, enabling companies to raise capital for expansion and operations. However, the stock market can be very risky for any investor because of the fluctuating prices and uncertainties of the market. Integrating deep learning into stock market analysis enables researchers and practitioners to gain a deeper understanding of the trends and variations that will improve investment decisions. Recent advancements in the area of deep learning, more specifically with the invention of transformer-based models, have revolutionized research in stock market prediction. The Temporal Fusion Transformer (TFT) was introduced as a model that uses self-attention mechanisms to capture complex temporal dynamics across multiple time-series sequences. This study investigates feature engineering and technical data integrated into the TFT models to improve short-term stock market prediction. The Variance Inflation Factor (VIF) was used to quantify the severity of multicollinearity in the dataset. Evaluation metrics were used to evaluate TFT models' effectiveness in improving the accuracy of stock market forecasting compared to other transformer models and traditional statistical Naïve models used as baselines. The results prove that TFT models excel in forecasting by effectively identifying multiple patterns, resulting in better predictive accuracy. Furthermore, considering the unique patterns of individual stocks, TFT obtained a remarkable SMAPE of 0.0022.**

Keywords—Time series forecasting; stock price prediction; capital market; technical analysis; TFT

I. Introduction

Stock market indices show the health of the economy. It allows people to trade in the shares of publicly held corporations. It serves as a platform for investors to trade ownership in businesses, enabling companies to raise capital for expansion and operations. Changes in the equity markets will indicate the economic situation, investors' sentiment, and expectations about future economic performance. This can be very risky for any investor because of the price fluctuations and uncertainties of the market. In addition, stock markets play a vital role in determining the companies' value. Prediction of stock prices is a very complex and highly challenging task due to the intrinsic volatility and multi-dimensionality of financial markets [1]. Indeed, most traditional models are challenged to identify exactly the complex trends and variables that impact stock price movements.

Research on stock market prediction has paid considerable attention to deep learning algorithms in recent years. Some techniques involve training models using large datasets to come up with complex patterns and correlations [2, 3, 4, 5]. These may also combine other data sources, like financial and non-financial data, in a model to be trained for the increase in prediction accuracy [6]. Researchers have just commenced exploring how Transformer-based models [7, 8] apply alongside Reinforcement Learning for forecasting trends in the stock market [9, 10, 11].

TFT is a new transformer-based model for handling multiple time series sequences with complicated temporal dynamics. By merging the LSTM Sequence-to-Sequence framework with the self-attention mechanism of Transformers, TFT adeptly captures temporal dependencies across varying scales while enriching temporal representations with static contextual information about measured entities. In contrast to RNN-based models, Transformers offer expedited processing by simultaneously ingesting all input, thereby bypassing the sequential nature of RNNs. Moreover, it is easier to train Transformers because they have fewer parameters compared to LSTM networks. Transfer learning is also possible with Transformers, which is not the case with LSTM networks. Notably, TFT fits the detailed subtleties within hydrographs, peaks, and transitional phases much more effectively than both LSTM and Transformers.

Generalizing models may not provide valuable insights to analysts and investors in view of the uniqueness of trends and patterns that individual stocks exhibit to make meaningful short-term decisions. It needs more comprehensive indicators that directly impact the market behavior. This involves identifying a few exogenous input features that help the model recognize the patterns of history, evaluate its performance against real market fluctuations so that it can be agile to volatility, and thereby provide valuable insights for short-term stock price predictions.

In this research, five years of stock market data from the Indonesia Stock Exchange (IDX) were used in analyzing with the TFT model, particularly in mining, communications, and industrial sectors. The main objective is to develop a comprehensive analysis of TFT with regards to short-term stock price prediction by using historical technical indicators.

In addition, several feature engineering techniques, model architectures, and training strategies are also evaluated for their effects on the accuracy of prediction. Evaluation metrics were used against baselines composed of Transformer models and Naïve models, comparing the performance of TFT. Lastly, the model was tested under real-market conditions to evaluate its performance in generating accurate predictions on the stock exchange.

II. Related Studies

In this vast domain of time series forecasting, there exist a large number of theories and methodologies that act as the foundation for predictive analysis in different fields. These models provide insight into future trends and events that range from classic statistical approaches to modern deep learning algorithms [12].

Naïve models are very simple, fairly easy to use, and provide a simple starting point in developing or predicting stock prices. They are quick to calculate and inform us about the performance of a more complex method compared to something quite simple. While being relatively interpretable and tolerant of noise, they may miss small details that drive stock prices [13]. In this Naïve approach, each estimate is set based on the last observed value.

$$\hat{y}_{T+h|T} = \text{yт} \tag{1}$$

Transformers have gained prominence in Natural Language Processing (NLP) and computer vision, their application in the realm of time-series data remains relatively unexplored. Our approach addresses this gap through a self-attention mechanism that helps identify complex nonlinear trends and intrinsic dynamics in time series data, which are consolidated under high volatility and nonlinearity. The predictive power of our model includes providing closing price forecasts for the next trading day with insights derived from multiple stock price inputs. Our model is rigorously validated by testing through four different error evaluation metrics. The fact that our model can predict the closing prices with a probability of more than 90% makes this model very useful for fintech [14].

Employing a combination of CNNs, RNNs, LSTMs, and BERT, alongside textual data from social media. It is posited that, by incorporating deep learning models with the state-of-the-art BERT word embedding model, classification performance will be improved. When such deep learning algorithms are combined with such a state-of-the-art natural language processing model, it incurs improvement in performance every time. In predicting stock directional movement, it leads to up to 96.26% accuracy performance [15].

LSTM neural network models are suitable for monitoring trends and capturing seasonality over long forecast periods. A study [16] reveals an increase in model performance with a new approach that uses six variables: High, Low, Open, Volume, HiLo, and OpSe. Give rise to the urge to explore new forecasting strategies with respect to the various scenarios that can be studied. These efforts can provide meaningful insights for investors and analysts who want to understand the working mechanisms of the stock market to better grasp future trends [17].

Recently, studies on the application of Transformer-based models and Reinforcement Learning (RL) models in stock market forecasting have already been initiated. The purpose of the survey is to consolidate the latest developments in methodologies like Transformers and RL with in-depth analysis and discourse on their implications and advancement in this domain [9, 10].

Temporal Fusion Transformer is a model architecture designed for time series forecasting. It intrinsically combines the concepts of transformers very successfully in natural language processing and related sequence data tasks with techniques specifically developed for dealing with temporal data [18, 19, 20]. The primary function of TFT is to enhance learnt temporal representations with static data about measured entities and to capture temporal dependencies at various time scales using a combination of the Transformer's Self Attention mechanism and the LSTM Sequence-to-Sequence [21]. Transformers process all of the input at once, making them faster than RNN-based models [22]. Compared to transformer networks, LSTM networks require longer training due to their significantly larger parameter set. Furthermore, transfer learning is not feasible with LSTM networks. TFT is more effective than LSTM or Transformers at capturing the subtleties of the hydrographs, such as the peaks and limbs.

A study in [21] proposed the TFT model as a solution for multi-horizon time series forecasting, where the goal is to predict multiple future time steps of a sequence simultaneously. The TFT architecture generalizes transformer attention mechanisms and encoder-decoder structures to capture complex temporal patterns in the data while offering interpretability through attention weights. This study encompasses data from four major categories: Electricity, Traffic, Retail, and Volatility. The regional variables in the volatility category are indices of the Americas, Europe, or Asia. There are 31 stock indices in total with open-to-close returns acting as supplementary exogenous inputs, and the time span was from 2000 to 2019. Comparisons against TFT were made with a number of models DeepAR, ConTrans, Seq2Seq, and MQRNN with respective results including 0.050, 0.047, 0.042, 0.042, and 0.039.

Acknowledging the distinct trends and patterns observed in individual stocks, the study aims to evaluate the effectiveness of the TFT model in analyzing short-term trends in Indonesian stock prices, particularly within the mining, communications, and industrial sectors. It seeks to determine whether TFT models can provide valuable insights to analysts and investors for short-term decision-making purposes.

III. Research Methodology

Advanced methodology that drives our research is unveiled. It is imperative to establish a nuanced understanding of what kind of guiding principles and meticulous procedures we put in motion for an in-depth review, starting from careful data collection to rigorous analysis. Fig. 1 depicts the research stages.

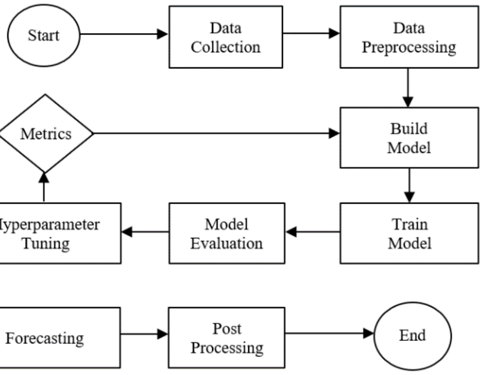

Fig. 1. Research stages.

A. Dataset

The landscape of this research utilized datasets sourced from emerging markets, the Indonesia Stock Exchange (IDX), in order to reflect a growing recognition of the significance of diversifying data sources to attain a more comprehensive understanding of global economic trends. This approach acknowledges the high probability of new trends, market behaviors, and investment patterns that might not be captured or be sufficiently represented within past research datasets.

The dataset is sourced from publicly available data provided by Yahoo!Finance [23]. General market stability and behavior will drive data requirements, in highly volatile markets or in exceptional circumstances such as an economic crisis, longer historical data may be required. However, longer periods of data might increase the risk of overfitting, where the model learns noise in the data rather than true patterns. The investigation contemplated the incorporation of data covering roughly the previous five years.

Each stock exhibits a unique pattern. To acquire comprehensive insights, three different stock analyses were made for Aneka Tambang (ANTM) in the mining sector, XL Axiata (EXCL) in the communication sector, and Astra International (ASII) in the industrial sector. The transaction was specified for the date range from March 27, 2019, to March 27, 2024.

Table I presents a selection of five examples taken from the ANTM stock dataset, showing which main features are detected on each trading day. The main variables regarding the dataset include Close and Volume.

TABLE I. SUMMARY OF STOCK EXTRACTION DATA

Date	Close	Volume
2024-03-15	1490	51840100
2024-03-18	1526	66602000
2024-03-19	1531	49266200
2024-03-20	1531	38425600
2024-03-21	1568	85481500

"Close" represents the price level at which the last trade took place when the market closed for the day. "Volume" shows the degree of activity or liquidity for that stock on the market.

B. Data Preprocessing

In this study, historical stock data was retrieved from Yahoo!Finance. After acquiring the data, some of the columns were removed as they were irrelevant for the analysis. Sorting the dataset in order of date to keep chronological order is a very critical factor in almost all forms of time series analysis. Adding more features to a model is one step toward better capturing the nuanced relationships and dependencies existing within financial markets and hence leads to more accurate and robust predictions of stock prices from the model. Other variables that were included in this dataset to enhance the predictive power of the model were the gap between the opening and closing prices and indicators for working days and months. These new variables provide insight into temporal trends and behavior of the markets, which could not have been done otherwise, and thus facilitate better predictions.

- Gap between opening and closing price: The model will understand days in which prices move highly compared with days when prices remain unchanged. This will help the model understand short-term price trend predictions.
- Working days and months: These variables enabled the model to accommodate known breaks or closures within the markets and seasonal adjustments in demand.

Despite TFT's capability to manage multicollinearity, VIF was utilized in this study to converge the results under the statistical requirements. The VIF was calculated for each predictor variable to measure the degree of multicollinearity. VIF refers to the measure of how much multicollinearity inflates the variance of a regression coefficient. Table II presents the results of VIF.

TABLE II. EVALUATION OF MULTICOLLINEARITY

Variables	Variance Inflation Factor (VIF)		
	ANTM	EXCL	ASII
Close	4.186406	5.989167	6.953210
Volume	2.413983	2.115669	3.727508
Gap_Open_Close	2.784901	2.486082	2.675353
Months	2.641024	3.239180	3.317118
Working_Days	2.482500	2.854557	2.880108

C. Proposed Method

In this section, a discussion and description regarding several deep learning methodologies are presented, followed by careful integration of these methods into the proposed model architecture.

Attention mechanisms are key components that allow the model to selectively focus on different segments in the input sequence while processing the temporal data for purposes of forecasting. Attentional mechanisms thus play a very important role in capturing complex temporal patterns, especially temporal interdependencies across a variety of time steps.

Recurrent Neural Network (RNN) stands as a deep learning model designed to process and transform sequential data inputs into specific sequential data outputs. Such sequential data typically encompasses words, sentences, or time-series data, where sequential elements are interconnected through complex semantic and syntactic rules.

Long Short-Term Memory (LSTM) is one such subtype of RNN, it is applied to sequence data to identify any underlying patterns within it. There may be present sequence data in the form of sensor readings, stock prices, or natural language. All these, while taking the position in the sequence of not only the actual value into account, are obtained during the prediction phase.

The Transformer, a deep learning architecture reliant on attention mechanisms [24], distinguishes itself by necessitating shorter training times compared to preceding recurrent neural architectures like LSTM. More precisely, this model accepts tokenized input tokens and, at each layer, contextualizes each token concurrently with other input tokens through attention mechanisms. Through their self-attention mechanisms, these models adeptly discern patterns spanning extensive sequences, effectively weighing the significance of each time step for accurate predictions. Parallel processing capabilities of Transformers expedite training and inference, useful for long time series. Moreover, by construction, Transformers inherently learn meaningful features from data, avoiding thorough manual feature engineering. By design ready to scale up and adapt, the Transformers are tailored to decode complex relationships in time and positions them as very powerful tools to uncover insights and predict trends within time series data.

The Temporal Fusion Transformer (TFT) represents a transformer-derived model utilizing self-attention mechanisms to grasp the intricate temporal variations across multiple time sequences. It stands as a potent tool for addressing multi-horizon and multivariate time series forecasting scenarios.

TFT uses time-dependent exogenous input features, which are made up of apriori unknown inputs (z) and known inputs (x), as well as static covariates (s), which offer contextual metadata about measured entities that is independent of time, to predict the future. Past target values (y) within a look-back window of length k are used as input. TFT uses quantiles to output prediction intervals rather than just a single value. At time t, every quantile q forecast of τ-step-ahead is expressed as follows:

$$\hat{y}_i(q,t,\tau) = f_q(\tau,\ y_{i,t-k:t},\ z_{i,t-k:t},\ x_{i,t-k:t+\tau},\ s_i) \qquad (2)$$

Where, q: quantile, $y_{i,t-k:t}$: historical target values, $z_{i,t-k:t}$: unknown inputs, $x_{i,t-k:t+\tau}$: known inputs, s_i: static covariates.

The proposed method is visualized in Fig. 2.

Fig. 2. The TFT Architecture [21].

To improve the flexibility of the TFT architecture, Gated Residual Networks (GRN) are incorporated into several layers of the architecture. They accomplish this by adding skip/residual connections, which transfer a layer's output to higher, non-adjacent levels in the network. As a result, the model has the ability to identify superfluous non-linear processing layers and exclude them. GRN dramatically lowers the number of parameters and processes needed while enhancing the model's generalization capabilities across a variety of application contexts. Fig. 3 illustrates the GRN architecture. ELU stands for Exponential Linear Unit activation function.

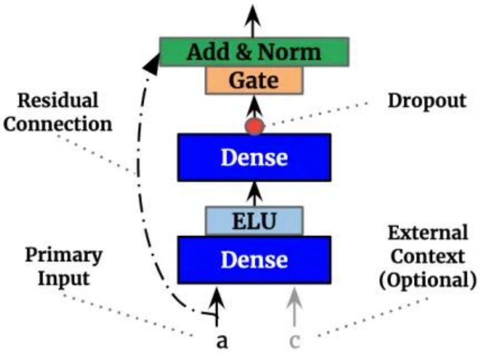

Fig. 3. Gated Residual Network [21].

In order to enable temporal variable selection, local temporal representation processing in the Sequence-to-Sequence layer, and static temporal representation enrichment, static covariate encoders obtain context vectors from static metadata and embed them into various TFT network segments. The conditioning of temporal representation learning with static data is made possible by this integration.

A different variable selection block is constructed for every type of input in the variable selection network, which includes static covariates, past inputs (both known and unknown that vary over time), and known future inputs. By learning to assess the importance of every input feature, these blocks allow the Sequence-to-Sequence layer that follows to handle the reweighted sums of the transformed inputs at each time step. Learned linear transformations of continuous data and entity embeddings of categorical features are examples of transformed inputs. Thus, the variable selection block of static covariates omits the external context vector, which is obtained from the output of the static covariate encoder block. Fig. 4 illustrates the Variable Selection architecture.

Fig. 4. Variable Selection Network [21].

The TFT network substitutes a Sequence-to-Sequence layer for the positional encoding commonly found in Transformers in the Sequence-to-Sequence component. Due to its ability to capture local temporal trends through recurrent connections, this adaptation is more suited for time series data. This block uses context vectors to initialize the first LSTM unit's cell state and concealed state. Additionally, they add to the static enrichment layer by adding static data to the temporal representation that was learned from the Sequence-to-Sequence layer.

Value relevance is evaluated by the Interpretable Multi-head attention mechanism on the basis of the connections between keys and queries. It works similarly to information retrieval in that it finds the most pertinent documents (values) by comparing a search query (query) to document embeddings (keys) [25]. Fig. 5 shows the adjustments made by the TFT to ensure interpretation. Instead, it shares many head-specific weights for values across all the attention heads.

$$InterpretableMultiHead\ (Q,K,V) = \frac{1}{h}\sum_{i=1}^{h} head_i W_H$$

Using a combination of the Transformer's Self Attention mechanism and the LSTM Sequence-to-Sequence, TFT was utilized to augment learnt temporal representations with static data about measured entities and to capture temporal dependencies at various time scales. In this study, a historical data window size of 12 was employed, with a prediction horizon of 3 for forecasting stock prices.

Table III presents a comprehensive outline of the TFT method utilized for forecasting stock prices.

D. Evaluation Metrics

This research incorporates prevalent loss functions for time-series forecasting, MAE (Mean Absolute Error), MAPE (Mean Absolute Percentage Error), and SMAPE (Symmetric Mean Absolute Percentage Error). The respective equations for each loss function are computed as follows:

- MAE measures the average absolute difference between the predicted values and the actual values.

$$MAE = \frac{1}{N}\sum_{i}^{N}|\mathrm{y}_i - \hat{y}_i| \quad (4)$$

- where, N: number of observation, $\mathrm{y_i}$: the actual value of the i^th^ observation, $\hat{\mathrm{y}}_\mathrm{i}$: the predicted value of the $\mathrm{i^{th}}$ observation.

- MAPE measures the average absolute percentage difference between actual and predicted values [26].

$$MAPE = \frac{1}{N}\sum_{t=1}^{N}\left|\frac{\mathrm{A}_t - \mathrm{F}_t}{A_t}\right| \quad (5)$$

- where, N is the number of data points, At and $\mathrm{F_t}$ denote the actual and forecast values at data point $_\mathrm{t}$, respectively.

- SMAPE calculates the percentage error for each data point, but it takes into account the scale of the actual and forecasted values by using their average.

$$SMAPE = \frac{100\%}{n}\sum_{t=1}^{n}\frac{|\mathrm{F}_t - A_t|}{(|\mathrm{A}_t| + |F_t|)/2} \quad (6)$$

- where, n is the number of data points, $\mathrm{F_t}$ is the forecasted value, $\mathrm{A_t}$ is the actual value.

E. Training Procedure and Computational Cost

Data splitting was carried out based on window size and horizon. It commences by ordering the dataset based on transaction dates. Subsequently, the dataset undergoes segmentation into training and validation sets. Spanning 5 years, the dataset comprises 1227 rows per individual stock, divided into 90% for training and 10% for validation.

It used a window size of 12 days, refers to the number of prior time steps in consideration while predicting future time steps. The horizon parameter was set to three days, and its meaning was how far the forecasting horizon was to be projected into the future.

Close, Volume, and GapOpenClose were used as exogenous inputs, complemented by working days and months as known categoricals, which are indispensable for predicting closing price as the output target. The training and validation processes were executed on a computer equipped with a 2.3 GHz Intel Core i7 quad-core CPU and 16GB of RAM. It was estimated that each of the individual final models would complete training in less than 30 minutes and use approximately 89% of the CPU's computational resources. Variability of patterns between the different stocks posed a challenge because optimality in hyperparameters configuration had to be identified. Moreover, the extended duration of model training posed a significant obstacle.

IV. Result and Discussion

Based on research findings, TFT models have been very effective in problems of time series forecasting, especially in short-term stock price prediction. It has been shown that the model is capable of handling complicated and dynamic temporal patterns in stock price data [21], drawing from information in multiple variables including seasonality. The superiority of TFT is further manifested in its flexibility when trends change. Compared with Transformer models and Naïve models, the TFT models perform better and provide more accurate predictions. TFT is an effective and sophisticated way to increase accuracy and precision in time series forecasting analysis [21].

While TFT has demonstrated significant effectiveness in resolving time series forecasting issues, it is necessary to admit that some element of uncertainty always remains in the stock market. The dynamics of the market may alter due to some unpredictable events, sudden economic changes, or other external events that may remain hidden in historical data alone [27]. Other complementary strategies would be the incorporation of real-time market sentiment analysis, macroeconomic indicators, or geopolitical events into the model in order to increase its performance [28, 29]. This would yield an all-inclusive view of dynamic market conditions to TFT and help in making better decisions due to the uncertainties that characterize changes in stock prices. Table IV presents the comparison metrics used for TFT, Transformer, and Naïve models.

TABLE IV. Performance Evaluation Metrics

Ticker	**Model**	**Evaluation Metrics**		
		MAE	***MAPE***	***SMAPE***
ANTM	TFT	3.3324	0.0022	0.0022
	Transformer	43.6452	0.0289	2.8845
	Naïve	35.0000	2.1027	2.0805
EXCL	TFT	9.7546	0.0041	0.0041
	Transformer	57.3425	0.0265	2.6567
	Naïve	115.4754	4.8732	4.7502
ASII	TFT	38.2241	0.0078	0.0078
	Transformer	84.3230	0.0167	1.6806
	Naïve	125.2116	2.5817	2.6285

The TFT models use multivariate data: Close, Volume, GapOpenClose, Month, Day. At the same time, Transformer and Naïve models use univariate data: Close. Based on the above-presented evaluation metrics, TFT models significantly outperform Transformer and Naïve models.

The closing price informs about performance and price trends, the volume conveys relevant information about trading activity. GapOpenClose allows highlighting of days with large price fluctuations, Time_Idx puts information into the context of time, while months and working days serve to enable the model to capture seasonal and daily trends. Based on several effective variables, the TFT model has proved to be very effective in predicting short-term stock prices, as it indeed picked up complex patterns hidden within the stock price time series data.

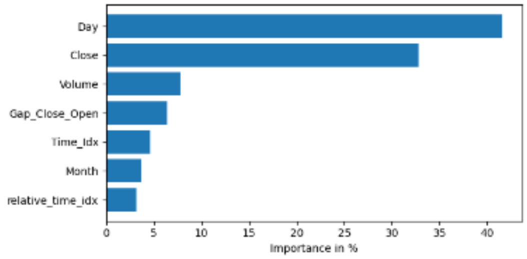

Fig. 6. ANTM encoder variables importance.

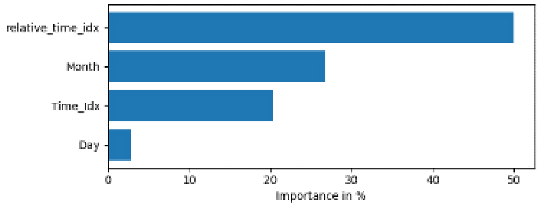

Fig. 7. ANTM decoder variables importance.

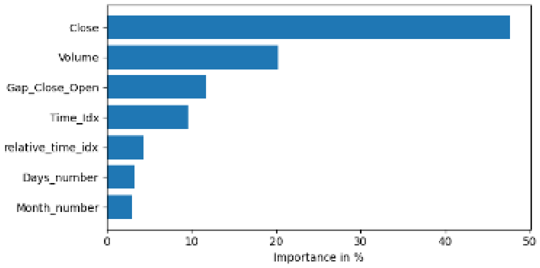

Fig. 8. EXCL encoder variables importance.

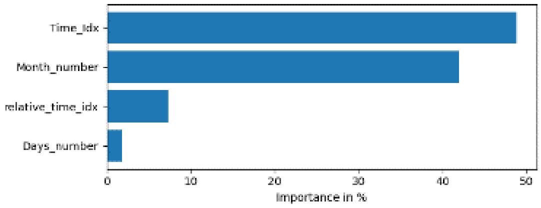

Fig. 9. EXCL decoder variables importance.

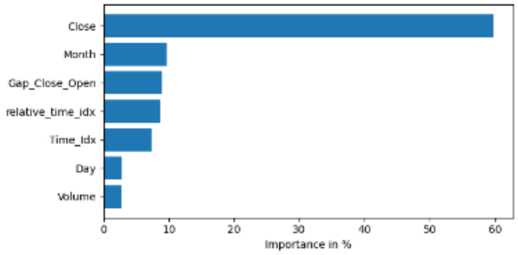

Fig. 10. ASII encoder variables importance.

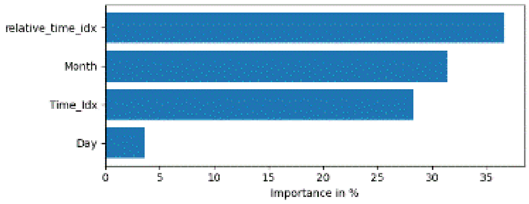

Fig. 11. ASII decoder variables importance.

Fig. 6 to Fig. 11 present evaluations of variables importance used in the encoder and decoder of the TFT models for forecasting ANTM, EXCL and ASII stocks. Encoder variables importance refers to how influential or informative the input variables are in the prediction task. It measures the effect of these variables on how well the model can capture and understand the patterns of data during it's encode phase. Decoder variables importance refers to the relevance of different features used during decoding.

Since every stock trend and patterns are different, the importance of encoder and decoder variables underline different priorities for each individual stock. This underlines the fact that customized approaches must be addressed for each individual stock.

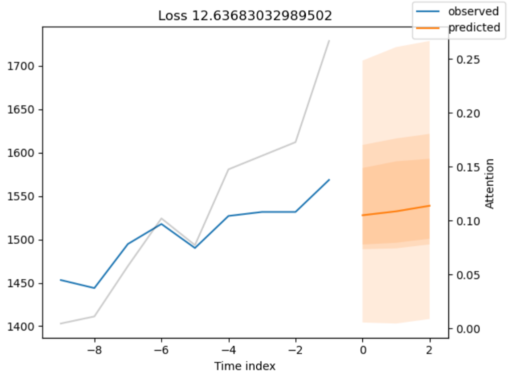

Fig. 12. ANTM prediction results.

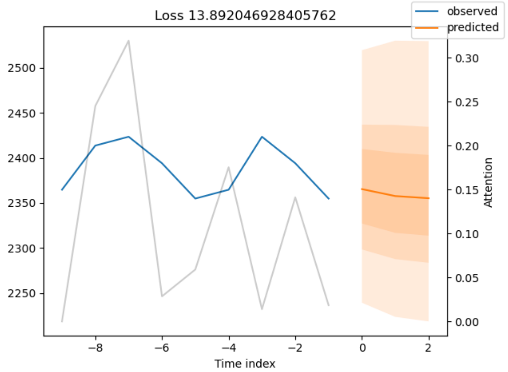

Fig. 13. EXCL prediction results.

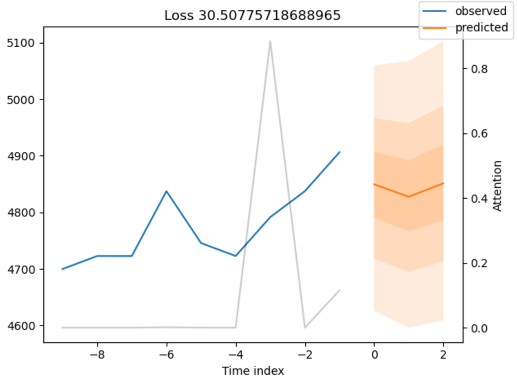

Fig. 14. ASII prediction results.

Fig. 12, 13, and 14 illustrates the prediction results within a real-world market scenario. The aim was to forecast three days ahead without having future data. The TFT model was employed to generate market predictions as of March 27, 2024. These predictions were subsequently compared with actual stock price movements observed at a later date.

The time index represents transaction dates in the dataset, numbers -6 to -1 denote historical dates given to the model, while 0, 1, and 2 are the predicted dates. Specifically, -1 corresponds to March 27, 2024 (the last date in the dataset), 0 corresponds to March 28, 2024, 1 corresponds to April 01, 2024, and 2 corresponds to April 02, 2024.

Grey lines in the plot represent the attention weights to understand the temporal patterns across past time steps. Observed line denotes the amount of attention the model pays to different points in time when making the prediction. Predicted line is an extrapolation, it refers to estimating an unknown value based on extending a known sequence of values or facts. Deviation in the prediction area is calculated using Quantile Loss, with output size=7.

$$\text{QuantileLoss(pred, outcome)} = \max\{q(\text{pred-outcome}),(q-1)(\text{pred-outcome})\} \quad (7)$$

Following a comprehensive evaluation three days later, the TFT model has demonstrated exemplary performance by accurately mirroring real-world stock movements in subsequent days. A key differentiator is the TFT model's ability to adapt to stock volatility, a capability that the Transformer and Naïve models lack.

The approach enables the TFT model to recognize the repeated patterns in closing prices at different time frames, which include trends, cycles, and seasonal variations. This aids in deciding when to make entries and exits for investments. Furthermore, the TFT model uses the opening and closing price differences to identify the patterns that may indicate reversals or continuations in markets. Other contributors to the sentiment analysis include day-of-the-week and month effects. For instance, due to weekend outlooks, the market sentiment is usually optimistic on Fridays, or cautious on the first trading day of the month since there are economic data releases.

This work has emphasized that the TFT model is very effective at capturing temporal patterns. From an application perspective, the TFT model represents one of the more advanced tools available for development in pattern recognition and predictive modeling tools, providing investors and analysts with increased and empowered analytical skills in terms of spanning market dynamics, and making fully informed and reasoned short-term decisions.

V. Conclusion

In this study, we proposed a TFT model for stock price prediction by employing multiple variables to find the influence of each variable on stock price prediction. This approach achieved an outstanding MAPE score of 0.0022. Additionally, the TFT architecture is also applied to detect sudden fluctuations in stock markets, as can be seen from the results. Nevertheless, these fluctuations may not consistently manifest at regular intervals or adhere to identical cycles on each occasion. It is imperative to acknowledge the inherent unpredictability inherent in stock market dynamics. Future research aims to investigate the integration of emerging technologies, such as reinforcement learning, with the objective of augmenting the model's robustness and efficacy in discerning intricate and dynamic patterns.

Method for Prediction of Motion Based on Recursive Least Squares Method with Time Warp Parameter and its Application to Physical Therapy

Kohei Arai[1], Kosuke Eto[2], Mariko Oda[3]
Information Science Department-Saga University, Saga City, Japan[1]
Applied AI Laboratory, Kurume Institute Technology, Kurume City, Japan[1, 2, 3]

***Abstract*—We build an exercise therapy support system for children with disabilities that applies artificial intelligence technology. In this study, a 3DCG character shows a model body-building exercise, and at the same time provides feedback such as calling out to the trainee. At that time, to make the exercise therapy work more effectively, the trainee's movement is attempted to be corrected by notifying the trainee with a voice or other means before the trainee's movement deviates significantly from that of the 3DCG character. Since there is inevitably a delay between the movements of the 3DCG characters playing the role of the trainee and the trainer, it is necessary to predict this delay using time series analysis. The Recursive Least-Squares estimation: RLS method was used for this prediction method. In addition, the similarity of the movements of both companies was evaluated using the Dynamic Time Warping: DTW method, and the time warp calculated in this process was used as input for the RLS method. The results of the experiment confirmed that the predictions were made with sufficient accuracy and that when the degree of similarity was low, the 3DCG character playing the trainer's role spoke to them, leading to improvements in the trainees' movements.**

Keywords—Exercise therapy; disabled person; body-building exercise; 3D character; Recursive Least-Squares estimation: RLS method; Dynamic Time Warping: DTW method

I. Introduction

There are various body-building exercises as exercise therapy for children with disabilities [1]. Physical training is important not only for overcoming functions that are impaired by a disability, but also for mental and emotional stability, releasing stress, adapting to a group, and developing social skills. However, because children with disabilities have significantly different physical fitness characteristics depending on their stage of growth and the type and severity of their disability, it is necessary to provide guidance tailored to everyone, rather than one-size-fits-all guidance. It is also important to determine the appropriate amount of exercise for the trainee. However, many years of teaching experience and knowledge are required to select the type and amount of exercise that are appropriate for the trainee. Therefore, it is important to develop trainers who can select body-building exercises that are suitable for each individual and show them model movements.

In this research, we build an exercise therapy support system for children with disabilities that applies artificial intelligence technology. In this study, a 3DCG character shows a model body-building exercise, and at the same time provides feedback such as calling out to the trainee. At that time, to make the exercise therapy work more effectively, the trainee's movement is attempted to be corrected by notifying the trainee with a voice or other means before the trainee's movement deviates significantly from that of the 3DCG character.

Since there is inevitably a delay between the movements of the 3DCG characters playing the role of the trainee and the trainer, it is necessary to predict this delay using time series analysis. The Recursive Least-Squares estimation: RLS method [2] was used for this prediction method. In addition, the similarity of the movements of both companies was evaluated using the Dynamic Time Warping: DTW method [3], and the time warp calculated in this process was used as input for the RLS method. This approach is original. Namely, using time warp information as a time series of data, trainee’s action is predicted with a one-period ahead prediction based on RLS method is a new method. Conventional methods evaluate a user's action after it is completed, but the proposed method provides instructions to the user in real-time while the user is performing the action. By providing instructions to users in real-time, it is expected that the learning effect will be improved compared to conventional methods.

Meantime, using ThreeDPose [4], save the 3DCG character of the trainer and the movement of the trainee, that is, information on the skeletal coordinates of the positions and angles of each joint of the human body, in CSV formatted data. Based on this information, the difference in movement between the two is detected, and time-series prediction (one-period ahead prediction) is performed considering the delay in movement between the two, if the difference is likely to become large, a 3DCG character playing the role of a trainer is created. Accordingly, the character makes suggestions to the trainees.

The results of the experiment confirmed that the predictions were made with sufficient accuracy and that when the degree of similarity was low, the 3DCG character playing the trainer's role spoke to them, leading to improvements in the trainees' movements.

In the next section, related research works are described followed by the proposed methods. Then, experiments are described followed by a conclusion with some discussions.

II. Related Research Works

As for the RLS method related research works, there are the following papers, prediction method for time series data including many missing data based on RLS method is proposed [5]. On the other hand, limits of application of RLS method in parameter estimation of Kalman filter is clarified [6].

Meanwhile, there are the following papers which deals with time series analysis, prediction method for time series of imagery data in eigen space is proposed [7]. On the other hand, Geography Markup Language: GML based representation of time series of assimilation data and its application to animation content creation and representations are created [8]. Meantime, recovering method of missing data based on the proposed modified Kalman filter when time series of mean data is known is proposed [9]. Furthermore, time series analysis for shortened labor mean interval of dairy cattle with the data of BCS, RFS, weight, amount of milk and outlook is conducted [10]. Moreover, Recursive Least Square: RLS method-based time series data prediction for many missing data is attempted [11].

Meanwhile, there are the following skeleton related research works, 3D skeleton model derived from Kinect depth sensor camera and its application to walking style quality evaluations is proposed [12]. Human gait skeleton model acquired with single side video camera and its application and implementation for gender classification is attempted [13]. Furthermore, human gait skeleton model acquired with single side video camera and its application and implementation for gender classification is also conducted [14].

On the other hand, there are the following similarity related research works, Fuzzy Genetic Algorithm: FGA for prioritization determination with techniques for order performance by similarity to ideal solution is proposed [15].

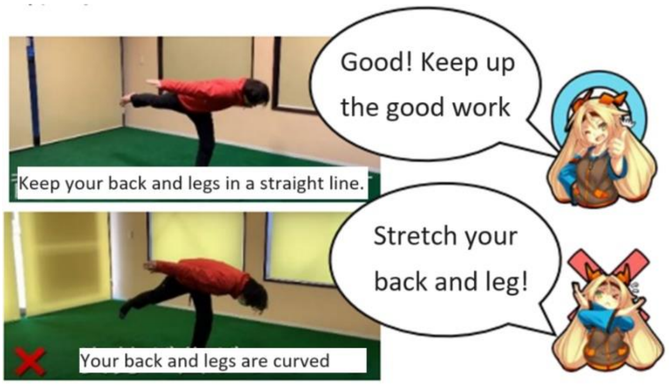
Meantime, there are the following matching related research works, Ground Control Point: GCP acquisition using simulated Synthetic Aperture Radar: SAR and evaluation of GCP matching accuracy with texture features is attempted [16]. Also, Dynamic Programming: DP matching based image retrieval method with wavelet Multi Resolution Analysis: MRA which is robust against magnification of image size is proposed [17]. On the other hand, methods for wild pig identifications from moving pictures and discrimination of female wild pigs based on feature matching methods are proposed [18].

Meanwhile, there are the following prediction-related research works, a comparative study between eigen space and real space-based image prediction methods by means of the Autoregressive Model: AR is conducted [19]. Also, a comparative study on image prediction methods between the proposed morphing utilized method and the Kalman filtering method is conducted [20]. A prediction method for time series of imagery data in eigen space is proposed [21]. On the other hand, image prediction method with non-linear control lines derived from Kriging method with extracted feature points based on morphing is proposed [22].

III. Proposed Methods and System

A. System Overview

The motivation of this study is to provide guidance tailored to everyone, rather than one-size-fits-all guidance for physical therapy, training to disabled person. It is also important to determine the appropriate amount of exercise for the trainee. Therefore, encouragement to trainees is very important. Fig. 1 shows an example of an encouragement system using 3DCG character in a personalized basis for physical trainings. If the trainee action is just the same as 3DCG character of trainer action, then 3DCG character praise the trainee and if the trainee action is differed from the trainer action, then 3DCG character encourage trainee with the correct message.



Good! Keep up the good work
Keep your back and legs in a straight line.
Stretch your back and leg!
Your back and legs are curved

Fig. 1. Example of encouragement system using 3DCG character on a personalized basis for physical training.

Always trainee follows trainer's actions so that time delay would occur. Therefore, prediction of trainee action would be required for the creation of the most appropriate message for correction. Also, distance measurements between trainer and trainee actions are required as well. RLS method is used for the prediction while DTW is applied for distance measurements. To measure the distance of joint positions and angles between trainee and trainer, skeletons which are derived from ThreeDPose are used.

B. Procedure

The procedure of the proposed method is as follows:

1) Analysis of trainee movement by skeletal estimation: Extract the trainee's three-dimensional coordinate data using skeleton estimation technology (ThreeDPose),

2) Creating trainers' and leaners' movements using 3DCG characters: Create exercise motion animations of 3DCG characters to present sample body-building exercises which are made by the trainer.

3) Calculating the similarity between the ideal trainer's action and the trainee's action using DTW: Find the ideal trainer's movement in the body-building exercise and the movement of the trainee's skeleton and calculate the degree of similarity between them using DTW.

4) Judging the quality of physical movement in trainees: Determine the quality of the trainee's body movement based on the similarity obtained in Eq. (3) and the trainee's skeletal coordinate data.

5) Predicting trainee movement using RLS: Predict abnormal behavior (large discrepancy between both movements) in advance using the RLS method based on the similarity obtained in Eq. (3)

6) Make a caution (give a notice) to the trainees to correct their movement (behavior).

C. Methods

1) Creation of 3DCG characters: Unity3D is a game engine with a built-in IDE developed and sold by Unity Technologies. Content can be developed mainly by programming using C#. It is compatible with cross-platforms such as PC (Windows, macOS), mobile (iOS, Android), web browsers (WebGL), home game consoles (PlayStation 4, Xbox One, Nintendo Switch, etc.), and supports VR/AR/ It also supports content development for MR equipment.

2) Detection of skeleton: We use skeleton estimation AI to extract the coordinate information of the model 3D character and the learner. ThreeDPose, the skeleton estimation system used this time, has a program inside the script that manages the current coordinate data, and each script is written in C#. Information such as rotation and position is stored in it, and we use this to extract and understand the movements of the learner.

Python/MediaPipe is an alternative to a motion capture method, which is a technology that converts the movements of people and objects into data. With motion capture, it is possible to check the player's movements in real-time. The gymnastics movements performed by the trainer were filmed in advance, and the coordinates and angles of each body part and joint were converted into time-series data. By using this data as correct gymnastics movements, the trainee's movements captured with a web camera are scored.

3) Similarity measurement: DTW (Dynamic Time Warping) A method for comparing and matching time-series data and temporal fluctuations. The focus is on time warps. It is mainly used in various fields that require comparison and matching of temporal patterns, such as speech recognition and action recognition.

4) Prediction of movement: RLS method: The model that is often modeled using the RLS method is the ARX (Auto-Regressive with eXogenous input) model (it is not a particularly complex model, and the image is the output of 1, 2,…,n steps before or the output of 1, 2,…,n steps before). is a model whose input depends on the current output. The features are as follows, Predictions are stable even with little data, Prediction accuracy does not decrease significantly.

5) Quality evaluation of trainees' movement in comparison to the movement of trainers. The ideal amount of movement can be determined from the amount of movement of the trainer. Using this method, ideal coordinates are calculated and compared with the actual movements of the trainee.

IV. Experiment

A. Skeleton Extraction

Coordinates were extracted by comparing with a model 3DCG character. Information on each joint was managed using a C# script under the name "jointpoint." This stores information such as rotation (angle) and position (coordinates). An example of skeletal data read by ThreeDPose is shown in Fig. 2.

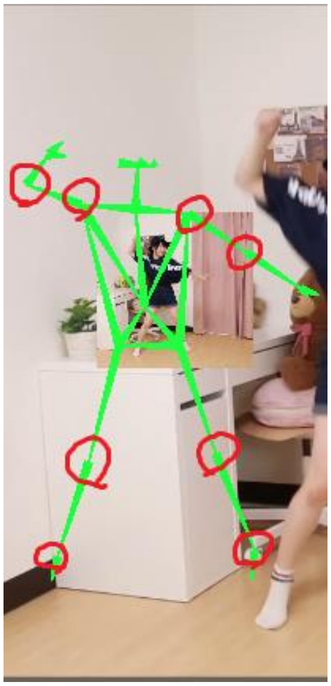


Fig. 2. Example of skeletal data read by ThreeDPose.

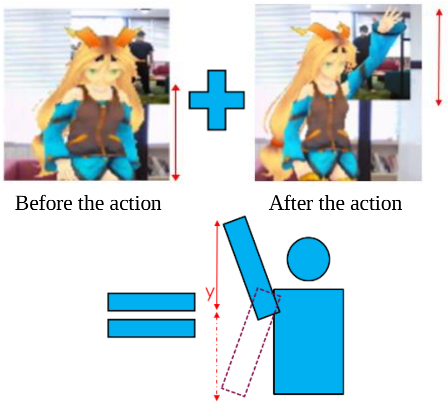
B. Comparison of Actions Between Trainer and Trainee

The method of calculating pass/fail differs depending on the exercise, but let's use the exercise of raising the left hand as an example (see Fig. 3). First, calculate the amount of movement from the change in coordinates before and after exercise. If the amount of movement of the trainer data is the ideal amount of movement, calculate the amount of movement of the trainee in the same way. By comparing these, it is determined whether the user is performing the same movements as the trainer.



Before the action

After the action

No change in x, z. Find the amount of movement of y

Fig. 3. An example of the exercise of raising the left hand.

We calculated the similarity using the speed of each part of the trainee and trainer characters. However, this method defeats the purpose of determining the similarity of "movements" because the speed at which the trainees move their bodies differs. Furthermore, there is also the problem that the speed changes rapidly, such as increasing, decreasing, or becoming 0, making the calculation of similarity unstable as shown in Fig. 4. Therefore, we conducted an experiment to perform DTW using information obtained through observation. An object that serves as an observation device is placed in 3D space, and it is programmed to collect information A and information B seen from the observation device. In this research, we mainly collect the coordinate distance between the observation device and the learner, and the coordinate distance between the observer and the 3DCG character as shown in Fig. 5.

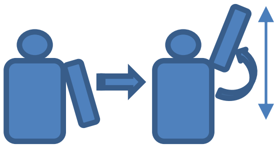


Fig. 4. Similarity calculation using the speed of each part of the trainee and trainer characters.

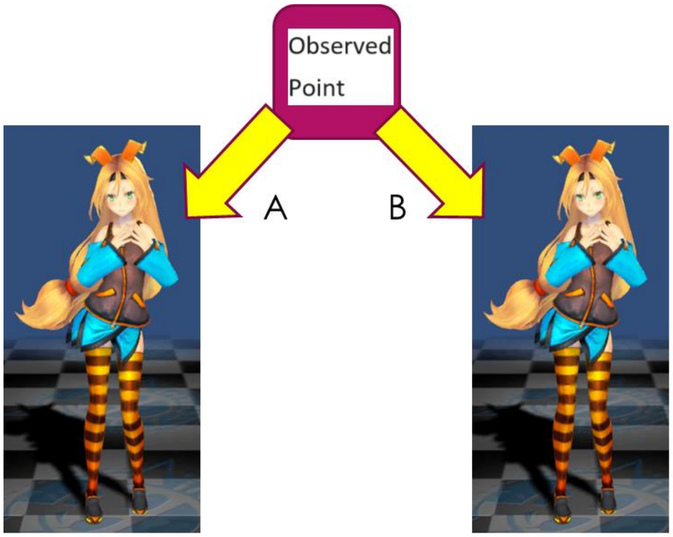

Fig. 5. Coordinate distance between the observer and the 3DCG characters.

C. Calculate Similarity by DTW (DTW Distance)

The distance from the observation point to each part of the trainee and the distance to each part of the trainer was recorded for every frame. Fig. 6 shows an example of the time series data of joint points.

Also, Fig. 7 shows an example of the time series of corresponding joint points connected. The graph below shows the difference in similarity when comparing the data of the upper trainer and the data of the lower trainee.

D. One-Period Ahead Prediction of Trainee's Actions

Next, we will explain how to predict learner movements (surveys and experiments) to eliminate feedback delays. To explain, there is a time delay between when the system detects the learner's movements and when the learner calls out to them. Even if the system can detect the learner's movement, the learner's behavior may have already finished by the time the system detects the learner's abnormal behavior and calls out to him. Therefore, we thought that it would be possible to correct the movements by predicting the movements of the learner using time-series data from time warp and giving feedback such as calling out to the learner before the learner engages in abnormal behavior.

LightGBM is a typical prediction method based on linear regression. Therefore, firstly, the LightGBM is tried to predict the actions of trainer and trainee. An example of the result is shown in Fig. 8.

	A	B		A
1	1.231215		1	1.037787
2	1.231215		2	1.037956
3	1.231215		3	1.037956
4	1.231215		4	1.037956
5	1.231215		5	1.037956
6	1.231215		6	1.037956
7	1.231215		7	1.037956
8	0.96367		8	1.037956
9	1.068625		9	1.056942
10	1.601985		10	1.059628
11	1.555619		11	1.061921
12	1.549107		12	1.06026
13	1.128521		13	1.060333

Fig. 6. Example of the time series data of the observed joint points between trainer and trainee.

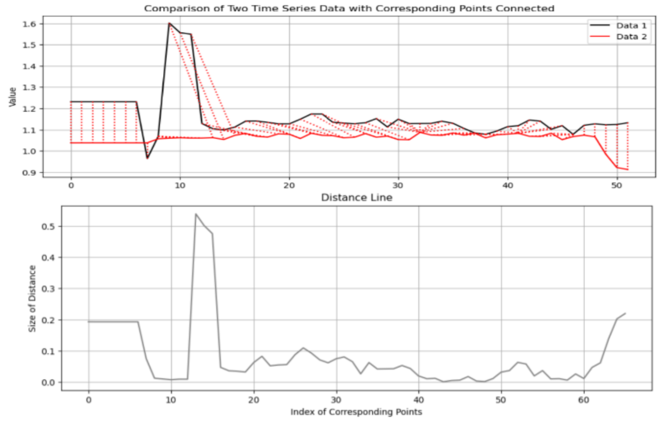

Fig. 7. Example of the time series of corresponding joint points connected.

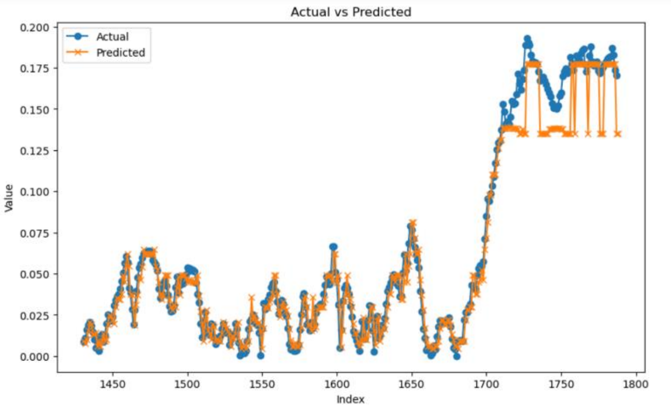

Fig. 8. Example of the prediction of action based on LightGBM.

As shown here, the prediction results with LightGBM can predict to some extent in the first half, but the prediction accuracy drops significantly in the second half. Also, adjusting various hyperparameters is made, but it did not stabilize. Furthermore, predictions were difficult with little data.

The actual DTW distance and the RLS predicted value match to some extent, and if this data can be incorporated into the system, it is inferred that it will be possible to predict the trainee's movements in advance and provide feedback based on that prediction.

Fig. 9 shows an example of one period ahead prediction of the action based on RLS (Comparison of the action between actual action and the predicted action).

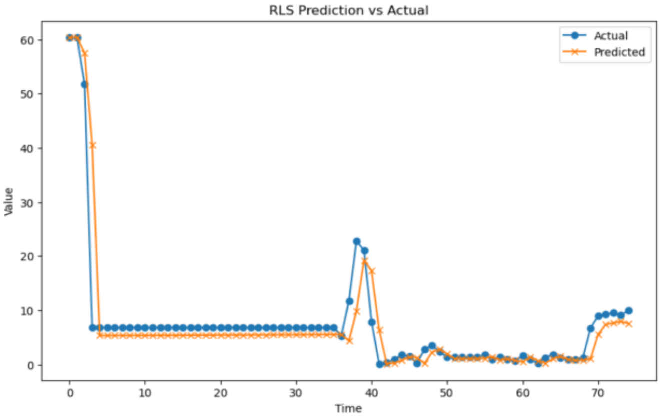

Fig. 9. Example of one period ahead prediction of the action based on RLS (Comparison of the action between actual action and the predicted action).

V. Conclusion

In this study, we build an exercise therapy support system for children with disabilities that applies artificial intelligence technology. In this study, a 3DCG character shows a model body-building exercise, and at the same time provides feedback such as calling out to the trainee. At that time, in order to make the exercise therapy work more effectively, the trainee's movement is attempted to be corrected by notifying the trainee with a voice or other means before the trainee's movement deviates significantly from that of the 3DCG character.

Since there is inevitably a delay between the movements of the 3DCG characters playing the role of the trainee and the trainer, it is necessary to predict this delay using time series analysis. The RLS method was used for this prediction method. In addition, the similarity of the movements of both companies was evaluated using the DTW method, and the time warp calculated in this process was used as input for the RLS method. The results of the experiment confirmed that the predictions were made with sufficient accuracy, and that when the degree of similarity was low, the 3DCG character playing the trainer's role spoke to them, leading to improvements in the trainees' movements.

Future Research Works

Further experiments are required for evaluation of the effect on physical trainings using the proposed methods and the system.

***Abstract*—The steady progression of information technology today is opening up opportunities for extensive automation across various sectors, including the automotive industry. The active development of IT systems has paved the way for V2X (Vehicle-to-Everything) technology, which enables communication such as "vehicle-to-vehicle" and "vehicle-to-road infrastructure". This article focuses on exploring the use of V2X technology to create "intelligent transportation". Currently, V2X technologies are not widely adopted due to the limited coverage of 5G networks. Although the existing 4G network is adequate for streaming HD content and playing online games, it cannot support the safer and smarter operation required for autonomous cars. Nevertheless, within the 4G network framework, it is possible to develop a comprehensive solution for automating car traffic. This would significantly reduce the number of road accidents and optimize traffic flow. This article explores the implementation of V2X technology in road traffic to achieve these goals.**

Keywords—V2X; V2V; autonomous vehicles; DSRC; scenarios; frequency spectrum

I. Introduction

In recent years, there has been a trend towards the widespread adoption and development of Internet of Things (IoT) systems, which enable various smart devices to fully interact through data transmission networks [1-9]. Within the IoT framework, a notable trend is the development of V2X (Vehicle-to-Everything) technology. This technology allows for the automation of all traffic and ensures synchronization with road systems, traffic lights, and road signs. Examples of the implementation of this technology are presented in publications [10-15].

The relevance of this study lies in the fact that V2X technology has not yet been implemented in neighboring countries. For the widespread adoption of such solutions, it is important to thoroughly examine their advantages and disadvantages before project development. The V2X system can provide complete connectivity between all vehicle systems, optimizing many processes. As shown in study [16-19], such systems enhance road safety and reduce road maintenance costs. This technology enables vehicles to connect to all devices through data transmission networks, with real-time data exchange [20-25].

As demonstrated in study [26-29], a more optimal approach to vehicular communication technology is cellular communication. For this purpose, the 3GPP organization has developed a specialized solution known as C-V2X. This solution can utilize LTE technology. LTE-V offers low cost, rapid development, and high efficiency.

The data transmission network between vehicles can use unlicensed frequencies, increasing the frequency range. However, licensed frequencies can be used for transmitting video and audio information from subscribers. Cloud access can be provided based on a commercially licensed spectrum for information transmission. This technology ensures data transmission to the cloud using a commercially licensed spectrum. All objects in the C-V2X data transmission network exchange data through the PC5 Sidelink data channel interface. Data transmission is based on Rel.14 and Rel.15 technologies. Data can be transmitted with low latency in two modes: Mode 1 and Mode 2. Data transmission can occur both within and outside the coverage area. As shown in [30-31], the technology can work with both the LTE radio interface and the wireless data transmission interface. The two data transmission modes are demonstrated in Fig. 1 [32].

Another type of data transmission using V2X technology can be organized based on the LTE-Uu wireless communication channel - this is a type of wireless interface for organizing communication between subscriber devices and the base station. Data transmission over such a line occurs in both the downstream and upstream directions with the allocation of special resources to subscribers for various information transfer processes. Most of the data traffic on such a channel will be periodic and have the same packet volumes.

If we consider data transmission based on the PC5 wireless communication channel, then during such transmission security messages are also transmitted, which makes it possible to ensure data confidentiality. This standard was developed by the 5GAA Association and operates at a frequency of 5900 MHz.

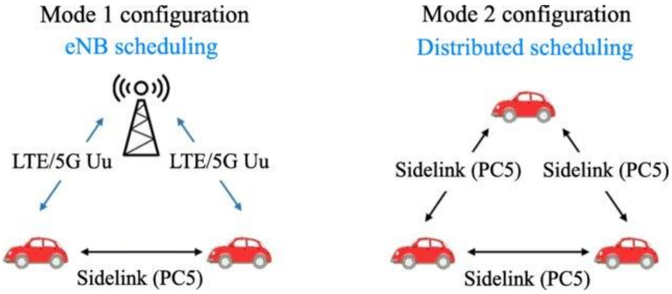

Fig. 1. Mode 1 and 2 data transmission in the V2X network.

Sidelink 1 mode provides scheduled data transmission when a base station is available. This mode uses three scheduling mechanisms: semi-persistent scheduling, UE message-based scheduling, and inter-carrier scheduling. The first mechanism is problematic when used on high mobility highways where all vehicles must be connected to a base station.

UE message-based scheduling mode operates regardless of the presence of a base station with direct communication between different devices. Interoperability can be achieved via PC5 interfaces at 5900 MHz. This means that this mode can be characterized as autonomous. Interaction is ensured within line of sight. This mode provides higher speed characteristics compared to the IEEE 802.11p protocol. In addition, the security of information in this mode is quite high.

Below in Table I we demonstrate the comparative characteristics of cellular communication technologies and DSRC.

TABLE I. COMPARATIVE CHARACTERISTICS OF CELLULAR COMMUNICATION TECHNOLOGIES AND DSRC

Options	DSRC	Cellular
Completion of technology	Fully developed	Versions 14 and 15 are fully developed, version 16 is under development
Data network	WI-FI standard	LTE/4G
Modulation technology	OFDM	CK-FDM
Relay technology	Not supported	HARQ
Communication model	Hybrid	Mixed
Support for network communication functionality	Limited functionality	Support available
Resource selection	CSMA-CS	Semi-permanent transmitter
Data transmission delay level	Low latency	Minor delay
Range of action	Short range	For long-term communication
Mobility	Up to 300 km/h	Up to 500 km/h
High traffic density	There will be losses	No losses
Security	Not much functionality	Have support

From Table I, it can be show that mobile communication technology has excellent characteristics for high traffic density and high reliability.

For roads with little traffic, DSRC technology is sufficient.

The modeling will be carried out on the basis of C-V2X, since Almaty can be classified as a city with high traffic density.

II. RESEARCH INTO POTENTIAL V2V WORK

The basis is the section of roads around Energo University, where numbers 1-5 are base stations (Fig. 2).

This is only a theoretical calculation, since at the moment leading telecom operators have just begun to launch 5G networks. As we know, the current 4G network is fast enough to stream HD content and play online games, but it cannot support safer and smarter autonomous cars.

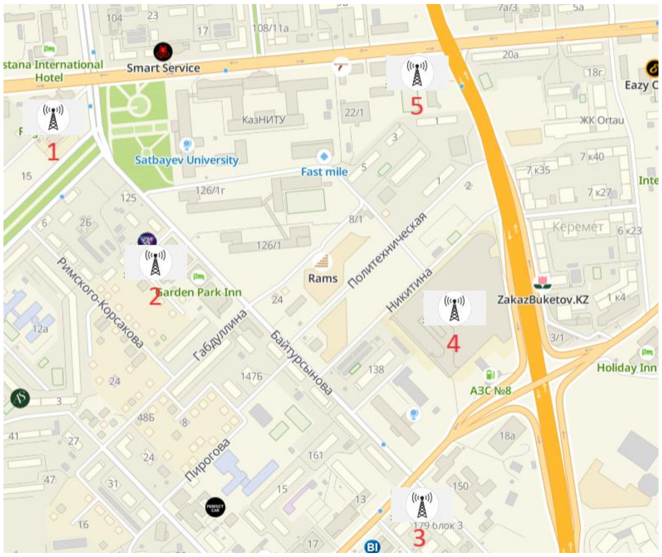

Fig. 2. Location of base stations.

Vehicles move in groups in two divided lanes down and up, respectively. It is assumed that the direction of propagation of messages is N, and the vehicles are moving at a constant speed c [m/s].

To integrate existing network infrastructure (V2I) with vehicle-to-vehicle (V2V) communications with lower transmission latencies, we use time latency as a key performance indicator to evaluate the effectiveness of this protocol switching mechanism. In particular, we measure the propagation rate of time latency when vehicles transmit warning messages via V2V or V2I protocols [33].

The time delay d for a message propagating within a group of connected machines can be expressed as the difference between the reception timestamps of the message at the destination and source machines. Specifically, if a message is sent from machine A and received by machine B, the time delay d is calculated using the reception timestamps T_B and T_A recorded at machines B and A, such as:

$$d = T_B - T_A \tag{1}$$

This measurement assumes that the clocks on machines A and B are synchronized. If the clocks are not synchronized, additional methods, such as clock synchronization protocols or time-stamping with a common reference, may be needed to accurately determine the time delay.

The time interval d(i,j) required for the successful end-to-end transmission of a message of length L (bits) between a pair of vehicles i and j, where the i-th vehicle transmits the message to the j-th vehicle, can be expressed using the data transfer rate f(i,j) (Mbit/s), such as:

$$d(i,j) = \frac{L}{f(i,j)} \tag{2}$$

L= 1024. As you know, in 5G networks the speed can reach 20 Gbit/s, but let’s take only 1000 Mbit/s.

Respectively: d_{IJ}=0,128 s.

In vehicle communication systems, ensuring high throughput and low latency is critical, particularly for safety and emergency prevention. The total delay D within a group of vehicles is influenced by the propagation speed and the time delays across individual links between pairs of vehicles. For the entire a group of vehicles, the total delay D is the sum of the delays across all links (i,j) in the path of communication:

$$D = \sum_{i,j} d(i,j) = L \sum_{i,j} \frac{1}{f(i,j)}, \qquad (3)$$

If we assume a constant data rate f for each link (i,j) in the a group of vehicles, and denote d(i,j) as the propagation delay for the communication channel between vehicle i and vehicle j, the total delay D for transmitting a message of length L across the cluster can be reformulated, Eq. (3) becomes:

$$D = \frac{L*h}{f} \qquad (4)$$

This equation highlights the total delay as a combination of the constant transmission delay and the cumulative propagation delays in the network. This is crucial for evaluating the performance and reliability of vehicle communication networks, especially in scenarios requiring low latency.

To incorporate the role of roadside units (RSUs) in the overall communication delay within a vehicular network, we consider the propagation delay dRSU specifically associated with the network infrastructure. This delay is defined as the time required to transmit a message of length L between two consecutive RSUs, denoted as the m-th and (m+1)-th RSUs, at an effective data rate fRSU. The formula for the propagation delay dRSU is given by:

$$d_{RSU} = \frac{L}{f_{RSU}} \qquad (5)$$

This consideration of RSUs is critical in vehicular communication networks, especially in scenarios of low traffic density where vehicle-to-vehicle (V2V) communication may not always be reliable. By integrating RSUs, the network can ensure more consistent and uninterrupted communication, enhancing the overall communication potential and resilience of the system.

Eq. (5) describes the propagation rate of the time delay within the existing network infrastructure in a VANET, focusing on both uplink and downlink communications between vehicles and roadside units (RSUs). The propagation rate of the time delay can vary depending on the direction of communication uplink (vehicle to RSU) or downlink (RSU to vehicle):

$$d_{UP} = \frac{L}{g(i,m)}, d_{DOWN} = \frac{L}{g(m,i)} \qquad (6)$$

Uplink Delay is the time delay for a message sent from a vehicle to an RSU. It depends on the message length L and the effective data rate g (i,m) for uplink communication.

Downlink Delay is the time delay for a message sent from an RSU to a vehicle. It similarly depends on the message length L and the effective data rate g (m,i) for downlink communication.

In practical scenarios, factors such as network congestion, signal interference, and infrastructure capacity can impact these delays, influencing the overall performance of the vehicular communication system.

The propagation rate of the time delay d_{V2I} for communication between vehicles and RSUs via Vehicle-to-Infrastructure (V2I) depends on the effective data transmission rates in both the uplink and downlink channels, as well as within the RSU itself. These delays can be denoted as d_{UP} and d_{DOWN} for the uplink and downlink, respectively, and d_{RSU} for the internal RSU communication delay.

The total time delay d_{V2I} for V2I communication can be expressed as the sum of these individual components:

$$d_{V2I} = d_{UP} + d_{RSU} + d_{DOWN} = L\left(\frac{1}{g(i,m)} + \frac{1}{f_{RSU}} + \frac{1}{g(m,i)}\right) \quad (7)$$

Similarly, we define the propagation speed with time delay for communication via V2V (i.e., d_V2V [s]) as:

$$d_{V2V} = d + \Delta T \qquad (8)$$

As defined in Eq. (3), d represents the time delay within the group of vehicles, which includes the message length L, data transfer rate f, and the propagation delays d(i,j) between vehicles in the cluster. The average value of d is approximately 0.128 seconds.

The time interval ΔT can be calculated using as:

$$\Delta T = \frac{\Delta x}{c} 50 \text{ км/ч} = 15 \text{ м/с} \qquad (9)$$

$$\Delta T = \frac{3}{15} = 0{,}2 \text{ с}$$

To calculate the average transmission time delay davg in a vehicular network, we consider various communication scenarios including Vehicle-to-Vehicle (V2V) and Vehicle-to-Infrastructure (V2I) communications, as well as the impact of traffic density and vehicle speed.

In the proposed model, the entire system is considered as an alternating update process, where the vehicle connection cycles through three distinct phases:

- Phase 1: No connection, where a vehicle moves alone in the vehicle grid, indicating a completely disconnected scenario. This can occur in low-density areas or in remote regions due to the lack of network infrastructure such as roadside units (RSUs).
- Phase 2: Short-range communication, where vehicles form clusters when the distance between vehicles is below a certain threshold, which typically favors V2V communication. The effectiveness of V2V communication depends on the distance between vehicles being within the upper communication bound (e.g. ⩽ 125 meters). It is assumed that V2I communication is not available either due to the lack of infrastructure or due to a preference for using V2V in a cluster.
- Phase 3: Long-range communication, where vehicles enter a wireless cell, allowing them to connect to an RSU via V2I. This phase typically occurs in areas with established network infrastructure. V2I communication

is available, allowing vehicles to communicate with the network infrastructure. V2V communication is not considered in this phase, possibly due to network policies or infrastructure-based communication priority.

In Phase 1, where a vehicle is initially isolated, the likelihood of establishing a multihop connection to another vehicle depends on the occupancy of cells in its path. For a vehicle to connect to the next vehicle via multihop V2V communication, each of the cells along the intended path must be occupied by at least one vehicle.

To calculate the average transmission time delay davg in a vehicular network based on the alternating phases of connectivity, we use the characteristics and assumptions defined for each phase:

$$d_{avg} = p(\tau = 1)\Delta T + p(\tau = 2)d + p(\tau = 3)d_{V2I} \qquad (10)$$

Since Almaty is taken as the starting point, R will be taken as 10 m (Figure 3).

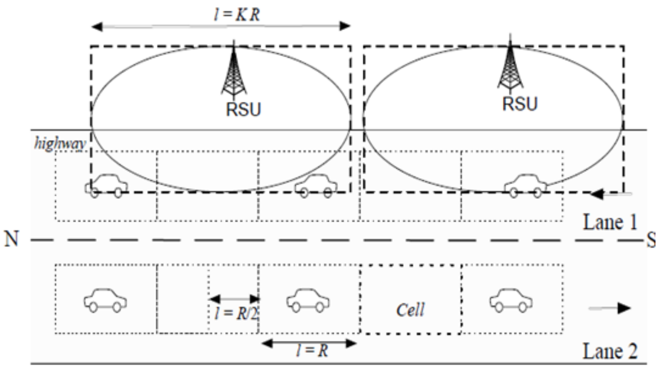

Fig. 3. Vehicle mesh.

Fig. 3 shows a vehicular network model where the coverage area is divided into cells shaped like honeycombs, each with a diameter L of 500 meters, we consider the connectivity of vehicles moving within these cells. Each cell can be occupied by one or more vehicles, and this occupancy affects the probability of establishing multihop communication, as:

$$(p_{e,w})^N = (1 - \exp(-\lambda_{e,w}R))^N, \qquad (11)$$

where, λ(e,w) is represents the density of cars per meter, indicating how vehicles are distributed along a particular direction (e.g., east-west); G is denotes the gap or distance between vehicles. In this context, G is set equal to R, the minimum inter-vehicle distance required for communication.

N = 1: The number of cells, N, is set to 1 because we are considering only the immediate gap (or cell) between two vehicles for determining connectivity.

In the scenario described, we are focusing on a situation where vehicles are distributed across a grid of cells, and the connectivity between vehicles is determined by the occupancy of these cells.

This equation reflects the likelihood of establishing a connection based on vehicle density and the minimum inter-vehicle distance required for communication:

$$p_{e,w} = (1 - \exp(-\lambda_{e,w}R)) \qquad (12)$$

$$\mathrm{N} = \frac{\mathrm{G}}{\mathrm{R}} \qquad (13)$$

$$\mathrm{p}_{\mathrm{e,w}} = 0{,}99$$

This equation reflects the likelihood of establishing a connection based on vehicle density and the minimum inter-vehicle distance required for communication. The model highlights that higher vehicle densities (larger λe,w) increase the probability of occupied cells, thereby enhancing connectivity within the vehicular network.

Density is taken as 0,2 auto/m according to Almaty statistics [33].

In Phase 3, the focus is on Vehicle-to-Infrastructure (V2I) communication, where vehicles rely on roadside units (RSUs) to establish and maintain connectivity. The probability that a vehicle moving in a specific direction (e.g., up/down) will connect via V2I to the next vehicle depends on the presence of RSUs within the network, then where in this case the number of cells N is:

$$N = \frac{G}{K * R} \qquad (14)$$

N=0,002.

In the context of vehicular networks partially covered by a wireless network, the mesh size L is defined as L=K−Rl = K - Rl=K−R, where K is a constant greater than zero, and R represents the minimum inter-vehicle distance. This setup suggests that the wireless network has larger coverage cells compared to the vehicular network's inter-vehicle communication range.

Given these parameters, we can state the following theorem regarding the average time delay dV2I for transmitting a message of length L from a vehicle in a vehicular network to another vehicle via a wireless network (V2I communication).

Theorem: the average time delay required for a vehicle moving in a vehicular network, which is partially covered by a wireless network, to transmit a message of length L is:

$$d_{avg} = p_{e,w}(N = 1) * \Delta T + p_{e,w}\left(N = \frac{G}{R}\right) * d +$$

$$+ p_{w,e}\left(N = \frac{G}{K * R}\right) * d_{V2I} \qquad (15)$$

$$d\_avg = 0{,}99 * 0{,}2 + 0{,}99 * 0{,}128 + 0{,}002 * 0{,}128 = 0{,}324\, s$$

This theorem implies that, under the given conditions, the average delay for transmitting a message from a vehicle to the infrastructure is approximately 0,128 seconds. This delay is assumed to be consistent across different scenarios, possibly due to uniform network conditions, standard data rates, and minimal variation in transmission distances.

The average delay of 0,128 seconds is an idealized constant, likely based on empirical data or theoretical models. In practice, this value may vary depending on factors such as network congestion, data rate variability, and environmental conditions.

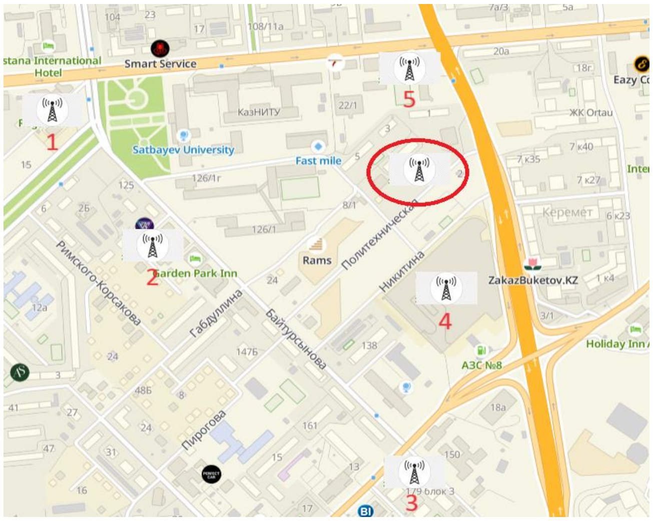

Fig. 4. Proposed location of BS.

This theorem provides a simplified model for understanding the delay characteristics in a vehicular network with partial wireless coverage, offering insights into the expected performance in terms of latency.

At a car speed of 15 m/s. This result complies with all V2X safety standards (3gpp rel.14).

In heavy traffic: the length of the selected section is 2500 m. Let's say there are 4 rows on each street, then it comes out to 10 000 m. The average length of a light car is 4 m. 2500 cars / 10 000 m = 0,25.

During traffic jams, the density reaches 0,25 cars/m. Accordingly, the speed will be lower - 20 km/h = 6 m/s. The distance between cars will also decrease to 1 m: d_avg ≈ 0,6 s.

Vehicle communication requires high throughput and low latency. Any delay can affect the prevention of an emergency. This is the result of 5G not being at its full potential.

BS are located around the perimeter of the block, but BS are located along the main roads. By placing the base station as in Fig. 4, it would be possible to solve two problems: reduce the delay for those driving along the streets (Fig. 5) and raise the level of customer service for students living in hostel #1.

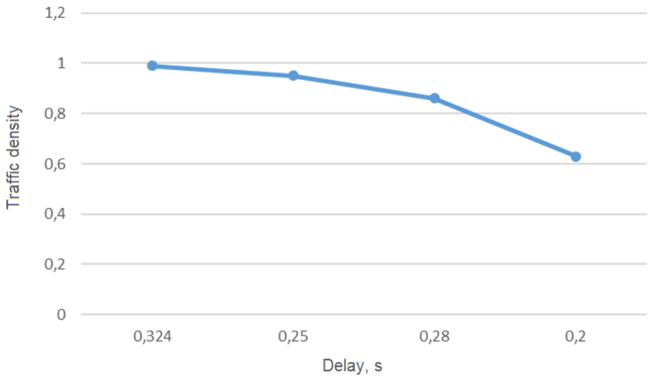

Fig. 5. Dependence of delay on traffic density.

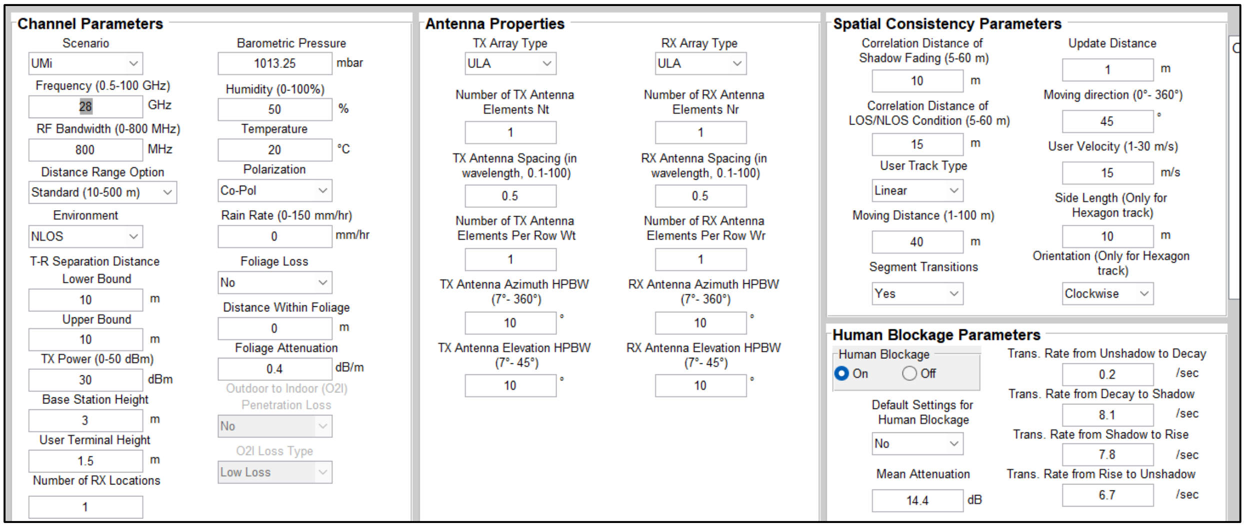
III. Software Modeling

With the advent of 5G solutions for automotive networks, the range of radio technologies is expanding to include the millimeter wave spectrum. This expansion is also supported by the recent move towards radar communications (RADCOM), which involves the integrated use of the 77 GHz band for both communications and sensing. The capabilities of existing programs for use in a transportation environment are being explored. Examples include WinProp, which uses deterministic ray tracing techniques, and NYUSIM, which relies on stochastic channel modeling.

Both modeling platforms have their unique advantages and disadvantages. WinProp provides results that closely match individual scenarios but requires more effort to model each scene accurately. On the other hand, NYUSIM is highly flexible and can be quickly adapted, although justifying a specific channel model parameterization can be challenging. The parameters were taken from the transmitting part (Fig. 6).



Channel Parameters

Scenario: UMi
Frequency (0.5-100 GHz): 28 GHz
RF Bandwidth (0-800 MHz): 800 MHz
Distance Range Option: Standard (10-500 m)
Environment: NLOS
T-R Separation Distance
Lower Bound: 10 m
Upper Bound: 10 m
TX Power (0-50 dBm): 30 dBm
Base Station Height: 3 m
User Terminal Height: 1.5 m
Number of RX Locations: 1

Barometric Pressure: 1013.25 mbar
Humidity (0-100%): 50 %
Temperature: 20 °C
Polarization: Co-Pol
Rain Rate (0-150 mm/hr): 0 mm/hr
Foliage Loss: No
Distance Within Foliage: 0 m
Foliage Attenuation: 0.4 dB/m
Outdoor to Indoor (O2I) Penetration Loss: No
O2I Loss Type: Low Loss

Antenna Properties

TX Array Type: ULA
Number of TX Antenna Elements Nt: 1
TX Antenna Spacing (in wavelength, 0.1-100): 0.5
Number of TX Antenna Elements Per Row Wt: 1
TX Antenna Azimuth HPBW (7°- 360°): 10 °
TX Antenna Elevation HPBW (7°- 45°): 10 °

RX Array Type: ULA
Number of RX Antenna Elements Nr: 1
RX Antenna Spacing (in wavelength, 0.1-100): 0.5
Number of RX Antenna Elements Per Row Wr: 1
RX Antenna Azimuth HPBW (7°- 360°): 10 °
RX Antenna Elevation HPBW (7°- 45°): 10 °

Spatial Consistency Parameters

Correlation Distance of Shadow Fading (5-60 m): 10 m
Correlation Distance of LOS/NLOS Condition (5-60 m): 15 m
User Track Type: Linear
Moving Distance (1-100 m): 40 m
Segment Transitions: Yes

Update Distance: 1 m
Moving direction (0°- 360°): 45 °
User Velocity (1-30 m/s): 15 m/s
Side Length (Only for Hexagon track): 10 m
Orientation (Only for Hexagon track): Clockwise

Human Blockage Parameters

Human Blockage: ● On ○ Off
Default Settings for Human Blockage: No
Mean Attenuation: 14.4 dB

Trans. Rate from Unshadow to Decay: 0.2 /sec
Trans. Rate from Decay to Shadow: 8.1 /sec
Trans. Rate from Shadow to Rise: 7.8 /sec
Trans. Rate from Rise to Unshadow: 6.7 /sec

Fig. 6. Input parameters.

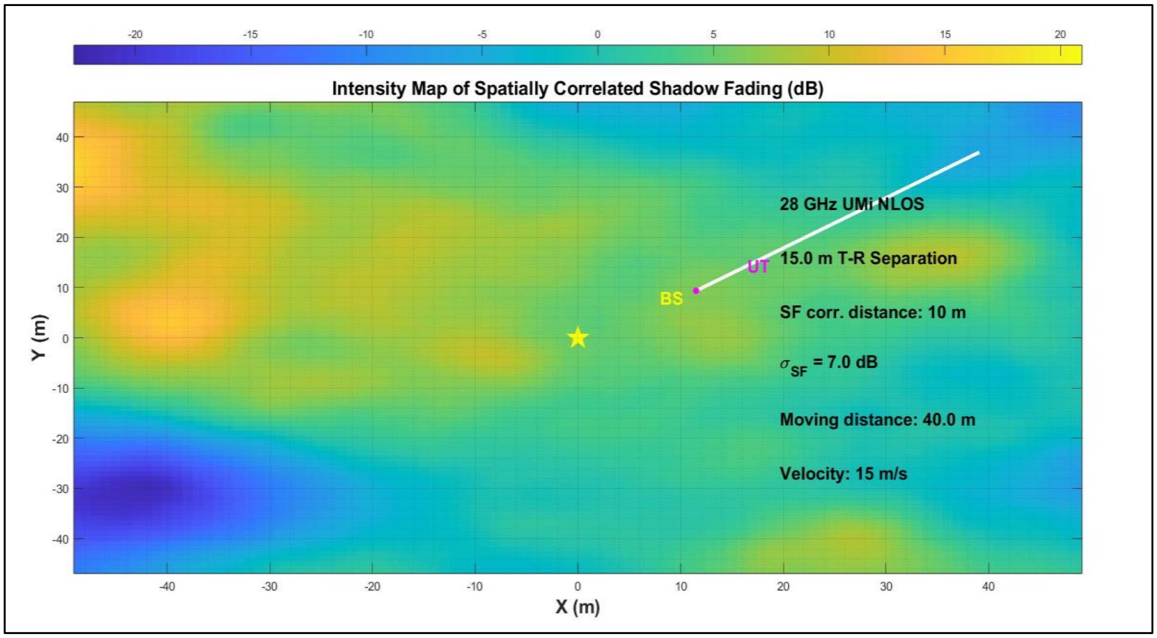


Fig. 7. The intensity map of spatially correlated shadow attenuation (dB).

User speed – 15 m/s (≈50 km/h). The intensity map of spatially correlated shadow attenuation (dB) is shows in the Fig. 7.

5G will operate at 28 GHz and it is important to consider signal attenuation when calculating the system's energy budget. Based on the graph, it can be seen that as the distance from the base station (BS) increases, the signal level decreases, and at the end the client receives an attenuation of 7 dB.

Signal attenuation (path loss) is measured in decibels (dB) and is usually expressed by the formula:

$$PL(dB) = 20\, log_{10}(d) + 20\, log_{10}(f) + C, \quad (16)$$

where d - distance between transmitter and receiver, f - signal frequency, C –constant.

Therefore, you can use this formula to calculate the signal attenuation over the distance to the end. Knowing that the client receives 7 dB of attenuation, given that SF (shadow fading) varies continuously from -20 dB to 20 dB, this parameter can be included in the energy budget calculation.

The energy budget of a system is defined as the difference between the transmitted power and the signal attenuation, taken into account by various factors such as losses in cables, amplifiers and others.

This information allows you to evaluate how effectively the signal transmission system copes with environmental conditions and how much power must be transmitted to ensure an acceptable signal level at the end (Fig. 9).

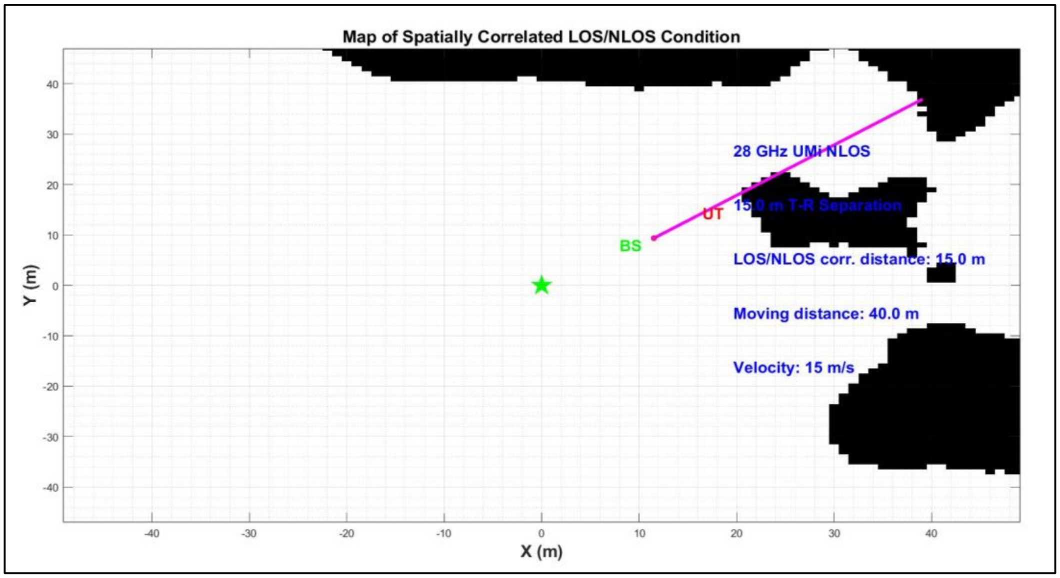

Fig. 8. Map of spatially correlated LOS/NLOS state.

The model clearly accounts for NLOS (non-line of sight) conditions, which are typical in urban environments. Urban areas often feature obstacles such as buildings and other structures that can create shadows and block signals.

Given that 5G utilizes millimeter waves, which have a higher frequency than previous generations of networks, these waves are more susceptible to attenuation when passing through obstacles. Consequently, a denser placement of base stations along roads is required to ensure reliable coverage in urban areas.

These base stations, placed along roads, will help improve signal availability for moving objects, reducing the effects of shadows and blocking. However, it is always important to consider specific characteristics of the urban environment, such as geography, building height, population density, and other factors, when designing and deploying a 5G network.

The power delay profile (PDP) is a crucial parameter for characterizing a multipath channel. PDP represents the intensity of the signal received through a channel with different time delays (Fig. 9).

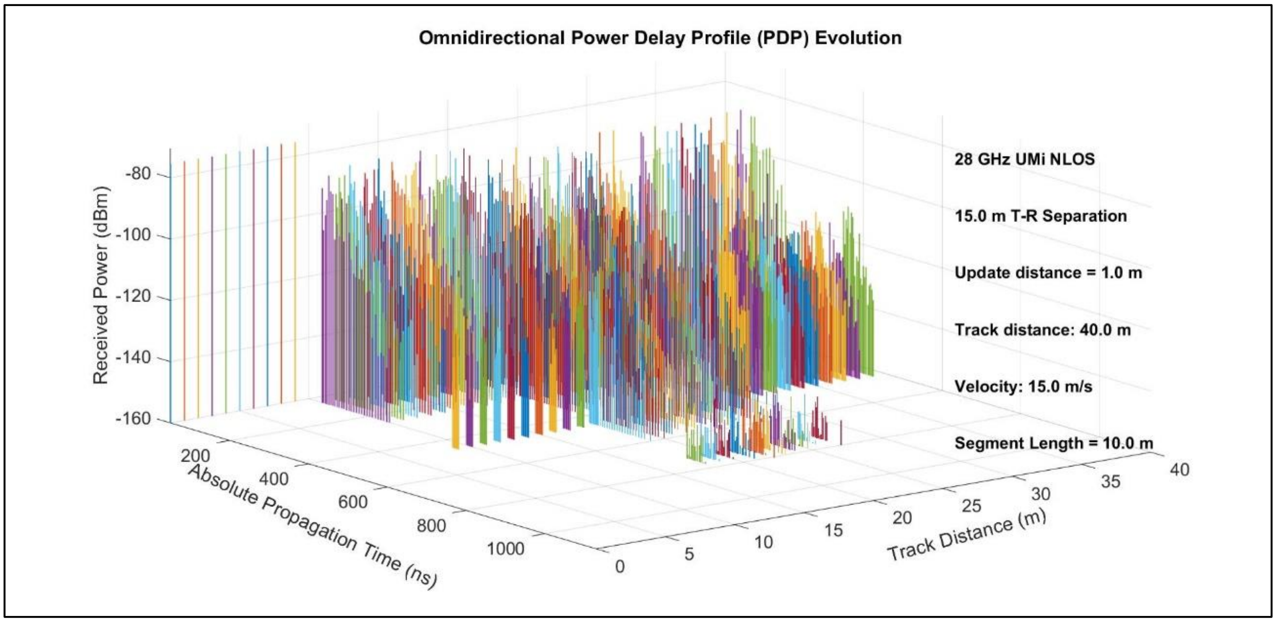

Fig. 9. Omnidirectional Power Delay Profile (PDP) (average values).

Recommendation ITU-R P.1407 specifies that the shape of the delay profile depends on the propagation parameters associated with the conditions under which the waves travel through the medium. The profile is created by multiple waves with different amplitudes and time delays. Waves with long delays have lower amplitudes due to propagation along a longer path.

From Fig. 9, it can be observed that an object located at 20-25 meters experiences maximum delay and minimum power. This may be attributed to the characteristics of the wave propagation path in the given medium, such as reflections and diffractions, which lead to multipath propagation of the signal. This observation is further supported by Fig. 8.

IV. CONCLUSION

The model of such a network represents a high-quality and expensive solution. Implementing it in Kazakhstan requires significant investments of both time and money. Discussions on the implementation of such networks are ongoing. To implement this solution, complete coverage of all highways and roads is necessary. Given the current challenges with full coverage in our country, the issue remains unresolved.

The research theorem considered allows us to estimate the average time delay for transmitting a message in a vehicular network that is partially covered by a wireless network. The average transmission time delay davg for a vehicle moving in a vehicular network, which is partially covered by a wireless network, is stated to be 0,324 seconds. This delay value is significant as it aligns with the safety standards for Vehicle-to-Everything (V2X) communications, particularly those specified in the 3GPP Release 14 standards.

In a heavy traffic scenario where the density reaches 0,25 cars per meter, the average time delay increases to approximately 0.6 seconds. This underscores the importance of delivering high throughput and low latency in high traffic environments.

The study results indicate the significant potential of 5G technology to provide reliable communications in vehicular networks. However, to fully realize this potential, additional infrastructure improvements and optimization of base station placement are required.

Message delay is critical to road safety, and the proposed solutions comply with 3GPP Rel.14. However, higher throughput and low latency are emphasized as necessary for vehicle interactions in dense traffic conditions.

Thus, the article highlights the importance of further research and development in the field of 5G networks to ensure secure and efficient communication in vehicular networks, especially under heavy traffic conditions.

IoT-Opthom-CAD: IoT-Enabled Classification System of Multiclass Retinal Eye Diseases Using Dynamic Swin Transformers and Explainable Artificial Intelligence

Talal AlBalawi, Mutlaq B. Aldajani, Qaisar Abbas, Yassine Daadaa
College of Computer and Information Sciences, Imam Mohammad Ibn Saud Islamic University (IMSIU), Riyadh

***Abstract*—Integrating Internet of Things (IoT)-assisted eye-related recognition incorporates connected devices and sensors for primary analysis and monitoring of eye conditions. Recent advancements in IoT-based retinal fundus recognition utilizing deep learning (DL) have significantly enhanced early analysis and monitoring of eye-related diseases. Ophthalmologists use retinal images in the diagnosis of different eye diseases. Numerous computer-aided diagnosis (CAD) studies have been conducted by using IoT and DL technologies on the early diagnosis of eye-related diseases. The retina is susceptible to microvascular alterations due to numerous retinal disorders. This study creates a new, non-invasive CAD system called IoT-Opthom-CAD. It uses Swin transformers and the gradient boosting (LightGBM) method to find different eye diseases in colored fundus images after applying data augmentations techniques. We introduce a Swin transformer (dc-swin) that is efficient and powerful by connecting a dynamic cross-attention layer to extract local and global features. In practice, this dynamic attention layer suggests a mechanism where the model dynamically focuses on different parts of the image at other times, learning to cross-reference or integrate information across these parts. Next, the LightGBM method is used to divide these features into multiple groups, including normal (NML), diabetic retinopathy (DR), tessellation (TSN), age-related macular degeneration (ARMD), Optic Disc Edema (ODE), and hypertensive retinopathy (HR). To find the causes of eye-related diseases, the Grad-CAM is used as an explainable artificial intelligence (xAI). To develop the Opthom-CAD system, preprocessing, and data augmentation steps are integrated to strengthen this architecture. Multi-label three retinal disease datasets, such as MuReD, BRSET, and OIA-ODIR, are utilized to evaluate this system. After ten times of cross-validation tests, the proposed Opthom-CAD system shows excellent results such as an AUC of 0.95, f1-score of 95.7, accuracy of up to 96.5%, precision of 95%, recall of 94% and f1-score of 95.7. The results indicated that the performance of the Opthom-CAD system is much better than that of numerous baseline state-of-the-art models. As a result, the Opthom-CAD system can assist dermatologists in detecting eye-related diseases. The source code is public and accessible for anyone to view and modify from GitHub (https://github.com/Qaisar256/Opthom-CAD).**

Keywords—*Computer-aided diagnosis; ophthalmology; multiclass classification; tessellation; age-related macular degeneration; Optic Disc Edema (ODE); hypertensive retinopathy; data augmentation; transformers; Swin; explainable AI; Internet of Things*

I. Introduction

The global burden of eye disorders, affecting 2.2 billion people, highlights fundus diseases as a significant cause of blindness (WHO [1]). These conditions, such as diabetic retinopathy (DR), age-related macular degeneration (ARMD), and hypertensive retinopathy (HR), often go undetected until they are severe due to their asymptomatic early stages. Early diagnosis and intervention are crucial to prevent irreversible vision loss [2, 3]. Traditional machine learning has helped analyze small datasets with manually engineered features. Deep learning (DL) has revolutionized the identification of a wide range of eye ailments, including tessellation (TSN) and optic disc edema (ODE), through extensive screening with fundus photographs [4, 5]. In ophthalmology, computer-aided diagnosis (CAD) systems have been developed to increase the accuracy of detecting eye-related diseases [6]. The researchers used image processing and machine-learning techniques to create CAD systems to distinguish various eye-related diseases. Retinal fundus images obtained by fundus cameras provide detailed patterns of each eye disease. Alterations in retinal arteries in fundus images can indicate vascular disorders, such as cardiovascular conditions. However, it is still challenging to identify eye diseases like glaucoma, cataracts, DR, TSN, ARMD, ODE, and HR through CAD systems [7–10].

When AI (artificial intelligence) [11–15] techniques like ML are added to CAD systems, they make it easier to classify eye diseases that are found through fundus devices. Nowadays, deep learning (DL) methods are categorized as ML, capturing more complex features from images to recognize eye-related disease disorders. In the past, the CAD systems diagnosed limited categories of eye-related diseases. Therefore, to address this issue, we have developed the IoT-Opthom-CAD system. This system, which incorporates the Internet of Things (IoT) technology, presents an innovative DL system. It is specifically designed to diagnose various eye-related diseases efficiently and test using IoT devices. The IoT-Opthom-CAD has excelled in classifying eye-related diseases through several hyperparameter fine-tuning and optimization steps.

The major contributions of this paper are given as follows:

1) We introduce a Swin transformer (Swin-DCL) that is efficient and powerful by connecting a dynamic cross-attention layer to extract local and global features. In practice, this dynamic attention layer suggests a mechanism where the model dynamically focuses on different parts of the image at other times, learning to cross-reference or integrate information across these parts.

2) The study introduces a novel IoT-based framework approach in ophthalmology diagnostics by combining lightweight Swin transformers with gradient boosting techniques, specifically LightGBM. This innovative method balances computational efficiency and high diagnostic performance, potentially revolutionizing disease detection in this field.

3) Applying Grad-CAM to explain the decision-making process for identifying eye diseases enhances model transparency and interpretability. While Grad-CAM is used in various fields, its application in elucidating diagnostic pathways in eye health through this new architecture is innovative.

4) The system has been validated across multiple datasets, demonstrating superior performance metrics compared to numerous baseline state-of-the-art models. The thorough validation and achieved metrics highlight the system's practical and clinical relevance, adding to its novelty.

II. Literature Review

Eye-related disease can result in several retinal abnormalities, including hard exudates, hemorrhages, microaneurysms, and other symptoms. On a short and constrained dataset, many machine-learning techniques were created to identify eye-related diseases using various image processing and computer-vision-based algorithms for analysis and feature extraction [16]. Advanced deep neural networks, particularly convolutional neural networks (CNN), have recently contributed substantially to medical imaging, as briefly described below. Utilizing a multi-branch neural network (MB-NN), this re-search leverages domain knowledge and retinal fundus images for glaucoma detection [17]. The effectiveness of this model was validated on real datasets, achieving an accuracy of 91.51%, sensitivity of 92.33%, and specificity of 90.90%. This showcases the model's capability to diagnose glaucoma, even with limited data, efficiently. This study developed a deep learning (DL) algorithm to predict referable glaucomatous optic neuropathy (GON) [18] from color fundus images. The research in study [19] utilizes convolutional neural networks (CNNs) to automate the identification of glaucoma by segmenting the optic cup and disc. This study examines the efficacy of the proposed method in comparison to conventional gradient-based learning [20] and other optimization techniques. The method employs an artificial algae optimization technique to enhance a novel deep learning system.

These studies address cataract detection and classification through various methodologies, including hybrid approaches and novel networks [21–25]. Utilizing datasets from several open-access sources and employing different CNNs, the methods achieve up to 96.25% accuracy in 4-class classification. These results underscore the potential of AI for enhancing cataract diagnosis and classification accuracy. Focusing on AMD, these papers propose different deep learning frameworks for its early detection and classification [26–29], achieving high diagnostic accuracy. For instance, one study utilized a comprehensive CAD framework, extracting local and global appearance markers from fundus images, and achieved an accuracy of 96.85%. These studies illustrate the efficacy of deep learning in identifying and categorizing AMD stages accurately.

Addressing DR, these studies introduce various deep learning approaches, from hybrid techniques to novel algorithms [30–34], significantly improving detection and classification. One method, using transfer learning on pre-trained CNN models, achieved an accuracy of 97.8% for binary classification. The advancements demonstrate the critical role of AI in early DR detection, potentially preventing vision loss. Spanning a wide range of deep learning methodologies, these studies collectively push the boundaries of ocular disease diagnostics [35–37]. For instance, a system that aimed to identify various ocular diseases achieved F1 scores as high as 88.56% and an AUC of 99.76%. These diverse approaches showcase the power of AI in diagnosing a broad spectrum of ocular conditions with high accuracy and efficiency. Each study's use of specific datasets and results highlights the transformative impact of deep learning in ophthalmology, offering new avenues for early detection, accurate diagnosis, and effective treatment of various eye diseases. Those state-of-the-art systems are compared in Table I.

TABLE I. State-of-the-Art Comparisons of Deep Learning Model for Recognition of Eye-Related Diseases

Cited Work	Methodology	Targeted Disease	Classes	Results	Limitations
[17]	Multi-branch neural network model for combining domain knowledge with retinal fundus images	Glaucoma	Binary (Glaucomatous/Non-Glaucomatous)	Accuracy: 91.51%, Sensitivity: 92.33%, Specificity: 90.90%	Relies on domain knowledge and important image regions
[18]	Deep learning algorithm for predicting referable glaucomatous optic neuropathy from fundus images	Glaucomatous Optic Neuropathy	Binary (Referable/Non-Referable)	AUC: 0.945, 0.855, 0.881 depending on dataset	Requires large dataset for training
[19]	Deep Learning with CNN for optic disc and cup segmentation	Glaucoma	Binary (Glaucomatous/Non-Glaucomatous)	Accuracy: 95.8% for disc, 93% for cup segmentation	Focuses on optic disc and cup segmentation
[20]	Deep learning with artificial algae optimization algorithm for glaucoma diagnosis	Glaucoma	Binary (Glaucomatous/Non-Glaucomatous)	High performance metrics (Accuracy: 98.15%)	Compares with traditional and other optimization methods
[21]-[24]	Various methodologies involving pre-trained CNNs, ensemble learning, and SVMs for cataract detection and classification	Cataract	Multi-class (Normal, Mild, Moderate, Severe)	Up to 96.25% accuracy	Varies, including image quality selection

[25]	Supervised miniature U-Net integrated with CNN for cataract detection and localization	Cataract	Binary (Cataract/Normal)	Accuracy: 96% with CLR	Focuses on early detection with CLR optimization
[26]-[28]	Various deep learning approaches for detecting and classifying age-related macular degeneration	Age-related Macular Degeneration	Multi-class for various AMD stages and types	Up to 98.76% AUC	Emphasizes on early detection and precise diagnosis
[29]	Explainable deep learning approach for AMD diagnosis through retinal lesion identification	Age-related Macular Degeneration	Binary/Multi-class for AMD and associated retinal lesions	-	Offers lesion-specific information for clinicians
[30]-[34]	Various deep learning models for detecting and classifying diabetic retinopathy	Diabetic Retinopathy	Binary and Multiclass for various DR stages	Up to 97.8% accuracy for binary classification	Focuses on early detection and classification
[35]-[37]	Deep learning models for retinal vessel segmentation	Various retinal disorders	-	High segmentation performance metrics	Addresses challenges in vessel segmentation

III. Proposed Methodology

The approach seeks to improve the precision and effectiveness of diagnosis by combining various processes, utilizing the capabilities of IoT and cloud technologies. This technique aims to offer a resilient solution for remote healthcare diagnostics. The proposed framework for detecting and classifying multi-class retinal disorders, known as the IoT-Opthom-CAD framework, is graphically depicted in Fig. 1.

B. Data Acquisition

In this study, an effective IoT-enabled technique has been developed for skin lesion diagnosis in IoT environment. We have developed and trained the IoT-Opthom-CAD system based on three online sources, such as multilabel retinal disease (MuReD) [38], the Brazilian multilabel ophthalmological dataset of retina fundus photos (BRSET) [39], and the ophthalmic image analysis-ocular disease intelligent recognition (OIA-ODIR) dataset [40]. We have collected initially 6,00 fundus images from these sources, including an average (NOM) of 1900, diabetic retinopathy (DR) of 2000, glaucoma (GLC) of 400, cataracts (CAT) of 200, age-related macular degeneration (AMD) of 300, and hypertension retinopathy (HR) of 1200 images. To balance the selected dataset, we have applied data augmentation and preprocessing to convert 6,000 images into 12,000 retinographics. Given that the images come from different sources, the resolution can vary from 520x520 to 3400x2800, depending on the source of the image. We have resized them to 224x224. Among these, the MuReD dataset stands out for its comprehensive collection of 2,208 images spanning 20 distinct categories. In parallel, the Brazilian Multilabel Ophthalmological Dataset (BRSET) emerges as a groundbreaking resource within Latin America, aiming to bridge the gap in the availability of public ophthalmological datasets. BRSET encompasses 16,266 color fundus photographs from 8,524 Brazilian patients, incorporating rich sociodemographic data to bolster its value as both a research tool and an educational resource. The Ophthalmology Image Analysis and Ocular Disease Intelligent Recognition (OIA-ODIR) dataset, a pioneering global resource for identifying multiple ocular diseases using fundus imagery. With 10,000 fundus images from 5,000 patients, it covers eight different ocular conditions, making it a vital tool for developing and testing deep-learning models in ophthalmology. All the numerical collected samples are shown as distribution in Fig. 2.

Fig. 1. A systematic flow diagram of proposed IoT-Opthom-CAD system.

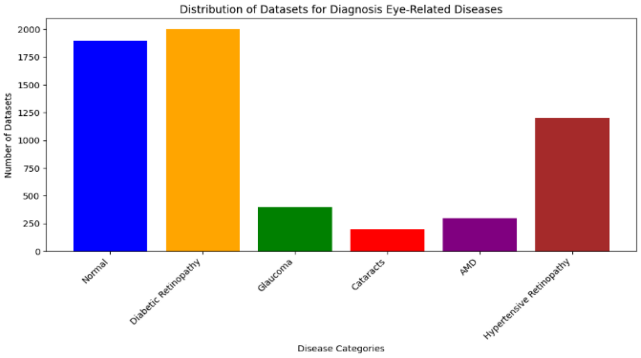

Fig. 2. A visual diagram of collection of datasets from different sources.

The MuReD, BRSET, and OIA-ODIR datasets as shown in Fig. 3 improve ophthalmic medical imaging and computer vision. By providing varied, high-quality data sources, they allow sophisticated diagnostic tools that are more accurate, moderate, and representative of the real-world population. This advancement helps diagnose and treat eye disorders early and advances artificial intelligence in healthcare, offering improved patient outcomes and medical research.

Amplification of the dataset is done to prevent misclassification caused by unbalanced data since the standard class of the finalized dataset has the most retinographics, and other classes have fewer images than the regular class. Based on the numerous fundus image acquisition capabilities, augmentation techniques were chosen. Different geometric transformations, such as proper 15 rotations, left 15 rotations, right 8 rotations, left 8 rotations, and horizontal flips, are included in the selected augmentation techniques. Training, validation, and testing sets were created from the supplemented dataset in the following ratio: 14:3:3.

An example of dataset acquired from different resources such as MuReD, BRSET, and OIA-ODIR, where figure (a) Shows the normal, (b) Represents the diabetic retinograph (DR) , figure (c) SHOWS the Glaucoma, figure (d) Display Cataracts, figure (e) Shows age-related macular degeneration (AMD), and (f) Represents hypertensive retinopathy (HR).

C. Color Preprocessing

All images are transformed into CIECAM02 color appearance model. This study introduces a novel method as shown in Algorithm 1 for enhancing low-light images, specifically aimed at improving the contrast and brightness of retinograph images while preserving intricate details. Initially, the non-uniform RGB retinograph images are transformed into the uniform CIECAM02 color space, where J denotes lightness, C represents chroma, and H signifies hue. Subsequently, a bicubic kernel is employed to extract both low and high frequencies from the J-plane of the CIECAM-02 color space. Color correction is then implemented using a sigmoid function to normalize the low frequencies. Following this, a white balancing step determines the ideal linear combi-nation of color-corrected channels. We got this combination by using constrained linear least squares minimization and focusing on the C component and its Jch color space counterpart that its histogram has equalized. Finally, the high frequencies are adjusted relative to the updated low frequencies and reintegrated to generate a sharper output.

Algorithm 1: Preprocessing : Color space transformation RGB to CIECAM02 and enhance the contrast

```
Input: A 2D array of RGB(x, y) where each row represents a time sample,
$low_{freq}$: Lower frequency bound for bandpass filter
$high_{freq}$: Upper frequency bound for bandpass filter
Output: contrast-enhance-image(x, y): preprocessed retinograph images
Function color-transformation ($image_{rgb}$):
    $Jch = image_{rgb} \rightarrow CIECAM02 - JCH(J, c, h)$
    $J = capture - channels(J_{ch}(i, j))$ ;
    $c = capture - channels(J_{ch}(i, j))$ ;
    $h = capture - channels(J_{ch}(i, j))$ ;
end
Function extract-frequency-low-high ($J_{image}$):
    Ly = $Bicubic_{convolution} - low(J_{image}, \theta, mode = 'same')$ ;
    $H_{image} = Extract - hight - frequency = J - Ly(Q)$;
end
Function color-balance ($Ly$,µ,$\sigma$):
$Ly$: $low\ frequencies$
µ: $Mean\ of\ low\ frequencies$
$\sigma$: $standard\ deviation\ of\ low\ frequencies$
    G = $color - balance - low(1/(1 + \exp(Ly - \mu)/\sigma))$ ;
    $return\ G$;
end
Function histogram- equalization ($G_{image}$):
    L-prime = $histogram - equal(G_{image})$ ;
    Return L-prime ;
end
Function modify-high-frequencies ($L - prime$,H):
$L$
$- prime$: $Histogram\ equalized\ version\ of\ the\ luminance\ component$
H: $High\ frequencies$
    Gy = $L - prime + (L - prime / L) \times H$ ;
    $return\ Gy$;
end

End of algorithm
```

D. Proposed Swin-DCL Architecture for Features Extraction

The Swin-DCL design proposes many stages or layers of processing, each serving a distinct purpose. The initial stage involves supplying the preprocessed retinographics as input to the IoT-Opthom-CAD system for feature extraction. This can enhance the accuracy and dependability of the diagnosis. Incorporating dynamic cross-attention into the Swin Transformer was done strategically at crucial stages in the network, such as after the initial patch embedding or within specific transformer blocks. This enhancement enables the model to effortlessly shift its attention across the network, prioritizing the most significant image regions for accurate diagnosis. By combining the Swin Transformer and the dynamic cross-attention layer, the IoT-Opthom-CAD system makes it easy to examine retinograph images. The system efficiently processes images through hierarchical stages as shown in Fig. 4, extracting features with increasing levels of abstraction. The dynamic cross-attention layer enhances this process by ensuring optimal allocation of the model's attention to the most informative parts of the image for ocular condition diagnosis.

Swin Transformer Block: A standard Swin Transformer block, S, operates on an input feature map, X∈RH×W×C, where H, W, and C represent the height, width, and number of channels, respectively. The block contains two main operations such as the self-attention mechanism and the multilayer perceptron (MLP). The self-attention mechanism can be represented as follows:

$$Attention(Q,K,V) = softmax\left(\frac{Qk^T}{\sqrt{d_k}}\right) \times V \qquad (1)$$

Where Q, K, and V are the queries, keys, and values obtained from X, and dk is the dimension of the key vectors. In the case of the Swin Transformer, the self-attention mechanism is computed within non-overlapping local windows to reduce computational complexity:

$$X'(L) = W - MSA(LN\big(X(l)\big) + X(L)) \qquad (2)$$

Where LN denotes Layer Normalization, W-MSA is the window-based multi-head self-attention, and ′ X ′ is the output feature map that will be passed to the MLP. The MLP with GELU non-linearity is then applied:

$$Y' = MLP(LN\big(X'^{(l)}\big) + X'(L)) \qquad (3)$$

Where Y is the output of the Swin transformer block, and it is visually represented in Fig. 4.

Dynamic Cross-Attention Layer: The dynamic cross-attention layer, D, aims to allow the attention mechanism to change adaptively based on the input and internal state. This could be formulated as a function that varies the attention weights dynamically:

$$DA(X_t) = softmax(\mathrm{f}_\theta(X_t - 1, \mathrm{P})\mathrm{K}_T) \times V \quad (4)$$

Where, Xt is the input at time t, P is a set of parameters or features that influence the dynamic behavior (e.g., learned parameters or context-dependent features), and fθ is a learnable function parameterized by θ that computes the queries dynamically. Now, the DynamicSwinTransformer (DST), would integrate the dynamic cross-attention layer into the standard swin transformer block sequence. The composite operation for DST with N blocks could be represented as follows:

$$\mathrm{DST(X)} = \mathrm{S}_N(\mathrm{DST}(\mathrm{S}_{N-1}(\cdots \mathrm{DST}(\mathrm{S}_1(\mathrm{X})) \cdots))) \qquad (5)$$

Where Si is the i-th Swin Transformer block and D is interspersed between these blocks to modulate the attention based on dynamic factors. Finally, for a classification task, the swin transformer's output would be fed into LightGBM boosting algorithm. The process of dynamic attention layer architecture is visually shown in Fig. 5. Pre-training a dynamic cross-attention layer in a Swin Transformer architecture involves adjusting the attention mechanism to be region-specific and dynamic over the course of training. Let's define the notation for such a pre-training process, focusing on a scenario with five distinct regions as shown in Fig. 6. Fig. 7 shows various regions of input retinograph.

Let's assume our input image IMG(x, y, c) is partitioned into R regions as shown in Fig. 5, where R=5 as visually described in Fig. 11. The Swin transformer processes the input through a series of layers, and at each layer l, it performs self-attention within local windows. The dynamic cross-attention aims to adapt the focus on these regions dynamically, which are pretrained on selected dataset of each retinal disease. For each region r∈{1,2,3,4,5}, the dynamic cross-attention mechanism at layer l can be represented by a function DLr that computes the attention weights dynamically based on the input feature map X_{lr} and a set of parameters θ_{LR}, which are learned during pre-training the Eq. (7) can be redefined as:

$$DLr(X_{lr}) = softmax\left(\frac{Q_{lr}k^T}{\sqrt{d_k}}\mathrm{K}_{lr} + A_{lr}\right) \times V_{lr} \qquad (6)$$

Where the Q_{lr}, K_{lr}, and V_{lr} parameters are the queries, keys, and values for region r at layer l, computed from X_{lr}. The A_{lr} parameter is an added term that represents the adaptive component of the attention for region r, influenced by the dynamic parameters θlr. Also, the dk parameter is the dimension of the key vectors. During pre-training, the objective is to learn θ_{LR} for each region r such that the model can attend to different parts of the image in a way that is beneficial for the task at hand (e.g., feature extraction relevant to eye diseases in retinal images). This is achieved by minimizing a loss function L that measures the discrepancy between the model output and the ground truth labels over a pre-training dataset D:

$$\min_{\theta} \theta_{LR}(D;\theta) \qquad (7)$$

Where θ denotes the set of all parameters, including θ_{LR} for all regions r and layers l. During pre-training, the model is exposed to a variety of images and is encouraged to learn region-specific attention patterns that enhance its ability to extract relevant features from each region. The dynamic aspect allows the model to adjust these patterns as it encounters new data and as it progresses through the layers of the transformer. After pre-training, the learned parameters θ_{lr} for each region r are used to initialize the dynamic cross-attention layers of the Swin Transformer for further fine-tuning on a specific target task, potentially with a new dataset. The overall process is shown in Algorithm 2.

$-l_i = label - features\ (f_i, c)$
End of algorithm
```

E. Multiclass Prediction using LightGBM

LightGBM (Light Gradient Boosting Machine) is a gradient-boosting framework that uses tree-based learning algorithms. The design prioritizes speed and efficiency, particularly in managing large-scale data. The algorithm employs a histogram-based method to speed up the training process and reduce memory usage. Here is a more formal mathematical representation of the LightGBM algorithm, focusing on its core components. Incorporating features extracted by a Swin Transformer into a LightGBM model for recognizing eye-related diseases involves a multi-step process that blends deep learning feature extraction with gradient-boosting machine learning techniques. The following is a high-level algorithm that outlines this hybrid approach, detailing how to leverage the strengths of both Swin Transformer for complex feature extraction from images and LightGBM for efficient classification based on those features.

We use these extracted characteristics, now high-dimensional vectors, and their labels to identify each image's eye illness. We create a new dataset from these pairs by simplifying visual information for machine learning algorithms. Next, train a LightGBM model on this fresh dataset. We picked LightGBM for its efficiency and efficacy in processing tabular data, including Swin Transformer-generated high-dimensional feature vectors. Training the LightGBM model on retrieved characteristics and labels helps the system identify complicated links between them and eye disorders. Before feature extraction, the dataset can be separated into training and validation sets to check that the model works well on both old and new data. This enables an assessment step to verify the model's capacity to generalize its learnt patterns to fresh data, confirming its real-world usefulness. Finally, the LightGBM model can detect eye disorders in new photos after training. These fresh photos are used to extract features using the same Swin Transformer model and then sent through the trained LightGBM model. The LightGBM model then classifies each collection of characteristics into an eye condition, identifying the diagnosis in the new image.

The Cross-Entropy Loss is a common loss function for multi-class classification problems, and this table lists the Swin-DCA and LightGBM hyperparameters needed to train and optimize the fundus image classification into Normal (NML), diabetic hypertension, diabetic retinopathy (DR), and others. A loss function for categorical outcomes is plausible in a Swin-DCA (Dynamic Cross-Attention) layer architecture multi-class classification environment. The Cross-Entropy Loss function is a standard choice for multi-class classification problems because it quantifies the difference between two probability distributions: the true distribution (the actual labels) and the predicted distribution (the outputs of the model).

Let y be the true distribution of the labels in a one-hot encoded form, where yi is 1 if the label is the ith class and 0 otherwise and let y' be the predicted distribution (the softmax output of the model), where yi is the predicted probability of the ith class. The Triplet Loss function is indeed a powerful tool for certain types of machine learning tasks such as transformers, particularly those involving learning embeddings or distances between examples, such as in different regions recognition compared to the weighted cross-entropy Loss or Focal Loss. It is defined as:

$$L(\mathrm{xa}, \mathrm{xp}, \mathrm{xn}) = \max\{\mathrm{d}(\mathrm{xa}, \mathrm{xp}) - \mathrm{d}(\mathrm{xa}, \mathrm{xn}) + margin, 0\} \quad (8)$$

Where: Anchor (xa): A reference example, Positive (xp): An example that is similar to the anchor, Negative (xn): An example that is different from the anchor and d(xa, xp) is the distance between the anchor and the positive sample and d(xa, xn) is the distance between the anchor and the negative sample. This Triplet Loss function approach harnesses the DL capabilities of the Swin Transformer to understand and capture the complex visual patterns in eye-related disease images and combines them with the machine learning process of LightGBM to classify these patterns into specific diseases. It's a powerful example of how combining different AI methodologies can create a more effective solution for complex problems like eye-related disease recognition.

Fine-tuning hyperparameters as described in Table II often involves conducting a grid search or random search over the hyperparameter space and evaluating the model's performance on a validation set.

TABLE II. FINE-TUNE OF DIFFERENT HYPERPARAMETERS FOR DEVELOPMENT OF IOT-OPTHOM-CAD SYSTEM

Hyperparameter	Swin Transformer	LightGBM Classifier
Number of Layers	24	-
Patch Size	4x4, 8x8, 16x16, 32x32	-
Embedding Dimension	224 x224	-
Learning Rate	0.01	-
Number of Trees	-	1000
Maximum Depth	-	8
Learning Rate	-	0.1
Regularization Parameter	-	0.1

IV. EXPERIMENTAL RESULTS

Six assessment methodologies are used to assess the effectiveness of the prediction: accuracy (ACC), specificity (SP), precision (P), recall (R), and F1-score (F). Using the PyTorch deep learning framework, we create the network. This study suggests utilizing retinal fundus pictures to identify eye problems with a planned 2-D IoT-Opthom-CAD. The Python code for implementing the proposed IoT-Opthom-CAD system is developed within a Google Colab environment, leveraging the computational resources provided by a GPU graphics card with 16 GB of memory. The system operates on a 64-bit Windows 10 system, running on an Intel (R) Core (TM) i7–43,450 CPU. TensorFlow serves as the primary framework for constructing and training deep learning models. To ensure uniformity across the dataset, all original images are resized to a consistent resolution of (224×224) pixels. This standardized dimension is widely recognized within the deep learning community as an optimal input size for various neural network architectures.

TensorFlow and Keras packages train the model in the Python 3.7.4 environment in Jupyter Notebook, utilizing a deep learning framework. Fundus photos are utilized as input data, which is subsequently enhanced using a variety of methodologies to address a range of potential real-world circumstances. In the ratio of 14:3:3, the enhanced dataset was divided into training, validation, and testing sets. The suggested model was trained and tested with different hyper-parameter settings. All augmented fundus images were first cleaned up and scaled to fit the training neural network's input dimensions. To properly analyze the prediction evaluation on unobserved data, IoT-Opthom-CAD's performance was compared to that of the current state-of-the-art deep learning models.

Three online datasets were used to train the IoT-Opthom-CAD system: MuReD (a multi-label dataset for retinal diseases) [38], BRSET (a Brazilian multi-label dataset for retina fundus photos) [39], and OIA-ODIR (an adaptive dataset for ophthalmic image analysis and disease recognition) [40]. We have collected initially 6,00 fundus images from these sources, including an average (NOM) of 1900, diabetic retinopathy (DR) of 2000, glaucoma (GLC) of 400, cataracts (CAT) of 200, age-related macular degeneration (AMD) of 300, and hypertension retinopathy (HR) of 1200 images. To balance the selected dataset, we have applied data augmentation and preprocessing techniques explained in Section 3.2 to convert 6,000 images into 12,000 retinographics. Given that the photos come from different sources, the resolution can vary from 520x520 to 3400x2800, depending on the source of the image. We have resized them to 224x224.

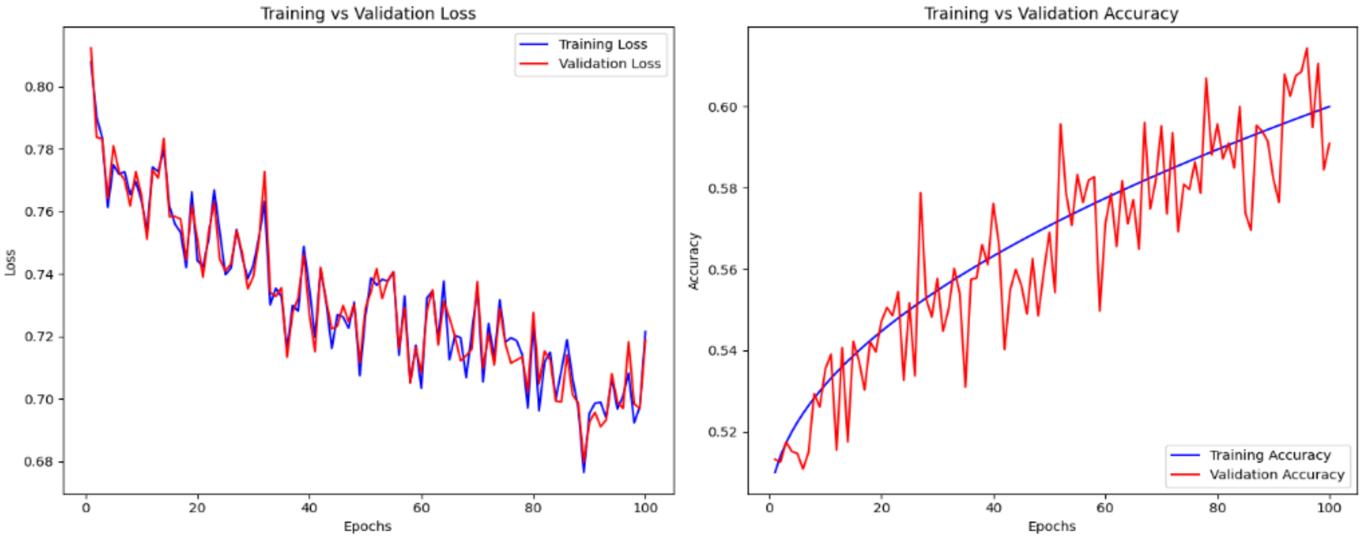

Fig. 8. Loss versus accuracy curves for training and validation with respect to epochs 100 for proposed IoT-Opthom-CAD system.

TABLE III. DIFFERENT PERFORMANCE METRICS WHEN APPLIED ON IOT-OPTHOM-CAD SYSTEM FOR RECOGNITION OF EYE-RELATED DISEASES WITH VARIOUS EXPERIMENTAL SETUP

Experiment ID	Alpha	Batch Size	Learning Rate Decay	Epochs	Acc(%)	P (%)	R (%)	F1-Score (%)	SP(%)
Exp1	0.001	32	0.1	100	95.0	96.0	95.0	95.0	94.11
Exp2	0.0001	64	0.05	100	94.5	95.0	94.0	94.5	93.11
Exp3	0.01	128	0.01	100	96.3	95.1	96.0	96.2	95.9

In Fig. 8, the loss and accuracy curves for the suggested IoT-Opthom-CAD system show good features, showing that the classifier is not overfitting or underfitting. Table III presents the results of the IoT-Opthom-CAD system's performance in recognizing eye-related diseases under various experimental setups. Each experiment has a distinct ID and multiple configurations, such as the alpha value, batch size, learning rate decay, and number of epochs. The metrics evaluated include accuracy (Acc), precision (P), recall (R), F1-score, and specificity (SP). The first experiment had an alpha value of 0.001, a batch size 32, a learning rate decay of 0.1, and 100 training epochs. It got an accuracy of 95.11%, with 95.11% for specificity and 95.10% for precision, recall, and F1-score.

Experiment 2, with an alpha of 0.0001, a 64-batch size, a 0.05 learning rate decay, and 100 epochs, showed the system's flexibility. Precision, recall, and F1-score were 95.0%, 94.0%, and 94.5%, respectively, while specificity was 93.11%. Accuracy fell to 94.5%. Experiment 3, with an alpha value of 0.01, a bigger batch size of 128, a lower learning rate decay of 0.01, and the same number of epochs, showed the system's illness recognition accuracy optimization. This setup produced 96.3% accuracy, 95.1% precision, 96.0% recall, and 96.2% F1-score, and 95.9% specificity. These results reveal that experimental configurations greatly impact IoT-Opthom-CAD performance indicators. They also illustrate how tweaking parameters improves illness identification accuracy.

Table IV compares models' eye-related illness recognition metrics. Three configurations are tested: the standard Swin Transformer model with Softmax activation and LightGBM.

Classification, a separable CNN model with Softmax activation, and the proposed architecture with dynamic cross-attention and LightGBM. Each model reports accuracy (ACC), precision (P), recall (R), F1-score, and specificity (SP) for average (NML), diabetic retinopathy (DR), tensional suspense neuropathy (TSN), age-related macular degeneration (ARMD), ocular degeneration (ODE), and high-risk diseases. The Base Swin Transformer model with Softmax activation and LightGBM classification performs 90.0% across all parameters for all illness categories. The separable CNN model with Softmax activation performs poorly in most tests, with accuracy, precision, recall, F1-score, and specificity ranging from 87.0% to 89.0% for various diseases. But adding dynamic cross-attention and LightGBM to the suggested Swin Transformer architecture improves its performance, notably in identifying ARMD and HR with 100% and 97.5% accuracy, respectively.

Fig. 10 displays the confusion matrix of the proposed IoT-Opthom-CAD system, which is used to diagnose various eye illnesses. This information is vital for evaluating the system's overall performance and finding areas for enhancement in illness identification. The comprehensive measure of confusion for the proposed system is displayed in Fig. 9 and Fig. 10. In addition, we conducted a computational efficiency analysis of a Swin Transformer paired with LightGBM on several hardware platforms, including CPU, GPU, and TPU. The results are presented in Table V.

TABLE IV. COMPARISONS OF BASIC SWIN TRANSFORMERS AND PROPOSED SWING AND DYNAMIC CROSS ATTENTION ARCHITECTURE ON SELECTED DATASET FOR RECOGNITION OF VARIOUS EYE-RELATED DISEASES

Model Configuration	*Metric	NML	DR	TSN	ARMD	ODE	HR	Overall
Base Swin +Softmax+ LightGBM	ACC (%)	90.0	90.0	90.0	90.0	90.0	90.0	90.0
	P (%)	89.0	89.0	89.0	89.0	89.0	89.0	89.0

Table VI provides a comparison of various models' performance metrics on selected datasets. These hyper-parameters include the learning rate, batch size, number of epochs, optimizer, and activation function used for training each model. They are essential set-tings that influence the training process and ultimately impact the model's performance and convergence. Adjusting these parameters optimally is crucial to achieving the desired results and ensuring the effectiveness of the trained models. Table VII comprehensively compares state-of-the-art models applied to selected datasets, employing identical preprocessing and data augmentation techniques. Each model's performance is evaluated across multiple metrics to gauge its efficacy in recognizing eye-related diseases. The Fahdawi-2024 (DRBM) model achieves an accuracy of 86.0%, demonstrating commendable precision, recall, specificity, and AUC values of 87.0%, 86.0%, 88.0%, and 0.875, respectively. Similarly, the Sengar-2023 (DNN) model attains an accuracy of 84.0%, with precision, recall, specificity, and AUC values of 86.0%, 85.0%, 86.0%, and 0.845, respectively. Meanwhile, the Triwijoyo-2020 (CNN) model achieves an accuracy of 83.0%, coupled with precision, recall, specificity, and AUC values of 86.0%, 85.0%, 86.0%, and 0.835, respectively. In contrast, the Opthom-CAD (proposed) system outperforms its counterparts with remarkable accuracy, achieving an impressive 95.16%. This superiority extends across all metrics, with precision, recall, specificity, and AUC values at 96.5%, 95.08%, 95.93%, and 0.95, respectively. Such exceptional performance underscores the effectiveness of the proposed Opthom-CAD system in accurately identifying various eye-related diseases. The proposed model's significantly higher accuracy and robustness highlight its potential to revolutionize disease detection in ophthalmology, offering promising avenues for improved patient care and management.

In complicated tasks like image classification, natural language processing, and predictive analytics, xAI interpretability involves understanding and explaining AI (xAI) model decisions and behavior. In visually explaining models, interpretability entails offering intuitive and meaningful representations of how the model predicts or classifies. Gradient-based approaches like Gradient-weighted Class Activation Mapping (Grad-CAM) provide output gradients considering input attributes. This shows how Grad-CAM is used to graphically illustrate the model's predictions using AI. Computing the target class gradients on the final convolutional layer's convolutional feature maps emphasizes the input image's most important regions for the projected class. Model judgments are easier to comprehend with this method. For the model's judgment, input pixels or characteristics matter most. Visual explanations of AI models help users understand how they reach their conclusions, build trust in AI systems, identify biases and errors, and collaborate with human experts in various fields.

The Swin Transformer architecture extracts Fig. 11 characteristics from colored fundus pictures. Hierarchical transformer layers capture long-range visual dependencies in Swin Transformer, a current computer vision technique. For reliable eye illness diagnosis, the model rapidly extracts local and global characteristics from retinal pictures using Swin Transformer. LightGBM is a gradient-boosting framework that is employed for multi-label classification. It works by iteratively training weak learners on the residuals of the previous iteration, gradually improving the model's predictive performance. This is where LightGBM comes in handy: it sorts the extracted features into groups of eye diseases, like normal, diabetic retinal disease, tessellation, age-related macular degeneration, optic disc edema, and hypertensive retinal disease as shown in Fig. 12.

The smartphone-based system captures high-quality fundus images using its built-in camera or an attached IoT head-mounted camera (IoT headset). These images are then uploaded to the cloud for further processing. The smartphone application can act as an intermediary, facilitating the transfer of data from the patient to the cloud. Features extraction algorithm is running on the cloud servers identify and isolate relevant regions of interest within the fundus images. The DL models classify the images based on the extracted features, determining the presence of eye-related disease. Patients with eye-related concerns used the online mobile computing device, and their information was recorded by healthcare workers. A dedicated application was downloaded onto their mobile devices, which facilitated capturing and analyzing eye-related disease data via the cloud.

Fig. 12. A visual diagram of proposed IoT-Opthom-CAD system for multiclass eye diseases using dynamic swin transformers and explainable artificial intelligence.

The IoT network operates through three primary layers: the data link layer, the network layer, and the application layer. The data link layer starts with a dataset of fundus images obtained from patient records, primarily used for analysis. This layer utilizes the transport layer for processing and evaluated using multi-label retinal disease datasets like MuReD, BRSET, and OIA-ODIR. These datasets are used for testing purposes. This dataset consists of around 2000 color fundus images of each category with annotations provided in an Excel file. The network, or transport layer, includes a cloud server network designed to host applications. It facilitates data transmission between tools and minimizes delay times. Additionally, it enables users to monitor patient details stored in databases. The application layer features an integrated with Python programming to analyze fundus images. This layer allows patients to upload their fundus images for analysis. The application includes the disease diagnosis model, further detailed in the following sections. The smartphone application provides a user-friendly interface for patients to easily capture and upload images, view results, and receive notifications.

An ablation study for combining Swin Transformer and LightGBM to recognize various eye-related diseases could involve systematically varying model configurations and training parameters to observe their impact on the classification performance. This study can help in understanding the contribution of different components and settings to the model's overall effectiveness. Table VIII outlining an ablation study for this purpose. Note that the performance metrics (e.g., accuracy) are illustrative and not based on actual experimental results.

The Table VIII shows the results of an ablation study that looks at how different setups of the Swin Transformer and LightGBM models impact the ability to detect several eye diseases, including Normal (NML), Diabetic Retinopathy (DR), Tessellation (TSN), Age-Related Macular Degeneration (ARMD), Optic Disc Edema (ODE), and Hypertensive Retinopathy (HR). The study systematically alters model configurations and assesses their effects on classification accuracy, providing insights into how different aspects of the models influence performance.

Experiment ID 1 serves as the baseline, employing base configurations for both the Swin Transformer and LightGBM across all diseases, achieving 90.0% accuracy. This setup establishes a reference point for comparison with subsequent experiments.

Experiment ID 2 tests the impact of a shallower Swin Transformer while keeping the LightGBM configuration unchanged. The reduction in depth leads to a slight de-crease in accuracy to 87.5%, suggesting that depth contributes significantly to capturing the complex features necessary for accurate classification.

Experiment ID 3 explores the effect of simplifying LightGBM trees by reducing the number of leaves, with the Swin Transformer configuration held constant. The result is a minor drop in accuracy to 89.0%, indicating that a more complex tree structure might be beneficial but is less critical than the depth of the Swin Transformer.

Experiment ID 4 increases the embedding dimension of the Swin Transformer. This adjustment leads to a higher accuracy of 91.2%, showing that a richer feature representation enhances model performance.

Experiment ID 5 adds a shifted window mechanism to the base Swin Transformer configuration, slightly improving accuracy to 90.5%. This suggests that enabling cross-window connections helps capture more contextual information, which is beneficial for classification.

Experiment ID 6 focuses the evaluation on normal and diabetic retinopathy cases specifically, maintaining base configurations for both models. A notable increase in accuracy to 92.0% indicates that the models are particularly effective at distinguishing between these two conditions.

Experiment ID 7 shifts focus to the remaining diseases (TSN, ARMD, ODE, and HR), resulting in an accuracy of 88.5%. Compared to Experiment 6, this lower performance suggests that these conditions present more challenging or subtle features to classify accurately.

Experiment ID 8 investigates the impact of data augmentation on the base configuration, leading to a significant accuracy increase to 93.0%. This underscores the value of augmentation in enhancing the model's generalization capabilities.

Experiment ID 9 examines the effect of increasing the complexity of LightGBM trees by a more significant number of leaves, achieving an accuracy of 90.8%. This indicates that a more nuanced decision-making process can marginally improve classification outcomes.

Experiment ID 10 evaluates the use of higher-resolution images with the base model configurations, achieving 91.5% accuracy. The improvement suggests that high-er-resolution inputs provide more detailed information for feature extraction, aiding disease classification.

Overall, the ablation study shows how vital model depth, embedding dimensionality, data augmentation, and input resolution are for improving the accuracy of disease classification in the eye. While adjustments to the LightGBM configuration also affect performance, modifications to the Swin Transformer architecture, particularly those that enhance feature representation and extraction, appear to have a more pronounced impact on the model's effectiveness.

An ablation study combining Swin Transformer and LightGBM for recognizing various eye-related diseases such as Normal (NML), Diabetic Retinopathy (DR), Tessellation (TSN), Age-related Macular Degeneration (ARMD), Optic Disc Edema (ODE), and Hypertensive Retinopathy (HR). Ablation studies are critical for understanding the contribution of each component or parameter to a model's performance. Imagine a table that systematically varies the parameters and configurations of the Swin Transformer and LightGBM models to evaluate their impact on the classification accuracy for these eye conditions. Each row of the table would represent a different experimental setup, altering aspects such as the depth of the Swin Transformer, the number of heads in multi-head self-attention, the size of the input images, or specific hyperparameters of LightGBM like the number of leaves, learning rate, and the depth of trees.

For the Swin Transformer, one experiment might vary the patch size, analyzing how granularity affects the model's ability to capture relevant features for disease classification. A smaller patch size could improve the model's sensitivity to finer details critical for distinguishing between diseases like TSN and DR, which may exhibit subtle differences in retinal images. Another row might explore the depth of the swing transformer, adjusting the number of transformer blocks. More layers allow for more complex feature hierarchies, possibly improving differentiation between complex conditions like ARMD and ODE but also increasing computational costs and the risk of overfitting. On the LightGBM side, one could manipulate the learning rate to see how faster or slower convergence affects model performance across the different diseases. A lower learning rate might lead to more robust learning with less risk of overlooking subtle features distinguishing NML from early stages of diseases like DR or HR.

Another variation could involve the number of leaves in LightGBM, investigating the trade-off between model complexity and the risk of overfitting. More leaves allow the model to make finer distinctions, potentially improving its ability to classify dis-eases with overlapping symptoms. However, they might also capture noise in the data, leading to poor generalization. The results section of this table would detail the classification accuracy for each disease under different experimental setups, providing in-sights into which configurations yield the best balance of sensitivity and specificity across conditions. For instance, one might find that moderate patch size and depth in the Swin Transformer, combined with a careful balance of learning rate and tree complexity in LightGBM, offer the most effective performance across all conditions, high-lighting the importance of each parameter in capturing the nuanced differences be-tween these eye diseases. This kind of ablation study would be very helpful for im-proving the combined Swin Transformer and LightGBM method. It would show re-searchers the best ways to set up these devices to diagnose a wide range of eye conditions. Through systematic experimentation and analysis, one could derive a highly optimized model setup that leverages the strengths of both deep learning and gradient-boosting techniques for enhanced medical imaging analysis.

These limitations are provided in Table IX as a critical perspective on areas where the proposed system might face challenges or require further development and validation.

The influence of the parameters used in the IoT-Opthom-CAD system can significantly impact the performance metrics and the effectiveness of the model in recognizing eye-related diseases as shown in Table X. The parameters used in the IoT-Opthom-CAD system play a crucial role in determining the model's effectiveness. By carefully tuning these parameters, the model's performance can be optimized, leading to more accurate and reliable predictions. Future work can explore the effects of these parameters in more detail, ensuring that the model is both robust and generalizable across different datasets and real-world scenarios. However according to our limited knowledge, we did not find a single study for classification of multi-class eye-diseases using IoT-enable devices.

TABLE VIII. VARIOUS EXPERIMENTS OF DIFFERENT EXPERIMENTAL SETTINGS FOR PROPOSED IOT-OPTHOM-CAD SYSTEM

Experiment ID	Swin Transformer Config	LightGBM Config	Evaluated Diseases	Accuracy (%)	Explains
1	Base config	Base config	All	90.0	Baseline for comparison
2	Reduced depth	Base config	All	87.5	Tests impact of shallower Swin Transformer
3	Base config	Reduced num_leaves	All	89.0	Impact of simpler LightGBM trees
4	Increased embed-dim	Base config	All	91.2	Higher dimensionality for embeddings
5	Base config + Shifted window	Base config	All	90.5	Shifted window impact
6	Base config	Base config	NML, DR	92.0	Focused on NML and DR
7	Base config	Base config	TSN, ARMD, ODE, HR	88.5	Focused on TSN, ARMD, ODE, HR
8	Base config with augmentation	Base config	All	93.0	Data augmentation impact
9	Base config	Increased num_leaves	All	90.8	More complex LightGBM trees
10	High-resolution images	Base config	All	91.5	Tests impact of using higher resolution images

TABLE IX. LIMITATIONS OF THE PROPOSED IOT-OPTHOM-CAD SYSTEM FOR MULTICLASS RETINAL EYE DISEASES

Limitation Description	Impact
Limited Dataset Diversity	The study uses three specific datasets (MuReD, BRSET, and OIA-ODIR), which might not cover all possible variations of retinal images in a real-world scenario.
Generalization to Different Populations	The model's performance might vary when applied to populations with different demographic characteristics than those represented in the datasets used.
Dependence on High-Quality Images	The accuracy of the system relies on the quality of retinal images; lower-quality images could affect diagnostic performance.
Explainability and Interpretability Challenges	While Grad-CAM is used for explainability, the complexity of the model might still pose challenges for clinicians to fully understand the decision-making process.
Potential Overfitting Due to Data Augmentation	Extensive data augmentation might lead to overfitting, where the model performs well on the training data but poorly on unseen data.
Scalability and Integration into Existing Clinical Workflows	Integrating the IoT-Opthom-CAD system into existing clinical workflows and ensuring its scalability in diverse healthcare settings might be challenging.
Future Adaptability to New Retinal Diseases	The system is designed for specific diseases; adapting it to recognize new or less common retinal diseases could require significant modifications and retraining.

TABLE X. INFLUENCE OF THE PARAMETERS USED IN THE IOT-OPTHOM-CAD SYSTEM

Parameter	Description	Influence on Model Performance
Alpha Value (Learning Rate)	Controls how much to change the model in response to the estimated error each time the model weights are updated.	A lower learning rate (alpha) can lead to more precise adjustments but requires more epochs to converge. A higher learning rate can speed up training but may overshoot the optimal solution.
Batch Size	Number of training samples used in one iteration.	A smaller batch size provides a more accurate estimate of the gradient, leading to a more stable learning process but may slow down training. A larger batch size can speed up training but might lead to less accurate updates.
Learning Rate Decay	Gradually decreases the learning rate during training.	Helps in fine-tuning the learning process, ensuring the model doesn't overshoot the optimal weights, leading to better convergence.
Number of Epochs	Number of times the entire training dataset passes through the neural network.	More epochs can lead to better training and fine-tuning of the model, but too many can cause overfitting.
Resolution of Input Images	Size to which input images are resized.	Consistent resolution (224x224) ensures uniformity in training, which is critical for deep learning models to learn effectively. Larger images may capture more details but require more computational resources.
Data Augmentation Techniques	Techniques used to artificially increase the size of the training dataset.	Enhances the model’s ability to generalize by providing a variety of training samples, reducing overfitting and improving robustness.
Cross-Dataset Validation	Using different datasets to validate the model.	Helps in testing the generalization capability of the model across diverse sets of data.
Model Architecture (Swin Transformers with Dynamic Cross-Attention + LightGBM)	Combination of different model architectures and algorithms.	Enhances feature extraction (local and global features) and improves classification performance by leveraging advanced architectures.
Grad-CAM	Explainable AI technique to visualize the areas in the image that the model focuses on.	Improves interpretability and trust in the model by showing which parts of the image contribute to the decision-making process.
GPU/TPU Utilization	Hardware used for training and inference.	High-end GPUs/TPUs speed up training and inference, making it feasible to train more complex models or use larger datasets.

V. Conclusion

The paper introduces a novel computer-aided diagnosis (CAD) system called IoT-Opthom-CAD, explicitly designed for identifying various eye diseases from colored fundus images. Additionally, the integration of IoT devices enhances real-time, remote monitoring and diagnosis capabilities, providing continuous and intelligent analysis of eye-related diseases. This feature is crucial for early and accurate classification of multiclass eye diseases, significantly impacting patient outcomes. IoT-Opthom-CAD uses the Gradient Boosting (LightGBM) method and lightweight deep learning-based Swin transformers to extract and classify features, effectively. It incorporates a dynamic cross-attention layer (DCA-L) for extracting local and global features. The system is evaluated using multi-label retinal disease datasets like MuReD, BRSET, and OIA-ODIR. Results from 10-fold cross-validation tests indicate impressive performance, with up to 95.0% accuracy, 97% sensitivity, 96% specificity, and an AUC of 0.95. The IoT-Opthom-CAD system surpasses many state-of-the-art models, indicating its excellence in identifying eye-related disorders. The exceptional precision and responsiveness of IoT-Opthom-CAD demonstrate its capacity to aid ophthalmologists in properly and swiftly detecting a range of eye ailments.

Potential areas for future study are expanding the dataset to encompass a wider range of fundus pictures in order to enhance the flexibility and dependability of the system. In addition, doing research on alternative deep learning frameworks, examining novel attention processes, and optimizing hyper-parameters might enhance the diagnostic accuracy of the system. Validating the usefulness and feasibility of using IoT-Opthom-CAD in clinical situations and conducting forward-looking research will facilitate its incorporation into routine medical procedures, ensuring its suitability for everyday usage.

***Abstract*—A novel method for verifying the proper use of helmet chin straps during clothing inspections at construction sites is proposed, prioritizing safety in construction environments. As the problem statement, existing helmet-wearing state detection systems often rely on approaches that might not be optimal. This research aims to address limitations in single-view detection and proposes a multi-view deep learning approach for improved accuracy. The proposed method leverages transfer learning for object detection using well-known models such as YOLOv8 and Detectron2. The annotation process for detecting helmet chin straps was conducted using the COCO format with the assistance of Roboflow. Through experimental analysis, the following findings were observed: Using images captured simultaneously from two different angles of the chin strap condition, Detectron2 demonstrated a remarkable ability to accurately determine the state of helmet usage. It could identify conditions such as the chin strap being removed or loosely fastened with 100% accuracy.**

Keywords—Detectron2; safety-first construction; helmet chin strap; annotation; roboflow; COCO annotator; YOLOv8

I. Introduction

At construction sites, workers are typically subjected to a clothing check before starting their tasks to ensure that all safety equipment, including work clothes and helmets, is worn correctly. A critical component of this safety check is the proper fastening of helmet chin straps. If a chin strap is not properly tightened, the helmet may dislodge during a fall, crash, or other impact, potentially leading to serious head injuries or fatalities.

According to the 2022 Occupational Accident Occurrence Status published by the Ministry of Health, Labor, and Welfare, the construction industry reported a total of 14,539 casualties from occupational accidents. Among these, falls were the most common, accounting for 4,594 cases (31.6%), followed by falls from heights (1,734 cases, 11.9%) [1]. This underscores the critical importance of wearing helmets correctly and checking their fit.

Currently, clothing checks, including helmet inspections, are performed visually by humans. This method can introduce variability in judgment criteria depending on the individual conducting the inspection, and it incurs significant personnel costs. Therefore, there is a need for a more efficient and consistent approach to these safety checks.

Research objective is to develop an AI-based clothing inspection system for construction workers that reduces personnel costs and ensures consistent inspection standards. A key feature of this system is the automatic detection of helmet chin straps, a task that is unprecedented and considered highly challenging. By automatically detecting the chin strap, the system can assess whether the helmet is worn correctly and if the chin strap is securely fastened.

Methodology used to achieve this objective, the following methodology and procedures are adopted:

Image Annotation and Augmentation: Annotate images to represent various states of chin strap usage. Augment these images to enhance the machine learning dataset.

Transfer Learning: Apply transfer learning techniques to the image data, specifically focusing on helmet chin straps, using advanced object detection models like YOLOv8 [1] and Detectron2[2].

AI Object Detection Application: Utilize AI object detection to identify chin straps in images of construction workers wearing helmets.

Experiment and results show that annotations were performed using the COCO format[3] via Roboflow[4], and transfer learning was applied to the annotated data. Experimental results indicated that Detectron2 could determine the helmet's wearing state (e.g., chin strap removed or loose) with 100% accuracy based on images taken from two different angles simultaneously.

In conclusion, the developed AI-based system for checking the appropriateness of wearing helmet chin straps at construction sites demonstrates high accuracy and consistency, addressing the limitations of human visual inspections. This system not only enhances safety by ensuring proper helmet usage but also reduces the need for manual inspections, thereby cutting down on personnel costs.

Related research works are described in the next section followed by the proposed method. Then, experiment method and result are described followed by conclusion with some discussions.

II. Related Research Works

Examples of helmet-wearing state detection systems using object detection AI include:

"Detection of people not wearing helmets" by SOREST Corporation [2]

"AIJO® Safety Series" by COMSYS Information Systems Co., Ltd. [3], [4]

"Helmet Detection" by AID Co., Ltd. [5]

These systems commonly detect the presence or absence of a helmet but cannot assess the state of the chin strap. Another system, Hertz Electronics Co., Ltd.'s helmet wearing sensor "ENS-HH01" [6], uses a built-in sensor to detect if the chin strap is loose or the buckle has come off. However, it requires the sensor to be physically attached to the chin strap.

Based on the review above, there is no precedent for a system that detects whether a helmet is being worn correctly by analyzing the chin strap using object detection AI. This research introduces such a system, addressing this significant gap in current safety inspection technologies.

As for related research works to the object detection, there are the followings: Embedded object detection with radar echo data by means of wavelet analysis of MRA: Multi Resolution Analysis is proposed [7]. Method for support length determination of base function of wavelet for edge and line detection as well as moving object and change detections is also proposed [8]. On the other hand, visualization of 3D object shape complexity with wavelet descriptor and its application to image retrievals is introduced [9]. Meantime, method for 3D object recognition using several portions of 2D images through different aspects acquired with image scope included in the fiber retractor is proposed [10]. Meanwhile, method for 3D rendering based on intersection image display which allows representation of internal structure of 3D objects is proposed [11].

Method for object motion characteristics estimation based on wavelet Multi resolution Analysis: MRA is proposed [12]. On the other hand, modified seam curving changing resizing depending on the object size in time and space domains is conducted [13]. Meanwhile, object detection system to help navigating visual impairments is created [14]. Meantime, detection objects using Haar cascade[5] for counting number of humans implemented in OpenMV[6] is proposed [15].

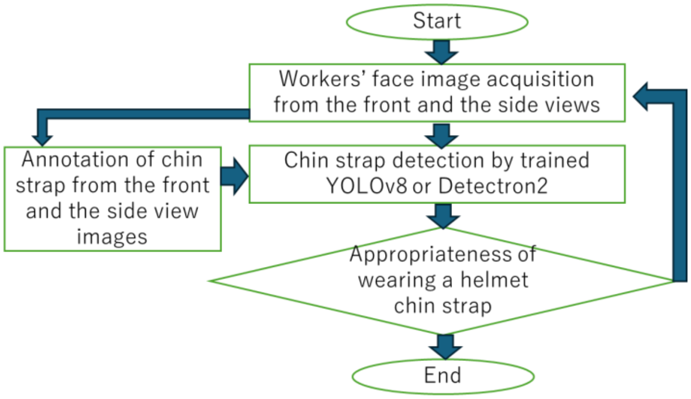
Image retrieval method based on hue information and wavelet description-based shape information as well as texture information of the objects extracted with dyadic wavelet transformation is proposed [16]. Also, method for 3D object of content representation and manipulations on 2D display using human eyes only is proposed [17]. On the other hand, object classification using a deep convolutional neural network and its application to myoelectric hand control is proposed [18] together with object classification with deep convolutional neural network using spatial information [19].

Development of a prosthetic hand control system Based on general object recognition analysis of recognition accuracy during approach phase is conducted [20]. Meanwhile, extraction of dynamic moving feature of rotating objects with wavelets is proposed and demonstrated [21].

Intelligent method for 3D image display with semitransparent object representations is proposed in study [22]. On the other hand, real time wheeled soccer robot omnidirectional image object tracking using faster region based convolutional neural network is proposed and created [23].

III. Proposed Method

Process flow of the proposed method and system is shown in Fig. 1. When workers' face image acquisition from the front and the side view, authentication is performed followed by cloth check. Safety shoes, harnesses, helmet (including chin strap appropriateness) are checked. In these processes, object detection model (YOLOv8 or Detectron2) is required together with annotation (COCO Annotator) of these items. Once the trained object detection model is created, then the cloth check can be done using the front and the side view images of workers.



Start
Workers' face image acquisition from the front and the side views
Annotation of chin strap from the front and the side view images
Chin strap detection by trained YOLOv8 or Detectron2
Appropriateness of wearing a helmet chin strap
End

Fig. 1. Process flow of the proposed method for checking the appropriateness of wearing a helmet chin strap.

The required processes of the proposed method are as follows,

1) Annotation with acquired images

2) Training data collection with augmentation

3) Training of the object detection models of YOLOv8 and Detectron2 as well as deployment of the models

The detailed descriptions for these are as follows:

A. Data Collection and Augmentation

Since AI object detection relies on learning from image data, we acquired images of workers wearing helmets. To increase the amount of training data and improve model robustness, we employed data augmentation techniques. This process involves manipulating existing images through methods like rotation, scaling, and color jittering, essentially creating variations of the original data. This allows the model to learn the target object (chin strap) under various conditions, enhancing its generalization capabilities.

[5] https://github.com/opencv/opencv/tree/master/data/haarcascades

[6] https://openmv.io/

B. Image Annotation for Accurate Detection

Following augmentation, we meticulously annotated the chin straps in the images using a tool named COCO Annotator [24][7], as shown in Fig. 2.

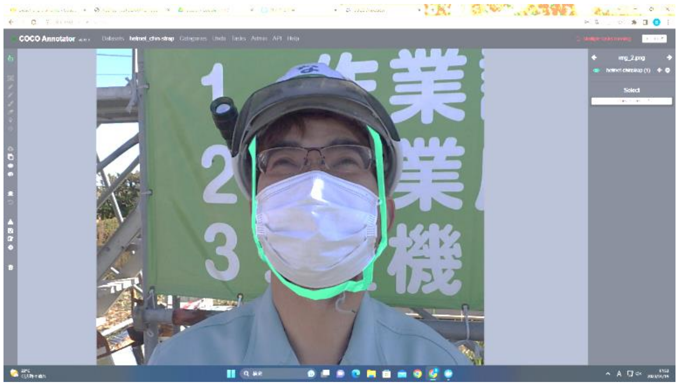


Fig. 2. Example of the annotated image using coco annotator.

This tool facilitates the creation and management of image annotations in the COCO format, a popular standard for object detection datasets. We employed polygon segmentation, a technique that precisely outlines the chin strap's shape in each image. This detailed annotation empowers the AI model to distinguish the chin strap from other elements in the image with greater accuracy.

C. Model Development and Deployment

Leveraging the annotated image dataset, we built a deep learning model using Detectron2 [25], a well-established object detection library. Through the training process, the model learns to identify the specific features of a helmet chin strap within an image. Once trained, the model can be integrated with a camera system, enabling real-time detection of chin straps in live video feeds.

IV. Experimental Method and Results

A. Data Augmentation for Enhanced Model Generalizability

To enrich the training dataset and improve the model's ability to handle real-world variations, we employed data augmentation techniques on the images captured from three viewpoints (front, right side, left side). As illustrated in Fig. 3, these techniques included the followings:

1) *Random rotation*: Images were randomly rotated within a range of -10° to 10°, simulating scenarios where workers might be positioned at slight angles relative to the camera.

2) *Sandstorm-like noise injection*: We introduced artificial noise to the images, mimicking real-world conditions with reduced visibility due to dust, rain, or other environmental factors. This helps the model learn to detect chin straps even under less-than-ideal conditions.

Combined Augmentation: We also applied a combination of rotation and noise injection to create even more diverse training data.

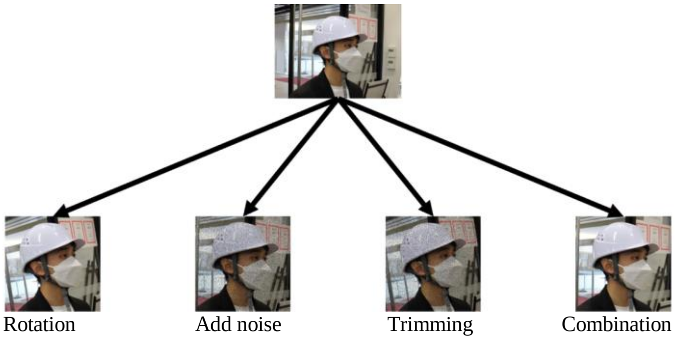

Fig. 3. Augmentation.

Furthermore, all images, including those generated through augmentation, were resized to a standard dimension of 800 by 800 pixels for consistency within the dataset. This standardization simplifies processing for the deep learning model.

By incorporating these variations, we effectively quadrupled the amount of training data available, enhancing the model's robustness and generalizability to real-world scenarios.

B. Refining the Training Dataset for Improved Detection

Following data augmentation, we meticulously annotated the chin straps in the images using COCO Annotator. A new label, "helmet-chinstrap", was created and applied to each chin strap instance. We then initiated training using Detectron2 on this initial set of 60 images.

However, to achieve robust detection of chin straps from various angles, particularly diagonal and sideways views, we acknowledged the limitations of the initial dataset. To address this, we expanded the training data by collecting additional photographs:

Workers wearing helmets from diagonal and sideways angles broadened the model's exposure to real-world scenarios beyond frontal views.

Workers with improper helmet use: Images depicting loose chin straps or no chin straps were included to enhance the model's ability to identify deviations from proper helmet wear.

These additional images were captured not only from the sides but also from both left and right diagonal viewpoints. It's important to note that frontal views were intentionally excluded to focus on the previously underrepresented angles.

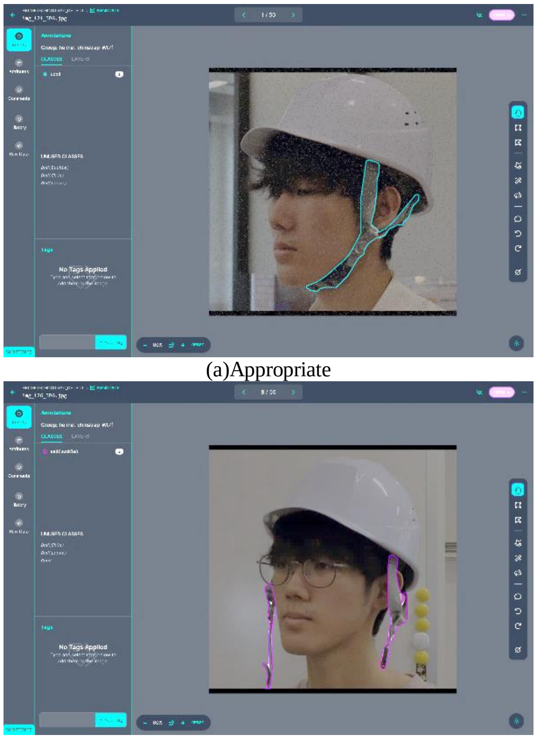
The newly collected images underwent the same augmentation and annotation processes described earlier. This diligent approach significantly increased the training data size from 60 to 283 images.

C. Enhancing Efficiency with Roboflow

Recognizing the potential for improved efficiency, we adopted Roboflow [26] as our primary platform for data augmentation and annotation. Roboflow is a comprehensive AI development tool that streamlines the entire process, from creating training data through augmentation and annotation to building the final learning models. Notably, Roboflow's

[7] https://github.com/jsbroks/coco-annotator

annotation functionality offers a valuable feature: when an object is selected within an image, it automatically performs polygon segmentation, significantly reducing annotation time (see Fig. 4).



(a)Appropriate

(b)Not appropriate

Fig. 4. Examples of annotated images by Roboflow.

By leveraging Roboflow's capabilities, we were able to streamline the data preparation process and expedite the creation of a more robust training dataset.

D. Leveraging YOLOv8 for Enhanced Detection Accuracy

In our pursuit of optimal chin strap detection accuracy, we strategically transitioned from Detectron2 to YOLOv8 [27] as the object detection library for transfer learning within our deep learning model. YOLOv8 is recognized for its superior accuracy compared to Detectron2, making it a more suitable choice for this critical task.

E. Expanding Label Granularity for Comprehensive Detection

Furthermore, to effectively detect chin straps even in scenarios of improper helmet use, we refined our annotation approach. During the annotation process, we created and implemented additional labels for various helmet wearing conditions. These labels went beyond simply identifying the chin strap and encompassed situations such as loose chin straps or missing chin straps altogether. By incorporating this expanded labeling scheme within our training data, we empowered the model to not only detect the presence of a chin strap but also to classify the specific way the helmet is being worn.

F. Transfer Learning with YOLOv8

With the enhanced training data incorporating the new helmet condition labels, we performed transfer learning using YOLOv8. This process leveraged the pre-trained knowledge of YOLOv8 on general object detection and adapted it to the specific task of identifying and classifying chin strap states within our helmet usage context. This resulted in the creation of a highly optimized deep learning model specifically tailored for our chin strap detection requirements.

G. Rigorous Training and Evaluation

For optimal model training, the dataset was strategically divided into the followings,

1) *Training data (245 images)*: This primary set provided the foundation for YOLOv8's learning process.

2) *Validation data (42 images)*: This subset served as a critical checkpoint to monitor the model's performance during training and prevent overfitting.

3) *Test data (63 images)*: This unseen data provided a final assessment of the model's generalizability and ability to perform effectively on new examples.

We then leveraged YOLOv8 for transfer learning on the training data. The achieved results were demonstrably superior to those obtained with Detectron2, as illustrated in Fig. 5.

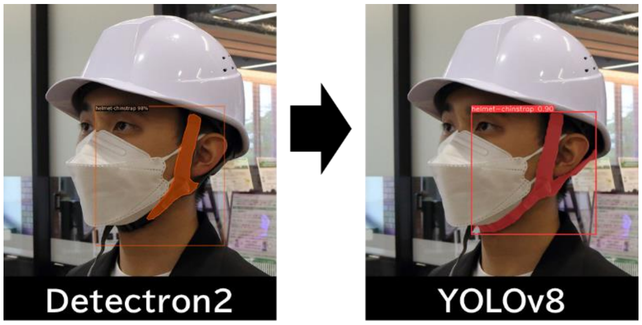


Fig. 5. Comparison of helmet chin strap detection performances between Detectron2 and YOLOv8.

YOLOv8 exhibited the following several key advantages:

1) *Expanded detection area*: The model accurately identified the chin strap across a larger image region, encompassing even partially obscured areas.

2) *Enhanced front-facing detection*: YOLOv8 excelled at detecting chin straps in frontal views, where they might follow the facial contours or be hidden behind the chin, posing a challenge for traditional methods.

Overall, a significant improvement in detection accuracy was confirmed compared to Detectron2. This translated into the model's ability to reliably detect a wider range of chin strap conditions, including the followings:

1) *Loose chin straps*: The model can effectively identify situations where the chin strap is not properly tightened.

2) *Missing chin straps*: Scenarios where the helmet is worn without the chin strap fastened are accurately detected.

3) Other variations: YOLOv8 demonstrates robustness in detecting chin straps in various lighting conditions, backgrounds, and partial occlusions.

H. *Enhanced Chin Strap Detection for Various Wearing Conditions*

Building upon the success of YOLOv8 for chin strap detection, we further refined our approach to encompass diverse helmet wearing states. This section details the creation of a labeling scheme and the evaluation of detection accuracy for the following three specific conditions:

1) Properly worn: This scenario represents the ideal state where the helmet is securely fastened with the chin strap tightened.

2) Unbuckled buckle: This condition signifies that the chin strap buckle is not engaged, potentially compromising helmet security.

3) Loose chin strap: This scenario identifies situations where the chin strap is not properly tightened, potentially allowing the helmet to come loose during an impact.

I. *Helmet Wearing State Annotation*

To effectively detect these various wearing states, we expanded the annotation process within Roboflow. New labels were created and assigned to each image based on the observed helmet condition. This enriched labeling scheme provided the model with the necessary information to distinguish between different wearing scenarios.

J. *Data Augmentation and Training*

The data augmentation techniques remained largely consistent with the previous approach. Images were subjected to random rotations within a -10° to 10° range, and sandstorm-like noise was introduced to simulate challenging real-world conditions. This process enhanced the model's generalization capabilities and robustness to variations in lighting, background, and partial occlusions.

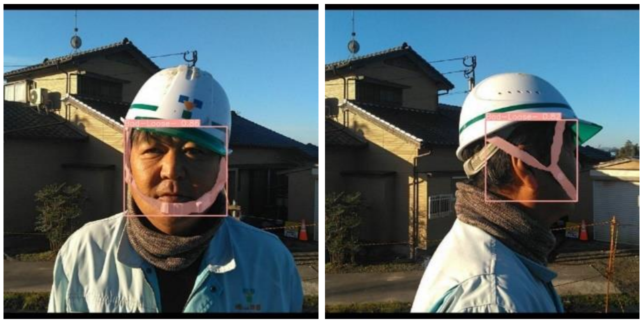
K. *Evaluation of Detection Accuracy*

The learning results for the three wearing conditions are presented in Fig. 6 as follows,

1) Properly worn: We achieved remarkable detection accuracy for properly worn helmets, with successful detection from both frontal and side views. This confirms the model's ability to effectively identify helmets secured in the optimal configuration.

2) Unbuckled buckle: Detection accuracy for unbuckled buckles proved to be excellent from the front view, as shown in Fig. 6. However, detection from the side exhibited an accuracy of 80%, suggesting a potential area for further improvement.

3) Loose chin strap: The system demonstrated a detection accuracy of 60% for loose chin straps from the front view (see Fig. 6). This indicates some room for enhancement. In contrast, detection accuracy from the side view reached a commendable 90%, highlighting the model's proficiency in identifying this condition under side-angle perspectives.



(a) Front view (b) Side view

Fig. 6. Loose helmet chin strap.

L. *Detailed Analysis of Loose Chin Strap Detection*

Within the "loose chin strap" category, we identified the following two distinct scenarios:

1) Chin strap above chin: This situation occurs when the chin strap is fastened but rests above the wearer's chin, potentially compromising its effectiveness.

2) Chin strap loose under chin: This scenario represents a loose chin strap positioned beneath the chin, offering some level of protection but not secured optimally.

Interestingly, the model exhibited a clear preference for detecting these variations based on the following viewpoints:

1) Front view: Detection accuracy for loose chin straps was more effective when the chin strap was positioned above the chin.

2) Side view: Conversely, detection from the side proved considerably more accurate when the chin strap was loose under the chin.

This observation suggests a potential strategy for future optimization. Namely, the model might be trained to leverage a combination of frontal and side-view detection to achieve comprehensive and robust identification of loose chin straps regardless of their specific position relative to the chin.

Table I provides a comprehensive overview of the detection accuracies achieved for all five helmet-wearing conditions.

TABLE I. DETECTING ACCURACY

Image_Used	Properly	Unbuckled	Loose	Loose(up)	Loose(down)
Front_view	100.0	100.0	57.1	100.0	40.0
Side_view	100.0	83.3	85.7	50.0	100.0
Both	100.0	100.0	100.0	100.0	100.0

M. *Challenges of Single-View Detection and Proposed Multi-View Solution*

Our analysis revealed limitations associated with relying solely on a single viewpoint for detecting loose chin straps and unbuckled buckles as follows,

1) Unbuckled buckles: While frontal views excelled at detecting unbuckled buckles, side views might miss instances where the remaining strap points in the direction of detection.

This highlights the potential for misclassification if only a single viewpoint is considered.

2) Loose chin strap variations: The model demonstrated a dependency on viewpoint for detecting loose chin strap variations. Frontal views were more effective for chin straps positioned above the chin, while side views excelled at detecting loose straps under the chin. This suggests a single viewpoint might not capture the full spectrum of loose chin strap configurations.

To address these limitations, we propose a multi-view detection approach. By simultaneously analyzing images from both frontal and side viewpoints, the model can achieve more comprehensive and robust detection of various helmet wearing states. The followings are how it would work:

1) Combined detection: The system would process images from both the front and side, leveraging the strengths of each viewpoint.

2) Independent judgment: Each viewpoint would independently assess the helmet wearing state (properly worn, unbuckled, loose).

3) Final classification: If either viewpoint identifies inappropriate wear (unbuckled, loose), the overall classification would be "inappropriate wear." This ensures a stricter safety standard, catching potential safety hazards even if missed from one viewpoint.

This multi-view approach offers the following several advantages:

1) Improved accuracy: By combining information from multiple perspectives, the system can achieve a higher overall detection accuracy for various helmet wearing conditions.

2) Enhanced robustness: The system becomes less susceptible to limitations inherent in any single viewpoint, resulting in a more robust and reliable detection solution.

3) Increased safety: The stricter safety classification based on "either viewpoint detecting inappropriate wear" minimizes the risk of missed detections and promotes a safer work environment.

N. Novelty and Contribution

This multi-view detection approach represents a significant contribution to the field of helmet wearing state detection systems. By leveraging object detection AI to analyze chin straps from multiple viewpoints, our system offers a unique and effective solution that surpasses existing technologies.

V. Conclusion

Ensuring proper helmet usage is paramount in construction sites to protect workers from head injuries. This paper proposes a novel method for detecting the appropriateness of helmet chin strap wear during safety checks.

As the problem statement, existing helmet wearing state detection systems often rely on approaches that might not be optimal. This research aims to address limitations in single-view detection and proposes a multi-view deep learning approach for improved accuracy.

In the proposed method, we leverage transfer learning with well-established object detection libraries like YOLOv8 or Detectron2. Roboflow is employed for efficient image annotation using the COCO format to train the model on helmet chin straps.

The key innovation lies in the multi-view approach of which images are captured simultaneously from both the front and side of the worker wearing the helmet.

The model analyzes each viewpoint independently, assessing the chin strap condition (properly worn, unbuckled, loose) as follows,

1) A stricter safety standard is implemented: if either viewpoint detects inappropriate wear, the overall classification is "inappropriate wear."

2) Key findings: Experiments revealed that Detectron2, trained with images from both frontal and side viewpoints, achieved 100% accuracy in determining the helmet wearing state (including unbuckled chin straps and loose chin straps). This demonstrates the effectiveness of the proposed multi-view approach.

3) Significance: This research offers a unique and effective solution for helmet chin strap detection, surpassing existing technologies. The system leverages object detection AI to analyze chin straps from multiple viewpoints, enhancing safety in construction sites.

Future Research Works

Future research may focus on extending this technology to detect other essential safety equipment and attire, further integrating AI into comprehensive safety management systems. Additionally, field trials at various construction sites will help refine the system’s performance and adaptability to real-world conditions.

Acknowledgment

The authors would like to thank Mr. Taijiro Senjyu for his providing the photos of construction workers wearing helmet with chin strap and also to thank Professor Dr. Hiroshi Okumura and Professor Dr. Osamu Fukuda of Saga University for their valuable discussions.

AUTHORS' PROFILE

Kohei Arai, received BS, MS and PhD degrees in 1972, 1974 and 1982, respectively. He was with The Institute for Industrial Science and Technology of the University of Tokyo from April 1974 to December 1978 also was with National Space Development Agency of Japan from January, 1979 to March, 1990. During from 1985 to 1987, he was with Canada Centre for Remote Sensing as a Post Doctoral Fellow of National Science and Engineering Research Council of Canada. He moved to Saga University as a Professor in Department of Information Science in April 1990. He was a councilor for the Aeronautics and Space related to the Technology Committee of the Ministry of Science and Technology during from 1998 to 2000. He was a councilor of Saga University for 2002 and 2003. He also was an executive councilor for the Remote Sensing Society of Japan for 2003 to 2005. He is a Science Council of Japan Special Member since 2012. He is an Adjunct Professor of University of Arizona, USA since 1998. He also is Vice Chairman of the Science Commission "A" of ICSU/COSPAR since 2008 then he is now award committee member of ICSU/COSPAR. He wrote 87 books and published 710 journal papers as well as 560 conference papers. He received 66 of awards including ICSU/COSPAR Vikram Sarabhai Medal in 2016, and Science award of Ministry of Mister of Education of Japan in 2015. He is now Editor-in-Chief of IJACSA and IJISA.

***Abstract*—The global crisis problem related to climate change, one of the main factors is the accumulation of waste which is getting higher every day. One effective way to reduce the accumulation of waste is by sorting the waste and recycling the waste. However, the waste sorting process in Indonesia is still less effective because only 1.4% can be processed and sorted. One of the biggest causes is a lack of knowledge regarding the types of waste that exist. Based on these problems, the aim of this research is: to create augmented reality-based waste sorting educational technology which is expected to increase knowledge of types of waste and increase environmentally conscious behavior. In addition, the ADDIE development model is used for the research methods that will be used. This research has successfully built an Augmented Reality sorting waste for mobile application and received a good rating on SUS questionnaire and consider acceptable with average score 84.5 out of 100.**

***Keywords*—Augmented reality; pemilahan sampah; Unity3D; vuforia**

I. INTRODUCTION

In the current era's advancements, it positively impacted the improvement of human living standards. However, these advancements also caused the global crisis of climate change [1]. One of the factors influencing climate change is the ever-increasing accumulation of waste [2]. This occurs because the decomposition process of waste, primarily produces carbon dioxide and methane [3], [4]. These gases contribute significantly to the greenhouse effect, that is one of the primary causes of global warming [5], [6], [7]. Besides environmental impacts, plastic waste negatively affects ecosystems and can alter soil structure due to physical and chemical processes resulting from waste accumulation [8]. Despite the negative impacts of waste, the accumulation of waste, particularly plastic waste, continues to increase significantly each year [9]. This can be observed from the escalating use of plastic materials, which increased tenfold from 1% in the 1960s to 10% in 2015 [10], [11].

Waste management issues are global problems that occurring in almost every part of the world, including Indonesia [12]. This is because Indonesia ranks second in the world for waste production [13]. Waste production in Indonesia increases annually and is predicted to rise by 2-4% each year if significant efforts to reduce waste production are not implemented yet [14], [15]. Based on the research regarding the significant increase in waste, especially in Indonesia, concludes that efforts are needed to curb the growth rate of waste. One effective and crucial step in reducing waste accumulation is waste sorting [16]. According to research [17], [18], after implementing a waste sorting program, clinical waste decreased by 82%, and waste management costs were reduced by up to 60%. However, waste sorting processes in Indonesia are still ineffective, as only about 14% of the 7,000 tons of waste produced can be processed and sorted [19], [20]. Surveys also show that most people do not sort their waste correctly [21]. A lack of knowledge and proper handling are among the reasons for the low rates of waste sorting and recycling in Indonesia [22]. Waste sorting cannot be solely conducted by the government; the community also plays a significant role in the success of waste sorting education [23], which can save time and costs in the process [24].

Based on the problem about sorting waste that explain in the background. It can be concluded, that the need for educational technology related to waste sorting, particularly in Indonesia, according to the types of waste commonly encountered by the community is very important. The presence of the educational application of sorting garbage considered to help increase environmental awareness, especially regarding waste types, among the public. Additionally, it can educate users on identifying the types of waste that need to be sorted. Therefore, one solution to this problem is educating the public about the types of waste. This approach is considered effective because, according to study [25], educational processes have the potential to change public behavior. Furthermore, technology is utilized as it can effectively alter public behavior [26]. The use of games is one of the frequently used technologies today, with over one billion users [7]. Many previous studies on games have focused on negative impacts, including increased aggression, addiction to games, and difficulties in managing playtime [27], [28], [29]. However, in recent years, gamification has provided many positive impacts, such as enhancing learning motivation, raising pollution awareness, and increasing user engagement and attention as a promotional medium [30], [31], [32]. Apart from that, research on [33] also found that games on mobile application have a fairly good level of user acceptance. Another study about gamification stated that using education game able to help student learning process more effective and efficient [34]. The interest level of education game also found out in study [35] which stated that user eager to play educational games continuously. Based on the popularity of games and their positive impacts, this study developed an augmented reality (AR) application that contains educational content on waste types using gamification elements. The objective of this research to bridge gap between environmental education and technology. It demonstrates the innovative solution through AR able to addressing global challenges like waste management. However, the reason about choosing AR technologies compare to others will be discussed further in literature review chapter. It followed by the proposed methodology, result and discussion, and conclusion and future work in each chapter respectively.

II. Literature Review

In this research, Augmented Reality (AR) technology was chosen because AR brings the 3D world into the real world, transforming the dimensions of learning becoming more realistic and enhancing brain productivity [36]. Additionally, AR provides and effective solution in the learning process [37] and according to literature studies [38] it can be concluded that AR has a positive contribution to learning outcomes in children. Research in study [39] found that AR application able to help children to gain their memory about places that located in playmate and spell it easily. Other studies [40] shows the comparison in group of students between AR based application, Video based, and traditional teaching method. The outcome of the study concludes that AR based outweighs the other two methods in terms of learning achievement through some quizzes in the class. Study about AR also discussed in study [41], it found that some volunteers said that AR technology help them increasing their willingness to study the book, even outside the class.

Beside AR, several studies also describe the importance of the presence of gamification elements in learning mobile application. Firstly, the development of 2D puzzle game application [42] successfully transform learning into an engaging learning environment and educated student on proper waste sorting methods. It contains several gamification concepts, including scoring, and level. Secondly, another study [43] developed a 2D waste sorting game that divided trash into two types, are organist and inorganic. The research built in Unity3D and used gamification elements, namely: level, score, time limit, reward, and level. Another study in study [43] that use gamification standards also gives positives feedback from the user. It stated that above 80% said that thorough the application it helps user to understand more about the material. According to its successfulness of contributions from users. Therefore, this research also takes the gamification into consideration while design an AR sorting waste application.

Study about Mixed Reality (MR) including Virtual Reality (VR) and AR about environment and waste sortation already conducted. One of the studies about VR game related to waste sorting called “KEEPIN” also categorized waste into two types, organic and inorganic, the main subject of the application are children between aged 7-12 years [44]. The results of the study indicated that the majority children responded positively to the game and were able to complete the challenges successfully. AR has also been developed by study [45] to recycle existing waste by scanning barcodes. Mini games of recycling using AR has been discussed in study [46], it categorizes waste into three types, are: organic, non-organic, and electronic. Besides that, it also includes reward point for every correct answer. The outcome result of the experiment shows that user gain knowledge and improve their attitudes about climate change issue according to material presented in AR mobile. According to the discussion on several topics about waste sortation, it can be concluded that, mostly there are two and three types of garbage bin in mobile application development.

Complementing other studies related to waste, the novelty of this research is to create an AR application that categorizes waste into seven types: organic waste, paper waste, electronic waste, hazardous and toxic waste, plastic waste, metal waste, and residual waste [47]. Additionally, the educational technology using AR in this study has a wider user reach because it can be used not only for children but also for adult.

However, the gamification function in this study is focused on children starting at the age of seven because children can more effectively transfer their knowledge to other family members [23]. Moreover, the introduction of new information related to waste types will be more effective if introduced from an early age [43]. According to study [48], children at the age of seven are already able to use simple AR applications, making this technology relevant for children.

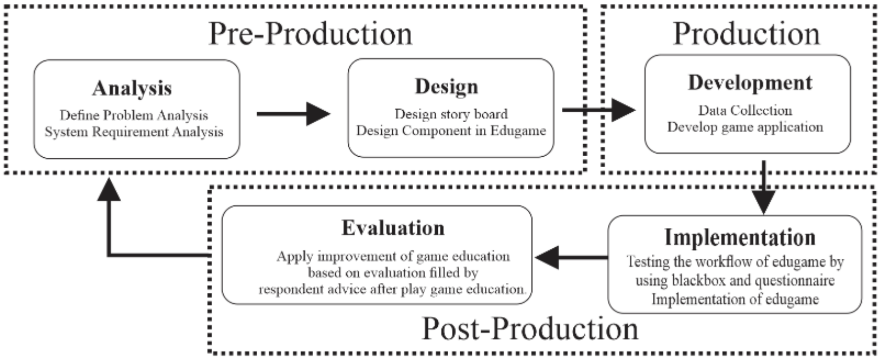
According to some papers that conduct AR research, it can be summarized that VR and AR application for waste sorting that contains gamification elements show positive results. However, the types of waste that has been developed not complete enough. Therefore, this research aims to develop an AR application that divide waste into seven types. In terms of subject target, this research focus on children based on their ability to transfer knowledge within their family and relatives. Besides that, it also relevant with their receptiveness to AR technology.

III. Methodology

This research uses ADDIE (Analysis, Design, Development, Implementation, and Evaluation) development model. This method was chosen because based on [49] ADDIE is the recommended method that uses in educational or training application which able for independent learning. ADDIE model which used in this research presented in Fig. 1. The model generally has three main process, are pre-production, production, and post-production.

A. Analysis

In the pre-production process, a needs analysis was carried out by identifying types of waste in seven categories which were discussed in the literature review to be implemented in the AR application using literature studies. Apart from that, interviews with users were also carried out, and the types of waste that were often found in the surrounding environment were obtained, as well as children's ability to operate smartphones.



Pre-Production
Analysis
Define Problem Analysis
System Requirement Analysis
Design
Design story board
Design Component in Edugame
Production
Development
Data Collection
Develop game application
Implementation
Testing the workflow of edugame by using blackbox and questionnaire
Implementation of edugame
Evaluation
Apply improvement of game education based on evaluation filled by respondent advice after play game education
Post-Production

Fig. 1. ADDIE research method.

B. Design

Design process becoming the second stage that need to be done based on ADDIE development. In design of AR application, it considered important to have six basics elements [50], namely: application users, AR interactions, devices, servers, virtual and real content, as well as the process of moving between screens that runs well and smoothly. In the AR technology design process, researchers used CCI (Child-Computer Interaction) standards and gamification elements including: scoring system, sound, level, animation, large picture, and button. This standard is quite important to implement, because it combines learning concepts in the mobile application design process [48]. Further implementation about design application can be seen in Section IV.

C. Development

In the production stage, AR technology mainly was developed using Unity3D software of game development that important to build an interactive interface and experience of VR and AR. Besides that, Vuforia SDK also implemented to perform AR package that connected with Unit3D. Vuforia SDK was chosen based on its ability to recognize markers on all types of objects which other platforms do not have [51]. Other tools are: Playmaker visual scripting, and Visual Studio (C#) that useful to perform scripting code in Unity3D. In this research, blender software also used to perform modelling 3D and adding animation movement in 3D object. Detail workflow in the AR development process presented in Fig. 2.

Based on the AR Development process in Fig. 2, describes the process of detecting AR started with the smartphone device capture the marker using camera. After that, Vuforia SDK that equipped with AR camera try to find similar marker in database that already uploaded in vuforia website. In this research image target marker that used local database (database stored in device) has been used. Vuforia SDK will analyse and find similarities between image and features in marker. Whenever the marker able to detect through devices the render view has been sent to the application and display in user mobile application. The virtual button option also appeared that useful to perform many actions based on logic programming that has been written using C# or Playmaker visual scripting.

The building process of application in APK and AAB extensions requires some customization, including: need to equipped ARM 64, using target API level 33 on android system, and it is necessary setting several input systems on build setting. Complete explanation about build setting discussed further in Section IV.

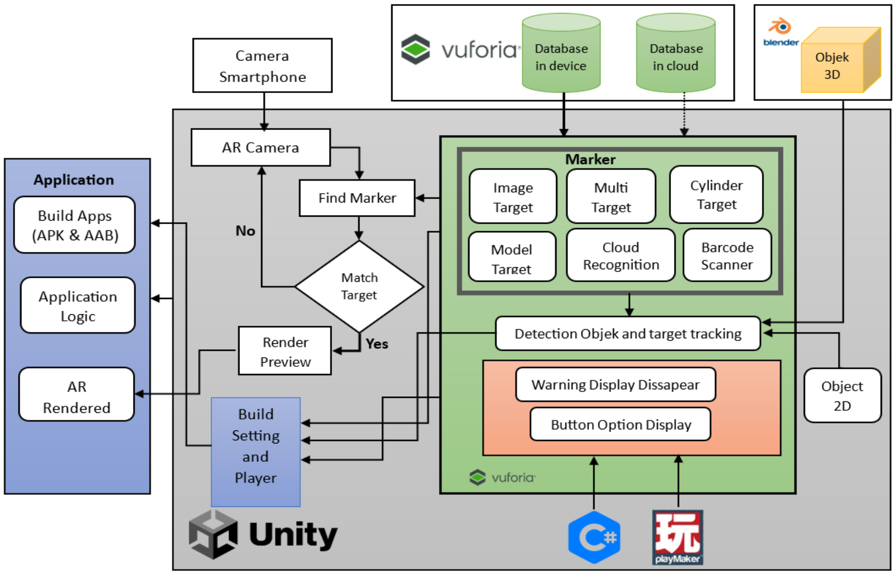


Fig. 2. AR development process.

D. Implementation

In the implementation steps, before application deliver to the users, it considers necessary to apply several testing methods to ensure the application run without any error and accepted by users. Therefore, in this research used blackbox and System Usabiliy Scale (SUS) testing. The first testing has been chosen because its effectiveness and it became one of fungsional testing that gives accurate result [5][52]. While the latter carried out during testing process, because it used to determine the acceptance rate and usability of the system according to users [6], [7] [53], [54]. SUS method has been used despite other testing because it is one of the most test carried out for testing the usability of system and still relevant nowadays [6] [53]. SUS question in this research can be seen in Table I. It uses the original list of question that published by [7] [54]. However, to make it relevant baes on this study the question already undergone slight modification. The scoring scale in SUS used five degrees of scoring, that start from 1 (strongly disagree) to 5 (strongly agree) [8] [55].

TABLE I. LIST OF SUS QUESTIONNAIRE

No	List of Question
1	I think that I would like to use this application frequently
2	I found the application unnecessarily complex
3	I thought the application was easy to use
4	I think that I would need the support of a technical person to be able to use this application
5	I found the various functions in this application were well integrated.
6	I thought there was too much inconsistency in this application
7	I would imagine that most people would learn to use this application very quickly.
8	I found the application very cumbersome to use
9	I felt very confident using the application
10	I needed to learn a lot of things before I could get going with this application

E. Evaluation

This stage becoming important because it use to improve AR technology based on recommendation from users. After that the next stage start from the beginning again. It can be seen in Fig. 1 that ADDIE method not run only in one phase, it is an iteration process. Therefore, the application will become better in every phase.

IV. Results and Discussion

According to research method described in section three, this AR application was made for children start from seven years old. This decision has been made based on discussion on literature review and interview from user. Some tools that used in this research discussed in chapter three already imported in Unity3D. The overview of the project design can be seen in Fig. 3 and Fig. 4.

According to Fig. 3, shows that CCI elements need to be inputted in AR application as discuss in chapter three in design method. Therefore, it already implemented in main menu, such as: large picture and button, sound in the application, and animation that already made in Unity3D using animation and animator tab. Fig. 4 describe the menu of AR in application that mainly used Vuforia SDK which used for implementing augmented reality that already discussed in chapter three. It can be seen from Fig. 4, that AR menu requires AR camera that useful to scanning marker and match the marker captured by AR with database in devices.

Some configurations for controlling object and events that appears and disappears in AR menu when marker match with database already described in Fig. 5. This is useful to prevent unwanted objects appear unexpectedly.

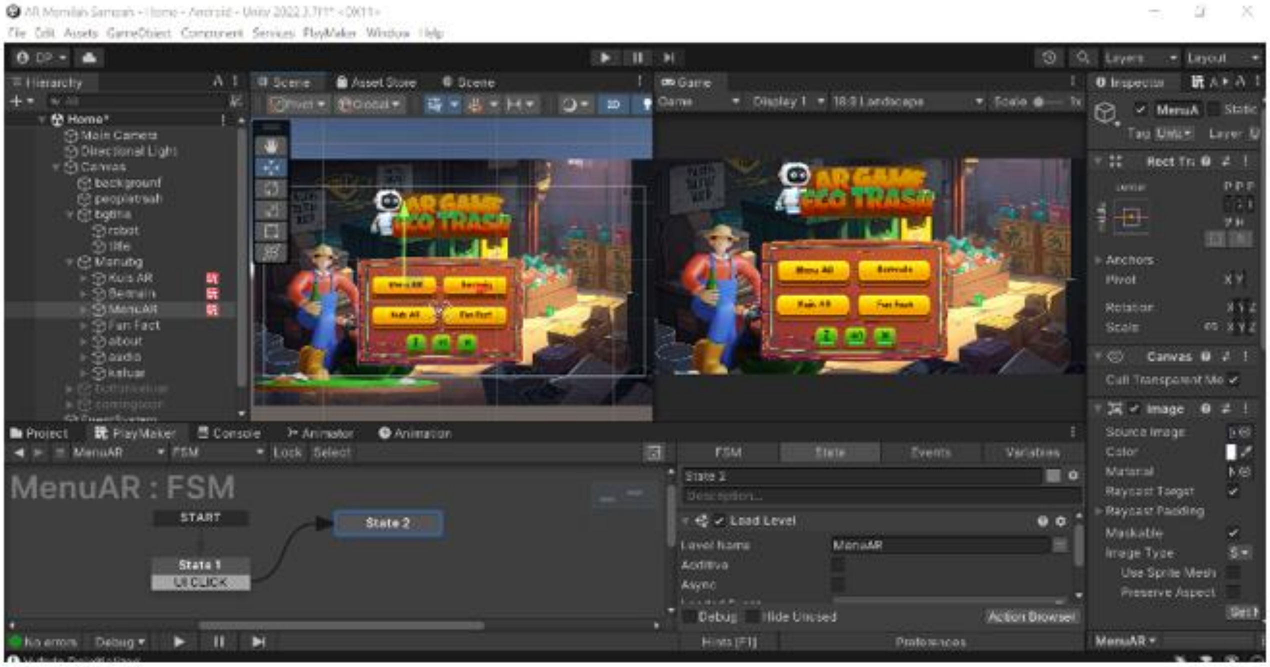

Fig. 3. Main menu in Unity3D.

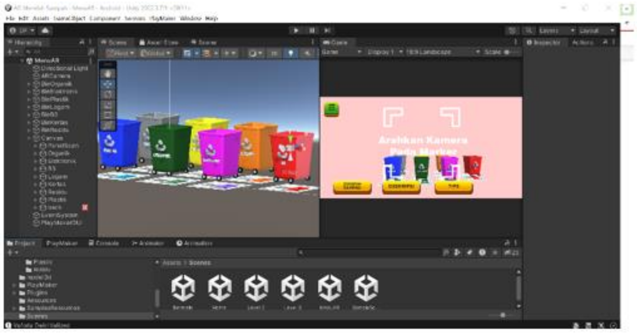

Fig. 4. AR menu in unity3D.

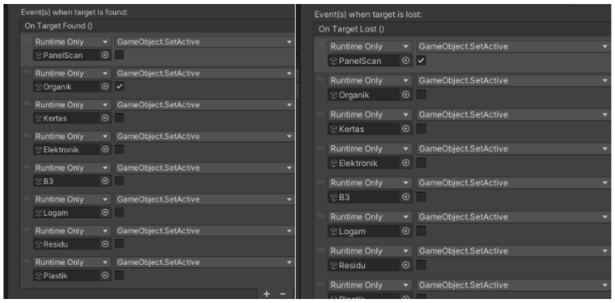
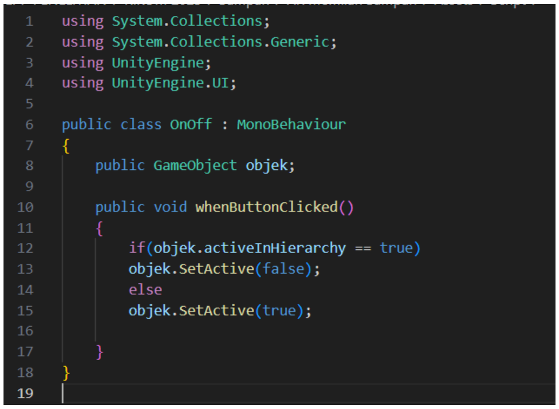


Event(s) when target is found:
On Target Found ()
Runtime Only GameObject.SetActive PanelScan □
Runtime Only GameObject.SetActive Organik ☑
Runtime Only GameObject.SetActive Kertas □
Runtime Only GameObject.SetActive Elektronik □
Runtime Only GameObject.SetActive B3 □
Runtime Only GameObject.SetActive Logam □
Runtime Only GameObject.SetActive Residu □
Runtime Only GameObject.SetActive Plastik □

Event(s) when target is lost:
On Target Lost ()
Runtime Only GameObject.SetActive PanelScan ☑
Runtime Only GameObject.SetActive Organik □
Runtime Only GameObject.SetActive Kertas □
Runtime Only GameObject.SetActive Elektronik □
Runtime Only GameObject.SetActive B3 □
Runtime Only GameObject.SetActive Logam □
Runtime Only GameObject.SetActive Residu □
Runtime Only GameObject.SetActive

Fig. 5. Event when target found and lost.

According to Fig. 4, it can be assumed that whenever the target found it will display bin "organik" object, while others object will remain unactive. Otherwise, when the target lost it will display "panelscan" that contain instruction command to capture marker that available using camera. The snipped code to control game object which active or not whenever the button pressed can be seen in Fig. 6.



```
using System.Collections;
using System.Collections.Generic;
using UnityEngine;
using UnityEngine.UI;

public class OnOff : MonoBehaviour
{
    public GameObject objek;

    public void whenButtonClicked()
    {
        if(objek.activeInHierarchy == true)
        objek.SetActive(false);
        else
        objek.SetActive(true);

    }
}
```

Fig. 6. On-off button display.

Beside AR menu, this application also has quiz menu that divided into AR Quiz and Drag and drop quiz that presented in Fig. 7 and Fig. 8. The design of quiz menu also follows CCI elements that has level of game, scoring system, and simple challenge.

In AR Quiz menu, it will detect the correct answer by searching the same name from the multiple choice presented and game object that active. According to Fig. 8, there are 18 questions and the score point will be added in the right top corner of the screen. The snipped code about scoring system and correct answer can be seen in Fig. 9.

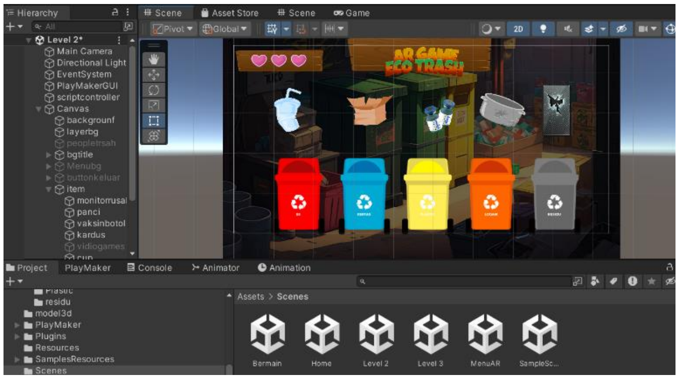


Fig. 7. Drag and drop quiz.

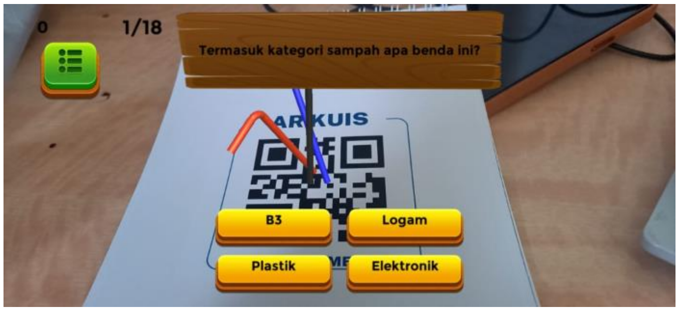

Fig. 8. AR quiz menu.

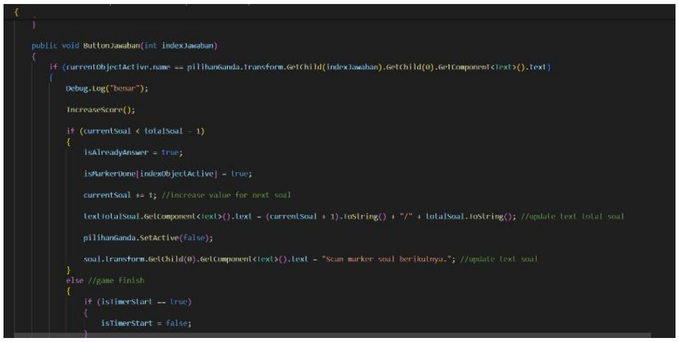

```
{
    }

    public void ButtonJawaban(int indexJawaban)
    {
        if (currentObjectActive.name == pilihanGanda.transform.GetChild(indexJawaban).GetChild(0).GetComponent<Text>().text)
        {
            Debug.Log("benar");

            IncreaseScore();

            if (currentSoal < totalSoal - 1)
            {
                isAlreadyAnswer = true;

                isMarkerDone[indexObjectActive] = true;

                currentSoal += 1; //increase value for next soal

                textTotalSoal.GetComponent<Text>().text = (currentSoal + 1).ToString() + "/" + totalSoal.ToString(); //update text total soal

                pilihanGanda.SetActive(false);

                soal.transform.GetChild(0).GetComponent<Text>().text = "Scan marker soal berikutnya."; //update text soal
            }
            else //game finish
            {
                if (isTimerStart == true)
                {
                    isTimerStart = false;
                }
```

Fig. 9. Snipped code for AR quiz.

After the development process are finished, it is necessary to perform blackbox testing to prevent error and make sure that every function in application run as expected. The result of blackbox testing for this application presented in Table II.

After buildbox testing run successfully without any errors, the SUS questionnaire then conducted to make sure that application can be useful and easy for user to play. The score and answer based on SUS questionnaire that already presented in Table I can be seen in Table III.

According to table three, the average score of obtain 84,5 that based on Fig. 10 lies on "good" area and the application already acceptable for users.

Based on result of SUS in Table III, it can be seen, that the lowest score about 70 that still in a "good" area. Therefore, it can be concluded this AR application already acceptable to be used for end user.

TABLE II. BLACKBOX TESTING

No	Test Class	Scenario Testing	Expected	Result
	Menu AR	Pressing Menu AR Button	Display Menu AR and if marker capture displayed Object 3D and three options: contoh sampah, deskripsi, tips	Valid
	Contoh Sampah	Pressing Contoh Sampah Button	Display several items garbage in seven categories based on marker that capture	Valid
	Deksripsi	Pressing deskripsi Button	Display description of garbage that belongs in each category based on marker that capture	Valid
	Tips	Pressing Tips Button	Display tips to reduce garbage that belongs in each category based on marker that capture	Valid
	Bermain	Pressing Bermain Button	Display bermain menu that allows user drag garbage and drop it in each bin	Valid
	Level 1 in Bermain Menu	Finished level 1	Display level 1 of bermain menu which consists of four types of garbage and four times to play	Valid
	Level 2 in Bermain Menu	Finished level 2	Display level 2 of bermain menu which consists of five types of garbage and three times to play	Valid
	Level 3 in Bermain Menu	Finished level 3	Display level 3 of bermain menu which consists of six types of garbage and three times to play	Valid
	Kuis AR	Pressing Kuis AR Button	Display Kuis AR that allow user to answer the question by capturing marker	Valid
	Fun Fact	Pressing Fun Fact Button	Display fun fact menu about sorting waste	Valid
	Exit	Pressing Exit Button	Display exit menu which allows user to exit from application	Valid
	Sound	Pressing Sound Button	Enable and disable sound form application	Valid
	About	Pressing About Button	Display information about application	Valid

TABLE III. RESULT OF SUS QUESTIONNAIRE

V. Conclusion and Future Work

Based on the result obtain in chapter four, it can be assumed that the objective of this research was successfully achieved, as evidence by the development and implementation of AR garbage sortation on mobile application. Besides that, the use of AR technology has proven to be effective in creating and engaging and interactive learning environment. The AR application able to transform types of waste into visual experience by combine the virtual and real world. This visualization making it easier for children to understand and remember the different types of waste.

According to the user acceptance, it concludes that the application received positive feedbacks. It can be seen based on the average score that obtain average of 84.5 out of 100 that lies on "good" category. It is indicated that the application accepted and consider user friendly by users. All in all, the novelty of this research lies on its comprehensive categories of waste into seven types, which more detailed compared to previous studies. Additionally, the integration of AR technology alongside with gamification elements enhances users learning experience. Therefore, the used not only enlarge their knowledge but also able to enjoy the application.

Despite its successfulness, this application has many works to do in the future, including addition of types of waste, and fun fact. Besides that, the knowledge effect of this AR application needs to be tested as well. Furthermore, the extension of education content also considers important for the future improvements.

Acknowledgment

The authors would like to express their sincere gratitude to UMS and RisetMu for their invaluable support esepecially for research grant. This research is fully funded by Riset Muhammadiyah (RisetMu) Majelis Pendidikan Tinggi Penelitian dan Pengembangan Pimpinan Pusat Muhammadiyah under the grant number 0258.039/I.3/D/2024.

***Abstract*—Over recent years, disruptive technologies have shown considerable potential to improve supply chain efficiency. In this regard, numerous papers have explored the link between machine learning techniques and supply chain performance. However, research works still need more systematization. To fill this gap, this paper aims to systematize published papers highlighting the impact of advanced technologies, such as machine learning, on supply chain performance. A structured content analysis was conducted on 91 selected journal articles from the Scopus and Web of Science databases. Bibliometric analysis has identified nine distinct groupings of research papers that explore the relationship between the machine learning and supply chain performance. These clusters cover topics such as big data and supply chain management, knowledge management, decision-making processes, business process management, and the applications of big data analytics within this domain. Each cluster's content was clarified through a rigorous systematic literature review. The proposed study can be seen as a kind of comprehensive initiative to systematically map and consolidate this rapidly evolving body of literature. By identifying the key research themes and their interrelationships, this analysis seeks to elucidate the current state-of-the-art and to highlight potential directions for future research in this critical field.**

***Keywords*—Bibliometric analysis; machine learning; ProKnow-C methodology; supply chain performance**

I. Introduction

The convergence of digitalization, information technology, robotics, communication technologies, and artificial intelligence (AI) has marked the beginning of a transformative era known as the Fourth Industrial Revolution [1, 2]. This era is characterized by machines gaining intelligence and the ability to make decisions, replacing human cognitive capabilities [1, 3]. Machine Learning (ML) is a key technique within this revolution, involving the creation and implementation of computer algorithms that can "learn" from experience [4]. Indeed, ML has evolved alongside advancements in machine capabilities to process vast amounts of input data over the past few decades. Additionally, machines can now identify hidden patterns and intricate relationships, enabling them to make reliable and appropriate decisions even in the face of disruptive and discontinuous information, where human capabilities may fall short [5].

However, the inefficient implementation of ML in supply chain networks can be attributed to a lack of understanding of how to apply machine learning effectively, insufficient integration into the company's culture, and the challenge of obtaining relevant and appropriate data [5]. In addition, the low association of ML and SCP could be mainly related to the need to understand the latest developments in machine learning algorithms. Specifically, knowledge of taxonomies or guidelines for supply chain researchers and practitioners to select the correct machine learning algorithms for practical activities of supply chain performance [5]. Hence, there is an immediate requirement for a comprehensive assessment aimed at quantitatively examining the current research patterns, investigating commonly employed machine learning algorithms relevant to supply chain performance, and identifying the most suitable areas for applying machine learning techniques [5].

In this context, this paper conducts a systematic analysis of research publications retrieved from international databases such as Scopus and Web of Science. It examines the machine learning algorithms commonly utilized in the context of supply chain management (SCM), aiming to serve as a foundational reference for future research in this field. The study endeavors to offer a comprehensive overview of ML applications in SCM research, addressing current gaps regarding the impact of ML techniques on supply chain performance. The findings highlight the importance of balanced ML applications to mitigate discrepancies between ML implementations and supply chain outcomes. The imbalance in ML algorithm applications poses a heightened risk of impeding progress in research-driven industries. That is, this work represents a useful systematic review of ML applications and their impact on supply chain performance, emphasizing the critical need to bridge this gap in the literature.

This paper is structured in six sections, beginning with this introduction. Section II provides a succinct overview of existing research on machine learning and its influence on supply chain performance. Section III details the research methodology employed in this study. Section IV presents the findings derived from the research. Finally, Section VI concludes the paper by discussing the primary results in Section V, acknowledging the study's limitations, and offering recommendations for future research.

II. Literature Review

A. Machine Learning

The scientific exploration of algorithms and computational models that enable computers to improve their performance on specific tasks or make accurate predictions by leveraging experience is known as machine learning [6]. Unlike traditional programming approaches, machine learning relies on statistical techniques and data-driven processes, granting computer systems the ability to learn and adapt autonomously [7]. It is widely recognized as a powerful tool in various domains of scientific research [8]. According to Du and Sun [9], machine learning systems utilize labeled and unlabeled training data from diverse sources as inputs. The learning system's knowledge base is used to select an appropriate machine learning algorithm, while considering the organization's decision-making requirements [10].

According to Zhu et al. [11], machine learning can be broken down into three primary tasks: supervised learning, unsupervised learning, and reinforcement learning. Supervised learning utilizes labeled data to construct a predictive model, with the aim of establishing a mapping between input and output variables [11, 12]. Techniques such as random forests, decision trees, Bayesian networks, and regression analysis fall under this category. Unsupervised learning operates on unlabeled datasets, seeking to uncover hidden patterns within the data [11]. This approach is primarily used for data reduction and exploratory analysis and encompasses techniques such as artificial neural networks (ANN), genetic algorithms, instance-based learning models, deep learning, and clustering. Reinforcement learning combines training and testing datasets to enable the learner to interact with the environment while gathering information [11].

Significant advancements in machine learning algorithms and computational power have propelled its transition from a laboratory curiosity to a practical technology with widespread commercial adoption across various industries [13].

The application of machine learning techniques in supply chain management has been extensively investigated by several researchers, starting with Estelles-Lopez et al. [14]. These studies have explored a range of approaches, including decision trees, random forests (RF), logistic regression (LR) [15], support vector machines (SVM) [16], and neural networks [17]. However, Ni et al [5] reported that, despite its potential, machine learning remains under-utilized in practical supply chain operations. Indeed, Sasaki and Sakata [18] have examined the adoption of machine learning in supply chain research up until 2018 and identified key reasons for its limited implementation, including a lack of understanding regarding its practical applications, insufficient integration into company culture, and difficulties in obtaining relevant and suitable data. Addressing these challenges, Štrumbelj and Kononenko [19] have sought to overcome the interpretability issues associated with machine learning models, particularly in risk-sensitive domains like finance and medicine. The need for increased confidence in utilizing machine learning models is significant, even when their interpretation is challenging, especially in critical application areas. Ensuring the reliability, transparency and accountability of these complex models is crucial when they are deployed in high-stakes domains. Developing robust techniques for model explanation and validation can help build trust and facilitate the responsible use of machine learning [19].

B. Supply Chain Performance

Performance measurement underpins effective planning, control, and decision-making by providing essential insights [20, 21]. Bititci et al. [22] argue that the context in which performance measurement is used is constantly evolving. They question whether current performance measurement practices are equipped to handle emerging trends and identify gaps in our understanding. The authors propose a holistic, systems-based approach to performance measurement research, recognizing the interconnected nature of challenges faced by practitioners and the field.

Lemghari et al. [23] argue that performance measurement is crucial for companies to evaluate their supply chain effectiveness and efficiency, especially in the highly competitive automotive industry. They emphasize the importance of having a structured approach and adequate methodological tools, such as the SCOR® model, to identify appropriate performance indicators and guide continuous improvement initiatives. They highlight the need for a comprehensive framework that covers the entire global automotive supply chain, encompassing different actors and business typologies, to ensure a holistic understanding of performance and enable effective benchmarking.

Supply chain performance is a complex and widely studied topic within the supply chain management literature [20, 24]. Najmi and Makui [25] have evaluated supply chain performance by examining factors such as reliability, flexibility, quality, responsiveness, and asset management. Similarly, Bourlakis et al. [26] have considered performance indicators related to flexibility, efficiency, responsiveness, and quality. Balfaqih et al. [27] and Reddy et al. [28] have categorized articles based on different approaches and techniques concerning supply chain performance. Dreyer et al. [29] offer another perspective, measuring performance improvement in terms of innovation, variety, price, time, and availability. Effective information exchange is recognized as a crucial element in supply chain relationships management and enhancing supply chain performance [30, 31]. Companies invest in technological innovation to facilitate efficient collaborative mechanisms and communication channels, thereby improving supply chain performance by sharing more information [32, 33].

In order to facilitate efficient information exchange and seamless end-to-end business processes, Supply Chain Integration (SCI) plays a crucial role [2, 34]. SCI encompasses both external and internal integration [35]. External integration (EI) involves establishing connections between a company's logistics operations and its customers and suppliers beyond organizational boundaries [36]. On the other hand, internal integration (II) pertains to the sharing of information among different functions within the supply chain, promoting strategic cross-functional cooperation and collaboration [37]. Enhanced integration has the potential to enhance performance indicators such as quality, variety, cost, and service level [38]. Collaboration and integration throughout the supply chain also contribute to Collaboration and integration throughout the supply chain also contribute to an enhanced level of flexibility, which in turn positively impacts supply chain performance [39]. Effective information sharing and collaboration, as discussed earlier, result in operational improvements in terms of flexibility and responsiveness [40]. The agility and resilience of the supply chain are also crucial factors influencing supply chain performance, as they enable effective management of supply chain risks [41]. Operational performance is expected to be significantly improved by increasing visibility and transparency across the supply chain [42].

III. Methodology

This research is classified as theoretical due to its technical approach, involving structured content analysis that draws on data and findings directly from existing literature on the topic [43]. The research objectives can be classified as both explorative and descriptive in nature. The aim of this research is to gather specific information and characteristics related to the subject matter in question [44]. To construct a comprehensive literature review, a structured approach utilizing bibliometric analysis was employed. The ProKnow-C (Constructivist Knowledge Development) approach suggested by Ensslin et al. [44] was utilized for the selection of a bibliographic analysis. This method is divided into four distinct stages [44] (see Fig. 1):

a) Initial selection: In this phase of the process, it is necessary to select appropriate keywords, identify relevant databases, search for articles and verify the accuracy of the keywords in use [44].

b) Database filtering: This stage filters the raw database elements for redundancy and removes elements that are not repeated by title matching [44].

c) Article database filtering: This stage determines the scientific recognition of the articles and identifies the authors [44].

d) Full article relevance filtering: This stage covers the full text of the articles, ensuring relevance to the research topic [44].

Firstly, in April 2024, we began by defining the keywords "Supply chain*", "Performance", and "Machine learning". These keywords were selected as primary terms to guide our research focus. To ensure comprehensive coverage, we opted to utilize the Scopus and Web of Science databases. These databases were chosen for their multidisciplinary nature and their inclusion of highly cited journals within various fields. Notably, the Scopus and Web of Science databases comprise a vast collection of resources, encompassing approximately 265 million Web pages, over 15000 periodicals, 18 million patents, and other relevant documents [45].

Fig. 1. Bibliometric analysis workflow.

Conducting our search using these defined keywords and databases, we obtained a total of 186 relevant articles about the subject of our study. These articles were published within the past 14 years and served as valuable sources for our research. To further analyze the literature, we classified the articles according to their respective research areas, as illustrated in Fig. 2. Engineering accounted for the highest proportion, representing 32% of the articles, followed by computer science (10%), physics and astronomy (12%), environmental sciences (13%), and materials science (7%). Given the considerable number of articles and our expertise, we concentrated our study within the field of engineering.

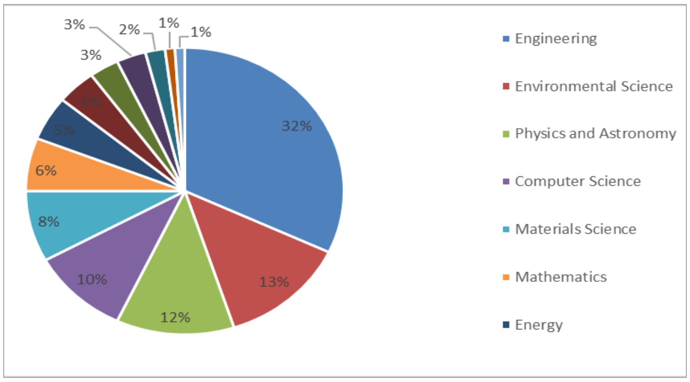

Fig. 2. Item domains found in scopus.

We applied consecutive filters to narrow down the initial set of articles to a more refined result aligned with our research objectives. The purpose of these filters was to eliminate unwanted articles and enhance the search process. The filtering method involved considering various features: (i) identification and removal of duplicate articles (1 article in total); (ii) relevance to the field of engineering (119 articles); (iii) publication in reputable journals (116 articles); (iv) alignment of article titles and abstracts with the research scope (98 articles); and (v) accessibility of full-text articles (91 articles).

Bibliometric analysis is a method used to map key authors, journals, and keywords within a specific research area [43]. Vanalle and Santos [46] explain that these methods depend on a methodologically recognized theoretical-methodological foundation, which allows the use of statistical and mathematical techniques to analyze information from bibliographic databases. In this study, content analysis was carried out following the criteria established by Bardin [47] to organize the analysis, encode data, categorize information, draw inferences, and identify research gaps related to machine learning and supply chain performance.

As shown in Fig. 1, the authors established certain criteria. Two software applications were used to manage and compile the collected data: (i) Mendeley [48] and (ii) VosViewer [43].

Mendeley is an online reference management software developed by Mendeley Ltd [48]. It facilitates research and scholarly work by collecting references from online databases, importing their metadata, and grouping them according to various methods [43]. In this study, Mendeley was used to perform quantitative analyses of authors, keywords, journals, research centers, citations and countries [43].

VosViewer, on the other hand, is a software used to construct bibliometric networks based on data obtained from bibliographic databases such as Web of Science and Scopus [43]. This software allows the user to choose between total and fractional counting methods [49]. In the current study, VosViewer was used to perform co-author and co-occurrence analyses of keywords [45].

IV. Findings

The literature review serves as the initial step for researchers to delve into a study and acquire knowledge within a specific context [50]. It offers an introductory perspective on enhancing research projects and examines the existing body of scientific knowledge in the field [50]. Additionally, it enables researchers to familiarize themselves with the subject matter, gaining exposure to new concepts and definitions [50]. Creswell [51] has highlighted the multiple purposes of a literature review, including sharing the findings of related studies with readers, fostering dialogue around the research, contributing to the existing body of knowledge, addressing research gaps, and extending prior studies.

In this study, we analyzed 91 articles authored by 331 individuals or collaborations, which were published in 70 journals over a 14-year period. These articles collectively cited 4148 references and generated 67 keywords. Contributions were made by researchers from 24 countries, including Japan, United States, India, France, and Netherlands, affiliated with 75 institutions or research centers.

Fig. 3 displays the chronological distribution of the 91 articles analyzed in this study. The earliest identified article on the subject was published in 2007, titled "Machine learning-based demand forecasting in supply chains" by Carbonneau et al. [52]. This paper aimed to compare the performance of novel predictive techniques based on machine learning (ML) with more conventional methods. The authors utilized data from various sources, including a chocolate manufacturer, a toner cartridges manufacturer, and the Statistics Canada manufacturing survey, to conduct their analysis.

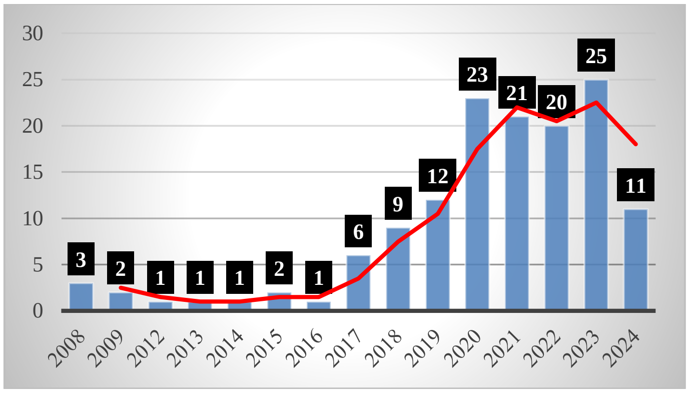

Fig. 3. Publications per year.

Concerning the authors of articles, we identified 331 authors and co-authors for 91 selected articles. The most productive authors are V. Kumar, S.P. Singh, Y. Liu, R. Carbonneau, G.J. Wang, E.M. Frazzon, K. Laframboise, A. Gunasekaran, S.

Punia, B. Jin, R. Vahidov, B. Karimi, C. Xie, Y. Zhu, and J. Kim, with two articles each.

Fig. 4 depicts the co-authorship network of the authors involved in the study, comprising 331 individuals. The network consists of 20 distinct groups connected by 98 links. The visualization suggests that authors within the "Machine Learning and supply chain performance" domain tend to work in isolation, with only a limited number of collaborations observed.

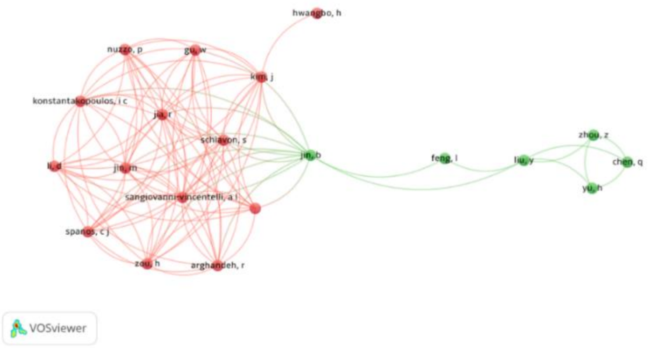

Fig. 4. Co-authorship of authors.

Fig. 5 portrays the co-occurrence of 67 keywords, with 16 items forming four distinct clusters. Notably, the visualization highlights two main themes associated with the keywords "Performance*", "Supply chain," and "Machine learning". The first theme revolves around "Machine learning," while the second theme centers around "Supply chain management". These clusters represent the prominent topics that emerge when exploring the interconnections between performance, supply chain, and machine learning in the literature.

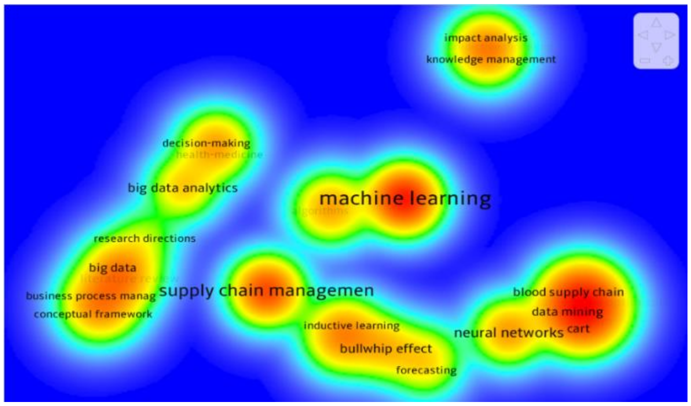

Fig. 5. Keyword co-occurrence.

At least one citation was found in the Scopus database for 59 of the 91 articles selected for this study. There are two main ways of checking citations, as explained by Mingers and Leydesdorff [53]. The first is to use the Web of Science or Scopus databases, which require subscriptions and offer different levels of access based on payment plans, allowing researchers to access resources accordingly. The second option is to use Google Scholar, which is more easily accessible and offers in general free access to resources. Since our laboratory has access to the Scopus database through the IMIST platform [43], we have also chosen to use it in this study. Articles with more than 10 citations are shown in Fig. 6.

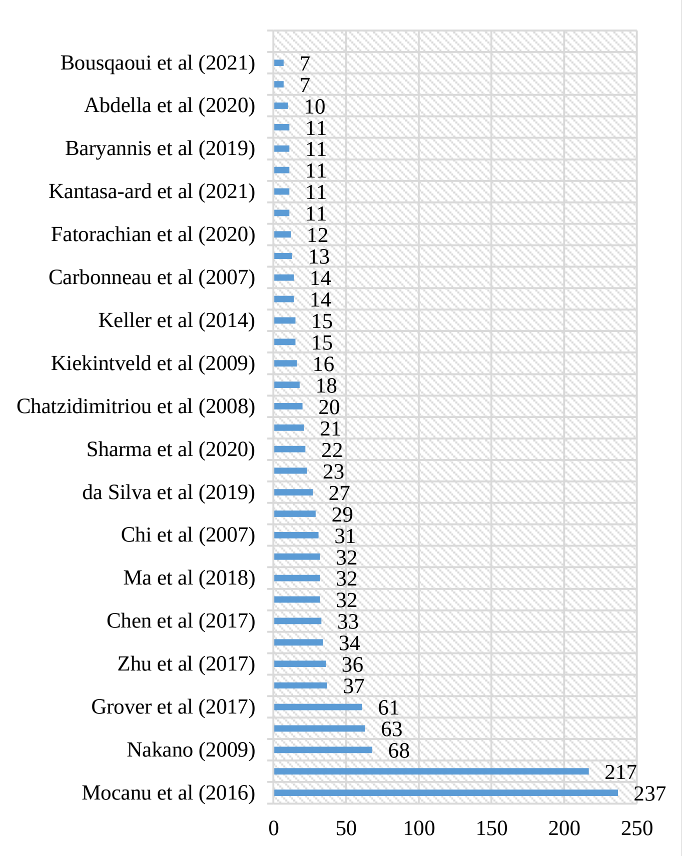

Fig. 6. Most cited articles.

V. Discussion

The authors have verified that among the 91 selected articles, 51% are empirical, 24% theoretical and 25% are a mixture of both, knowing that the publications were made between 2008 and 2024. It should be noted that our investigation has identified only one article corresponding to the considered subject for each of the four following years: 2012, 2013, 2014, and 2016. The distribution of articles by theoretical and empirical nature, and the mix of both, is shown in Fig. 7.

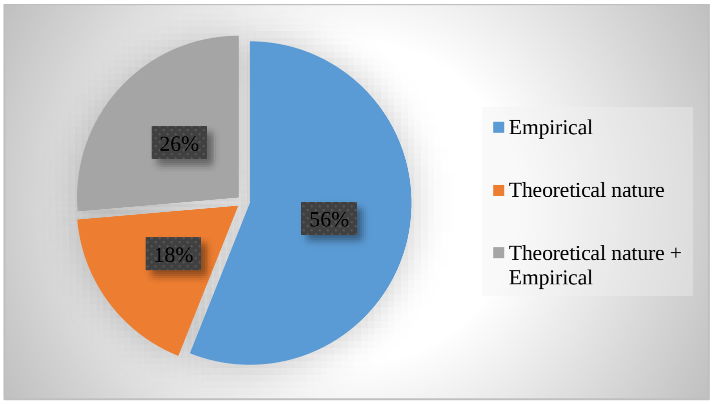

Fig. 7. Item breakdown by nature.

Furthermore, Fig. 8 presents the research methodologies used in the 91 articles. Indeed, we can state that 36% of the articles are experimental studies, such as the research conducted by Zhou et al. [54] that deals with information collaboration on supply chain management and the Internet of Things (IoT). In addition, Dubey et al. [3] have investigated artificial intelligence (AI) and Big Data Analytics (BDA) in production companies.

On the other hand, 24% of the studies were theoretical, distributed as follows: 10% systematic literature reviews, 18% theoretical frameworks, 7% conceptual models, and 3% classical literature reviews. Finally, 25% are mixed research between theoretical and empirical study, such as the research presented by Pereira and Frazzon [55] which proposes a conceptual model and validates it through a practical case study.

In the following Table I, we will present the synthesis of articles by category.

This table provides a summary of key findings and contributions for each considered article. It is not exhaustive and does not cover all aspects of each study. For detailed information, please refer to the original publications.

That is, the final section of this paper will give some conclusions from the above analysis as well as possible perspectives for future research in the same field.

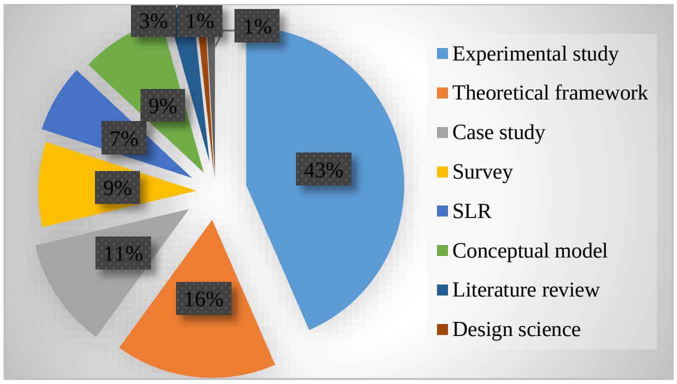

Fig. 8. Distribution of articles according to their methodologies.

TABLE I. MACHINE LEARNING APPLICATIONS IN SUPPLY CHAIN PERFORMANCE

Category	Study	Methodology	Key Findings/Contributions
Case Studies	Gonçalves et al. (2021)	Multivariate approach	Predicting component manufacturers' demand across multiple forecast horizons using leading demand change indicators.
	Brintrup et al. (2020)	Data analytics	Predicting first-level supply chain disruptions using historical OEM data.
	Abbasi et al. (2020)	Machine learning	Solving large stochastic operational optimization problems.
	Kim et al. (2018)	Stochastic control and optimization	Solving mathematical problems related to initial fashion product distribution using real data.
	Pereira et al. (2021)	Machine learning demand forecasting and simulation-based optimization	Synchronizing demand and supply in omnichannel retail supply chains.
	Leung et al. (2020)	Adaptive neuro-fuzzy inference system	Developing a novel predictive methodology by integrating data time series features.
	Priore et al. (2019)	Inductive learning algorithm	Defining appropriate replenishment policies in response to environmental changes.
	Baryannis et al. (2019)	Data-driven AI techniques	Developing a framework for predicting supply chain risks, balancing prediction performance with interpretability.
	Fu and Chien (2019)	UNISON analytical framework	Predicting intermittent electronic component demands using machine learning and temporal aggregation mechanisms.
	Gabellini et al. (2024)	Deep learning (LSTM) model trained on preprocessed data including macroeconomic indicators	Predicting supply chain delivery delay risk using deep learning and macroeconomic indicators. Deep learning approach outperforms benchmarks, highlighting the importance of macroeconomic indicators for accurate predictions
Theoretical Frameworks	Galetsi et al. (2020)	Systematic literature review	Mapping the scientific field of machine learning in supply chain management using a resource-based theory framework.
	Hatamlah et al. (2023)	Conceptual model development, literature review	Develops a conceptual model that outlines how AI can be leveraged to enhance supply chain risk management, focusing on areas like early warning systems, predictive analytics, and scenario planning.
	Sharma et al. (2020)	Systematic literature review	Reviewing machine learning applications in agricultural supply chains and highlighting their contribution to sustainability.
	Dhamija and Bag (2020)	Systematic literature review	Analyzing prominent research on artificial intelligence in supply chain management.
	Fatorachian et al. (2020)	Systems theory	Studying the impact of Industry 4.0 on supply chain performance and developing an operational framework.
	Ni et al. (2020)	Overview	Providing an overview of machine learning applications in supply chain management and offering future research directions.
	Aryal et al. (2018)	Exploration of disruptive technologies	Examining how research approaches differ when managing disruptive change, particularly with massive data analytics and IoT.
	Nguyen et al. (2017)	Classification framework	Proposing a classification framework for big data analytics applications in supply chain management.
	Grover and Kar (2017)	Investigation	Studying the primary use of big data analytics in various industries, investigating its role in resource utilization and sustainability.
	Abdella et al. (2020)	New method	Presenting a new method for assessing and modeling the sustainable impacts of food consumption.

	Bahaghighat et al. (2019)	Machine-learning vision	Using machine-learning vision to monitor and control drug packaging in pharmaceutical product lines.
	Bucur et al. (2019)	Multi-view tuning	Proposing merging information sources and considering tuning as a multi-view problem.
	Kim et al. (2008)	Supplier selection	Focusing on supplier selection in a manufacturing company, allowing suppliers to compete for purchase.
	Souza et al. (2019)	Literature review	Identifying different approaches for assessing sustainable performance.
	da Silva et al. (2019)	Contextualization	Contextualizing technology transfer in the supply chain of Industry 4.0, focusing on supply, manufacturing, and consumer stages.
	Wu et al. (2020)	Conceptual model	Proposing a conceptual multi-partner classification model for partner qualification and classification.
	Brinch (2018)	Structured content review	Addressing the poor understanding of massive data's value in supply chain management from a business process perspective.
Investigation Methods	Mishra et al. (2023)	Survey-based research, statistical analysis	Examines the adoption of digital technologies in supply chains within the manufacturing sector, identifying key trends, challenges, and best practices.
	Benzidia et al. (2021)	Survey	Investigating the impact of massive data analysis and artificial intelligence on green supply chain processes.
	El-Khchine et al. (2018)	Exploration	Exploring the application of social metadata networks and their analysis in supply chain management.
	Keller et al. (2014)	Study	Studying the use of data mining techniques for filtering and aggregating raw RFID data.
Experimental Studies	Zhou et al. (2021)	Demonstration	Demonstrating that logistics cooperation based on supply chain management reduces costs and improves services.
	Islam and Amin (2020)	Exploration	Exploring the use of machine learning models for predicting backorders to enhance decision-making.
	Yan et al. (2020)	Proposal	Proposing a distributed anti-collision algorithm for RFID systems incorporating machine learning.
	Feizabadi (2020)	Development	Developing hybrid demand forecasting methods based on machine learning.
	Tamy et al. (2020)	Description	Describing a machine learning approach to build an efficient and accurate network intrusion detection system.
	Liu et al. (2020)	Presentation	Presenting a surrogate mechanism using supervised learning, where sets of decision trees are trained on historical data.
	Liu Y. et al. (2020)	Proposal	Proposing a new model, F-TADA, derived from trend alignment with recurrent multi-task dual attention neural networks.
	Tosida et al. (2020)	Optimization	Optimizing an assistance classification model for Indonesian telematics SMEs using deep learning.
	Cavalcante et al. (2019)	Presentation	Presenting a new approach to resilient supplier selection using data analytics.
	Zhu et al. (2019)	Proposal	Proposing an improved hybrid ensemble machine learning approach for SME credit risk prediction.
	Shankar et al. (2019)	Prediction	Aiming to predict container throughput using deep learning methods.
	Lau et al. (2018)	Design	Designing a novel big data analytics methodology based on a parallel aspect-oriented sentiment analysis algorithm.
	Ma et al. (2018)	Proposal	Proposing a method to determine false positives in RFID systems using machine learning algorithms.
	Gyulai et al. (2018)	Analysis and comparison	Analyzing and comparing analytical and machine learning prediction techniques.
	Çimen et al. (2017)	Proposal	Proposing an Approximate Dynamic Programming (ADP) methodology to overcome computational challenges.
	Mocanu et al. (2016)	Study	Studying two stochastic models for energy consumption time series prediction.
	Hogenboom et al. (2015)	Proposal	Proposing a two-level machine learning approach for computing tactical pricing decisions.
	Kandananond (2012)	Development	Developing two machine learning methods (ANN and SVM) and a traditional approach (ARIMA) for predicting consumer product demand.
	Kiekintveld et al. (2009)	Documentation	Documenting successful approaches for price forecasting, emphasizing the exploitation of information sources.
	Carbonneau et al. (2008)	Investigation	Investigating the applicability of advanced machine learning techniques to predict demand distortion.
	Chatzidimitriou et al. (2008)	Presentation	Presenting Mertacor, an SCM agent using heuristic techniques and statistical modeling.
	Chen Yu (2024)	Exploration	The study examines the revolutionary potential of artificial intelligence (AI) and machine learning (ML) in contemporary supply chain management, and their effects on supply chain performance.
	Chi et al. (2007)	Demonstration	Demonstrating the feasibility of applying computational intelligence (machine learning) and evolutionary algorithms to optimize data-rich environments.

VI. Conclusion

This research delves into the burgeoning landscape of Machine Learning (ML) applications within supply chain management, analyzing a comprehensive collection of literature from 2008 to 2024. Through a rigorous bibliometric and content analysis approach, utilizing the ProKnow-C method and data from Scopus and Web of Science databases, this study unveils key trends, advancements, and future research directions within this dynamic field.

Our analysis reveals a clear trajectory of increasing sophistication in ML applications for supply chain management. Demand forecasting, a cornerstone of effective supply chain operations, stands out as a domain where ML has achieved significant maturity, with well-defined performance measurement and evaluation methods. However, the reach of ML extends far beyond demand prediction, encompassing a diverse range of applications that address critical challenges within the supply chain ecosystem.

The study highlights the transformative potential of ML in tackling complex issues such as disruption prediction, inventory optimization, risk management, and the integration of disruptive technologies like Big Data Analytics (BDA) and the Internet of Things (IoT). Furthermore, ML is proving instrumental in enhancing supply chain resilience through the development of robust supplier selection methodologies, leveraging data analytics to assess disruption likelihood and predict performance impacts.

The integration of ML into partner qualification and classification processes, employing ensemble learning and fuzzy set theory, demonstrates its ability to optimize collaboration and strategic partnerships within the supply chain. ML's capacity to predict consumer product demand, exemplified by the development of methods like Artificial Neural Networks (ANN) and Support Vector Machines (SVM), underscores its role in driving informed decision-making and enhancing market responsiveness.

The study also underscores the growing awareness of ML's environmental impact. The significant influence of BDA and AI on the integration of environmental processes necessitates the development of adaptive replenishment policies, leveraging inductive learning algorithms to respond effectively to environmental changes.

Looking ahead, this research identifies several promising avenues for future research. A case study focusing on the application of ML methods to enhance the performance of automotive supply chains would provide valuable insights into industry-specific applications. Additionally, experimental analysis of integrating ML models into the best practices outlined by the SCOR model would contribute to a deeper understanding of ML's practical implementation within established frameworks.

Finally, the exploration of conceptual frameworks and empirical evidence that examine the influence of adopting ML algorithms on supply chain performance is crucial. This endeavor would aim to quantify the extent to which manufacturing firms can leverage ML algorithms to achieve tangible improvements in supply chain efficiency, resilience, and sustainability.

In conclusion, this research underscores the transformative potential of ML in revolutionizing supply chain management. The diverse applications, ongoing research efforts, and emerging trends suggest a promising future for ML in optimizing performance, enhancing resilience, and fostering sustainability within the complex and dynamic landscape of global supply chains.

***Abstract*—Internet enterprises, as the representative enterprises of technology-based enterprises, contribute more and more to the growth of the world economy. To ensure the sustainable development of enterprises, it is necessary to predict the risks in the operation of Internet enterprises. An accurate risk prediction model can not only safeguard the interests of enterprises but also provide certain references for investors. Therefore, this study designed a Convolutional Neural Network (CNN) model based on the Kepler optimization algorithm (KOA) for risk prediction of Internet enterprises, aiming to maximize the accuracy of the prediction model, and to help Internet enterprises carry out risk management. Firstly, we select the indicators related to the financial risk of Internet enterprises, and predict the risk based on the traditional statistical analysis of Logistic regression model. On this basis, KOA was improved based on evolutionary strategies and fish foraging strategies, and the improved algorithm was applied to optimize CNN. Based on improved KOA and CNN algorithms, an IKOA-CNN risk prediction model is proposed. Finally, by comparing traditional statistical analysis-based models and other learning-based models, the results show that the IKOA-CNN algorithm proposed in this study has the highest prediction accuracy.**

Keywords—Risk management; Kepler optimization algorithm; Convolutional Neural Network; Internet enterprises

I. Introduction

Internet enterprises are facing diversified risks while developing rapidly. These risks mainly come from internal operations, technical implementation, and data management. The main content of Internet enterprise risk management includes risk identification, risk assessment, risk control and risk monitoring [1]. Effective risk management can not only help enterprises develop steadily in uncertain market environments but also enhance their market competitiveness and improve the quality of their decision-making. For Internet enterprises, risk management is not only a necessary defense mechanism, but also an important tool to enhance enterprise value and competitiveness [2]. Therefore, Internet enterprises urgently need a risk management system, which can not only accurately identify the business risks of enterprises, but also accurately assess the risk level.

Improving the accuracy of Internet enterprise business risk prediction has always been the focus of relevant researchers. For the risk management system of interconnected enterprises, business risk identification and business risk assessment have always been two widely discussed topics. Risk management of Internet enterprises is a continuous process, which requires enterprises to constantly identify and evaluate new risks, and use cutting-edge technologies to improve the efficiency and effect of risk management [3]. In the process of risk identification and assessment, Internet enterprises often use big data analysis and artificial intelligence technology. Among them, big data analysis means that Internet enterprises use big data tools to analyze user behaviour, market trends and other content, to accurately predict potential risks. The disadvantage of this method is that it requires extracting massive amounts of user data and internal enterprise data. Due to some privacy issues, the data is unavailable, making risk prediction impossible or inaccurate [4]. Therefore, a large number of researchers use artificial intelligence technology to predict the operational risks of enterprises. The risk prediction model based on artificial intelligence technology refers to the use of AI models, such as machine learning and deep learning models, to identify and predict risk patterns in enterprises [5]. Compared to risk prediction models based on big data, learning based models do not require massive amounts of data. In addition, with the development of technology, blockchain technology and cloud computing technology have also been used to enhance data security and prevent tampering, especially in the fields of financial transactions and data storage.

Risk prediction of Internet enterprises is a complex and changeable process. The factors related to risk prediction of Internet enterprises mainly include technological change, market competition, laws and regulations, user behavior, economic environment and corporate governance. The accuracy of risk prediction of Internet enterprises is mainly affected by data and prediction technology [6]. The data aspect mainly includes data quality and availability, and the breadth, depth, and accuracy of data collection directly affect the reliability of prediction results. The technical aspect mainly includes the prediction technology used, such as the applicability and progressiveness of statistical models and machine learning algorithms. In addition, the integration between systems may also affect the accuracy of prediction results. The degree of integration between the risk management system and other management systems in the enterprise affects

*Corresponding Author.

data flow and information sharing, thereby affecting the comprehensiveness and timeliness of predictions [7].

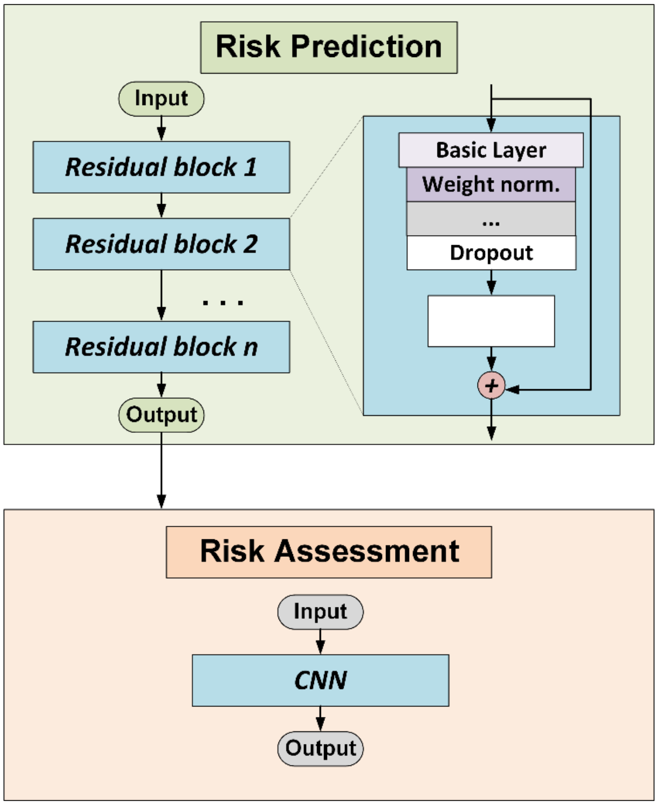

Fig. 1. The framework of Internet enterprise risk management system.

Deep learning models have shown great potential in the field of enterprise risk management. Deep learning technology can process and analyze a large amount of unstructured data, which is particularly important for predicting business risks. In enterprise risk management systems, deep learning is mainly applied in three aspects: enterprise credit risk prediction, enterprise market risk prediction, and enterprise financial risk prediction [8]. CNN, as a deep learning architecture, is particularly suitable for processing data with grid like topological structures. Due to this characteristic, CNN has been widely used in fields such as image recognition, healthcare, autonomous driving, and natural language processing. At present, there is relatively little research on the application of CNN to predict business risks. Li et al. proposed a model for predicting loan credit risk based on CNN and conducted preliminary exploration of CNN based prediction models [9]. The risk prediction model based on CNN mainly includes three steps: data collection and preprocessing, network design and training of CNN algorithm, and validation and testing of CNN algorithm. Therefore, based on the work [9], this study introduces intelligent optimization algorithms in the design process of CNN to improve the accuracy of prediction. Further, for the risk prediction of Internet enterprises, a risk management system is designed. Fig. 1 shows the operational risk management system designed in this paper for Internet enterprises.

Aiming at the problems of inaccurate prediction results and unsatisfactory evaluation results in the risk prediction and evaluation of Internet enterprises at this stage, this study designed a system for Internet enterprise risk management, aiming to improve the accuracy of risk prediction and risk evaluation. The main contributions of this study are summarized as follows:

- In this study, a model for Internet enterprise risk management was established, and the model was tested through a dataset of 100 Internet companies, which verified the effectiveness of the model.
- This study developed an IKOA-CNN algorithm based on KOA and CNN algorithms. Firstly, the classic KOA algorithm was improved by designing improvement strategies, and the CNN model was optimized using the improved KOA algorithm. The results indicate that the IKOA-CNN algorithm can effectively improve the prediction accuracy of CNN.
- A two-stage prediction risk management model was developed. In the first stage, the operational risk of Internet enterprises was predicted based on the data of Internet enterprises. The second stage is to assess the level of operational risk according to the prediction results, to provide a basis for risk management of Internet enterprises.

The rest of this article is organized as follows. Section II reviews the work related to risk prediction and machine learning algorithms. Section III designs an improved CNN model. Section IV is the result display of the organized dataset to validate the developed algorithm. Finally, the entire article was summarized in the Section V.

II. Literature Review

A. *Operational Risks of Internet Enterprises*

Internet enterprises face a wide range of risks, which can be analyzed from technology, market, law, operation and other dimensions. Technical risks mainly include two aspects: data security and privacy leakage. Internet enterprises will collect and store a large amount of user data in the operation process, and the security of these data has become the main concern of enterprises. At present, the technologies mainly used to prevent technological risks include blockchain technology [10]. The operational risks of Internet enterprises mainly include supply chain interruption risk, brain drain risk, financial risk, credit risk and currency fluctuation risk [11]. Financial and credit risks are crucial for the development of enterprises. Therefore, this research focuses on the financial risk and credit risk of Internet enterprises. In addition, although the supply chain disruption of Internet enterprises can also lead to serious operational problems, the risk of supply chain disruption can be solved by designing flexible supply chains and introducing other advanced transportation equipment [12]. Therefore, Lee et al. explored how to establish a resilient supply chain to reduce the risk of supply chain disruptions [13].

B. *Financial Risk Prediction*

The traditional financial ratio analysis method is a commonly used method by early scholars in the process of enterprise financial risk analysis. Delen et al. used financial ratio analysis methods and knowledge graph techniques to predict a company's financial risk by analyzing its financial ratios [14]. The financial ratio analysis method is simple and does not require a large amount of data, but it also has certain limitations, such as ignoring non-financial information, etc. These limitations often lead to unsatisfactory predictive performance of this method. In response to this issue, researchers have started using more complex statistical models to predict financial risk. For example, logistic regression and multiple regression analysis methods [15]. In recent years, with the development of artificial intelligence technology, machine learning and deep learning techniques have also been applied to financial risk prediction. For example, machine learning algorithms such as artificial neural networks, support vector machines, and random forests are used to process large amounts of financial and non-financial data to improve prediction accuracy. These methods can capture nonlinear relationships in data and process high-dimensional data [16]. In addition, some researchers use text analysis and unstructured data to predict financial risks. For example, by analyzing text information such as annual reports, news reports, and social media of enterprises, natural language processing techniques are used to extract relevant information, thereby helping to improve the accuracy of financial risk prediction [17].

C. Credit Risk Prediction

The credit prediction of Internet enterprises is also an important research direction in the field of Internet business risk assessment, especially in the assessment of credit risk. In recent years, with the development of artificial intelligence technology, credit prediction methods and applications have made significant progress. Similar to financial risk prediction, the credit risk assessment of Internet enterprises also includes the traditional scoring model and the prediction model based on artificial intelligence technology. Linear statistical models, as representatives of traditional models, mainly include two types: logistic regression and discriminant analysis. The linear statistical model relies on the historical financial data and credit history of the enterprise to predict credit risk [18]. The credit risk prediction model based on artificial intelligence technology mainly uses machine learning and deep learning techniques. Zhang et al. provided an in-depth description of credit risk prediction methods for small and medium-sized enterprises. The deep learning model proposed by him can effectively integrate various types of data, thereby improving the accuracy of prediction [19]. Liu et al. also designed a two-stage prediction algorithm based on deep learning models to predict the credit risk of enterprises [20]. Yao et al. designed a support vector machine model for risk prediction in supply chain enterprises, which can effectively integrate multiple types of data [21]. It can be said that the credit prediction of Internet enterprises is changing from traditional statistical methods to the use of artificial intelligence technology. These modern methods can handle more complex and dynamic data sets, provide more accurate and personalized credit evaluation, and thus help Internet enterprises more effectively manage credit risk [22]-[23].

D. Convolutional Neural Network

Convolutional Neural Networks (CNNs) have the advantages of automatically extracting data features, a concise hierarchical structure, and the ability to share parameters. Therefore, they are gradually being applied in the financial risk assessment process of enterprises [24]. However, CNN also has drawbacks such as a large demand for training data and unsatisfactory performance in handling non visual tasks. Therefore, when applying CNN to the process of enterprise risk prediction, it is necessary to improve it [25]. In recent research, the application of CNN has been extended to multiple cutting-edge technological fields, and relevant researchers have made improvements to it from different perspectives. Deepak Khatri et al. developed an intelligent framework based on serverless computing in their research, aiming to improve service efficiency through the use of artificial intelligence and machine learning [26]. Qin developed a financial risk prediction model for listed companies using CNN, which preliminarily demonstrated the potential of CNN in processing non-traditional image datasets [27]. In the study of network systems, Lou et al. (2023) proposed using a CNN algorithm to predict the robustness of networks, which utilizes CNN's powerful feature extraction ability to analyze the complex interactions of network structures [28]. In addition, de la Cruz et al. used an improved CNN model to detect eye flicker integrity in their study, which not only demonstrated the effectiveness of CNN in time series data processing, but also emphasized the importance of combining recurrent neural networks [29]. These studies collectively demonstrate the breadth and depth of CNN applications in multiple fields, from traditional image processing to complex time series analysis and 3D data processing, demonstrating its sustained development and innovation as a powerful machine learning tool [30]-[31].

III. Algorithm Design

In this section, we designed an IKOA-CNN algorithm aimed at optimizing the learning rate in CNN using IKOA [32]. In CNN-based prediction models, learning rate has a significant impact on prediction performance. We first introduced the improved KOA algorithm. Fig. 2 shows the flowchart of the IKOA algorithm.

A. The Improved Kepler Optimization Algorithm

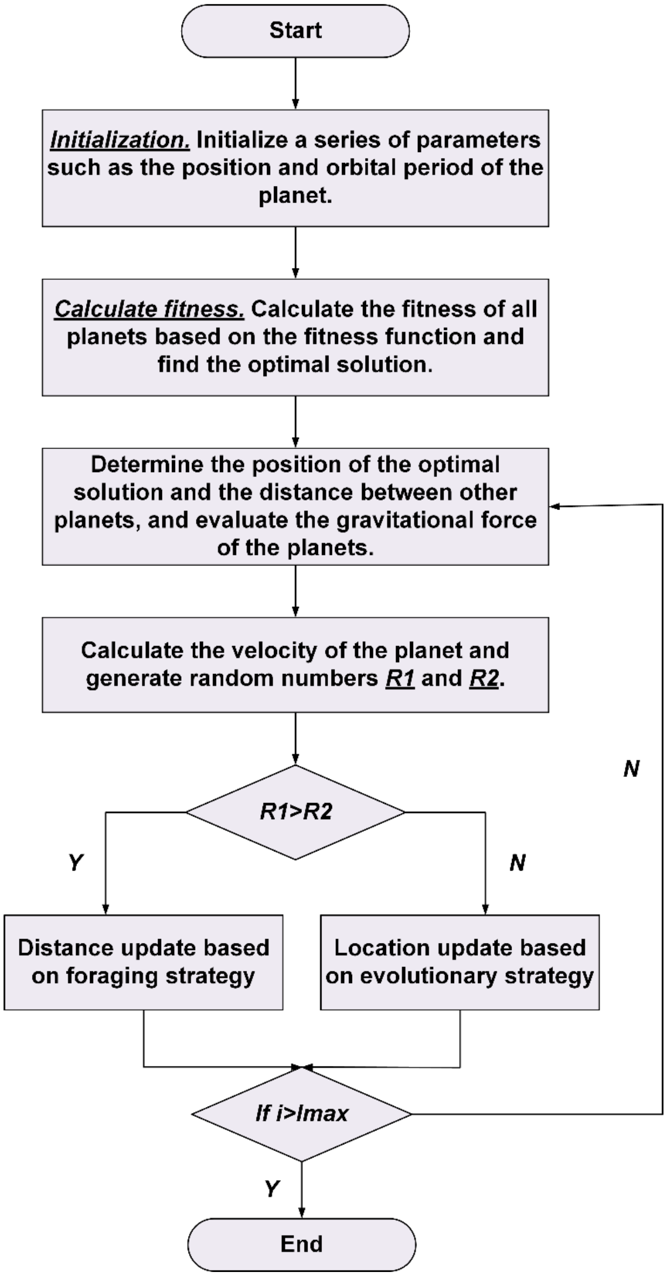
We improved the KOA algorithm by utilizing the evolutionary strategy of the genetic algorithm (GA) and the foraging strategy of the artificial fish swarm algorithm (AFSA). The main steps of the improvement are as follows:

Step 1: Initialize the parameters of the KOA algorithm based on Eq. (1) and Eq. (2).

$$\rho_k = Rand(0,1), k \in \{0,1,\cdots,k_{max}\} \tag{1}$$

$$Ha_i = |R\_n|, k \in \{0,1,\cdots,k_{max}\} \tag{2}$$

where, ρ_k is the eccentricity of the planet's orbit. Ha_i is the period of the planet's orbit, and R_n is a random number that follows a normal distribution pattern. $\{0,1,\cdots,k_{max}\}$ is a set of the number of planets.



Start
Initialization. Initialize a series of parameters such as the position and orbital period of the planet.
Calculate fitness. Calculate the fitness of all planets based on the fitness function and find the optimal solution.
Determine the position of the optimal solution and the distance between other planets, and evaluate the gravitational force of the planets.
Calculate the velocity of the planet and generate random numbers R1 and R2.
R1>R2
Y
N
Distance update based on foraging strategy
Location update based on evolutionary strategy
If i>Imax
N
Y
End

Fig. 2. The flowchart of the improved Kepler optimization algorithm.

Step 2: Update celestial body velocity $V_k(i)$ based on the formula for updating celestial body velocity in work [32].

Step 3: Inspired by the rotation of planets around the sun, the KOA algorithm's planets rotate around the sun. During each iteration, the planet updates its position based on the optimal solution. Unlike the classic KOA algorithm, we introduce the evolutionary strategy of GA algorithm into the update strategy of planetary position, as shown in Eq. (3).

$$S_k(i+1)=S_k(i)+\chi\times V_k(i)+\delta+\vec{S}_k(i) \tag{3}$$

where, $S_k(i+1)$ is the position of planet k in the $i+1$ st iteration process. χ and δ are two small variables.

Step 4: Introducing the foraging strategy of AFSA algorithm into the planetary distance update strategy, the update process of distance $\vec{S}_k(i)$ is shown in Eq. (4).

$$\vec{S}_k(i+1)=\frac{\vec{S}_k(i)+\vec{S}_a(i)+\vec{S}_b(i)}{3} \tag{4}$$

where, $\vec{S}_a(i)$ and $\vec{S}_b(i)$ are two randomly selected distances.

Step 5: Update Determine if the maximum number of iterations has been reached, and if so, output the result. If not, restart the loop.

B. Risk Management Based on CNN

Before conducting calculations, it is necessary to first rate all influencing factors based on expert experience, and weight and accumulate the obtained random probability of risk to obtain the comprehensive random probability P_n of risk factors.

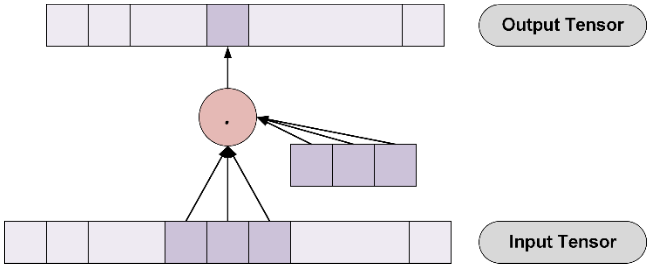


Fig. 3. The process of calculating the elements of the output tensor.

Fig. 3 shows the calculation process of CNN at each level, and the convolution $C(j)^l$ calculation formula is as follows:

$$C(j)^l=\delta\times\left(\sum C(j)^{l-1}\times K(j)^l+a(j)^l\right) \tag{4}$$

where l represents hierarchy. $C(j)^{l-1}$ is the j th feature of the input layer. $K(j)^l$ is a convolutional kernel. δ is the activation function.

IV. Result Display

This study selects a dataset of 100 Internet enterprises to verify the algorithm. The data of 40 Internet companies are used as the training set, and the data of 60 companies are used as the test set. We compared five algorithms: BP neural network, CNN, AFSA-CNN, KOA-CNN, and IKOA-CNN. The comparison results are reflected through the following four indicators: root mean square error (MSE), mean pure square error (MSPE), mean absolute error (MAE), and mean absolute percentage error (MAPE). In this study, risks were categorized into five levels: low risk, medium low risk, medium risk, medium high risk, and high risk. For the purposes of statistical analysis, the numerical ranges assigned to these risk categories were 0 to 5, 5 to 10, 10 to 15, 15 to 20, and 20 to 25, respectively.

A. Financial Risk Prediction Results of Internet Enterprises

Ours	0.0093	2.17*10^(-15)	0.0358	0.0763

Tables I, II, and III respectively show the results of applying BP, CNN, KOA-CNN, AFSA-CNN and IKOA-CNN algorithms in financial risk prediction, credit risk prediction, and business risk prediction. The results show that compared with BP, CNN, KOA-CNN and AFSA-CNN algorithms, algorithm IKOA-CNN consistently exhibits the lowest MSE and MSPE values, indicating higher prediction accuracy compared to other algorithms. In addition, the MAE and MAPE values of IKOA-CNN algorithm are also the lowest, indicating its robustness in maintaining lower average deviations. The output results of BP and CNN algorithms differ significantly from the true values. The output results of AFSA-CNN and KOA-CNN algorithms also have certain deviations from the true values. In contrast, the overall risk prediction performance of the IKOA-CNN model is the best, and the difference between its trend and the true value is smaller. The prediction results show that IKOA-CNN model has a high performance in financial risk, credit risk and operational risk prediction, and this model can be effectively applied to the financial management process of Internet enterprises.

V. CONCLUSION

To foster the sustainable development of Internet enterprises, this study developed a risk prediction model utilizing the CNN algorithm. The architecture of the deep neural network model was optimized using an enhanced KOA, which is defined as IKOA-CNN. The research employed a dataset comprising data from 100 Internet enterprises. Comparative analysis with other learning-based risk prediction models demonstrates that the IKOA-CNN algorithm, as proposed in this study, achieves the highest prediction accuracy. Although IKOA-CNN algorithm in this study can accurately predict the financial risk, credit risk and business risk of Internet enterprises, the accuracy of this model for the prediction of business risk of other industries has not yet been explored. Therefore, in the next stage, we will further improve the generalization ability of the model.

Advancing Urban Infrastructure Safety: Modern Research in Deep Learning for Manhole Situation Supervision Through Drone Imaging and Geographic Information System Integration

Ayoub Oulahyane, Mohcine Kodad
MATSI Research Lab, ESTO, Mohammed First University, Oujda, Morocco

***Abstract*—This paper research introduces a cutting-edge approach to enhancing urban infrastructure safety through the integration of modern technologies. Leveraging state of the art deep learning techniques, specifically the recent object detection models, with a focus on YOLOv8, we propose a system for supervising and detecting manhole situations using drone imagery and GPS location data. Our experiments with object detection models demonstrate exceptional results, showcasing high accuracy and efficiency in the detection of manhole covers and potential hazards in real-time drone imagery. The best trained model is YOLOv8, which achieves a mAP@50 rate of 89% and a Precision rate of 95%, surpassing existing methods. By combining this visual information with precise GPS location data, our system offers a comprehensive solution for monitoring urban landscapes. The integration of YOLOv8 not only improves the efficiency of manhole detection but also contributes to proactive maintenance and risk mitigation in urban environments. This research represents also a significant step forward in leveraging modern research methodologies, and the outstanding results of our trained models underscore the effectiveness of Object detection models in addressing critical infrastructure challenges.**

***Keywords*—Urban infrastructure safety; object detection; Deep Learning (DL); UAV (Drones); Computer Vision (CV)**

I. Introduction

In the contemporary landscape of urban development, ensuring the safety and integrity of critical infrastructure is a paramount concern. Among the myriad challenges faced by urban planners and maintenance authorities [1], [2], the efficient and accurate detection of manhole covers, and potential hazards stands out as a pivotal aspect of proactive risk management [3]. This research seeks to address this challenge head-on by embracing the convergence of advanced technologies, with a specific focus on the You Only Look Once (YOLO) object detection model, particularly the latest iteration, YOLOv8 [4]. The proliferation of unmanned aerial vehicles (UAVs) or drones [5], [6], coupled with the advancements in deep learning [7], has opened new avenues for real-time surveillance and analysis of urban landscapes. The ability to deploy drones for high-resolution imaging provides a dynamic and flexible solution for monitoring infrastructure elements that are typically challenging to inspect manually or through conventional means.

Concurrently, the integration of Global Positioning System (GPS) technology adds a layer of precision by providing accurate geospatial information [8]. At the heart of this research are the Object detection models, renowned for its state-of-the-art object detection capabilities. YOLOv8 excels in processing images swiftly while maintaining a high level of accuracy, making it an ideal candidate for real-time applications. By training the models to recognize manhole covers and potential hazards in diverse urban settings, we aim to harness the full potential of deep learning models to bolster the efficiency and efficacy of infrastructure monitoring [9]. The integration of these technologies holds the promise of transforming traditional approaches to urban infrastructure supervision. Rather than relying on periodic inspections or reactive measures, our proposed system aims to establish a proactive and intelligent framework. By fusing the power of object detection methods with drone imagery and GPS location data, we aspire to create a comprehensive solution that not only detects and supervises manhole situations (see Fig. 1), but also contributes to a deeper understanding of the evolving dynamics within urban environments.

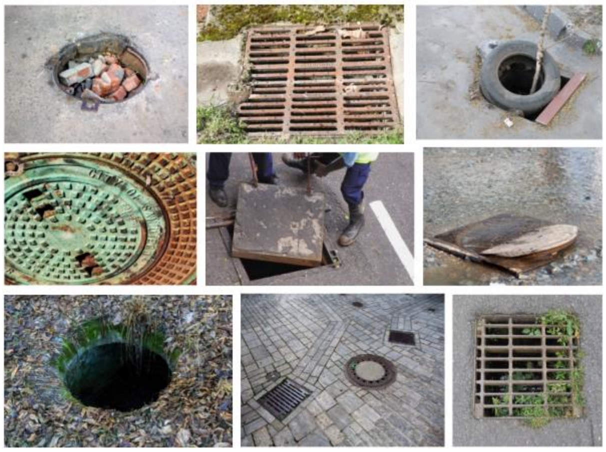

Fig. 1. Samples of varied manhole situations.

As we embark on this exploration of technology-driven urban research, the subsequent sections will delve into the methodology employed, the experimental results obtained, and the broader implications of our findings. Through this interdisciplinary approach, we endeavor to contribute to the burgeoning field of intelligent infrastructure management, paving the way for safer, more resilient urban environments in the face of evolving challenges.

This paper will be structured as follows: Background in Section II will be followed by related work in Section III. Next, we will present our methodology in the Section IV, followed by the presentation of our results in Section V. Finally, we will conclude this paper in Section VI.

II. Background

In this section we will try to give a general vision of the deep learning models that we will use in our approach and related work, which will be divided into two parts, the first related to data measurement classification models, as for the second presents some models of image detection models.

A. *Computer Vision*

Computer vision is a field of artificial intelligence (AI) that enables machines to interpret and make decisions based on visual data. It seeks to teach computers how to gain a high-level understanding of digital images or videos, similar to the way humans interpret and understand visual information. This involves tasks such as image recognition, object detection, image segmentation, and more. Computer vision has diverse applications, ranging from facial recognition and autonomous vehicles to medical image analysis and industrial automation [10].

1) *Enhancing urban infrastructure safety*: The integration of computer vision with an edge approach can significantly contribute to enhancing urban infrastructure safety [12].

2) *Computer vision edge approach*: The term "edge" in computer vision often refers to processing data closer to the source of generation rather than relying on a centralized server or cloud. The edge approach involves deploying computer vision algorithms on devices like edge computing devices, cameras, or sensors, enabling real-time analysis and decision-making without the need for constant connectivity to a central server. This approach is particularly beneficial in scenarios where low latency and immediate responses are crucial [11].

3) *Surveillance and monitoring*: Computer vision can be used to analyze live camera feeds for suspicious activities, unauthorized access, or potential safety hazards. By deploying this capability at the edge, responses can be immediate, addressing security concerns in real-time [13].

By combining the capabilities of computer vision with an edge computing approach, urban areas can benefit from faster and more efficient responses to safety and infrastructure challenges, ultimately creating smarter and safer cities.

B. *YOLO (You Only Look Once)*

YOLO (You Only Look Once) is a popular object detection algorithm that is widely used in computer vision applications. The key idea behind YOLO is to divide the input image into a grid and, for each grid cell, predict bounding boxes and class probabilities.

This allows YOLO to simultaneously detect multiple objects in an image in real-time [14], [15]. Here are some key features and concepts associated with YOLO:

1) *Real-time detection*: YOLO is known for its efficiency, and it can perform object detection in real-time, making it suitable for applications like video analysis.

2) *Single forward pass*: YOLO performs object detection in a single forward pass through the neural network, as opposed to two-stage detectors, which involve region proposal networks and classification networks separately.

3) *Bounding box prediction*: For each grid cell, YOLO predicts bounding boxes along with confidence scores and class probabilities. This allows it to detect multiple objects of different classes in a single pass.

4) *Anchor boxes*: YOLO uses anchor boxes to improve the accuracy of bounding box predictions. These anchor boxes are pre-defined bounding box shapes, and the model learns to adjust these anchors during training.

5) *Darknet*: YOLO is typically implemented using the Darknet framework, which is an open-source neural network framework written in C and CUDA. Darknet supports YOLO and allows for training and using YOLO models.

C. *ArcGIS (Geographic Information System)*

ArcGIS, developed by Esri (Environmental Systems Research Institute), is a geographic information system (GIS) software suite. It is widely used for creating, managing, analyzing, and displaying spatial data. GIS is a technology that combines geography (maps) and data to provide valuable insights, enabling users to make informed decisions based on geographic information. ArcGIS provides a comprehensive platform for working with spatial data at various scales, from local to global. The suite includes a range of desktop, server, and web-based applications. Overall, ArcGIS is a powerful tool for spatial analysis and mapping across various industries, including environmental management, urban planning, public health, transportation, and more. It is widely used by professionals and organizations to understand, interpret, and visualize geographic patterns and relationships in their data [16], [17].

III. Related Work

This study integrates multiple technologies, including deep learning, object detection, UAV (Unmanned Aerial Vehicle) technology, and ArcGIS positioning, with a specific focus on manhole detection. There is a limited number of published papers that cite these technologies in conjunction. Existing studies in this field attempt to develop new datasets to enhance detection accuracy. Additionally, they strive to balance accuracy with computational efficiency. This balance is crucial for drone implementation, especially when utilizing parallel processing co-processors. The objective is to optimize the system for real-time applications while maintaining high detection accuracy, which is essential for efficient urban planning and infrastructure management.

In their research, Pang et al. developed a method for detecting road manhole covers using a stereo depth camera and the MGB-YOLO model, achieving a notable accuracy of 96.6%. This approach, which outperforms several existing models, is particularly efficient for deployment in in-vehicle devices, contributing significantly to urban infrastructure management and vehicular safety [18].

In their work, Andersen et al. address the challenge of drone navigation in dark, GPS-denied, and confined spaces, focusing on the high processing power required for maintaining detailed environmental maps. They note the particular difficulty in navigating narrow spaces where low-resolution voxel representations can impede trajectory planning. Inspired by the Inspectrone Project, which involves inspecting large marine vessels, the authors propose a deep learning model for detecting manholes using only depth images. This study aims to balance accuracy with computational efficiency, making it suitable for drone implementation on parallel processing co-processors. A key feature of their approach is the use of a temporal filter to enhance robustness and reduce false positives, requiring multiple detections within a timeframe to confirm the manhole's location. The effectiveness of their method, which is agnostic to scene texture, is demonstrated through successful drone flights through a standard-sized manhole on a marine vessel, showcasing a viable solution for manhole detection in challenging environments [19].

In their research, Timofte, Radu et al. focus on the challenge of accurately 3D localizing road fixtures, particularly manhole covers, across extensive road networks. They propose an innovative pipeline utilizing images captured by vans to detect, recognize, and localize manholes, a task complicated by issues like occlusions, varying illumination conditions, and significant viewpoint differences. Additionally, the diversity in manhole cover designs adds to the complexity. Their approach effectively combines 2D and 3D computer vision techniques to handle large volumes of image data, achieving notable performance. This study is distinguished as the first to report on manhole mapping using solely computer vision techniques and GPS, marking a significant advancement in the field of automated road surveying [20].

Despite the advancements, these papers also address challenges such as the difficulty in detecting manholes under certain conditions (e.g., poor lighting, obscured by objects, or in densely built-up areas) [21].

IV. Methodology

A. Proposed Method

The research paper introduces a comprehensive methodology employing drones and deep learning (DL) models for the efficient monitoring, detection, and precise localization of manholes. This approach is methodically structured into interconnected phases as shown in Fig. 2:

1) *Drones for surveillance*: Utilizing drones equipped with cameras and potentially other sensors, the methodology involves aerial surveillance to collect visual data of manholes. This step is pivotal for acquiring the necessary imagery for further analysis [22].

2) *Detection of manhole conditions*: The visual data gathered by drones are transmitted to a cloud-based framework. Here, a specialized deep learning model, already trained, scrutinizes the images. The primary task of this DL model is to identify both the presence and condition of manholes from the collected visuals [23].

3) *Precise localization of manholes*: Concurrent with condition detection, the system also focuses on accurately localizing the manholes. It leverages geographical data obtained from the drones to pinpoint the exact physical locations of the manholes, a crucial element for subsequent maintenance or monitoring operations [24].

4) *Informed decision making*: Following the successful detection and localization of manholes and the evaluation of their state, the system then classifies these findings. This classification is essential for determining the appropriate actions needed, such as cleaning, repairs, cover replacements, sediment removal, coatings, or comprehensive structural assessments [25].

This enhanced methodology signifies a significant advancement in the field, leveraging cutting-edge technology for urban infrastructure management.

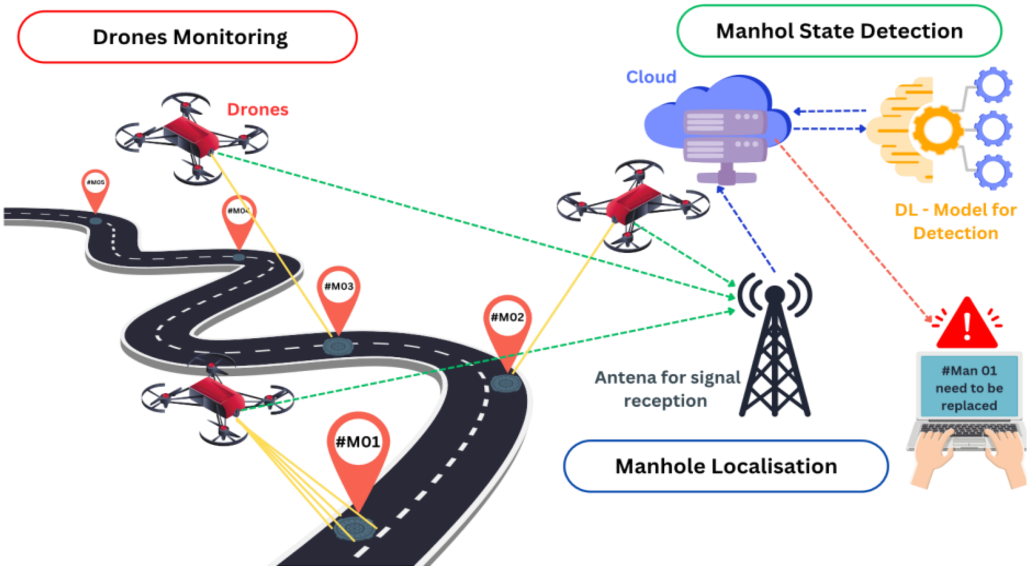

Fig. 2. Proposed monitoring, detection, and localization system for manholes.

B. *Architecture for Training Process*

The proposed methodology (see Fig. 3), delineates a sophisticated and integrated system for manhole identification and maintenance, utilizing a combination of modern technologies including unmanned aerial vehicles (UAVs), cloud computing, deep learning, and potentially geographic information systems (GIS). This system is structured into four critical steps:

1) Data collection and input: The initial phase involves compiling a comprehensive dataset of manhole images. These images are meticulously annotated, likely with bounding boxes or similar markers, to highlight the presence of manholes. This dataset forms the foundation of the entire process.

2) Model development and training: A deep learning model, though its specific neural network architecture is not detailed, is meticulously trained using the aforementioned dataset. This model is intricately designed to effectively recognize and pinpoint manholes from the visual data collected by the drones.

3) Object detection and output: Once the model is trained, it enters the object detection phase. In this stage, the model applies its learned patterns to new images captured by drones, successfully identifying manholes in these fresh visuals.

4) Analysis and decision making: The final stage involves a critical analysis of the model's output. This analysis is pivotal in making informed decisions regarding the maintenance and other necessary actions for the manholes detected.

This method represents a significant leap in infrastructure monitoring and maintenance, harnessing the power of advanced technologies to create an automated and intelligent system. This system not only increases efficiency but also potentially enhances the safety and reliability of urban infrastructure management.

C. *Testing Sample*

The chosen area for testing our manhole cover detection and monitoring method via drones is illustrated in Fig. 4, which displays a region with diverse urban characteristics. The area is demarcated by a series of waypoints forming a boundary within which the drone operations are to be conducted. On the left side, we have a simplified schematic from ArcGIS Maps, which provides a clear and uncluttered view of streets and key establishments like the "Coffee El Jabah," a "Pharmacy," and educational institutions like "El Ouafa School" and "Pythagoras Private School." This representation is beneficial for initial planning and coordination purposes.

The right side of the figure contrasts this with two views from Google - one from satellite imagery offering a detailed, real-world perspective of the area's layout and another from Google Maps, which includes street names and a blue overlay indicating the operational path of the drone. The satellite imagery provides a comprehensive view of the density and structure of buildings, roads, and vegetation, which is crucial for understanding potential obstacles and optimizing flight paths.

We suggest to studying this area that has eleven manhole covers within a one-kilometer range, signifying the target objects for the drone's detection system. The area is chosen for its typical urban features and the presence of manhole covers that need monitoring, and close to our laboratory making it an ideal test bed for validating the effectiveness of the drone-based surveillance system in actual road settings. The dual representation of the area through different mapping services aids in cross-verifying details and planning the drone's flight more accurately.

D. *Decisions Related to Manhole Situations*

Certainly, there are more specific examples of decisions related to manhole situations, including actions like cleaning and replacement:

- Cleaning Procedures: Implement regular cleaning schedules to remove debris, sediment, and blockages from manholes, ensuring optimal functionality.
- Repairs and Patching: Promptly address minor damages through patching or localized repairs to prevent further deterioration.
- Manhole Cover Replacement: Evaluate and replace worn-out or damaged manhole covers to ensure the safety of pedestrians and motorists.
- Sediment Removal: Implement strategies for the systematic removal of sediment buildup within manholes to maintain proper drainage and prevent blockages.
- Coating and Sealing: Apply protective coatings or sealants to manhole surfaces to enhance durability and resistance to environmental factors.
- Structural Assessment: Conduct thorough structural assessments to identify weak- nesses or defects, making informed decisions on repairs or replacements.

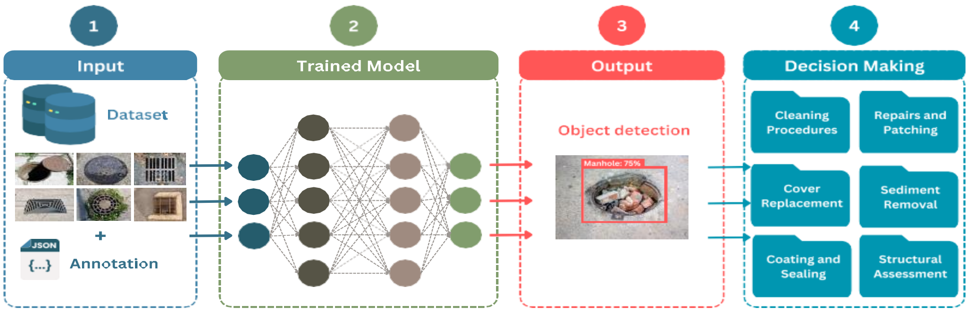

Fig. 3. Approaches of our experimental studies.

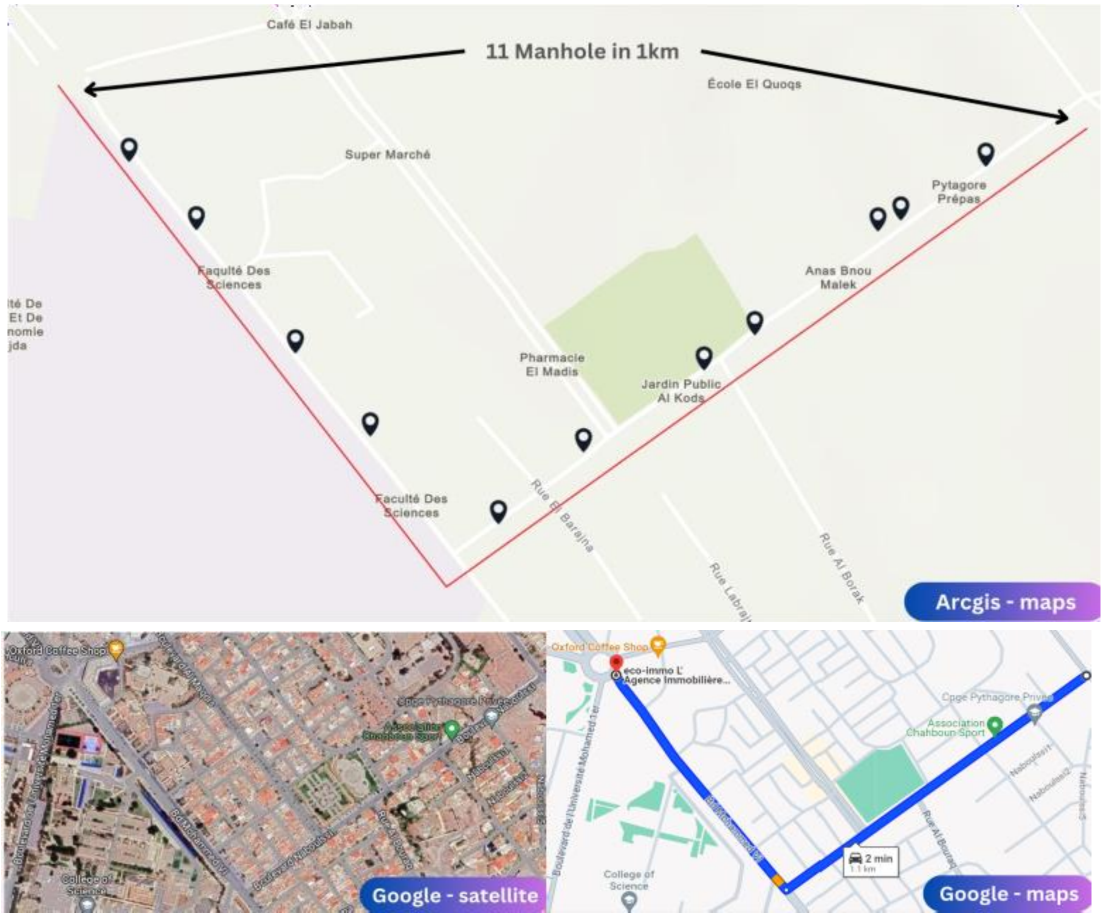

Fig. 4. Region designated for analyzing our architectures in actual road settings.

- Odor Control Measures: Introduce measures such as deodorizing agents or ventilation systems to address unpleasant odors associated with manhole situations.
- Emergency Pumping: Establish protocols for emergency pumping in situations where water accumulates rapidly, preventing potential flooding and infrastructure damage.
- Rehabilitation Programs: Develop rehabilitation plans for aging manholes, including strategies for structural reinforcement and longevity extension.
- Upgraded Materials: Consider using advanced, durable materials for manhole construction and covers to enhance longevity and reduce maintenance needs.

These decisions encompass a range of actions aimed at addressing specific issues within manhole situations, from routine maintenance to emergency response and infra- structure upgrades.

V. Results and Discussions

A. Hardware and Software Characteristics

To assemble a comprehensive dataset of manhole covers from web sources for effective labeling, we employ a variety of online databases and repositories, including platforms such as Kaggle and other internet resources that provide copyright-free imagery. Following the collection phase, we utilize a suite of labeling tools for image annotation, such as LabelImg and VGG Image Annotator (VIA). These tools facilitate the precise placement of bounding boxes around each manhole cover within the images. Each image must undergoes a meticulous review process to verify the accuracy of the annotations. This ensures the integrity of the dataset, which is crucial for the subsequent training of machine learning models.

B. Implementation Setup

For our implementation, we have used TensorFlow and PyTorch, two open-source data analysis and deep learning software library, on a high-performance computing system (HPC) equipped with the following hardware specifications:

- Two Intel Gold 6148 (2.4 GHz/20 cores) processors.
- Two NVIDIA Tesla V100 graphics cards, each with 32GB of RAM.

C. Evaluation Metrics

Table I summarizes the metrics, their application in the context of computer vision and object detection, and their respective formulas [26], [27].

TABLE I. ENHANCED AND REFINED METRICS FOR MODEL EVALUATION ANALYSIS

Metric	Explanation	Mathematical Representation
IoU	Measures the overlap between two bounding boxes, used in evaluating the accuracy of object detection models.	IoU = Area of Overlap / Area of Union
mAP	Average of the Average Precision (AP) across all classes and/or IoU thresholds, used in object detection.	mAP = (1/N) * Σ(AP_i) from i=1 to N
Precision	Ratio of correctly predicted positive observations to the total predicted positives.	Precision = TP / (TP + FP)
Recall	Ratio of correctly predicted positive observations to all observations in the actual class.	Recall = TP / (TP + FN)
F1-Score	Harmonic mean of Precision and Recall, used for balancing the two and helpful in case of uneven class distribution.	F1-Score = 2 * (Precision * Re- call) / (Precision + Recall)

D. Evaluating the Results

Table II, presents the performance results of various deep learning models for the task of object detection, specifically for detecting manhole covers. The models listed are YOLOv8, GroundingDINO, DETR, Faster R-CNN, MobileNet SSD v2, and Detectron2. They are evaluated on several metrics, which include Intersection over Union (IoU), mean Average Precision (mAP) at IoU thresholds of 0.5 and 0.75, Inference time per image, Precision, Recall, and F1-Score.

YOLOv8 outperforms the other models in almost all the metrics, with an IoU of 94%, mAP@0.5 of 87.74%, and mAP@0.75 of 89.44%. Its precision, recall, and F1- Score are all equal at 95%. These numbers indicate a highly accurate and reliable model for the specified detection task. On the other side, the inference time per image is 60 frames per second for YOLOv8 which outperforms other models. The inference time per image is an important factor in real-world applications where processing speed can be crucial.

The other models show varying degrees of success. GroundingDINO and MobileNet SSD v2 demonstrate moderate performance, with GroundingDINO achieving a higher mAP@0.5 but lower F1-Score compared to MobileNet SSD v2. DETR and Faster RCNN have comparable performance, with DETR having a slightly better IoU and mAP@0.75, suggesting better localization and confidence in detections at stricter thresholds.

The graph depicts the training progress of various deep learning models for the object detection of manhole covers, with a focus on the mean Average Precision (mAP) at an Intersection over Union (IoU) threshold of 0.5. This metric, mAP@0.5, is a standard performance measure in object detection that combines both precision and recall to evaluate the quality of the predictions, specifically at an IoU threshold of 50%.

The training process is shown in Fig. 5, over several epochs, which represent full iterations over the entire dataset. As the epochs increase, we generally expect the model to improve in its detection capabilities as it learns from the data. YOLOv8 shows a rapid and steady improvement, achieving a high mAP@0.5 early on and maintaining that lead throughout the training process. This indicates that YOLOv8 is learning effectively and can generalize well from the training data to detect manhole covers with high precision and recall.

TABLE II. OBTAINED RESULTS FOR THE IMPLEMENTED MODELS

DEEP LEARNING MODEL	IoU	mAP	mAP	Inference	Precision	Recall	F1-Score
	%	@0.5 %	@0.75 %	s/Image	%	%	%
YOLOv8	94.00	87.74	89.44	60	95.03	95.02	95.02
GroundingDINO	73.00	82.74	81.12	9	78.74	74.21	76.41
DETR	89.00	79.56	81.17	11	83.95	72.58	77.85
Faster R-CNN	80.00	80.68	84.44	15	71.20	76.31	73.67
MobileNet SSD v2	78.00	75.19	81.82	45	83.34	77.27	80.19
Detectron2	0.00	81.07	67.74	39	-	-	-

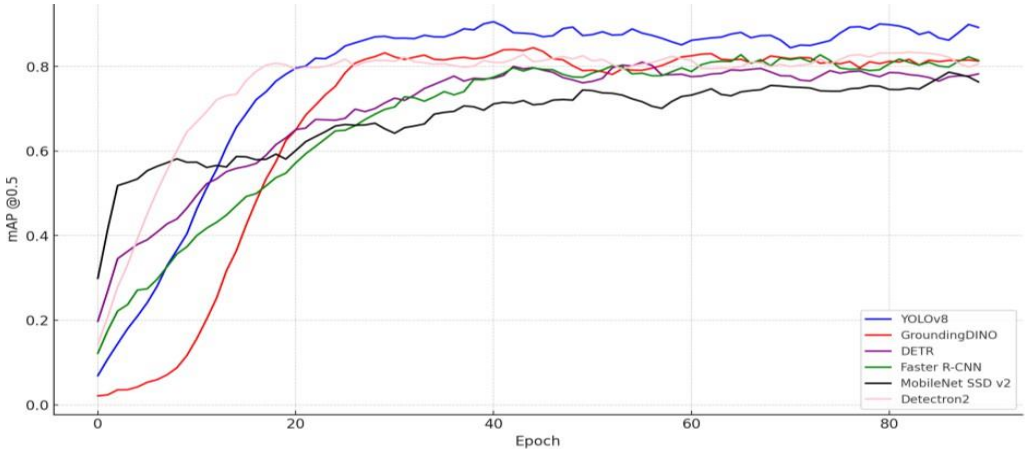

Fig. 5. Simulation of mAP@0.5 training progress over 100 epochs.

Other models, such as GroundingDINO, DETR, Faster R-CNN, and MobileNet SSD v2, also show improvement over time but with different learning curves. GroundingDINO and Faster R-CNN, for instance, demonstrate a more gradual improvement. DETR and MobileNet SSD v2 have similar trajectories, with MobileNet SSD v2 starting off stronger but DETR overtaking it by the end. These variations in learning curves can be due to differences in model architectures, learning rates, data augmentation, and other hyperparameters that affect how quickly and effectively a model learns.

Detectron2, however, appears to have a different trend. It starts with poor performance and takes a longer time to begin improving. Once it does start to improve, it shows a more gradual and less stable increase in mAP@0.5, with fluctuations that suggest the model may not be learning consistently or is struggling with the dataset. This could be indicative of issues such as overfitting, underfitting, or inadequate training data, which may require further investigation and adjustment of the training process. Overall, the graph is an essential tool for understanding the learning dynamics of each model and for diagnosing potential issues in the training process.

Fig. 6 provided showcases the results of a machine learning object detection algorithm, specifically YOLOv8, as it attempts to identify manhole covers in various settings. The image demonstrates instances, where the YOLOv8 model has successfully identified manhole covers with high confidence scores, as indicated by the numbers next to the word "Manhole" within the red bounding boxes. These scores represent the model's confidence in its predictions, with 1.0 being the highest, signifying 100% confidence.

On the other hand, Fig. 7 illustrates scenarios where the YOLOv8 model has incorrectly detected manhole covers or assigned lower confidence scores to its predictions. These false positives or less certain detections can occur due to a variety of factors such as occlusions, varying lighting conditions, unusual manhole cover designs, or similarities between the manhole covers and other objects in the environment.

YOLOv8, like other machine learning models, is not infallible and can sometimes fail to make accurate predictions. This is often due to the limitations in the training data or the inherent challenges in interpreting complex and dynamic real-world scenes. These misclassifications and uncertainties in object detection models highlight the need for continuous improvement and training with diverse datasets to enhance the model's accuracy and reliability in various conditions.

E. Discussions

For the improved and expanded implementation, the drone system operates by transmitting real-time images of detected manholes via an RTMP server. These images are accompanied by precise geolocation data, including the exact address and GPS coordinates. Once this information is relayed to the central monitoring system, operators can assess the condition of the manhole and determine the necessary course of action. This decision-making process involves evaluating the status of the manhole, such as its current state, potential hazards, and maintenance requirements. The information, along with the operator's decision, is then systematically cataloged in a structured database. An example of such data organization can be seen in Table III, which illustrates the format and type of data stored.

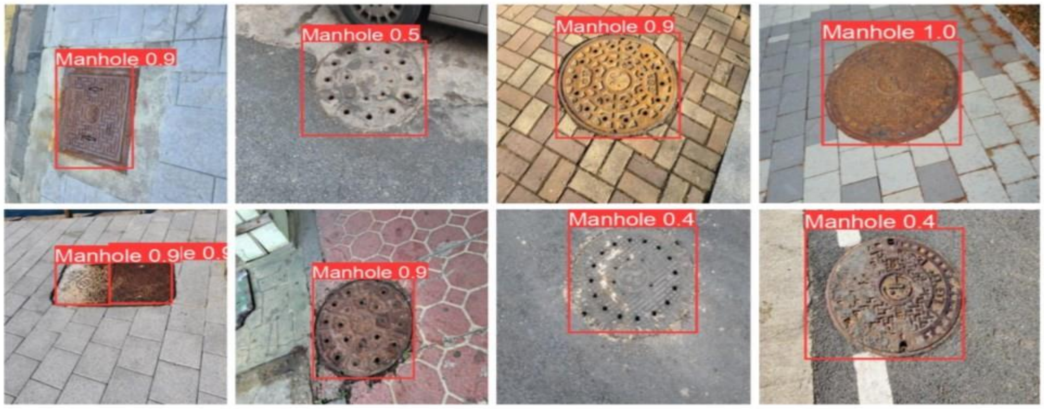

Fig. 6. Examples of good detection of manholes cover using Yolov8.

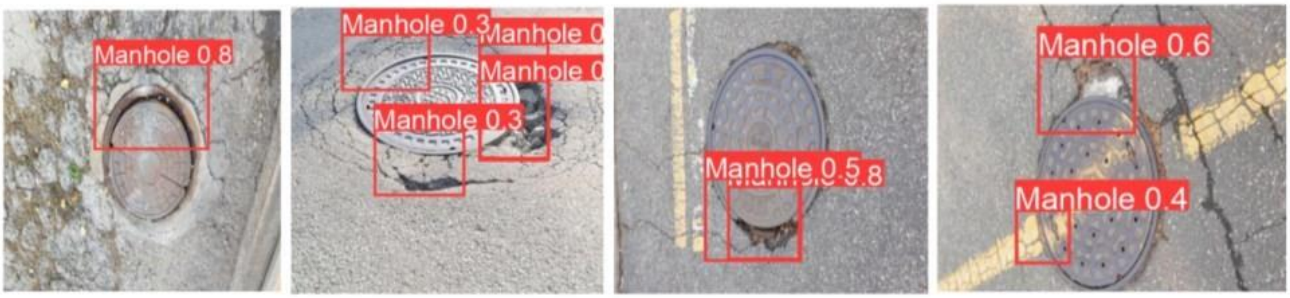

Fig. 7. Examples of wrongly detection of manholes cover using Yolov8.

TABLE III. DATA USED FOR THE IMPLEMENTATION

ID	City	Address	Latitude	Longitude	Description	Status	PicURL	Action
1	OUJDA	Boulevard Nabloussi	34.655204	-1.892503	Manhole in the middle of the road.	1	/Manhole/#man01.jpg	none
2	OUJDA	Boulevard Nabloussi	34.655902	-1.891422	Manhole in the left side of the road.	0	/Manhole/#man02.jpg	Cleaning Procedures
6	OUJDA	Bd Mohammed VI	34.654240	-1.898296	Manhole in the middle of the road.	1	/Manhole/#man06.jpg	none
11	OUJDA	Bd Mohammed VI	34.655922	-1.899748	Manhole in the right side of the road.	0	/Manhole/#man011.jpg	Repairs and patching

As the database grows with more entries, it becomes a rich source of information for training machine learning algorithms. By analyzing the accumulated data, these algorithms can learn to recognize patterns and anomalies associated with different manhole conditions. Over time, with sufficient training and refinement, the system can evolve to autonomously identify issues and suggest or even initiate appropriate actions without human intervention. This advancement in autonomous decision-making not only enhances efficiency but also reduces the response time in addressing urban infrastructure issues, thereby contributing to a safer and more effectively managed city environment.

VI. CONCLUSION

In conclusion, this research has successfully demonstrated the effectiveness of employing the YOLOv8 object detection model for the real-time supervision and detection of manhole situations using drone imagery and GPS integration. Our experiments showcased the model's exceptional precision and efficiency, underscoring its potential as a robust solution for proactive urban infrastructure monitoring. The integration of YOLOv8 proved instrumental in surpassing traditional methods, offering a swift and accurate means of identifying manhole covers and potential hazards across diverse urban landscapes. The synergy between deep learning, drone technology, and GPS data not only enhanced the speed of detection but also provided a comprehensive understanding of the spatial dynamics inherent in complex urban environments. The integration of advanced deep learning models, coupled with real-world performance metrics, establishes a robust foundation for the practical implementation of our proposed system in urban environments.

As a perspective, we will continue to find more models and to make another experiment to strengthen our research in this field.

Abstract—**Federated Learning (FL) has received a lot of attention lately when it comes to protecting data privacy, especially in industries with sensitive data like healthcare, banking, and the Internet of Things (IoT). However, although FL protects privacy by not sharing raw data, the information transfer during its model update process can still potentially leak user privacy. Differential Privacy (DP), as an advanced privacy protection technology, introduces random noise during data queries or model updates, further enhancing the privacy protection capability of Federated Learning. This paper delves into the theory, technology, development, and future research recommendations of Differential Privacy Federated Learning (DP-FL). Firstly, the article introduces the basic concepts of Federated Learning, including synchronous and asynchronous optimization algorithms, and explains the fundamentals of Differential Privacy, including centralized and local DP mechanisms. Then, the paper discusses in detail the application of DP in Federated Learning under different gradient clipping strategies, including fixed clipping and adaptive clipping methods, and explores the application of user-level and sample-level DP in Federated Learning. Finally, the paper discusses future research directions for DP-FL, emphasizing advancements in asynchronous DP-FL and personalized DP-FL.**

Keywords—Federated learning; differential privacy; privacy protection; gradient clipping

I. Introduction

Concerns over data security and privacy, particularly in the context of the Internet of Things (IoT), healthcare, and finance, have led to a surge in the adoption of federated learning (FL) technologies in recent years. For instance, FL can be used for disease monitoring [1], financial analysis [2], and IoT data sharing [3] FL enables the training of models using data from multiple participants without sharing sensitive data, thus obtaining a broader and more representative data perspective. Despite its significant advantages in protecting data privacy, FL involves the transmission and sharing of data and model parameters between participants, which raises concerns about the security and integrity of communications. If the communication channels are not protected or are vulnerable to man-in-the-middle attacks, it can lead to issues such as data leakage, tampering, or forgery. In fact, even if attackers cannot directly access the datasets, user privacy can still be threatened. By analyzing model parameter updates, attackers can infer information about the original data [4], a type of attack known as an inference attack. Attackers can also introduce false labels or tags into the training set, a technique called as "data poisoning" [5], which lowers the accuracy of the model's predictions by making it learn the wrong patterns. It is vital to safeguard privacy and fend against these attacks in FL as a result.

In this paper, we introduce various techniques proposed to address privacy issues in Federated Learning. Specifically, we focus on Differential Privacy (DP), which has become the de facto standard for protecting user privacy in statistical computations. These techniques can be categorized into three types:

- Data Privacy Protection: The goal is to protect raw data from being leaked or illegally accessed. Key techniques include Differential Privacy, which reduces the risk of data identification by adding random noise to data queries or statistical processes; Data privacy is preserved during computations thanks to homomorphic encryption, which enables calculations on secret information without the need to decrypt it; and Data Masking techniques, which prevent identification by altering the structure or form of the data.
- Model Privacy Protection: This aims to protect trained models from reverse engineering or illegal analysis. Techniques include Model Compression and Model Distillation. Model Compression reduces the complexity and number of parameters in a model, thereby lowering the risk of model leakage. Model Distillation involves transferring the knowledge of a large model to a smaller, simpler model, reducing the amount of data that needs protection. Additionally, Model Watermarking techniques embed specific markers in the model to track and protect its usage.
- Communication Privacy Protection: This focuses on securing data transmission during the communication process in Federated Learning. To guarantee the safety and confidentiality of data during transmission, it mainly uses secure communication protocols and encryption technologies, such as Secure Sockets Layer/Transport Layer Security (SSL/TLS). Additionally, Trusted Execution Environments (TEEs) allow for secure data aggregation and model updates without revealing individual inputs.

1) Data privacy protection: Secure Multi-Party Computation (SMC) [6][7] enables multiple parties (also known as entities) to collaboratively compute any function on secret data without revealing any other secret information besides the function's output. The concept of SMC was introduced by the academic community in the 1980s, along with various feasible design methods for MPC protocols for any function. These design methods form the basic framework for most subsequent MPC protocols. SMC ensures that the inputs are neither disclosed to each other nor to a central server, thus doing away with the requirement for a reliable third party.

A unique type of encryption called homomorphic encryption (HE) [8] [9] permits certain actions to be carried out on encrypted data while maintaining the data's encryption. The plaintext and the outcome of applying the identical procedures directly to the original plaintext data are consistent when the encrypted result is decrypted. HE has now evolved to support floating-point operations with the fourth generation FHE schemes. The primary feature of the fourth generation FHE schemes is their support for floating-point homomorphic operations. In 2017, Cheon et al. introduced the CKKS scheme in ASIACRYPT 2017, which for the first time handled floating-point numbers in FHE [10]. Although the CKKS scheme is simpler and offers improved performance, making it a strong privacy protection tool, its computational complexity makes using HE in FL practically inefficient, particularly in cases where the training dataset exceeds the capacity of the computer's memory.

Differential Privacy (DP) [11][12] is an advanced privacy protection technique that allows for the analysis and release of datasets without compromising individual privacy. DP accomplishes this by balancing the trade-off between data utility and individual privacy by injecting controlled noise into the data analysis process. Although the first definition of DP appeared in 2006, it has only recently gained attention for practical applications. Accuracy is the primary obstacle to the practical application of DP; accuracy is frequently diminished when privacy protection is increased. Investigators attempt to resolve this issue by integrating DP with other techniques to ensure its usability or by attempting to reconcile privacy and accuracy.

2) Model privacy protection: Knowledge Distillation (KD) [13][14][15] does not transmit model updates but instead, if the local model size is greater than the public dataset, communicates local model predictions among several clients on a shared public dataset, saving communication costs. In its initial form, information is passed on by simulating the output of the teacher model on the same set of data. Subsequent research revealed the function copying might guide student model training in addition to imitating outcomes [16]. These days, Federated Learning (FL) frequently uses KD as a standard technique [18][19]. It is possible to apply alternative solutions in an adaptable manner to different scenarios while still imitating the global model and the local preceding model. In order to minimize shared bits, Li and Wang [14] investigated Federated Knowledge Distillation by averaging logits for each sample. Gong et al. To solve telecommunication inefficiencies, [16] suggested a one-shot learning paradigm for one-way distillation. Knowledge was extracted from anticipated soft labels and subsequent results by Wu et al. [17]. Compared to device selection-based and model compression-based approaches, KD-based systems share fewer bits in each interaction cycle and do not require a trade-off between model accuracy and the number of participating devices. While significantly reducing communication overhead.

Model Watermarking is a technique used to protect the intellectual property of deep learning models. With the widespread application of machine learning models across various domains, ensuring that these models are not illegally copied, redistributed, or used without authorization becomes crucial. Model watermarking embeds specific identification information into the model, allowing the original owner to track and prove ownership if the model is misappropriated. Watermark embedding methods include directly modifying model parameters or creating specific trigger datasets that cause the model to exhibit abnormal prediction behavior when processing these data. Watermark verification can be done through white-box (direct access to model parameters) or black-box (simply via the input-output interface of the model) techniques to confirm the watermark's existence [56]. With ongoing research, various watermarking methods have emerged, including parameter-based watermarks, trigger data point-based watermarks, and leveraging the backdoor characteristics of neural networks for watermarking [57].

3) Communication Privacy Protection: Trusted Execution Environment (TEE) [20] is a secure computing environment that provides an isolated execution space to protect code and data from external software and hardware attacks or unauthorized access. To protect sensitive operations and guarantee the security and integrity of code executed and data processed inside TEE, TEE typically makes use of hardware-supported security capabilities. The concept of TEE originated in smartphones and embedded systems to protect sensitive information such as payments and personal data. For instance, ARM TrustZone technology is an early TEE implementation that divides the system into secure and normal worlds using hardware support. As open-source software and hardware continue to advance, the RISC-V architecture has garnered significant attention due to its flexibility and openness. TEE implementations on the RISC-V architecture, such as the Keystone framework [21], provide a customizable TEE solution allowing developers to tailor TEE characteristics and functionalities based on specific requirements.

The remainder of the document is arranged as follows. The fundamentals of synchronous, asynchronous FL, and differential privacy are covered in Section II, which also presents the theory of federated learning and differential privacy. In Section III, we summarize the relevant knowledge of differentially private FL, including the tailoring of gradients and the differential privacy at the user and customer levels. We discuss and make suggestions for future research in Section IV. In section V, we give our conclusions.

II. Federated Learning and Differential Privacy-Related Theories

A. *Federated Learning*

Based on the different update strategies in federated learning, the two types of federated learning that we may distinguish are synchronous and asynchronous. In synchronous federated learning, all participants (or clients) must wait for each other to complete their local computations before sending updates to the central server. The global model is then produced by the central server integrating these updates. This approach ensures that all participants use the same or similar data for training in each round, but it can lead to inefficiencies as it requires waiting for the slowest participant (i.e., the straggler). In contrast, asynchronous federated learning is characterized by its asynchronous update process. The central server can receive and immediately integrate updates from any participant that is ready, without waiting for all participants to complete. This design improves system efficiency and scalability; however, it also introduces new challenges, such as handling data inconsistency and model update delays.

1) Synchronous federated learning optimization algorithm: Data privacy protection is federated learning's primary goal. and security, improve model training efficiency and address the problem of data silos. Stated differently, its goal is to optimize data use across many devices to improve user experience while maintaining the highest level of security and confidentiality for user data. Nowadays, deep learning has made extensive use of optimization based on the stochastic gradient descent (SGD) algorithm. and can also be applied in simple federated learning scenarios. The system architecture diagram of Synchronous federated learning is shown in Fig. 1.

Each client in FedSGD [22] separately computes the loss function's gradient using its dataset, and then transmits that gradient to a main server [23]. Next, the central server combines these gradients (sometimes by averaging them) and updates the global model parameters. All clients receive the revised model parameters back, and they use these new values to continue computing their local gradients. The model is iterated through till it merges.

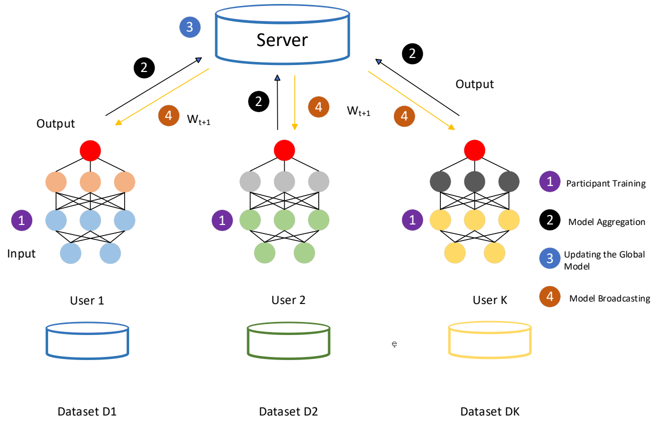

Fig. 1. Schematic diagram of the system architecture of synchronous federated learning.

Building on this, the federated averaging algorithm (FedAvg) was introduced in [24], which combines local stochastic gradient descent computations on clients with model averaging on the server. Local model updates are carried out by clients, and the modified values from every client are averaged by the central server, taking into account the quantity of local updates completed. Each client can independently update its model parameters multiple times before sending the updated parameters to the central server for weighted averaging. The specific formula is represented as follows:

$$w_{t+1} \leftarrow w_t - \eta \sum_{k=1}^{K} \frac{n_k}{n} g_k = w_t - \eta \nabla f(w_t) \tag{1}$$

$$w_{t+1} \leftarrow \sum_{k=1}^{K} \frac{n_k}{n} w_{t+1}^{k} \quad \text{where} \quad \forall k, w_{t+1}^{k} \leftrightarrow w_t - \eta g_k \tag{2}$$

In this case, n_k is the number of local datasets for the *k-th* user, and k is the *k-th* user. Early algorithms in federated learning were easy to grasp in notes, but lacked theoretical assurances in practical applications, necessitating extensive experimentation and validation for different environments and sample scenarios [25]. To address non-iid scenarios, where data distributions among clients are uneven, the FedProx algorithm was proposed. Unlike FedAvg, FedProx adds a regularization term to the client-side loss function (while considering the central model) to prevent overfitting during local iterations. Subsequently, [26] introduced a control algorithm for situations where local iteration and edge computing resources are limited in federated learning. By finding the ideal ratio between local updates and global parameter aggregation, this technique maximizes client participation in central aggregation by figuring out how frequently local iterations should occur. Addressing the issue of varying computational capabilities among multiple clients [27], the FedNova algorithm was proposed, assuming heterogeneous client computing resources (i.e., different capacities for local iterations). In study [28], personalized weighting of model parameters per layer on the central server was achieved through a hypernetwork. This strategy entails relearning the model parameters for every client at each layer and minimizing the loss by calculating the disparity between each client's model and the central model from the previous round. Subsequently, to reduce communication costs, layers with significant locally retained weights were excluded from federated participation.

2) Asynchronous federated learning optimization algorithm: Widespread 5G network rollout and quick hardware development are improving the connectivity and computing abilities of heterogeneous devices, such as edge and IoT gadgets and opening up new application areas [29]. Federated learning is gradually integrating functionalities learned from other devices to improve model quality.

However, when federated learning is applied on resource-constrained devices using classical learning methods, several disadvantages become apparent. Due to the presence of heterogeneous devices, the aggregation server needs to wait for updates from different devices, which may unexpectedly go offline due to instability. Faster devices in federated learning training rounds have to wait for slower devices to finish calculations, resulting in low resource utilization due to device performance differences (device heterogeneity) and uneven data distributions (data heterogeneity).

The inefficiency of current node selection algorithms often leads to the involvement of few capable devices. Security and privacy vulnerabilities are also concerns. Security risks like data poisoning and backdoor access might affect traditional federated learning techniques. Privacy concerns also surface because of possible data leaks that occur during training.

Asynchronous federated learning (AFL) offers an answer to these problems. A novel federated learning mechanism called Fed2A was proposed in [30], designed specifically for asynchronous and adaptive modes. Fed2A uses three adaptive methods and a two-phase asynchronous learning approach to support AFL successfully. Specifically, one of the core formulas of Fed2A for global model aggregation is as follows:

$$w_{t+1} = \sum_{l=1}^{L}\sum_{k=1}^{K}(\alpha_{l_k} \times w_{l_k}), \quad \alpha_{l_k} \leftarrow g(t_k, t, w_{l_t}, w_{l_k}) \tag{3}$$

This formula illustrates how Fed2A considers the heterogeneity of time and information during global model aggregation. Here, W_{t+1} represents the global model at global round *t+1*, *L* is the number of layers in the DNN being trained, *K* is the total number of participating clients, W_{lk} is the local model parameters of client *k* at layer *l*, a_{lk} is the aggregation weight of client *k* at layer *l*, g is a function used to compute the aggregation weight. This function considers the generation time t_k of the client's local model, the parameters W_{lk} of the current global model at layer *l*, and the current global model reception time *t*.

Regarding the three key challenges of federated learning—edge heterogeneity, non-iid data distribution, and communication resource constraints proposed a mechanism called Grouped Asynchronous Federated Learning (FedGA) [31]. They introduced the Magic-Mirror Method (MMM) scheduling strategy within groups to optimize the completion time of model updates in a single round. By designing scheduling algorithms that determine the order of model uploads and downloads, the system achieves computing-at-the-edge while communicating, enhancing adaptability to heterogeneous edges.

Regarding federated learning (FL) in wireless network scenarios, article [32] proposes an asynchronous FL framework. It addresses the slow startup issue (stragglers) inherent in traditional synchronous FL by implementing periodic aggregation to enhance training efficiency. The article describes the process of global model aggregation as follows:

$$w_{t+1} = w_t + \sum_{k\in\Pi(t)} \frac{|S_k|}{|S|}\Delta w_k(t) \tag{4}$$

The formula indicates that the global model w_{t+1} at global round *t+1* is obtained by aggregating the current global model w_t with the aggregated local model updates $\Sigma k \in \Pi(t)$. The collection of devices slated to submit model changes at global round *t* is denoted by *Π(t)* in this instance, $|S_k|$ is the size of device k local training dataset, |S| is the total size of training datasets across all devices, and $\triangle w_k(t)$ denotes the model update completed by device k in its local round t.

To address asynchronous update issues, the article introduces an age-aware aggregation weight design, formulated as follows:

$$\alpha_k(t) = \frac{|S_k| \cdot \delta^{ALU_k(t)}}{\sum_{j\in\Pi(t)} |S_j| \cdot \delta^{ALU_j(t)}} \tag{5}$$

In this formula, $\alpha_k(t)$ represents the aggregation weight of device k at global round t. $\text{ALU}_{k(t)}$ denotes the age of device k's local model update, which is the number of iterations since it last received the global model. Δ is a constant used to adjust the influence of age on the weight.

MAPA-S and MAPA-C are two conceptually justified multi-stage adaptive privacy algorithms that were created by the authors of [33] for use in asynchronous federated learning (AFL) scenarios. By utilizing fading clipping thresholds during model convergence to lessen unnecessary noise and enhance learning performance, these algorithms aim to increase the ratio of protecting privacy to model efficacy.

The multi-stage adaptive clipping threshold adjusts the clipping threshold adaptively during training using a decaying clipping threshold θ_c . This approach reduces noise, where θ_c is a decay factor of the initial clipping threshold *c*. These algorithms enhance model utility while preserving privacy by adjusting clipping thresholds and learning rates. Through adaptive tweaking of these parameters at different training phases, MAPA-S and MAPA-C can more accurately balance privacy protection with functionality.

$$\gamma = \min\left\{\frac{\Delta_{\sigma,K}}{K^2 L\Delta_{\sigma,\tau_C}\tau_C}, \frac{\theta_G^2}{8L\Delta_{\sigma,K}}, \frac{1}{4L}\right\} T \geq \frac{8\Gamma}{\gamma\theta_G^2} \tag{6}$$

The *gamma* (γ) is the learning rate, and *T* denotes the total number of global iterations. $\Delta_{\sigma,k}$ and $\Delta_{\sigma,\tau c}$ represent parameters related to the model and data. θ_G is the decay ratio of the clipping threshold, and *Γ* is the upper bound of the loss function. The initial learning rate and the number of iterations in the initial stage are determined using these calculations and are updated in each new stage based on the current model and data conditions.

B. Differential Privacy

The primary goal of differential privacy is to allow the study of overall properties of a dataset without revealing individual information. Put differently, differential privacy entails introducing noise into original datasets or statistical queries. Sacrificing some data accuracy to provide strict privacy protection for user data. This ensures that attackers cannot determine whether specific individual effects are present in the dataset.

1) Centralized differential privacy: A centralized differential privacy paradigm, differential privacy [36] was first introduced by Dwork et al. in 2006 [34]. The article defines that differential privacy requires a trusted central authority, allowing users to send their data directly to the data center without any modifications. The data received from users is stored on a central server. The central authority, however, has little faith in outsiders or data analysts. Therefore, the central authority uses differential privacy to obscure the source dataset before answering statistical inquiries for analysis from outside parties. Centralized differential privacy is the term used to describe this kind of differential privacy implementation.

In general, differential privacy uses strict mathematical definitions to limit this probability gap, as defined in Definition 1:

Definition 1 (ε-differential privacy): A randomized mechanism *M* satisfies ε-differential privacy (ε > 0) if and only if for any adjacent input datasets S and S' and for any possible output value set *R*,the following holds:

$$Pr[M(S)\in R],, e^{\varepsilon}\cdot Pr[M(S')\in R \qquad (7)$$

Definition 2 *(ε, δ)*-differential privacy): A randomized mechanism M satisfies *(ε, δ)*-differential privacy *(ε > 0, δ > 0)* if and only if for any adjacent input datasets *S* and *S'* and for any possible the following holds:output value set R.

$$Pr[M(S)\in R],, e^{\varepsilon}\cdot Pr[M(S')\in R]+\delta \qquad (8)$$

Subsequently, in [35], the authors proposed the Laplace mechanism, a widely recognized differential privacy technique. Through the introduction of random noise into numerical statistical results, this method safeguards individual privacy. A zero-centered Laplace distribution is used to sample the noise. A precise scale parameter selection is necessary for the Laplace distribution in order to guarantee adherence to the stringent requirements of differential privacy. This scale parameter is closely related to the sensitivity of the statistical query, which represents the maximum possible change in query results in the worst-case scenario. As a result, the Laplace mechanism takes the query's sensitivity into account while determining the right amount of noise, enabling the publication of approximate statistical data without disclosing personal information.

Definition 3 (Sensitivity of a Statistical Function): For any numerical statistical function f : D^N→R the sensitivity is as follows:

$$\Delta f := \max_{S,S'\in D^N} |\, f(S) - f(S')\,| \qquad (9)$$

2) Local differential privacy: By doing away with the need for a certified server, local differential privacy, or LDP, is a decentralized enhancement over hierarchical approaches. In this approach, a randomized method is used to locally randomize each data item that is disseminated among N user interfaces. The information that has been collected is then safely sent via an encrypted link to the server. The server compiles the information and applies the appropriate adjustment algorithm to produce objective estimations of statistical quantities. The local randomization process at the client side ensures that every data item received by the server is unique, hence the LDP model does not rely on the server being trusted.

Definition 4 (ε -LDP): If and only if the following true for any feasible output value y and any pairings of input values *V* and *V ′* , then the randomization method M fulfills ε -LDP (ε > 0):

$$Pr[M(V)=y],, e^{\varepsilon}\cdot Pr[M(V')=y] \qquad (10)$$

Definition 5 (ε , δ)-LDP: A randomized mechanism M satisfies (ε , δ)-LDP (ε > 0, δ > 0) if and only if for any input value pairs V and V′ and for any possible output value y, the following holds:

$$Pr[M(V)=y],, e^{\varepsilon}\cdot Pr[M(V')=y]+\delta \qquad (11)$$

The Harmony system was presented by the authors in [37]. It is a useful, precise, and effective system that is mainly intended for gathering and evaluating data from users of smart devices while meeting LDP requirements. Multidimensional data with both numerical and category qualities might benefit from harmony. In addition to sophisticated machine learning tasks like linear regression, logistic regression, and SVM classification, it provides fundamental statistics like mean and frequency estimates. Additionally, the authors discuss the limitations of existing LDP solutions and propose improvement methods such as mini-batch gradient descent and dimensionality reduction techniques to enhance the performance of machine learning models under LDP constraints. The article concludes by exploring potential applications of Harmony in practical settings and identifying future research directions, including its deployment in real-world scenarios like diagnostic information reporting applications for Samsung smartphones.

In traditional Local Differential Privacy (LDP) techniques, the privacy budget ε is typically allocated to related attributes or processed through sampling methods for high-dimensional data. However, these methods have some limitations. First, allocating the privacy budget evenly to all attributes reduces the density of useful information, thereby affecting the utility of the data. Second, attributes in high-dimensional data often have correlations, and existing models do not fully utilize these correlations to optimize the balance between privacy protection and data utility.

The authors of [38] suggested Univariate Dominance Local Differential Privacy (UDLDP), a novel LDP model, to solve these problems. Through the quantification of attribute correlations, the UDLDP model optimizes the allocation of the privacy budget. Specifically, instead of just spreading the budget uniformly, the UDLDP model permits a more precise distribution of the privacy budget on each associated characteristic via a correlation-bounded perturbation method. This effectively gets around the drawbacks of conventional techniques. To further enhance sampling, a widely used bandwidth reduction method in sensor networks and the Internet of Things, this research extends the correlation-bounded perturbation mechanism. The research further improves the correlation-bounded perturbation mechanism with sampling by finding the optimal sampling probability distribution method with regard to of data utility.

3) Rényi differential privacy: A notion of privacy based on Rényi divergence is called Rényi Differential Privacy (RDP). Rényi divergence is a tool for measuring the difference between two probability distributions and can be viewed as a generalization of Kullback-Leibler divergence. RDP defines a new measure of privacy loss using Rényi divergence, providing a more flexible and fine-grained way to quantify privacy loss.

Definition 6: Given two adjacent datasets D and D′ , which differ by one data point, and a random mechanism M that outputs distributions P and Q, respectively. If for all α >1, the mechanism M satisfies the following inequality, it is said to satisfy (α, ϵ)-Rényi differential privacy:

$$D_{\alpha}(P \| Q) = \frac{1}{\alpha - 1} \log \mathrm{E}_{x \sim Q}\left[\left(\frac{P(x)}{Q(x)}\right)^{\alpha}\right] \leq \epsilon \tag{12}$$

Here, D_α(P||Q) represents the α-order Rényi divergence between distributions P and Q. This measure captures privacy loss more precisely by considering higher-order moments of the distributions, providing tighter bounds compared to traditional differential privacy measures.

In order to train deep neural networks to address non-convex optimization problems while ensuring privacy, [39] first presented a revolutionary algorithmic technique. The authors developed an improved Stochastic Gradient Descent (SGD) algorithm that incorporates privacy protection at each step by using gradient clipping and noise addition to control the dependence on individual data points during training. Additionally, the paper introduced a novel privacy loss estimation method called Moments Accountant, which offers tighter privacy guarantees than traditional differential privacy analyses. This method provides a more accurate estimation of the algorithm's privacy cost by tracking higher-order moments of privacy loss.

Based on the method of tracking higher-order moments of privacy loss, Ilya Mironov et al. proposed an extended framework for Differential Privacy (DP) based on Rényi divergence in study [40], known as Rényi Differential Privacy (RDP). RDP aims to improve existing differential privacy techniques by providing a more granular measure of privacy loss. The core of RDP is quantifying slight changes in the output distribution of randomized algorithms. Compared to traditional differential privacy, RDP offers more precise privacy loss estimation by considering higher-order moments of the distribution. This measure allows for more detailed analysis of the algorithm's output while protecting privacy.

Additionally, in study [41], the authors focused on studying the Sampling Gaussian Mechanism (SGM), a widely used technique in machine learning that combines data subsampling and Gaussian noise addition to provide privacy protection. They proposed a numerically stable procedure to accurately compute the RDP of SGM. The researchers demonstrated that SGM satisfies (α,ϵ)-RDP under specific conditions and provided an almost tight closed-form bound. This work fills previous research gaps and unifies the understanding of SGM's privacy properties. The authors provided deep insights into understanding and applying RDP, especially in analyzing and designing privacy-preserving machine learning algorithms. By accurately computing the RDP of SGM, this research advances theoretical development and offers practical tools and guidance for privacy protection in real-world applications.

In "Hypothesis Testing Interpretations and Rényi Differential Privacy," the authors proposed a new perspective by interpreting differential privacy through statistical hypothesis testing. Within this framework, differential privacy ensures that no test can simultaneously have high significance (low Type I error rate) and high power (low Type II error rate). Additionally, the authors provided improved conversion rules from RDP to (ϵ,δ)-DP and explored the relationship with Gaussian Differential Privacy (GDP). Finally, they proposed a sufficient and necessary condition to ensure that a quasi-convex divergence is k-generated. By requiring divergences to be defined using a 2-generated function F, this aids in the construction of divergences that support the interpretation of the hypothesis test.

III. Differential Privacy for Federated Learning

A. *Federated Learning with Differential Privacy with Different Gradient Clipping*

Several participants can train models on their local data using the central server in traditional Federated Learning (FL), eliminating the requirement to centralize the data on a single server. However, during the transmission of model parameters, if communication is not encrypted or if there are vulnerabilities, it may be susceptible to eavesdropping or tampering. An untrusted central server could infer sensitive information by analyzing model updates and gradient information. Differential Privacy (DP) effectively addresses these issues by adding noise to gradients to prevent such information leaks. However, in study [42], it was first proposed to use a fixed gradient clipping approach.

On one hand, the amount of noise added in fixed gradient clipping differential privacy remains constant throughout the training process. This could lead to excessive negative impacts on model performance due to noise in the later stages of model training, thus affecting the model's usability. On the other hand, a fixed clipping threshold may not be suitable for all datasets or training scenarios. Different data distributions and models may require different clipping strategies to achieve optimal privacy protection.

1) Federated learning with fixed gradient clipping differential privacy: To address the shortcomings of fixed clipping, the authors in study [43] attempted to solve the issues of parameter privacy protection and high communication costs by combining distinguished differential privacy with gradient trimming in two stages. The trained model's gradients are pruned in the first stage of the proposed IsmDP-FL, and the key variables that are chosen are then given differential privacy. To finish the federated learning manage, gradient trimming is carried out in the subsequent phase while the data is being sent to the server for consolidation. The final result is then sent back to the client. Comparing the IsmDP-FL algorithm to other approaches, experimental results showed that it achieves higher model accuracy while maintaining high communication efficiency and model privacy.

In study [44], the authors proposed a layer pruning method based on gradient correlation to further reduce communication overhead. Instead of uniformly clipping the parameters of all layers, the CLFLDP model uses a layer selection method based on model correlation metrics to choose layers with higher correlation to the global model for upload, excluding those with lower correlation. By using a Top-k gradient reduction strategy, the model further decreases the total amount of parameters uploaded inside the chosen layers; only the parameters with the highest gradient values are chosen and uploaded to the server.

2) Federated learning with adaptive gradient clipping differential privacy: In study [45], the AdaCliP algorithm is introduced, with its core innovation being an adaptive clipping mechanism that dynamically adjusts the clipping threshold based on the gradient characteristics of each coordinate. This approach not only reduces unnecessary noise addition but also enhances the model's sensitivity to data during training, thereby improving model accuracy without sacrificing privacy. The implementation of AdaCliP is based on precise control of gradients during the stochastic gradient descent (SGD) process. By introducing dynamic estimates of the mean and standard deviation, the algorithm can adaptively adjust gradient clipping and noise addition at each iteration. Moreover, the convergence analysis provided in the paper offers a solid theoretical foundation for the algorithm's performance.

The authors of study [46] suggest an adaptive clipping technique that modifies the clipping threshold to roughly represent a particular quantile in the updates' norm distribution. This adaptive clipping is implemented using an online gradient descent algorithm by designing a loss function $\ell\gamma(C;X)$ for a random variable X and quantile γ to estimate and update the clipping threshold C. The form of the loss function ensures that the expected value of its derivative reflects the relationship between C and the quantile of X, allowing C to approach the true quantile of X via gradient descent. This approach not only closely tracks the quantile of update norms but is also compatible with techniques like compression and secure aggregation in federated learning, all while consuming minimal privacy budget.

In study [47], the authors propose a novel adaptive differential privacy method that shifts focus away from gradients to determine the amount of noise injected based on the importance of features. Less noise is injected for important features, whereas more noise is added for less important ones. The paper introduces two adaptive methods: Sensitivity-Based Method: This method evaluates the importance of features by computing changes in model accuracy after adding noise. After updating local parameters, the client computes and stores the model accuracy as a reference. The weights associated with each input characteristic are then increased by noise and the accuracy of the new model is computed. Feature importance is determined by comparing the accuracy before and after noise addition. Variance-Based Method: This approach assumes that weights associated with more important features undergo greater changes during training. A value that is equal to the influence on output is generated by computing the variance of the weights attached to each input neuron. Following the determination of the significance of each feature, the differential privacy parameters are tuned to balance privacy protection and model performance by adding more noise to less significant characteristics and less noise to key ones.

B. User-level and Sample-level Differential Privacy Federated Learning

1) User-level differential privacy federated learning: A privacy-preserving method used in federated learning to safeguard participants' privacy inside the framework is called user-level differential privacy. In this configuration, several users work together to train a machine-learning model while maintaining the privacy of their personal information. In user-level differential privacy for federated learning, all user data is usually protected, which means that all sample gathering on a user's device is protected [48]. This is significant because, even if an attacker manages to access the data of every other user, they will still be unable to deduce each individual user's data from the combined findings.

To protect all data of each user, user-level differential privacy in federated learning requires adding noise to the model updates computed locally by each user, in order to satisfy user-level differential privacy requirements. This means that after local training, noise is added to the gradients or model parameter updates of the entire dataset.

In study [49], Mcmahan et al. first proposed DP-FedAvg and DP-FedSGD, where sampling is performed on the client side, and noise addition occurs centrally. Sensitivity computation is based on the sampling rate and the federated weights of each client. In the same period, another article [50] distinguished itself from DP-FedAvg by having client-side model uploads trimmed at the central server. The algorithm in this paper achieves client-level differential privacy protection through the aggregation of distorted updates using random sub-sampling and Gaussian mechanisms. The algorithm's secret is to strike a balance between model performance and privacy protection. According to experimental findings, CDPFL can provide client-level differential privacy with a minimum loss in model performance provided there are enough clients involved.

In the paper [51], the authors focus on the scenario where model parameters in federated learning may be analyzed by malicious servers. They propose a User-Level Differential Privacy (UDP) algorithm aimed at enhancing privacy protection in FL. The primary goal of the UDP technique is to obfuscate the relationship between model parameters and users' original data by introducing fake noise to the shared model prior to uploading it to the server. By adjusting the variance of the noise, the algorithm can provide different levels of privacy protection for each mobile terminal, meeting the (ϵ_i, δ_i)-LDP privacy protection standard. Here, ϵ_i and δ_i are privacy parameters associated with the i-th mobile terminal, and by adjusting the variance σi^2 of the noise, the level of privacy protection can be controlled. According to the analysis in the paper, the specific formula for computing the noise variance is as follows:

$$\sigma_i = \frac{\Delta\ell}{\sqrt{2qT\ln(1/\delta_i)}} \cdot \frac{1}{\grave{o}_i} \tag{13}$$

Here, $\Delta\ell$ represents the sensitivity of the local training process, q is the random sampling rate, T denotes the quantity of communication cycles, ε_i denotes the privacy protection parameter, and δi stands for the failure probability.

User-level differential privacy in federated learning ensures privacy protection at the user level in FL. User-level DP focuses on protecting all data of each user or agent, rather than individual data instances. For example, in scenarios such as banks jointly training fraud detection models, user-level DP can protect individual records from any bank from being identified. In scenarios like learning facial recognition models on smartphone apps, user-level DP can protect the privacy of each user as a unit. However, existing user-level DP methods, such as DP-FedAvg based on Gaussian mechanism, often sacrifice model utility because they require trimming of model updates for each agent before uploading, and adding Gaussian noise proportional to the trimming threshold. This can lead to decreased model performance.

To address these issues, in [52], the authors analyzed the reasons behind the significant decrease in model accuracy when ensuring user-level DP using existing methods. They proposed two techniques: Two methods are Local Update Sparsification (LUS) and Local Update Regularization (BLUR). Through the addition of regularization terms to the agents' local objective function, BLUR constrains the L2 standard for local changes. While LUS further reduces the norm of updates by zeroing out values that have minimal impact on local model performance before trimming. Both techniques aim to enhance model utility without compromising privacy.

2) Sample-level differential privacy federated learning: Differential privacy at the sample level Federated learning is a machine learning paradigm that safeguards the privacy of individual data while enabling several users to work together on model training. The core of this paradigm ensures that each participant's data remains private even in distributed data environments, preventing data leakage to other participants or potential attackers.

In traditional federated learning, although data does not need to be centrally stored or processed, there remains a risk of privacy leakage. Attackers could potentially infer information about individual clients by analyzing shared model updates or gradient information among clients. To address this issue, researchers have proposed sample-level differential privacy federated learning, aiming to provide privacy protection for each data record of every client.

The research in [53] further advances research in this field. The authors introduce the concept of federated ε-differential privacy, a novel privacy protection measure based on the Gaussian differential privacy framework. It focuses on the record level, protecting each client's unique data record from other clients' attacks by offering privacy protection. The PriFedSync framework proposed in the paper is a generic private federated learning framework capable of accommodating various existing federated learning algorithms and demonstrating its effectiveness in achieving federated ε-differential privacy. The paper also conducts experiments in computer vision tasks, demonstrating that while ensuring privacy, the model can still maintain high predictive performance. This indicates the potential of sample-level differential privacy federated learning in practical applications, especially in fields such as healthcare and finance where data privacy requirements are stringent.

In study [54], the authors propose a novel sample-level differential privacy federated learning method—DP-SCAFFOLD, aiming to address both data heterogeneity and privacy protection issues. This method integrates differential privacy constraints into the popular SCAFFOLD algorithm to achieve sample-level privacy protection for participating users. In scenarios without trusted intermediaries, users communicate with "honest but curious" servers. This approach not only targets privacy protection from third-party observations of the final model but also ensures that "honest but curious" servers themselves cannot accurately reconstruct user data in the absence of a trusted intermediary. The paper provides in-depth analysis of the convergence of the DP-SCAFFOLD algorithm, demonstrating its convergence under convex and non-convex objectives. Additionally, using Rényi differential privacy (RDP) tools, the authors formally describe the privacy-utility trade-offs of DP-FedAvg and DP-SCAFFOLD algorithms at different privacy protection levels. Results show that DP-SCAFFOLD exhibits superiority over DP-FedAvg especially in scenarios with a large number of local updates or high data heterogeneity.

In study [55], the authors address the model evaluation issue in federated learning (FL) by proposing a novel algorithm to compute the AUC metric while ensuring the privacy of labels. AUC is a critical metric for assessing the performance of classification models, and its computation process can potentially expose sensitive information within the dataset. To mitigate this issue, the algorithm in the paper employs differential privacy techniques, particularly the Laplace mechanism, to inject appropriate noise into intermediate results during the computation process.

$$\Pr[M(D) \in S] \le e^{\grave{o}} \cdot \Pr[M(D') \in S] + \delta \tag{14}$$

Here, $\mathcal{M}$ represents the random mechanism, $\mathcal{D}$ and $\mathcal{D}'$ are two adjacent datasets differing in a single sample's label. S is a subset of the output results, ϵ is the privacy budget used to quantify the strength of privacy protection, and δ is a small non-negative value used for handling boundary cases. Specifically, the definition of label differential privacy proposed in the paper emphasizes sensitivity to changes in individual sample labels.

In the setting of federated learning (FL), each client independently predicts and computes statistics on their data, then sends the noisy statistics to the server. Without directly accessing the original labels, the server aggregates these noisy statistics to compute the AUC. This method guarantees the correctness of the model evaluation while simultaneously safeguarding the confidentiality of customer data.

IV. Discussion and Recommendations for Future Research

In this section, we will first discuss some key issues, and then introduce our recommendations for future research.

We first discuss the following key issues: Differential Privacy with Federated Learning (DPFL) is moving towards a more efficient and personalized direction, which helps to achieve a better balance between protecting privacy and maintaining model performance. We believe that future research should continue to explore more advanced adaptive privacy protection mechanisms. At the same time, we find that user-level and sample-level differential privacy each have their advantages. Researchers should choose the appropriate type based on specific application scenarios and privacy needs and can explore a hybrid privacy protection strategy that combines the two. Asynchronous DPFL has potential in dealing with the heterogeneity of devices in practical scenarios, but still needs to address the challenges of model convergence and privacy protection, which provides an important direction for our future research. We emphasize that developing personalized privacy protection strategies is crucial for improving the practicality of DPFL, and future research should focus on how to meet the differentiated privacy needs of individuals while protecting overall privacy. Finally, different application scenarios have different needs for privacy and utility, and future research should further explore the best balance point for different application scenarios.

Differential privacy federated learning combines the advantages of data privacy protection and distributed machine learning, making it a current hotspot in research. Most current research focuses on synchronous updating federated learning frameworks, but in practical applications, the computing and communication resources among participants are asynchronous, posing numerous unresolved challenges in this field. Existing federated learning frameworks often assume synchronous model updates across all participants, which is impractical in real-world scenarios. Current privacy protection strategies are typically one-size-fits-all and fail to fully consider personalized privacy needs among different participants. Validation of differential privacy federated learning in real-world applications and its cross-domain applications remain relatively limited.

In order to support the asynchronous computing and communication resources among participants, future research should concentrate on developing effective asynchronous communication protocols. This approach ensures model convergence and performance while maximizing the utilization of each participant's computing resources. Furthermore, future studies can explore asynchronous federated learning differential privacy and personalized federated learning to further advance this field. While current federated learning frameworks assume synchronous updates, the reality of varying computing and communication resources among participants necessitates efficient asynchronous communication protocols. Customized privacy protection strategies can also be explored to cater to the different privacy needs and sensitivities among participants, thereby enhancing the flexibility and adaptability of federated learning.

Moreover, applying differential privacy federated learning to more practical domains such as healthcare, finance, and the Internet of Things (IoT) will validate its effectiveness and potential in different application scenarios. By identifying and addressing new challenges through practical applications, continuous improvement and maturation of the technology can be achieved.

These future studies will help overcome the limitations of current research, enhancing the effectiveness and adaptability of differential privacy federated learning in practical applications. Research on asynchronous federated learning differential privacy will make model training more efficient, personalized privacy protection strategies will meet the specific needs of different participants, and cross-domain applications and validations will drive the application and development of the technology in more practical scenarios. These studies will provide new perspectives for theoretical development and offer a more solid foundation for practical applications

V. Conclusion

Federated Learning (FL) as an innovative distributed machine learning technique has shown enormous potential in protecting data privacy and security. However, FL still faces numerous privacy and security challenges in practical applications. This paper provides a detailed review of Differential Privacy Federated Learning (DPFL). After outlining the basic concepts of differential privacy and federated learning, we categorize their integration. Subsequently, we discuss DPFL using different gradient clipping strategies, including fixed clipping and adaptive clipping methods, to enhance the protection capability and efficiency of differential privacy. Additionally, we explore the differences between user-level and sample-level differential privacy in federated learning. This paper aims to assist researchers in identifying and developing optimal algorithms for DPFL, while also pointing out future research directions. These include designing asynchronous communication protocols, exploring personalized privacy protection strategies, and expanding the application of DPFL to broader practical scenarios. Through these studies, we hope to overcome the limitations of current research, enhance the effectiveness and adaptability of DPFL in practical applications, and provide a solid theoretical and practical foundation for efficient distributed learning while preserving user privacy.

Predictive Modeling of Student Performance Using RFECV-RF for Feature Selection and Machine Learning Techniques

Abdellatif HARIF, Moulay Abdellah KASSIMI
Laboratory of Science of Information Technology Data, Mathematics and Applications-
National School of Applied Sciences, IBN ZOHR University, Agadir, Morocco

***Abstract*—Predicting student performance has become a strategic challenge for universities, essential for increasing student success rates, retention, and tackling dropout rates. However, the large volume of educational data complicates this task. Therefore, many research projects have focused on using Machine Learning techniques to predict student success. This study aims to propose a performance prediction model for students at IBN ZOHR University in Morocco. We employ a combination of Random Forest and Recursive Feature Elimination with Cross-Validation (RFECV-RF) for optimal feature selection. Using these features, we build classification models with several Machine Learning algorithms, including AdaBoost, Logistic Regression (LR), k-Nearest Neighbors (k-NN), Naive Bayes (NB), Support Vector Machines (SVM), and Decision Trees (DT). Our results show that the SVM model, using the 8 features selected by RFECV-RF, outperforms the other classifiers with an accuracy of 87%. This demonstrates the effectiveness and efficiency of our feature selection method and the superiority of the SVM model in predicting student performance.**

I. Introduction

Education is the foundation of human development, providing individuals with the knowledge and skills necessary to navigate the world and achieve their goals. As digitization accelerates and data volumes increase in educational environments, it becomes crucial to understand how these tools can be used to measure and promote student well-being while supporting personalized learning experiences. Educational institutions have begun to explore the potential of big data technologies and Educational Data Mining (EDM) to more effectively support learning and education [1] [2].

In recent years, the use of Data Mining and Machine Learning in educational settings has significantly evolved [3]. These techniques enable understanding student behaviors and implementing targeted interventions. In this context, performance prediction is particularly relevant in Moroccan universities, where higher education institutions collect a multitude of data on their students. This information includes both qualitative and quantitative variables such as academic performance and socio-economic [4]. Experimental processes include data collection and preprocessing, the application of prediction models, as well as the evaluation of results. Additional techniques such as feature selection and cross-validation are also employed to enhance the quality of predictions [5].

This research employs an empirical framework to evaluate the accuracy and efficiency of different machine learning models in forecasting academic outcomes. By implementing a comprehensive framework, and finding the optimal features required, the main objective of this study is to develop a robust performance prediction model for students at the University of IBN ZOHR in Morocco. This will enable the accurate identification of final grades and provide insights that can guide educational interventions, ultimately enhancing the educational outcomes for students.

The remainder of this article is organized as follows: Section II is dedicated to related works, Section III presents our methodology, Section IV exposes the experimental results, Section V discusses the obtained results and analyzes the implications of our study for educational practice, and Section VI concludes by presenting perspectives for future work.

II. Related Works

Predicting student performance has become a critical area of research in educational data mining and learning analytics. The ability to accurately forecast academic outcomes not only aids in identifying students at risk of failing but also helps in tailoring educational interventions to enhance student success. Several studies have explored various techniques for predicting student performance using data mining techniques and machine-learning algorithms. In this section, we analyze the literature from 2009 to 2023 focusing on articles that demonstrate the effectiveness of Machine Learning methods in predicting student performance. It emphasizes the importance of feature selection, model optimization, and the incorporation of diverse data types, including demographic and behavioral information, to enhance the accuracy and reliability of predictive models in educational settings [6].

For instance, Asselman et al. [7] proposed a new approach that combines models such as Random Forest, AdaBoost, and XGBoost. Their experiments on three different datasets demonstrate that the XGBoost model significantly outperforms other models and the original Performance Factors Analysis (PFA) algorithm. The study concludes that ensemble learning methods, particularly XGBoost, enhance prediction accuracy in educational settings.

Similarly, Ajibade et al. [8] introduced behavioral features alongside traditional academic and demographic features as new predictors. Various classifiers, including Naïve Bayes, Decision Tree, K-Nearest Neighbor, Discriminant Analysis, and Pairwise Coupling, were used. The study found that incorporating behavioral features improved prediction accuracy from 72.6% to 84.2%. Furthermore, applying ensemble methods like AdaBoost, Bagging, and RUSBoost enhanced accuracy to 94.1%, demonstrating the effectiveness of these techniques in predicting academic performance.

Building on this, Shahiri et al. [9] aimed to identify gaps in current prediction methods, determine key attributes influencing student performance, and evaluate various predictive algorithms. Important attributes highlighted include cumulative grade point average (CGPA) and internal assessments.

Helal et al. [10] focused on predicting academic performance by considering student heterogeneity. Using data from an Australian university, the research shows that models trained on specific student sub-populations outperform those trained on the entire dataset. The study combines enrolment and LMS activity data, finding that this improves the precision of identifying at-risk students. Both black-box and white-box classification methods were used, with white-box methods being particularly useful for designing effective student support strategies.

Widyahastuti and Tjhin [11] aimed to predict students' performance in final examinations using linear regression and multilayer perceptron. Data was collected from e-learning logs and attendance records of 50 undergraduate students. The research concluded that the multilayer perceptron model provides better prediction results compared to linear regression in terms of accuracy, performance, and error rate. The findings highlight the importance of using neural network models for more accurate predictions in the educational context.

Furthermore, Yang et al. [12] investigated predicting student academic performance using Multiple Linear Regression (MLR) and Principal Component Analysis (PCA). Data was collected from 58 university students enrolled in a blended calculus course. The study found that combining MLR with PCA improves the predictive accuracy of the model. Traditional evaluation measures like MSE and R^2 were supplemented with new measures like pMSE and pMAPC to better assess predictive performance. The results indicated that using PCA components significantly enhances the model's accuracy.

El Aissaoui et al. [13] proposed a multiple linear regression-based approach to predict student outcomes, utilizing multivariate adaptive regression splines to select the most relevant variables, thereby improving the model's performance. Their methodology demonstrated that variables selected through Multivariate Adaptive Regression Splines (MARS) led to more accurate predictive models compared to other variable selection methods.

The approach used by Alshanqiti and Namoun [14] combined collaborative filtering, fuzzy set rules, and Lasso linear regression to optimize prediction accuracy. It also utilizes an optimized self-organizing map for multi-label classification to identify various factors affecting student performance. The method was tested on seven datasets, demonstrating significant improvements over baseline models, highlighting the importance of combining supervised and unsupervised learning for accurate predictions and explanatory insights into student performance.

The study by Turabieh et al. [15], proposed an enhanced version of the Harris Hawks Optimization (HHO) algorithm to improve feature selection for predicting student performance. By controlling population diversity using k-nearest neighbors (kNN) clustering, the modified HHO algorithm aims to overcome premature convergence and prevent trapping in local optima. The study employs various machine learning classifiers, such as kNN, Layered Recurrent Neural Network (LRNN), Naïve Bayes, and Artificial Neural Network, to evaluate the prediction system using a dataset from the UCI machine learning repository. Results indicate that the combination of the enhanced HHO and LRNN achieves the highest accuracy of 92%, highlighting the importance of early prediction to avoid student failure and improve educational outcomes.

Shivaji et al. [16] proposed a feature selection technique to enhance the performance of machine learning classifiers in predicting bugs in software changes. By applying the Gain Ratio for feature selection, the study aims to reduce the number of features, thereby improving classifier accuracy and scalability. The technique was evaluated using Naïve Bayes and Support Vector Machine (SVM) classifiers across multiple open-source projects. Results indicate that feature selection significantly improves bug prediction performance, achieving high precision and reducing false positives.

Another study by Zaffar et al. [17] investigated the effectiveness of various feature selection algorithms in predicting student academic performance. The research evaluates six filter-based feature selection algorithms (CfsSubsetEval, ChiSquaredAttributeEval, FilteredAttribute Eval, GainRatioAttributeEval, Principal Components, and ReliefAttributeEval) using two different datasets with varying numbers of features. The study finds that there is a significant performance difference based on the number of features, with a 10-20% accuracy variation.

Adejo and Connolly [18] investigated and compared the efficiency of multiple data sources, different classifiers, and ensemble techniques in predicting student academic performance. Using data from the University of the West of Scotland, the study employs Decision Tree (DT), Artificial Neural Network (ANN), and Support Vector Machine (SVM) classifiers, as well as their ensembles. Results indicate that combining multiple data sources with heterogeneous ensemble techniques significantly improves prediction accuracy and helps identify at-risk students early. The proposed hybrid model, which integrates various classifiers and data sources, achieves higher accuracy and efficiency compared to individual base classifiers.

Imran et al. [19] proposed a model to predict student performance using supervised learning algorithms. The research addresses common issues such as data high dimensionality, class imbalance, and classification errors. Using data from the UCI Machine Learning Repository, the study evaluates three classifiers: J48, NNge, and MLP, with J48 achieving the highest accuracy of 95.78%. The study demonstrates the importance of data preprocessing and the use of ensemble methods to improve prediction accuracy. This model is designed to help educational institutions make early interventions to support at-risk students.

Similarly, Razaque and Alajlan [20] evaluated six machine learning models (Decision Tree, Random Forest, Support Vector Machine, Logistic Regression, AdaBoost, and Stochastic Gradient Descent) to predict student performance. The dataset includes academic and demographic data from the UCI Machine Learning Repository. The models are assessed based on accuracy, precision, sensitivity, and F-measure. The results indicate that Stochastic Gradient Descent outperforms other models, achieving the highest accuracy. The study underscores the importance of preprocessing and proper model selection to enhance prediction accuracy, aiming to identify at-risk students early and support their academic success.

The study by Ghorbani and Ghousi [21] and Alija et al. [22], explored the application of various supervised machine learning algorithms for predicting student performance, with a particular emphasis on managing imbalanced datasets. The authors utilize the Synthetic Minority Over-sampling Technique (SMOTE) to balance the dataset. Multiple algorithms are evaluated in the research. These findings underscore the necessity of addressing imbalanced data to enhance the accuracy and reliability of predictive models in educational data mining.

H. Alamri et al. [23] explored the use of SVM and Random Forest algorithms to predict academic performance based on various influencing factors such as prior grades and social conditions. The study utilized two types of datasets focused on mathematics and Portuguese language courses, applying both binary classification and regression techniques. The results show that SVM and RF models achieve high accuracy levels, with RF performing slightly better in binary classification scenarios.

Moreover, the application of Recursive Feature Elimination (RFE) has shown considerable promise in various domains, particularly in enhancing the accuracy and efficiency of predictive models [24], [25]. In the context of student performance prediction, several studies have leveraged RFE to identify the most critical features influencing academic outcomes. Syed Mustapha [26] employed RFE with Random Forest to refine feature selection for predicting student grades. This approach evaluated the effectiveness of different models such as the Boruta algorithm and Lasso regression for regression tasks, and Recursive Feature Elimination (RFE) and Random Forest Importance (RFI) for classification tasks. Key findings included the superior performance of Gradient Boost in regression tasks and the effectiveness of Random Forest in classification tasks. The study emphasized the importance of proper feature selection to improve the accuracy and efficacy of predictive models.

III. Our Methodology

In this section, we detail the methodology adopted to conduct our study on student performance prediction. Our approach, illustrated in Fig. 1, is based on a series of structured processes, including data collection and preprocessing, feature selection, and model construction and evaluation. To build an efficient prediction model, we have integrated a method that optimizes feature selection. This approach aims to identify the most relevant attributes that directly influence the performance of the model.

A. Data Description

The data utilized in this research project belongs to IBN ZOHR University of Morocco and pertains to students enrolled at open-access establishments. It is sourced from two main systems:

- Pre-registration platform: Before enrolling at the faculty, students are required to fill out a form, providing a range of information.

- APOGEE datastore System: This system centralizes academic data, capturing student results throughout their academic journey.

Our dataset comprises 174,135 records and 21 attributes, captured during the period from 2016 to 2020. The following Fig. 2 displays the distribution of data during this period, and Table I lists the considered variables.

B. Data Preprocessing

Data preprocessing is an essential step in machine learning, ensuring the integrity and dependability of the data used for analysis. It involves cleaning, encoding, and normalizing data, reducing biases, and enhancing the precision of predictive models [27]. This section outlines the techniques used in the preprocessing stage, designed to effectively prepare the data for thorough analysis.

1) Data aggregation: The initial stage of our analysis involves aggregating data from the Pre-Registration Platform and the APOGEE Data Storage System. In this process, we merge these data sources utilizing SQL-style joins, which facilitate a precise combination of the data, ensuring thorough synchronization. This technique guarantees the effective integration of each student's information from both sources, minimizing data redundancy and enhancing the overall consistency of the dataset.

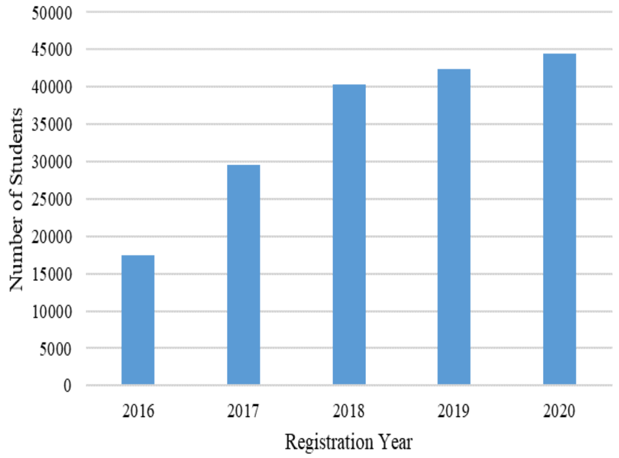

Fig. 2. Distribution of students by registration year.

TABLE I. DESCRIPTION OF CONSIDERED STUDENT ATTRIBUTES

Attributes	Values	Description
GENDER	{Female,Male}	Gender
LIV_ENV	{Urban, Rural}	Type of Environment in which the student lives
AGE_ENR	{(20-22) G1,(23-25) G2,(26-30) G3,(31 and above) G4}	Age at the time of Enrollment: G1, G2, G3 refer to Group 1, Group 2, and Group 3, respectively.
DISCIPLINE	{Literary,Scientist,Technical}	Discipline chosen
TEACH_LANG	{Mother tongue,Foreign Language}	Language of Studying at university
FAM_STAT	{Single,Married,Divorced}	Student's Family Status
REG_RES	{Sous Massa Region,Southern Regions,Rest of the Country}	Region of Residence
DISABLED	{No,Yes}	Indicates if the student is Disabled
STD_PRF	{Student,Professional Activity}	Student's Profession
FA_PRF	{Deceased,Unemployed/At Home,Public-Service/Army/police,Retirement,Low-income jobs,Middle-income jobs,Good-income jobs}	Father's Profession
FA_EDU_LIV	{None,Elementary,Intermediate,High}	Father's Education Level
MO_PRF	{Deceased,Unemployed/At Home,Public-Service/Army/police,Retirement,Low-income jobs,Middle-income jobs,Good-income jobs}	Mother's Profession
MO_EDU_LIV	{None,Elementary,Intermediate,High}	Mother's Education Level
PAR_REL	{Married,Divorced}	Parents Relationship
BAC_TYPE	{Literary,Scientist,Technical}	Baccalaureate Type
BAC_DEG	{Pass,Satisfactory,Good,Very Good}	Baccalaureate Degree
BAC_ACAD	{Agadir Sous Massa Region,Southern regions,Rest of the Country,Foreign Academy}	Baccalaureate Academy
MTANGUE_GRD	[3,19]	Grade in Mother Tongue
1F_LANG_GRD	[3,19]	Grade in First Foreign Language
2F_LANG_GRD	[3,19]	Grade in Second Foreign Language
F_GRADE	{<6 (Bad),[6,10[(Poor),[10,13] (Medium), >=13 (Good)}	Target: Final Grade

2) Data cleaning and encoding: During the initial preprocessing stage, crucial measures were taken to ensure data integrity and suitability for further analysis. The dataset initially consisted of 177,193 entries across 38 variables, which, after removing 3,058 redundant records and eliminating irrelevant attributes, was reduced to 174,135 entries and 21 variables. Following this, attention was directed towards data encoding, where, for example, the 'GENDER' attribute was encoded using label encoding, and 'AGE_ENR' as well as 'F_GRADE' were handled using ordinal encoding to facilitate computational processing and maintain the natural order of values. Fig. 3 illustrates the distribution of the target 'F_GRADE' for visualization.

3) Data normalization: Normalization is an essential preprocessing technique in machine learning, ensuring that the range of independent variables is uniform across the dataset. This process helps in achieving faster convergence during training, reduces the complexity of the model, and often leads to better overall performance [28].

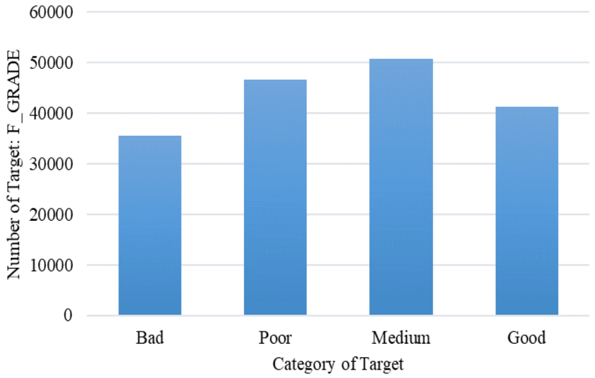

Fig. 3. Distribution of the F_GRADE target.

In our study, which analyzes student performance data with a wide variety of scales and distributions, Z-score normalization is identified as the most appropriate technique. It’s a statistical technique that transforms features to have a mean of zero and a standard deviation of one. This normalization is especially useful in machine learning when features vary in scale because it ensures that each feature contributes equally to the analysis and helps in improving the convergence of many algorithms. The formula for the Z-score given by:

$$Z = \frac{(X - \mu)}{\sigma} \qquad (1)$$

where X is the original data point, μ is the mean of the data, and σ is the standard deviation.

4) Outliers’ analyses: The Z-score is utilized not only for normalization but also for the effective identification of outliers by highlighting data points that substantially diverge from the mean. Once these outliers are detected, several strategies can be employed for their management, such as removal, capping, transformation, or imputation [29]. For our case study, we have chosen to manage outliers through logarithmic transformation. This technique mitigates the influence of outliers by compressing extreme values closer to the median, which helps in reducing skewness and improving the uniformity of the data distribution.

C. Features Selection

Feature selection is a critical step in machine learning, aimed at identifying the most relevant features for use in predictive models. This process is vital as it improves model performance by reducing overfitting, enhancing accuracy, and decreasing training time [30]. In our study, we adopted a systematic approach to optimize feature selection. Specifically, we employed Recursive Feature Elimination combined with Cross-Validation using a Random Forest as an estimator (RFECV-RF).

1) Random Forest (RF): Random Forest is a sophisticated machine learning technique extensively used for classification and regression tasks [31]. As an ensemble learning method, it constructs numerous decision trees during training and combines their outputs to boost classification accuracy and mitigate overfitting. By combining the predictions from multiple trees, RF lowers model variance and enhances generalization capabilities. This robust technique is particularly effective in managing large datasets with intricate feature interactions. Additionally, it provides estimates of feature importance, allowing for feature selection, because it can capture complex relationships and interactions between features, resulting in more reliable and accurate predictive performance. This makes it an excellent choice for predicting student performance [32].

2) Recursive Feature Elimination with Cross-Validation using RF (RFECV-RF): RFE is a wrapper feature selection method that iteratively removes the least important features based on model performance to identify and rank the most significant predictors. To determine the optimal number of features that maximize the performance of machine learning models, we combined RFE with cross-validation [33],[34]. We employed RF as the classification model within the RFECV framework to evaluate and iteratively eliminate features that did not improve classification accuracy. As shown in Algorithm 1, RFECV-RF initializes with the complete feature set S and an empty elimination list R. The algorithm sets a predefined number of features to eliminate in each iteration, known as step_size which is set to 1 in our case, then employs 5-fold cross-validation to robustly evaluate the RF classifier's performance on S. During each iteration, the classifier is trained, and the performance of the feature set is evaluated through cross-validation. Feature importance scores are calculated, and the least significant features, determined by the step_size, are moved from S to R and then removed from S. This process continues until S is empty, ensuring all features are assessed. The refined set S is then re-evaluated with 5-fold cross-validation to validate its effectiveness, and the algorithm outputs R, listing the eliminated features, and S, the curated set of key features for precise prediction.

Algorithm 1: RFECV-RF algorithm for feature selection

```
Input: Training sample set
Initialize the full feature set S = {1, 2, ..., N} where N is the total number of features.
Initialize the feature ranking list R = []
Determine the set of features to eliminate in each step, termed as step_size.
Specify n_folds = 5 for the cross-validation process.
While len(S) $\neq$ 0 do
    For (each subset of features) do
        Train the Random Forest classifier on the training data using the features in S.
        Perform 5-fold cross-validation to estimate the model's performance for each subset of features.
        Calculate the importance score for each feature in the current feature set S using the Random Forest.
        Rank the features based on their importance scores.
        If (condition) then
            Identify the least important features equal to step_size
            Add these to R and remove them from S.
        End If
    End For
    If S becomes empty, break the loop.
End While
The final set of features in S is used to perform a final round of training and 5-fold cross-validation.
Output the set R as the eliminated features and S as the selected feature subset.
```

D. Classification of Machine Learning Models and Evaluation Metrics

After performing feature selection to identify the most relevant predictors, we developed classification models to predict student performance using various supervised machine learning techniques, including Decision Tree (DT), Naive Bayes (NB), K-Nearest Neighbors (KNN), Support Vector Machine (SVM), Logistic Regression (LR), and AdaBoost. Evaluation measures such as accuracy, precision, recall, and F1 score were employed to assess the performance and robustness of each model. These measures provide a comprehensive understanding of the model's effectiveness in accurately identifying patterns, minimizing false positives and negatives, and managing imbalanced classes. Table II details the hyperparameters used for each classification algorithm, while Table III outlines the formulas for each evaluation metric.

TABLE II. HYPERPARAMETERS OF CLASSIFICATION MODELS

Classifier	Hyperparameters
Decision Tree (DT)	Criterion=entropy, max_depth = 10, splitter = best, min_samples_split = 2
Naive Bayes (NB)	Gaussian Naive Bayes doesn't require parameter tuning
K-Nearest Neighbors (KNN)	n_neighbors=5, weights=uniform , metric=minkowski
Support Vector Machine (SVM)	C=1, gamma=scale, kernel=rbf
Logistic Regression (LR)	C=100, penalty=l2, solver= newton-cg
AdaBoost	max_depth=3, n_estimators=200, learning_rate=0.1, algorithm=' SAMME.R'

TABLE III. EVALUATION METRICS AND THEIR DEFINITIONS

Metric	Formula	Description
Accuracy	$\mathrm{Acc} = \frac{\mathrm{TP}+\mathrm{TN}}{\mathrm{TP}+\mathrm{TN}+\mathrm{FP}+\mathrm{FN}}$ (2)	-TP (True Positives): samples correctly classified as positive. -TN (True Negatives): samples correctly classified as negative. -FP (False Positives): samples incorrectly classified as positive. -FN (False Negatives): Instances incorrectly classified as negative.
Precision	$\mathrm{Pre} = \frac{\mathrm{TP}}{\mathrm{TP}+\mathrm{FP}}$ (3)	
Recall	$\mathrm{Rec} = \frac{\mathrm{TP}}{\mathrm{TP}+\mathrm{FN}}$ (4)	
F1 score	$\mathrm{F1} = 2 * \frac{\mathrm{Pre} * \mathrm{Rec}}{\mathrm{Pre}+\mathrm{Rec}}$ (5)	

IV. RESULTS AND EXPERIMENTS

A. Hardware Used

The Experiments were run on a desktop computer using the Ubuntu 20.04 LTS Operating System. The system's technical specifications include 32GB of RAM, an Intel Core i7-12700F processor operating at a clock speed of 2.10 GHz with 12 cores, and an NVIDIA GeForce RTX 3060 graphics card.

B. Experimental Results

Our study aimed to evaluate the importance of feature selection and determine the most effective classifier for predicting the “Final Grade” target. We conducted several experiments using various supervised learning methods on our dataset. Initially, we used RFECV-RF for feature selection, as shown in Table IV. This method helped us identify the optimal subset of features that strongly predict our target. The selected features were then used to train and test several classifiers including DT, NB, KNN, SVM, LR, and AdaBoost to comprehensively evaluate each model's performance.

TABLE IV. USED CONFIGURATION FOR RFE ALGORITHM

Configuration	Value
Model	Random Forest (RF)
Cross-Validation	5-fold
Steps(step_size)	1

Fig. 4 depicts the relationship between the number of features and the classification scores across five cross-validation folds using RFECV-RF. This analysis ranked each feature based on its contribution to enhancing the prediction model's accuracy. The graph illustrated a notable increase in classification scores as the number of features increased from 1 to 6, highlighting the significance of these initial features. The classification score leveled off around eight features, indicating that this number optimally captured the essential information required for effective classification, stabilizing at approximately 87%. The eight highest-ranked features were identified as follows: “BAC_DEG”, “LIV_ENV”, “MTANGUE_GRD”, “FA_PRF”, “FA_EDU_LIV”, “AGE_ENR”, “1F_LANG_GRD”, and “2F_LANG_GRD”. The findings were consistent across different cross-validation folds, demonstrating the robustness and reliability of the approach. Furthermore, beyond 12 features, a slight decrease in the classification score was observed, suggesting that adding more features introduced noise or redundant information.

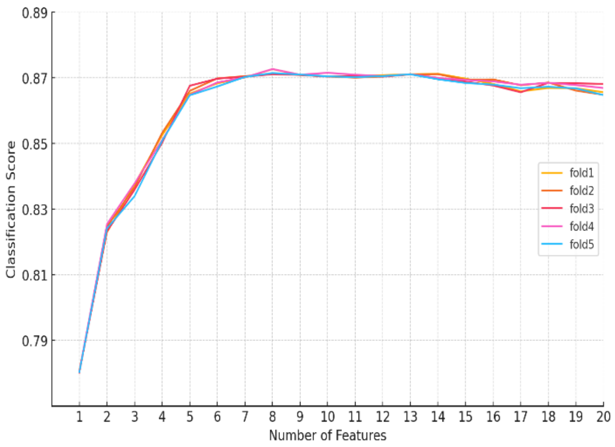

Fig. 4. Classification score vs. Number of selected features using RFECV-RF.

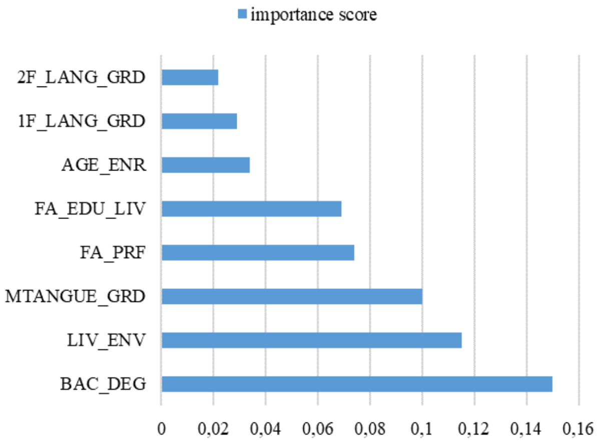

Fig. 5. Feature importance using RFECV-RF algorithm.

Fig. 5, generated through our algorithm, illustrates the relative importance of various features in the predictive model. The "BAC_DEG" feature emerged as the most impactful with an importance score of 0.15, highlighting the significant influence of the baccalaureate degree on our target prediction. The living environment “LIV_ENV” and proficiency in the mother tongue “MTANGUE_GRD” also featured prominently, indicating their critical roles within socio-economic and linguistic contexts. Other attributes such as the father's profession “FA_PRF” and his educational level “FA_EDU_LIV” exhibited considerable significance.

Fig. 6 illustrates the impact of feature selection on the accuracy of various machine learning models by comparing their performance with all features versus the top 8 selected features. The DT model shows an improvement in accuracy from 81% to 83%, indicating that feature reduction can help mitigate overfitting while maintaining the model's ability to make accurate predictions. The NB model, which has the lowest accuracy among the models, sees a marginal increase from 69% to 70%, suggesting that while feature selection provides some benefit, the model might still not be optimal for our dataset. The accuracy of the KNN model increases from 80% to 82%, likely benefiting from the dimensionality reduction. The SVM model, which already performed well with all features at 84% accuracy, further improves to 87% with eight features selected, highlighting the effectiveness of choosing the most relevant features for this model. LR sees a slight increase from 75% to 76%, suggesting that it remains relatively stable relative to the number of features. Finally, AdaBoost's improvement in accuracy from 82% to 84% with selected features indicates a positive response to feature selection, likely due to a reduction in variance and noise in the data.

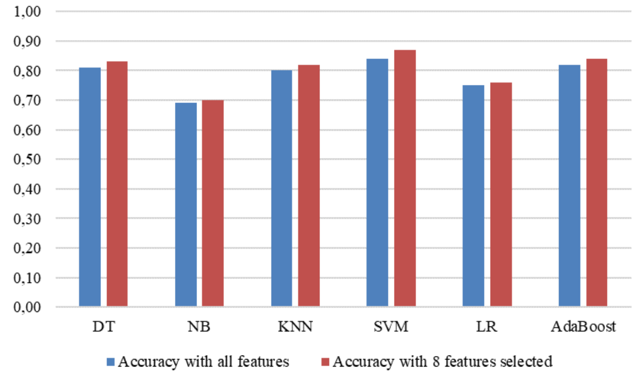

Fig. 6. Accuracy of models using all features vs. Top 8 selected features.

The comparison of various classifiers using full and top eight selected feature sets, as illustrated in Table V and Fig. 7, showcases how feature selection impacts the performance of machine learning models across several metrics such as precision, recall, and F1 score. Notably: the SVM model showed an impressive increase in precision from 76.33% to 82.09%, and in recall from 81.29% to 84.43%, with a corresponding improvement in the F1 score from 79.21% to 81.10%. These results indicate that the SVM model, with its ability to maximize the margin between classes, benefits from reducing complexity and noise by eliminating irrelevant features. Similarly, the AdaBoost model, demonstrated significant progress in terms of precision, increasing from 74.42% to 76.31%, and in recall from 80.14% to 82.71%, with an enhancement of its F1 score from 77.70% to 78.36%. This improvement shows that precise feature selection can indeed optimize AdaBoost’s capability. KNN also displayed notable improvements in all performance metrics with effective feature selection. Precision increased from 73.47% to 75.65%, recall from 75.86% to 76.29%, and the F1 score from 74.87% to 75.75%.

The performance of other models on datasets with all features and with the eight selected features also shows interesting results, though less dramatic than for SVM and AdaBoost. The DT model observed a slight improvement after feature selection. Precision increased from 72.29% to 73.10%, recall from 77.29% to 78.43%, and the F1 score from 76.29% to 76.53%. This modest improvement suggests that even for a relatively simple model like Decision Trees, which is less prone to overfitting, removing non-essential features can help clarify classification decisions.

TABLE V. EVALUATION METRICS OF VARIOUS CLASSIFIERS WITH ALL FEATURES VS. TOP EIGHT SELECTED FEATURES

Models	Dataset with all features (20 features)				Dataset with top 8 features selected			
	Accuracy	***Precision***	***Recall***	***F1 Score***	***Accuracy***	***Precision***	***Recall***	***F1 Score***
DT	0,81	0,722857143	0,772857143	0,762857143	0,83	0,730967742	0,784285714	0,765254237
NB	0,69	0,702857143	0,632857143	0,602857143	0,70	0,710967742	0,653654875	0,601254237
KNN	0,80	0,734705882	0,758571429	0,748709677	0,82	0,756451613	0,762857143	0,757457627
SVM	**0,84**	**0,763333333**	**0,812857143**	**0,792068966**	**0,87**	**0,820897652**	**0,844285714**	**0,811034483**
LR	0,75	0,701428571	0,616428571	0,607142857	0,76	0,711828571	0,616885714	0,609142857
AdaBoost	0,82	0,744193548	0,801428571	0,777017544	0,84	0,763103448	0,827142857	0,783559322

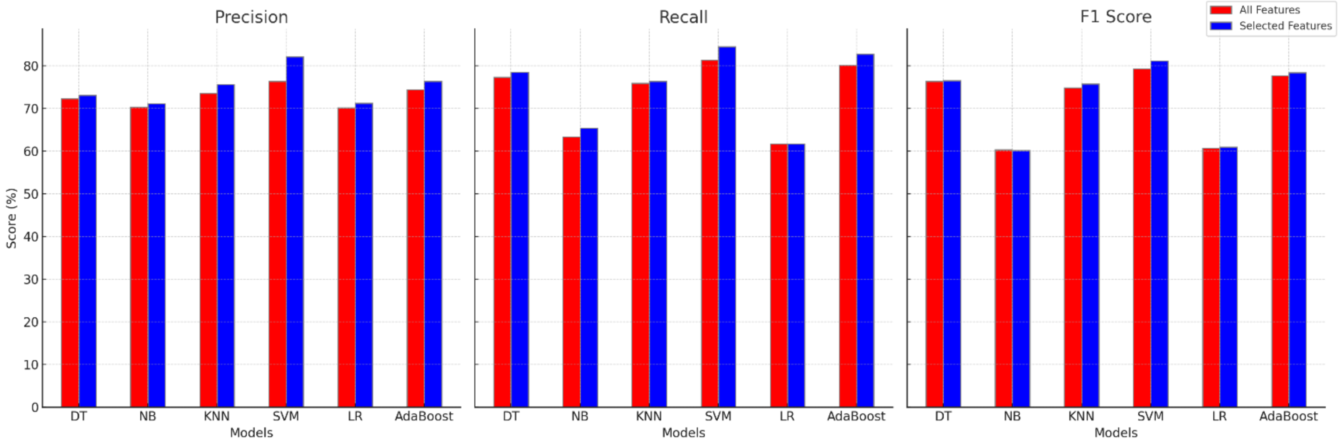

Fig. 7. Classifier metrics comparison with all features vs. selected features.

The NB model saw a minimal increase in precision, from 70.29% to 71.10%, and in recall, from 63.29% to 65.37%, but a slight decrease in the F1 score from 60.29% to 60.13%. These results indicate that while feature selection improved precision and recall, the overall impact on the harmony between these metrics was minimal. LR showed a slight increase in precision from 70.14% to 71.18% and recall from 61.64% to 61.69%, with a similar rise in the F1 score from 60.71% to 60.91%.

The analysis demonstrates that reducing the number of features from 20 to 8 generally enhances performance across most classifiers, albeit by varying degrees. These observations provide valuable insight into how different models respond to feature reduction and can guide modeling and preprocessing choices in future studies.

V. DISCUSSION

These results collectively highlight that feature selection can generally enhance the performance of the machine learning models in terms of accuracy, precision, recall, and the F1 score. Most models show an improvement across all metrics, especially notable in SVM and AdaBoost, which suggests that reducing the number of features to the most relevant ones can significantly enhance model performance. The NB model, while showing improvement in recall, does not show a proportional increase in the F1 score, this pattern may stem from the inherent probabilistic characteristics of this classifier. Also, the marginal improvements observed in the LR model suggest that not all models uniformly benefit from feature reduction, possibly due to the specific nature of the data.

The effectiveness of the SVM in student prediction applications is demonstrated by its higher performance when combined with feature selection utilizing Random Forest (RF) and Recursive Feature Elimination with Cross-Validation (RFECV). This method works especially well when dimensionality reduction is essential to increasing the interpretability and efficiency of the model, and when there is a complex relationship and interactions between attributes. The strategic feature selection approach complements SVM's resilience in determining the best hyperplane for classification and its ability to handle high-dimensional spaces.

However, it is imperative to recognize the possible disadvantages and limitations linked to this methodology. If the procedure is not appropriately fine-tuned, one drawback is the possibility of overfitting. It's also possible that the computational requirements will rise dramatically. Furthermore, the particular hyperparameters selected may significantly impact the method's effectiveness. This underscores the necessity for tailored feature selection strategies that align with the strengths of each model to optimize performance.

By focusing heavily on the predictive models of machine learning, we risk neglecting particular cases that could represent unique educational paths or specific challenges encountered by certain groups of students. Additionally, an overreliance on predictive analytics could lead decision-makers to prioritize adherence to the model, possibly sidelining broad educational goals. It is important to consider these factors when analyzing the effectiveness and suitability of strategies for predicting student's performances.

VI. Conclusion and Future Work

In this study, we developed a robust model for predicting student performance at IBN ZOHR University by employing a combination of Random Forest and Recursive Feature Elimination with Cross-Validation (RFECV-RF) for optimal feature selection. Our dataset consists of 174,135 records and 21 attributes, collected over the period from 2016 to 2020.

Our experiments demonstrated that the SVM classifier, utilizing the top 8 features selected through RFECV-RF, outperformed other models, achieving an impressive accuracy of 87%. This underscores the efficacy of our feature selection approach and the SVM model's robustness in accurately predicting student performance. Other classifiers, such as AdaBoost, Decision Tree (DT), K-Nearest Neighbors (KNN), Naive Bayes (NB), and Logistic Regression (LR) also showed varying degrees of improvement with feature selection, but none matched the performance of SVM.

Regarding future work, we look forward to addressing class imbalance within our dataset. Our current dataset shows variations in the representation of some classes. To address this variation, we plan to explore several rebalancing techniques. Additionally, we plan to explore additional feature selection techniques such as genetic algorithms, which have the potential to refine the selection of relevant features further and enhance the model's predictive accuracy. Furthermore, we plan to test our model on datasets from other universities to validate the generalizability of our approach. We aim to ensure the model's robustness and applicability across different student populations and academic environments by applying it to diverse educational contexts.

Applied Predictive Analytics Research Group-Faculty of Engineering-Universiti Malaysia Sabah, Sabah, Malaysia[1, 2, 3]
Electronic Engineering (Computer) Program-Faculty of Engineering-Universiti Malaysia Sabah, Sabah, Malaysia[4]

***Abstract*—This paper introduces a Contactless User Feedback System (CUFS) that provides an innovative solution for capturing user feedback through hand gestures. It comprises a User Feedback Device (UFD), a mobile application, and a cloud database. The CUFS operates through a structured sequence, guiding users through a series of questions displayed on an LCD. Using the Pi Camera V2 for contactless hand shape capture, users can express feedback through recognized hand signs. A live video feed enhances user accuracy, while secure data transmission to a database ensures comprehensive feedback collection, including timestamp, date, location, and a unique identifier. A mobile application offers real-time oversight for administrators, presenting facility status insights, data validation outcomes, and customization options for predefined feedback categories. This study also identifies and strategically addresses challenges in image quality, responsiveness, and data validation to enhance the CUFS's overall performance. Innovations include optimized lighting for superior image quality, a parallel multi-threading approach for improved responsiveness, and a data validation mechanism on the server side. The refined CUFS demonstrates recognition accuracies consistently surpassing 93%, validating the effectiveness of these improvements. This paper presents a novel and refined CUFS that combines hardware and software components, contributing significantly to the advancement of contactless human-computer interaction and Internet of Things-based systems.**

I. Introduction

The Feedback System (FS) is a platform that empowers users to actively engage and provide feedback, thereby establishing a channel for communication between clients and the respective company or authorities. This system has gained widespread adoption, particularly by companies heavily reliant on customers' opinions as a requirement for product and service improvement [1]. These opinions encompass various aspects such as product evaluation, facility experience, customer treatment, and overall user experience [2-3]. By going through user reviews, organizations can maintain user loyalty [4] by targeting their varying tastes [5] and ensuring they're satisfied with the current services.

Within facilities management, user feedback constitutes contextual information that demands prompt attention and an immediate response from the responsible party. The user feedback system allows facility users to alert workers [6] of any infrastructure-related problems and their overall experiences while using it [7]. There has been significant progress in the development of feedback systems tailored to facility monitoring, driven by a desire to better understand how people utilize buildings [8]. One such innovation is a user feedback system that analyzes user behavior within building environments. Building occupants can provide feedback about their comfort levels within specific spaces, enabling a comparison of this feedback with sensor data to evaluate whether building services meet user needs [9]. This synergy of user input and sensor data can potentially enhance building efficiency and user comfort.

A. Existing Facilities Management Feedback System

Among the most prevalent mechanisms for collecting such feedback are QR codes, which direct users to dedicated websites or online survey forms designed for feedback submission [3]. Using a QR code or physical note is a valid and practical alternative for gathering feedback, but it has some limitations. Users must actively scan a QR code or navigate to a specific URL to provide feedback [3]. Lengthy or complex forms can overwhelm users, leading them to abandon the feedback process [10-11]. Some users may lack the knowledge to access links provided in QR codes or have limited experience with web-based forms. These users are more accustomed to verbal communication rather than written or contextual communication. Furthermore, data collected through QR codes and forms is generally not in real-time. Responses become available only after users submit the form or scan the QR code [12], which might not be ideal for time-sensitive scenarios where immediate feedback is crucial.

Previous studies have incorporated sensors to establish a connection between the comfort levels in facilities. Users are required to provide reviews, which are then used to create a comfort map in conjunction with the sensor data. This information allows the sensors to serve as indicators for when the facilities may require maintenance or the attention of the facility owner. The problem with this method is its limited scalability and adaptability. The system struggles to accommodate an increasing number of facilities and to adapt to different types of facilities, such as transitioning from public services to laboratories.

The on-site feedback system could address many of these limitations and provide a more engaging and efficient feedback experience. This immediate feedback mechanism can lead to more accurate and timely responses. The real-time nature of the system allows for dynamic adjustments and improvements based on the data collected, contributing to a more responsive and user-centric environment. The adaptability of the system increases if facility owners have the ability to modify the review questions. However, when deployed in a public setting, such a system would affect the sanitary level due to the high volume of physical interactions [13] it necessitates. A contactless user feedback system presents a promising solution as it minimizes physical contact and reduces the risk of spreading germs or infections.

B. Existing Contactless Human-Computer Interaction

A contactless system operates through sensors capable of detecting various human signals, such as body and hand movements [14], as well as reactions [15]. Several innovative solutions can be employed to develop this technology, using ultrasonic [16] and infrared sensors [17] as virtual buttons. With this approach, users simply need to hover their hands near one of the sensors corresponding to their desired response, eliminating the need for physical contact.

Another viable option involves gesture sensors [18], which can detect changes in light and discern the direction of motion of an object in front of them. By utilizing this technology, users can select or provide feedback by moving their hand in specific directions, for instance, from left to right [19], without the need to touch the feedback system monitor. The method is viable for an on-site review system but is limited by the number of inputs it can accept. For instance, the ultrasonic method can only handle a few inputs and is sensitive to its surroundings at certain angles. This has been improved with infrared sensors, which offer better accuracy but have limited range. As a result, users must interact with the system within a restricted distance, and any potential infrared interference in the environment can cause the device to malfunction.

A more advanced solution involves the implementation of Artificial Intelligence (AI), using hand-sign optical images as input [20-22]. Available AI options include MediaPipe, an open-source framework that enables developers to construct complex pipelines for object detection, face detection, hand tracking, pose estimation, and more [23-25]. MediaPipe provides a solid foundation for building real-time multimedia processing pipelines, but the accuracy varies based on the task being performed [26-27]. Accurate interpretation of user responses is very important for the contactless system to ensure reliability. Accurateness is particularly crucial within the context of performance reviews, where feedback, provided at the right moments and for the right purposes, plays a pivotal role. This method incorporates the use of an AI model to map hand landmarks to specific movements, simulating mouse movements or keyboard keystrokes. However, this approach requires significant computational power, leading to an unpleasant stuttering experience on small form factor devices. Potential solutions include optimizing the AI model or implementing a transition algorithm to convert the AI model's output into computer input more efficiently.

C. The Contribution and Objective of the Study

This paper presents a pioneering contactless user feedback system that converges hardware and software technologies to revolutionize user interaction and feedback processes. By integrating the Raspberry Pi 4B+ microcomputer, Pi Camera V2, and the MediaPipe framework, the system introduces a contactless paradigm for real-time hand sign recognition, providing users with an intuitive medium for expressing immediate feedback. The study makes a substantial contribution to contactless human-computer interaction by systematically addressing and overcoming challenges associated with image quality, responsiveness, and data validation.

II. Methodology

A. The Contactless User Feedback System Assembly

A prototype of a Contactless User Feedback System (CUFS) depicted in Fig. 1 was developed in this study. It comprises a User Feedback Device (UFD), a cloud database, and a mobile application. The central processing unit for the CUFS is the Raspberry Pi 4B+ microcomputer, chosen for its ability to connect to an external display, robust processing power for AI applications [28-29], internet connectivity for cloud database integration, and support for computer vision applications.

The contactless approach is established using a Pi Camera V2, where it is used to capture the user's hand signs. Five hand signs, as illustrated in Fig. 2, are used to facilitate response submission. The hand signs are interpreted using MediaPipe, a machine-learning pipeline that provides a wide range of pre-built solutions and tools for tasks like object detection, pose estimation, hand tracking, and face recognition.

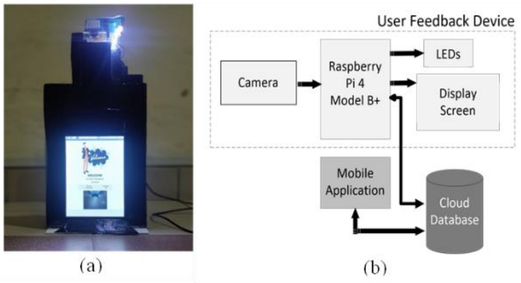

Fig. 1. Contactless user feedback system (a) UFD (b) Block diagram.

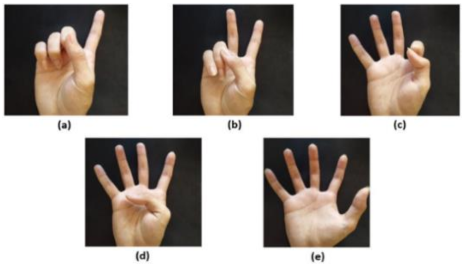

Fig. 2. The recognized hand signs are (a) one, (b) two, (c) three, (d) four, and (e) five.

To facilitate user interaction with the UFD, a seven-inch LCD screen provides instructions and guidance to users. Upon activating the UFD, users are welcomed with a message and clear instructions for assisting them throughout the process. Subsequently, the device presents a question, prompting users to respond. After receiving the response, the next question is displayed for further input. This sequential process repeats until all questions have been addressed. Upon completing the feedback process, the device securely transmits the data to the cloud database. The data includes valuable information such as the timestamp, date, location, and unique identifier, ensuring comprehensive and insightful feedback collection. Fig. 3 defines the CUFS's flow of operation.

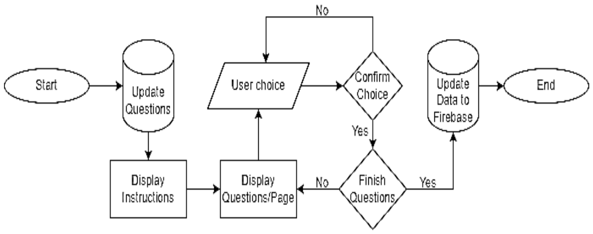

Fig. 3. The CUFS's flow of operation.

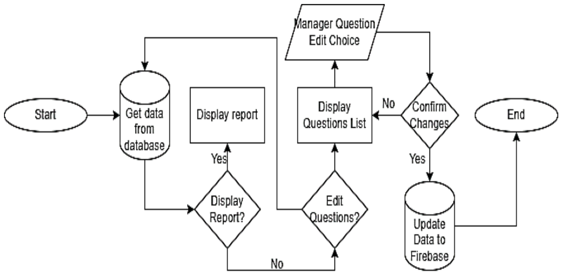

Fig. 4. Managerial application of the CUFS.

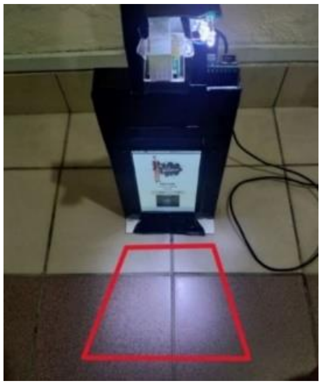

Fig. 5. Illumination area.

The mobile application offers two navigational choices, each catering to distinct aspects of system oversight. The first choice displays a 'Report Page,' a comprehensive dashboard that offers insights into overall facility status, data validation outcomes, and current operational conditions. This report page provides statistical data for facility conditions across different timeframes, encompassing daily, weekly, monthly, and annual perspectives. The second choice leads to a 'Question Edit Page', where the predefined questionnaire can be modified. This page displays the existing questions, with options to select, edit, or delete them. Any editing action prompts a confirmation step, ensuring that changes are deliberate. Once confirmed, the mobile application updates the amended list of questions in the database. The flowchart in Fig. 4 outlines the mobile application for the CUFS.

B. *On-Site Testing*

The CUFS underwent on-site testing, which uncovered deficiencies in image quality, responsiveness, resource management, and data validation. The subsequent sections delve into these limitations and detail the enhancements implemented to address them.

1) Image quality: The CUFS faces difficulties in hand detection and landmark identification, occasionally initiating premature detection and calculations, leading to data collection errors. Factors like background color, reflected light intensity from the hand, and background lighting contribute to suboptimal image quality, hindering accurate user interaction detection. MediaPipe misidentifying landmarks adds complexity, potentially affecting the precision of user gestures. Despite efforts with smart algorithms [30] to address low-light issues, solutions often involve increased computational load or sensor modifications [31-32].

In this study, the solution to address the challenge of poor hand images involves optimizing the intensity of reflected light from the user's hand. This improvement is achieved by strategically redirecting light at a specific angle, illuminating only the user's hand, as depicted in Fig. 5. This enhanced lighting also serves as a guide, indicating where to place the hands. The software was improved to initiate hand sign detection only when all hand landmarks (Fig. 6) are within the frame. To rectify the issue of incorrect landmark position identification, a collection of hand images is obtained for each question, with the most frequently occurring hand sign serving as the response.

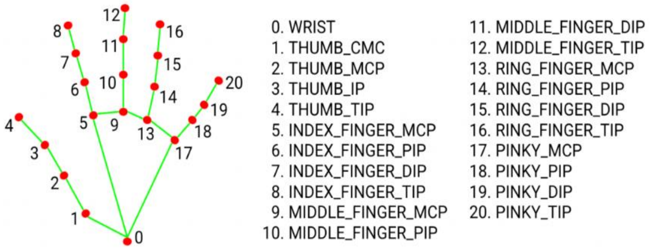

Fig. 6. Hand landmarks with keypoint localization of 21 hand-knuckle coordinates.

The hand images are processed using Algorithm 1. The algorithm takes the parameters of all the hand landmarks in Fig. 6, identified by the hand recognition algorithm offered by the MediaPipe Solutions. It is intended to accept right-hand signs by focusing on the index, middle, ring, and pinkie fingers to compare the tip and proximal interphalangeal joint (PIP) positions. However, when dealing with the thumb, a distinct approach is taken due to its horizontal movement, in contrast to the vertical movement of the other four fingers during hand contraction. Consequently, only the x-axis coordinates are considered for the thumb, while the y-axis coordinates are used for the other fingers.

2) Responsiveness and Resource management: The initial CUFS features a sequential programming flow, as detailed in Fig. 7. This programming structure, while simple, contributes to decreasing responsiveness over time. Video frames undergo extensive processing steps to display questions and recognize responses. These procedures significantly strain the system, leading to a noticeable decrease in frame rate. Additionally, delays can compound when the display process is required to wait for concurrent tasks such as answer handling, page management, and Tkinter rendering. Consequently, extended waiting times pose a challenge to the system's capacity to deliver prompt and responsive feedback.

Algorithm 1: Finger Counting Algorithm

```
Initialize finger up count to 0
Compute
While (Get hand landmarks) do
    For (every hand-knuckle coordinate) do
    Get Thumb IP's and TIP's x-axis coordinates
    If (x-axis coordinates of IP > TIP)
            Increase finger up count by one
            For (the rest of the fingers) do
                Get y-axis coordinates of PIP and TIP
                If (y-axis coordinates of PIP > TIP) then
                    Increase finger up count by one
    End                End
    End

Return finger up count
```

To address these challenges, multi-threading was initially implemented as a promising solution. However, over time, complications arose, leading to delays that gradually accumulated. After extended periods of inactivity, the system encountered an average delay of 3159 milliseconds, roughly a 3-second lag to accept a response. Resource queuing is an important aspect contributing to this issue, where resources can only be released after being used by all threads requiring them. This approach introduces complexities when managing threads with differing resource usage times and burst rates, ultimately affecting system performance and responsiveness.

The issues regarding responsiveness were effectively addressed through the implementation of parallel programming [33] and multi-threading. The program was logically divided into three components to incorporate multi-threading in Python, as shown in Fig. 8. The initial component focused on hand recognition, encompassing all hand landmark retrieval and computation tasks. The subsequent component handled the program's logic for processing user inputs. The final component was responsible for managing the feedback display from the Pi camera. Before implementing multi-threading, a few rules must be followed to maintain the integrity of the different threads.

A resource queuing solution was implemented to resolve this resource contention (Fig. 9). This introduced a third module or component, referred to as the capture component, which took on the responsibility of capturing video frames and placing them in designated queues. Each component operated independently as threads, ensuring a smoother and more responsive program execution.

3) Data validation: The developed CUFS faces issues with data validation, where it could not validate the feedback provided by users. This limitation raises concerns regarding the legitimacy and authenticity of the feedback received. In practical terms, this limitation can manifest as a scenario where employees submit feedback to inflate their ratings, potentially compromising the integrity of the data collected. As such, the absence of validation mechanisms underscores the need for improvements to ensure the trustworthiness and reliability of the CUFS.

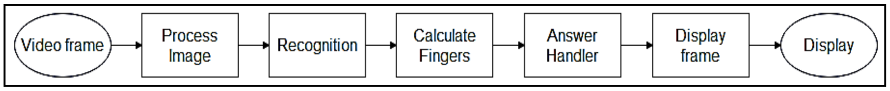

Fig. 7. Series programming flow of the UFD.

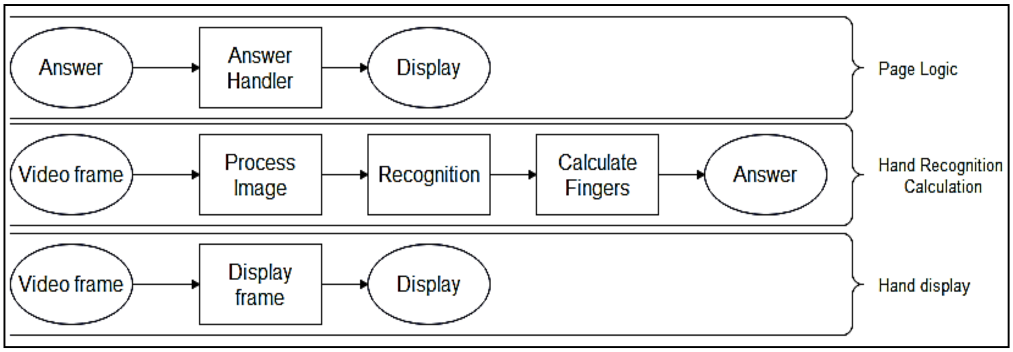

Fig. 8. The components of the UFD program.

For improvement, data validation is performed in the server by using the ratings and the time of those reviews. The server will run a scheduled validation for every prescribed duration. Rather than fetching all the data, including previously validated reviews, the server accesses a validation history stored in the database. This history will be used to identify and retrieve only the reviews that have yet to be validated. This approach significantly reduces the volume of data that requires review, which is particularly advantageous when dealing with large datasets. The data will be systematically sorted and organized upon retrieval into a list that aligns with the validation algorithm's requirements. The resulting list will then be processed, and the outcomes will be uploaded to the database. This approach streamlines the validation process and optimizes data handling, improving overall efficiency and resource utilization. Fig. 10 shows the flowchart for the data validation server on the local machine.

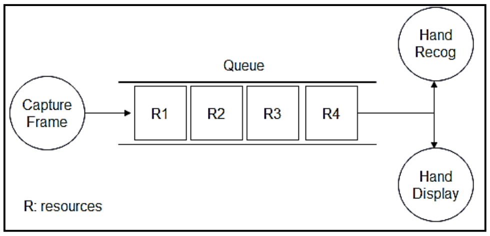

Fig. 9. Implementation of resource sharing from one-to-many threads.

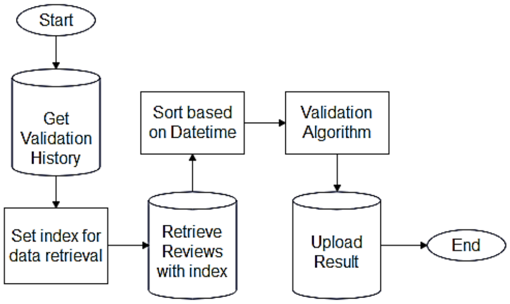

Fig. 10. Flowchart of data validation.

Algorithm 2 provides a structured approach to ensure the integrity of feedback data. This algorithm consists of two key functions, the first of which involves converting the ratings from the qualitative "good" and "bad" labels into a binary representation (1 for "good" and 0 for "bad"). This conversion simplifies the comparison process, making it more efficient. Once the ratings are converted into binary form, the algorithm proceeds with the analysis. The function responsible for the calculation takes two parameters: the rating list and the time period of the listings. By default, the time period is set to every 1 hour. However, this can be adjusted according to the facility owner's preferences to accommodate different facilities. The algorithm iterates through the binary list and checks for changes in ratings over time. Whenever the binary rating at the current time period differs from the previous one (excluding the initial binary), the change counter increments by one.

Algorithm 2: Validation Algorithm

```
Initialize finger up count to 0
rating list ex: {good, good, bad, good, bad, good}

Function converts ratings to binary (ratings list)
    Initialize an empty binary list
    For (every rating in rating list) do
    If (rating is 'good') then
        Append' 1' to binary list
    Else (the rest of the fingers) then
        Append' 0' to binary list
    End
    End
    Return binary list
End

Function calculates rate of change (list, time period)
    Compute binary list as converts ratings to binary (list)
    Initialize changes to 0
    For (every binary in binary list) do
        If (current binary is not equal to previous binary) then
            Increase changes by 1
        End
        End
    Compute rate of change as changes/ time period
    Return rate of change
End
```

This process continues until the algorithm reaches the end of the list. Finally, the algorithm calculates the rate of change by dividing the change count by the specified period for the sample being evaluated. This rate of change provides valuable insights into the consistency of feedback. Before executing the validation algorithm, it is imperative to ensure the data is pre-sorted based on date and time, facilitating a systematic analysis of feedback patterns. A simple pattern analysis has been developed to ensure the integrity of the feedback data. The algorithm collects feedback over a defined period and subjects it to pattern analysis. This approach helps detect anomalies and inconsistencies in the reviews. For instance, if a worker attempts to manipulate information by providing positive reviews while neglecting their responsibilities concerning the facility's condition, a pattern of inconsistent feedback emerges over time. If this deceptive behavior persists in subsequent periods, the system triggers alert to notify the manager about potential issues with the facility. This proactive approach ensures data accuracy and helps maintain the reliability of the feedback system.

III. Results and Discussion

A. Post-Improvement Testing

The improved CUFS was evaluated in real-time by six respondents using the following procedure:

- Respondents will receive a predefined sequence of five questions, guiding them through the CUFS.
- Respondents must answer each question by using hand sign feedback.
- If a respondent encounters a misidentification, they must notify the researcher for documentation.
- Respondents should resume and complete the sequence, notifying the researcher upon completion.
- Respondents must repeat the aforementioned steps five times. In the first cycle, the respondent must give a hand sign 'one'. In the second cycle, the respondent must give a hand sign 'two', etc.

In addition to real-time assessments, performance testing evaluates the system's responsiveness and stability under a certain workload [34]. Different performance tests were conducted: load, stress, and soak tests. Load tests simulate the maximum number of possible users that might use an application. Reproducing realistic usage and load conditions based on response times will identify potential bottlenecks [35]. Stress testing measures the performance of a system in peak activity, which involves an increment of users during the testing. This specific test helped identify any potential vulnerabilities in the system [36]. The last type of testing would be soaking test, which increases the number of users for a longer period to detect any drop in performance levels along the run.

Reviews of the CUFS were also conducted. To gather user feedback, the CUFS was left at the designated testing facility along with a QR code leading to a Google Form. Users were prompted to share their insights on the device's performance through a series of questions, each featuring a 5-point rating scale:

- Is the CUFS's operation smooth?
- Is the CUFS easy to use?
- Is the CUFS easy to understand?
- Does the CUFS accurately detect all my choices?

On the managerial side, reviews were primarily acquired through online channels and face-to-face interviews with facility personnel. Managers had the opportunity to use the system for several days, gaining hands-on experience. Subsequently, they provided feedback on various aspects, including responsiveness, identification of bugs, user-friendliness, and suggested improvements. This multifaceted approach ensures a thorough evaluation from both end-users and managerial perspectives.

B. *Real-Time Recognition Performance*

The performance of the CUFS in recognizing hand signs, post-improvement, is presented by the confusion matrices in Fig. 11. Two background scenarios were analyzed: simple (uniform) and complex (dynamic). The simple background does not contain any objects, while the complex background contains objects with various colors. A total of 30 hand inputs coming from six users (each contributed five hand sign) were collected for each class, resulting in 150 hand inputs for each background scenario. Each of the user have varied skin tone from dark to pale. The average accuracy, precision, recall, and F-1 score have been computed to assess the overall recognition performance (Table I). Results show that the CUFS achieved impressive accuracy levels, with more than 93% accuracy in simple and complex backgrounds. The CUFS also demonstrated high precision, recall, and F-1 scores across both background scenarios. This consistency highlights the CUFS's reliability in correctly identifying hand signs and its ability to minimize false detection.

Further analysis reveals that most discrepancies observed are attributed to variations in the reviewer's response attitude. Certain reviewers did not form the hand shape properly and made intermittent or sudden changes when giving the response. Though slight, the decrease in performance metrics in complex backgrounds points to the system's sensitivity to background variations. This sensitivity suggests a potential area for improvement, particularly in enhancing the system's ability to distinguish hand signs from visually noisy backgrounds. While the system performs well in controlled settings, its application in real-world scenarios, where background complexity and user behavior are less predictable, may present challenges. Understanding the limitations in these contexts is crucial for further development and deployment of the CUFS.

C. *System Performance*

The system device, operating on a Raspberry Pi, exhibits efficient resource utilization. The application, primarily running the hand recognition solutions, consumes an average of 42% of the CPU processing resources, as anticipated. This usage aligns with the computational demands of the machine learning algorithms employed. In terms of memory utilization, the system operates justly, utilizing only approximately 170.1 MB during runtime.

This accounts for less than 10% of the total available memory on the Raspberry Pi 4, indicating a well-optimized use of resources. Moreover, the storage footprint is minimal, with only 338.3 KB utilized for this project. This represents the lowest utilization among the system's resources, highlighting an efficient design that minimizes storage requirements while maintaining the necessary functionality. Table II records the resource utilization of the UFD.

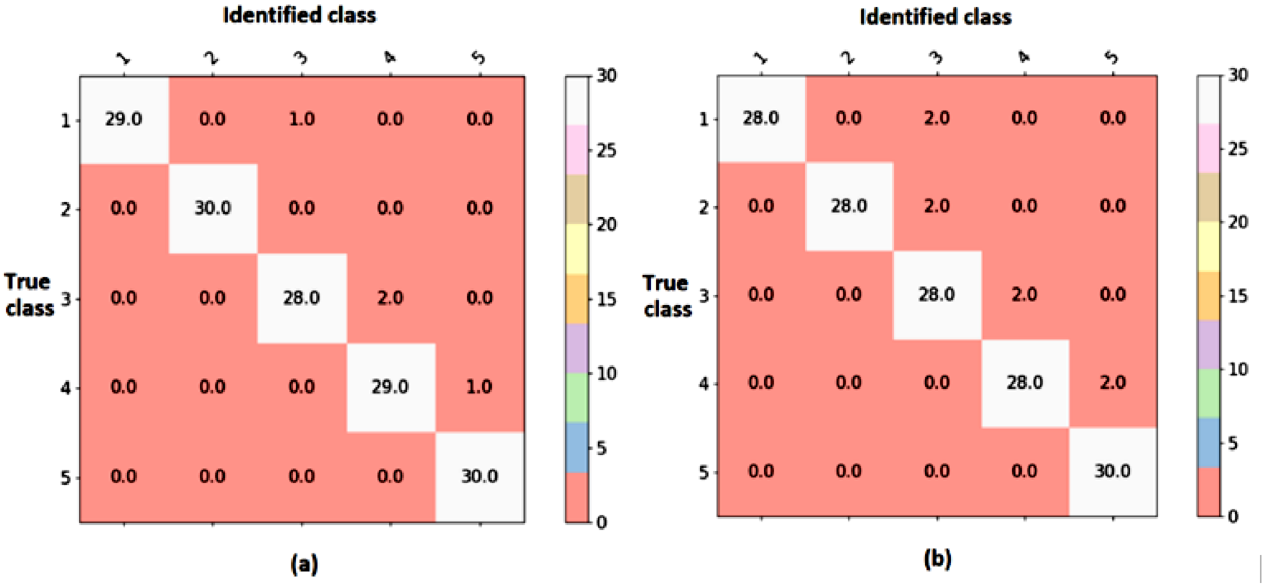

Fig. 11. Confusion matrices for (a) Simple background and (b) Complex background.

TABLE II. REAL-TIME RECOGNITION PERFORMANCE

Background	**Simple**						**Complex**					
Class	***1***	***2***	***3***	***4***	***5***	***Average***	***1***	***2***	***3***	***4***	***5***	***Average***
Accuracy	0.967	1.000	0.933	0.967	1.000	0.9734	0,933	0,933	0,933	0,933	1.000	0.9464
Precision	0.967	1.000	0.917	0.933	0.983	0.960	0.933	0.933	0.867	0.900	0.967	0.920
Recall	0.967	1.000	0.933	0.966	1.000	0.973	0.933	0.933	0.933	0.933	1.000	0.946
F-1 score	0.967	1.000	0.922	0.944	0.988	0.964	0.933	0.933	0.889	0.911	0.978	0.929

The soak test involved assessing the device's prolonged functionality under continuous operation to identify potential errors over an extended period. This test was conducted by leaving the device operational overnight, and it demonstrated robust performance, operating without any noticeable issues. Evaluating stress testing outcomes is intricate because this process typically involves multiple programs with diverse requests. It is essential to note that the current system has only one prototype available for testing, limiting the ability to comprehensively analyze requests from multiple users. Most reviews gathered for the CUFS were verbal, involving six users. They agree on the system's responsiveness and user-friendly interface. However, some expressed concerns about the small screen size and challenging font readability. Additional feedback included complaints about color schemes, styles, overall size, and minor features. In response to this feedback, specific enhancements were made, incorporating the addition of page numbers, a color indicator highlighting the current answer, and adjustments to font size.

The results confirm the effectiveness of the enhanced system development, as outlined in the methodology, which incorporates hardware and software modifications. The parallel multi-threading implementation has successfully addressed the low frame rate issue during the camera input display. Additionally, improvements in lighting, finger calculation, and the mod selection algorithm have notably boosted detection accuracy. Transitioning from a static image to a dynamic question format, editable by administrators, adds flexibility to the graphical user interface. Furthermore, the inclusion of page selection and robust data validation enhances the system's functionality. A summary of the comprehensive enhancements is provided in Table III, illustrating significant advancements in both features and overall system performance for the contactless user feedback device and the mobile application.

IV. CONCLUSION

This paper presents an innovative Contactless User Feedback System (CUFS) designed to enhance user interaction and feedback reliability. Using Raspberry Pi 4B+ microcomputer, Pi Camera V2, and MediaPipe for hand shape interpretation, the CUFS successfully integrates hardware and software components. Despite initial image quality and responsiveness challenges, the study systematically addresses these issues through a series of improvements. Post-testing refinements, including optimized lighting for improved image quality, parallel multi-threading for enhanced responsiveness, and a data validation mechanism, underscore the commitment to refining the CUFS's performance. Real-time recognition performance and comprehensive system testing further validate the effectiveness of these enhancements. User feedback in real-time assessments and reviews has been pivotal in shaping the system's evolution, highlighting the CUFS's responsiveness to end-users needs. In addition, adjustments based on user insights, such as font size, color schemes, and feature enhancements, demonstrate a user-centric approach. The CUFS study contributes valuable insights into human-computer interaction, offering a comprehensive understanding of challenges, innovative solutions, and iterative improvements necessary for developing reliable and user-centric feedback mechanisms. Future considerations should encompass scalability assessments and a broader exploration of system generalizability to different environments and user demographics.

TABLE III. RESOURCE UTILIZATION OF THE USER FEEDBACK DEVICE

	Resources		
	Average CPU Utilization (%)	***Memory Usage (MB)***	***Storage Size (KB)***
Min	32%	169.0	-
Max	43%	171.0	338.3
Mean	42%	170.1	-

***Abstract*—With the increasing demand for human-computer interaction and the development of emotional computing technology, facial expression recognition has become a major focus in research. In this paper, an improved VGG19 network model is proposed by involving enhancement strategies, and the facial expression recognition process with the improved VGG19 model is provided. We validated the model on FER2013 and CK+ datasets and conducted comparative experiments on facial expression recognition accuracy among the improved VGG19 and other classic models, including the original VGG19. Instance tests were also performed, using probability histograms to reflect the effectiveness of expression recognition. These experiments and tests demonstrate the superiority, as well as the applicability and stability of the improved VGG19 model on facial expression recognition.**

Keywords—Facial expression recognition; deep learning; VGG19 model

I. Introduction

Emotional recognition is a dynamic process aimed at understanding a person's emotional state, meaning the feelings corresponding to each individual's behaviour vary [1]. Generally, people express their emotions in different ways. To ensure meaningful communication, accurate interpretation of these emotions is essential [2]. Facial expressions are a primary means by which people convey emotions [3-6]. Mehrabian [7] observed that 7% of knowledge is transmitted between people through writing [8], 38% through voice, and 55% through facial expressions. Ekman and Friesen published the Facial Action Coding System (FACS) in 1978, which describes the seven main facial expressions people express without language, such as fear, detachment, surprise, disgust, good fortune, sincerity, and neutrality. This system is considered the threshold for Facial Expression Recognition (FER) [9].

Various applications involve understanding human emotions through facial expressions, including human-computer interaction, robotics, and healthcare [10-12]. However, emotion recognition in our daily lives is important for social contact, as emotions play a significant role in determining human behaviour [13].

In the field of school education, the emotional state of elementary school students can be immediately interpreted through Facial Expression Recognition (FER). It allows teachers to recognize their students' academic interests, including appropriate teaching methods to improve teaching efficiency [14]. Monitoring the analysis process of human posture over a period is crucial, for example, in museums where visitors can reflect on and explore what they see through this method. Expressions such as "neutral, surprise, fear" will be adjusted. This action provides basic semantic details and temporal structure to determine the category of speech signal [15].

Additionally, facial expression recognition is widely applied in other areas, such as lie detectors, smart healthcare, and so on [16].

In summary, facial expression recognition technology has broad applications and important significance in today's society [17]. It plays a positive role in improving human-computer interaction experience, enhancing intelligence levels, and improving quality of life.

In recent years, deep learning has been widely applied in facial expression extraction, such as FNN (feedforward neural network), CNN (convolutional neural network), etc. CNN-based image recognition methods have achieved good results. The multi-layer convolutional networks of CNN can effectively extract high-level, multi-level features of the whole face or part of the face, and achieve good face classification. Experimental results show that compared to other neural networks, CNN has better image recognition capabilities. The VGG network model, as an excellent representative of CNN, has been widely used in research and applications of facial expression recognition by many researchers [18]. VGG19 is a larger convolutional neural network model that contains 19 convolutional and fully connected layers and therefore requires larger storage and computational resources. In addition, due to the fact that VGG19 has more parameters and a deeper network structure, it is prone to overfitting, especially in face expression recognition applications, where the dataset is usually small, which can easily lead to a model that performs well on the training set but overfits on the test set. This paper will make improvements on the model design and loss functions of the original VGG19 model in the VGG network, as well as conduct the corresponding comparative experiments and applications.

II. Improved VGG19 Model

A. Modelling Design

An improved VGG19 model based on deep convolutional neural network is designed for feature extraction and decision making.

1) Each small piece in the improved VGG19 consists of the following components: A convolutional layer for feature

*Corresponding author

extraction, a BatchNorm layer for accelerating the training process and increasing the convergence speed of the network, a relu layer for introducing nonlinearities to enhance the model representation, and an average pooling layer for reducing the spatial dimensionality and extracting features. These components interact with each other and together build the deep structure of the VGG19 network, enabling efficient feature extraction and classification of images.

2) A dropout strategy is introduced between the final convolutional layer and the fully-connected layer, and this strategy allows the model to maintain a stable performance on new data, significantly enhancing the robustness of the model.

3) Instead of using several fully-connected layers, we ended up adding just one fully-connected layer, then another fully-connected layer, and used softmax to classify the input into one of seven expression categories involving: anger, disgust, fear, happiness, sadness, surprise and neutral.

Fig. 1 illustrates the structure of the improved VGG-19 model.

Fig. 1. The architecture of the improved VGG-19 model.

B. Loss Function Design

During the design process, the cross-entropy loss function is employed for calculations. A softmax layer is used to normalize the output probabilities of each class from the fully connected layer to 1, making data processing easier. Calculating the cross-entropy loss function is shown as Formula (1).

$$J(\theta) = -\frac{1}{m}\sum_{i=1}^{m}\left[y^{i}\log\left(h_{\theta}(x^{i})\right) + (1-y^{i})\log\left(1-h_{\theta}(x^{i})\right)\right] \quad (1)$$

In Formula (1), x^i represents the data for each category, y^i represents the correct answer for each category, $h_\theta(x^i)$ represents the predicted value obtained after processing with the improved VGG-19, and m represents the number of categories.

For the softmax regression multi-classification problem, this section solves it by using the normalized probabilities. The class label y can take k different values.

We use cross-entropy as the loss function, which corresponds to the softmax classifier we choose in the last layer. The softmax classifier is a logical classifier that is oriented towards multiple classes. Its normalized classification probabilities are more direct and sum up to 1. Cross-entropy can to some extent solve the problem of noisy labels [19], and using cross-entropy error functions can speed up training and have better generalization effects than sum-of-squares function [20].

III. Face Expression Recognition Process with Improved VGG19 Model

As shown in Fig. 2, the image is first taken as input and undergoes preprocessing including face alignment, data augmentation, normalization, etc. The resulting data is then fed into our improved VGG19 network model, which is trained on emotion class labels obtained from datasets such as CK+ and FER2013. After training, the best improved VGG19 model is obtained, and the model is then evaluated and tested. From the emotion input to the model's prediction output, scores are obtained for each category, and the final prediction is made based on the highest score value to obtain the result of emotion classification.

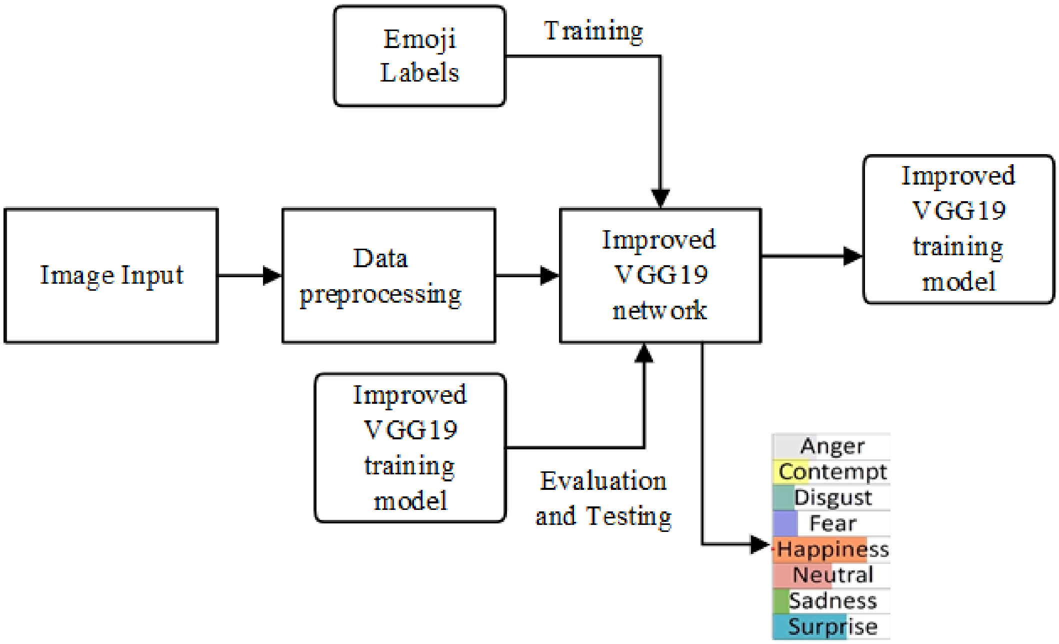

Fig. 2. Facial expression recognition process of the improved VGG19 model.

IV. Design of Experiments

A. Experimental Environment

The computer operating system used for the experiments in this paper is Windows 10，64-bit, 16G RAM. The CPU is 11th Gen Intel(R) Core(TM) i7-11800H @ 2.30GHz, the GPU is NVIDIA GeForce RTX3060 with 8G of graphics memory. The Python version used is 3.6, the deep learning framework is Pytorch 1.1, the CUDA version is 11.8, and the Python IDE is Pycharm version 2022.1.2. The specific hardware and software configurations are shown in Table I.

TABLE I. Experimental Hardware and Software Configuration

Items	Configuration
operating system	Windows10
RAM	16GB
CPU	Intel Core i7-11800H
GPU	NVIDIA RTX3060
graphics memory	8G
software framework	Anaconda Pytorch1.1
Python	3.6
CUDA	11.8
Main usage libraries	Numpy，H5py，Sklearn

B. Dataset

FER2013 and CK+ datasets were chosen for the experiments.

The FER2013 database is derived from the Representation Learning Challenge of 2013 ICML. FER2013 is a large, unrestricted database of all images registered through Google's Image Retrieval API and resized to 48*48 pixels after eliminating mislabelled frames and adjusting the cropping region. FER2013 has 28709 training images, 3589 validation images and 3589 test images with seven expressions including: anger, disgust, fear, happiness, sadness, surprise and neutral as shown in Fig. 3. Some of these images have watermarks and noise etc., as shown in Fig. 4.

The Cohn-Kanade (CK+) database, released in 2010, is an extension of the CK database. It is the most extensive laboratory-controlled database for evaluating FER (Facial Expression Recognition) systems. CK+ includes 123 subjects and a total of 593 video segments, ranging from 10 to 60 frames in length. These videos contain 327 sequences labeled with seven basic expression labels: anger, contempt, disgust, happiness, fear, surprise and sadness. The labels are based on the Facial Action Coding System (FACS). That is to say, compared with the FER2013 dataset, it replaces neutrality with contempt. Since CK+ does not provide a specific training set, validation set, and test set, the evaluation methods for this database are not unified. Fig. 5 shows some examples of expressions in the CK+ dataset.

C. Data Processing

To enhance the data used in this section and maximize the avoidance of overfitting, we enhanced the robustness of our predictions by performing data augmentation. Specifically, for each original image with a size of 48×48, we randomly created 10 cropped images with a size of 44×44. In addition, we also collected 10 processed images for each facial expression, which are cropped from the upper left, lower left, upper right, lower right, and center, and then their reflections are extracted from each cropped image for testing. To reduce classification errors, we used the average score of the 10 images as the final result.

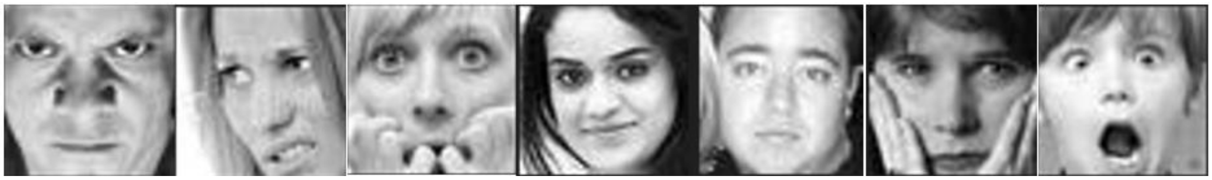

Fig. 3. FER Examples of dataset expressions (anger, disgust, fear, happiness, neutral, sadness, surprise).

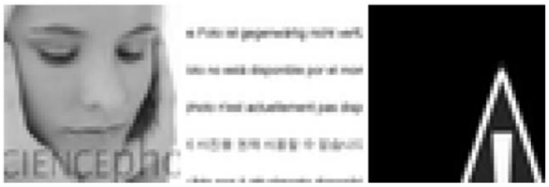

Fig. 4. Example of noise in the FER2013 dataset.

V. Experimental Results and Comparative Analysis

A. Experimental Analysis of Improved VGG19 vs. VGG19

As shown in Table II, the improved VGG19 model exhibits better accuracy on the FER2013 dataset compared to the original VGG19 model. The accuracy of the improved VGG19 model on the public and private FER2013 datasets is 70.911% and 73.029% respectively, and higher than that of original VGG19 model. The learning rate for the experiments was set at 0.01, with 250 epochs for the FER2013 dataset and 60 epochs for the CK+ dataset.

TABLE II. Comparison of Recognition Accuracy of VGG19 and Improved VGG19

Model	FER2013 public dataset	FER2013 private dataset
VGG19	68.821%	70.995%
Improved VGG19	70.911%	73.029%

B. Comparative Experiments on the FER2013 Dataset

Based on FER2013 dataset, we compared the accuracy in face expression recognition of the improved VGG19 network model and the top ten algorithms in the 2013 Kaggle facial expression recognition competition as well as DNNRL[21], CPC [22] methods, as shown in Table III.

According to Table III, the improved VGG19 network model presented in this paper achieved an impressive facial expression recognition accuracy of 73.029% on the FER2013 dataset. This result surpasses the accuracy of the top ten algorithms from the 2013 Kaggle competition, as shown in the first ten rows of Table III. It also outperforms the recognition effects of the DNNRL and CPC network structures, which are newer models listed from rows 11 to 12. The comparison clearly indicates that the improved VGG19 model has a significant advantage in accuracy.

The reason for such an achievement is the introduction of a Batch Normalization (BN) layer into the original VGG19 network structure. Additionally, a Dropout strategy is applied between the final convolutional layer and the fully connected layer. These enhancements effectively prevent overfitting issues that can arise from the deep nature of the network and also improve the training convergence speed of the model.

TABLE III. Accuracy of each Method on the FER2013 Dataset

	Method	Accuracy
1	RBM	71.161%
2	Unsupervised	69.267%
3	Maxim Milakov	68.821%
4	Radu+Marius+Cristi	67.483%
5	Lor.Voldy	65.254%
6	Ryank	65.087%
7	Eric Cartman	64.474%
8	Xavler Bouthller	64.224%
9	AlehandroDubrovsky	63.109%
10	Sayit	62.190%
11	DNNRL	70.60%
12	CPC	71.36%
13	Improved VGG19	73.029%

C. Comparative Experiments on the CK+ Dataset

Table IV clearly shows the accuracy of different methods for facial expression recognition on the CK+ dataset. The improved VGG19 model addresses the issue of overfitting, which can occur due to the small scale and limited number of samples in the CK+ dataset, by employing Dropout and Batch Normalization (BN) strategies.

For the CK+ dataset, we used a tenfold cross-validation method. The dataset is randomly divided into 90% for training and 10% for testing. The highest accuracy achieved in the tests is 93.939%. As can be seen from the comparative results in Table IV, although the accuracy of the improved VGG19 network model is not the highest, it has reached a relatively high level.

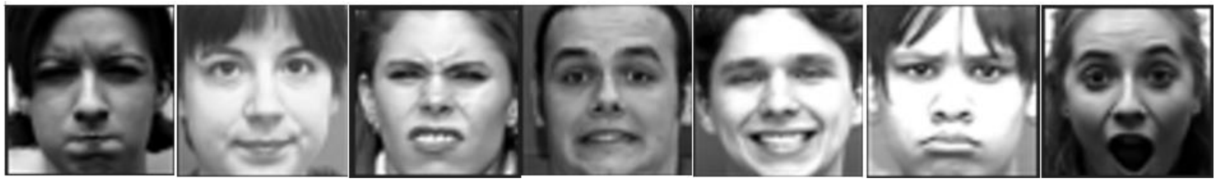

Fig. 5. Examples of expressions from the CK+ dataset (anger, contempt, disgust, fear, happiness, sadness, surprise).

Looking at Tables III and IV, there is a significant difference in the training effects of the improved VGG19 model on the FER2013 and CK+ datasets, with a considerable gap in recognition rates. Moreover, the results on the CK+ dataset are notably better than those on the FER2013 dataset. The CK+ dataset was obtained in a laboratory environment, where factors such as background lighting and camera quality were controlled and standardized, making the dataset cleaner and more reliable. As a result, samples are more easily recognized accurately. Additionally, the dataset has undergone augmentation, resulting in higher image quality. Therefore, the algorithm has demonstrated a high facial expression recognition accuracy on the CK+ dataset.

TABLE IV. ACCURACY COMPARISON ON THE CK+ DATASET

Method	Accuracy
Shan et al.[23]	89.1%
Jeni et al. [24]	96%
Kahou et al.[25]	91.3%
Improved VGG19	93.939%

D. *Confusion Matrix Analysis*

Fig. 6 illustrates that the accuracy for recognizing happiness and surprise is higher than for other emotions. However, the accuracy for recognizing fear is somewhat lower. There are two reasons for this issue.

Firstly, the dataset has an imbalance in the number of images with different emotion categories. There are as many as 7,215 images for happiness, but only 436 for disgust, while the average number of images for each category is around 4,000. Such an imbalance is sufficient to cause classification errors.

Secondly, some emotions have connections with each other. For instance, anger, disgust, fear, and sadness are often difficult to distinguish in real life, especially when people do not know each other well. Furthermore, misjudgments often occur with certain categories, perhaps because some categories are indeed hard to differentiate and are easily confused.

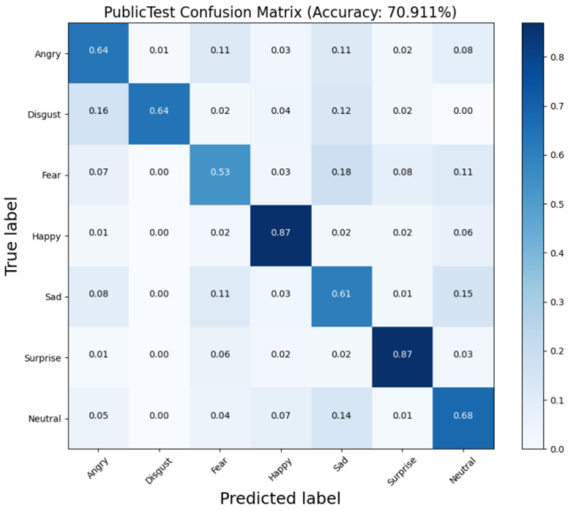

Fig. 6. Confusion matrix for the improved VGG19 model on the FER2013 PrivateTest dataset.

The next research direction will focus on modules that pay attention to specific expressions. By focusing on detailed information, the classification ability of the model can be further improved, providing more support for enhancing classification accuracy.

VI. EXAMPLE TEST

We conducted a facial expression recognition experiment using the improved VGG19 neural network and validated it. After training the best model on the FER2013 dataset, we tested it on test images to obtain the probabilities of various expressions. The probabilities of the images in each category and the model's predictions were visualized. The specific verification process includes as follows.

1) Input the test image into the improved VGG19 network to get the corresponding predicted values through the network's forward propagation.

2) Use the cross-entropy loss function to find the difference between the predicted values and the actual values.

3) Update the parameters of the network model at various levels using the backpropagation method.

Fig. 7 shows the specific test results for one of the test examples. The image of a sad expression, when identified and classified by the improved VGG19, yielded a fear probability of 0.2, a sadness probability of 0.7, and a minimal probability of neutrality. Since the highest probability was for sadness, the model outputted a sad expression, which is consistent with the test image. The analysis process for other expression examples such as Fig. 8 is similar to that shown in Fig. 7.

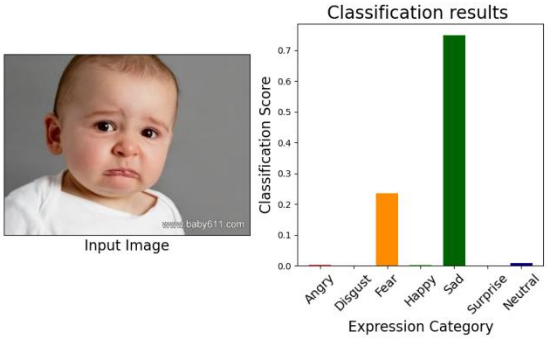

Fig. 7. Example of a sad expression.

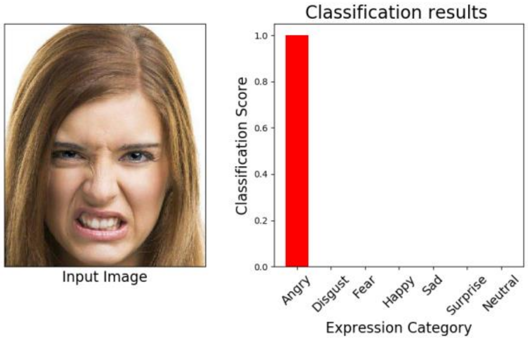

Fig. 8. Example of an angry expression.

VII. Conclusion

This paper provides an in-depth exploration of facial expression recognition and its applications using an improved VGG19 model. We designed the structure of the improved VGG-19 model involving enhancement strategies as well as the loss function, and describe facial expression recognition process with the improved VGG19 model. In the experimental design section, we detailed the selection of the dataset and the methods of data processing. In the section on experimental results and comparative analysis, we conducted comparative experiments on accuracy between the improved VGG19 and other classic models, including the original VGG19. We also performed instance tests, using probability histograms to reflect the effectiveness of expression recognition. These tests demonstrate the superiority, applicability, and stability of the improved VGG19 model. However, the accuracy of distinguishing some expressions, such as sadness, disgust and fear, could be improved. In this regard, future directions could focus on designing sub-networks for each expression that are dedicated to recognising specific expressions. For example, specific sub-network structures are designed for sad and upset expressions to better capture the features of these expressions.

Application of Optimizing Multifactor Correction in Fatigue Life Prediction and Reliability Evaluation of Structural Components

Yi Zhang
Department of Hydraulic Engineering, Henan Vocational College of Water Conservancy and Environment,
Zhengzhou, 450000, China

***Abstract*—Multi factor correction is optimized for fatigue life prediction and reliability evaluation of structural components. Based on the optimization of Bayesian theory, reliability evaluation is carried out to improve the efficiency of fatigue life prediction and reliability evaluation of structural components. The research results indicate that the crack propagation length increases with the increase in loading time. The average probability density of the modified method is 3.628, while the probability density of the traditional fracture mechanics model is 1.242. Based on the multi factor modified crack propagation prediction model, the predicted data accuracy exceeds the traditional fracture mechanics model. It is consistent with the experimental results. The crack propagation prediction model based on multi factor correction can ensure the accuracy of the prediction. The reliability of the model is evaluated. The average prediction accuracy of multiple sets of data is over 90%. This research method helps predict the fatigue life of structural components and evaluate reliability to ensure the safe operation of construction machinery.**

Keywords—Multi factor bayesian theory correction; structural components; fatigue life; reliability; Bayesian theory

I. Introduction

A. Research Background

Industrial machinery is an important equipment of modern industry and an indispensable core part of the machinery, shipbuilding and other industries. However, with the increasing complexity of construction machinery and the harsh service environment, the fatigue life and reliability of structural parts are increasingly prominent. In this case, accurate prediction of fatigue life and reliability assessment of structural components are particularly important [1]. Due to its large weight and high labor intensity, the minor failure of construction machinery structural parts will cause great losses, and even threaten personal safety in serious cases [2]. If the health status of the equipment is not fully considered and the life of the equipment is regarded as the standard, the blanket elimination of the equipment will lead to a great waste of resources [3]. However, due to the joint action of multiple factors such as material defects and local stress concentration, the damage process of structural parts has been expanded from microscopic to macroscopic, from cavity formation to growth, and from unknowable to observable. The influencing factors span time and space, including known and unknown, and the multi-scale comprehensive effect will have a multi-faceted impact on the evaluation results [4].

B. Research Status

In the existing studies, only the influence of a single factor on the life of structural parts is generally considered, and the evaluation results of this evaluation method are not comprehensive enough. The multi-factor correction method has also been paid more attention, but there are still some limitations. For example, traditional multi-factor correction methods tend to consider only a few major influencing factors and ignore other potential influencing factors. In addition, traditional correction methods are often based on empirical formulas or simple mathematical models, and it is difficult to accurately describe the complex variation laws of fatigue life and reliability of structural parts [5-6].

C. Research Content

Aiming at the limitations of existing studies, this study improved the multi-factor correction to improve the prediction and evaluation accuracy and constructed a fatigue life prediction and reliability evaluation method based on multi-factor optimization and modification. The purpose of this method is to grasp the health state of the structural parts in the process of mechanical production and maintain them in time. The innovation of the research is to predict the life of structural parts from multiple factors and introduce Bayesian theory to optimize the reliability evaluation results.

This research is mainly divided into six sections. Section II is a literature review, introducing the relevant research content of scholars in different fields. Section III is the research method, mainly introducing the fatigue life prediction and reliability evaluation of structural parts based on optimized multi-factor repair. Section IV and Section V are the result analysis, which explains the application analysis of optimized multi-factor correction in fatigue life prediction and reliability evaluation of structural parts. Section VI is the conclusion, and points out the future research direction. A structured roadmap of research content is shown in Fig. 1.

II. Related Works

The failure of construction machinery components may cause serious harm. Therefore, the research on FL prediction and reliability evaluation is very important. Due to the high working intensity and high use frequency of structural components, reliability has always been the focus of research in this field. Scholars in different fields have carried out a lot of research and achieved good results.

Kaplan h proposed a new IOT fatigue damage sensor system for residual FL prediction of key mechanical and structural components, which can estimate the cumulative fatigue damage and residual FL. According to the findings, it has high prediction accuracy, which is conducive to checking the operation of structural parts at any time [7]. Prakash designed a probability model based on the Palmgren-Miner rule to better evaluate the fatigue state of ageing infrastructure. Bayesian method is used to estimate the parameters. Markov chain Monte Carlo simulation is applied to predict the FL. According to the findings, it can effectively improve the residual FL prediction accuracy of bridge components [8]. Su and other scholars predicted the FL of steel bridges. Based on the equivalent structural stress, a general fatigue reliability calculation model is established. The practicability and effectiveness of the fatigue reliability model are verified by numerical calculation and sensitivity analysis. It can better solve the classification problem that is difficult to determine in the random FL assessment of steel bridge welded structures [9]. The high pole lamp pole is easy to be affected by the wind load, which causes the fatigue failure of the whole life cycle. Therefore, Tsai l w et al. carried out the FL assessment of the base-pipe joint under the wind load. On this basis, the damage fraction under wind load is used to evaluate the FL of different structural parts. According to the findings, it can provide a general framework for designers and producers to develop high-pole lighting pole equipment [10]. Klemenc and other scholars designed a step-stress accelerated life test to test the FL and structural component reliability of main failure modes. The expected acceleration factor is checked. The experimental results show that the predicted step stress accelerated life test duration has a good correlation with the actual experiment [11].

According to the specific reliability requirements of the current wind turbine life, Nielsen j s et al. proposed a risk-based derivation method for the specific target reliability level of wind turbine life extension. The experimental results show that the target annual reliability index is close to 3.1 [12]. Leonetti and other researchers designed a probabilistic FL prediction model based on S-N curve to evaluate the safety level of non-load bearing cross joints. The results show that the reliability index can be increased by 0.5:1 by using this model, which is conducive to the safety evaluation [13]. To test the fatigue characteristics of the laminated chip assembly under thermal cycle load, Li et al. developed a laminated chip assembly with multiple packaging methods and different chip positions. Through creep FL prediction models under various stress states, the FL of chips is evaluated. The outcomes indicated that the stress of the top mount solder joint is much smaller than that of the bottom mount solder joint. The middle position of the inner ring of the solder joint has the maximum value [14]. To evaluate the reliability of offshore wind turbine support structures with pitting fatigue, Shittu et al. used the damage tolerance modeling method to evaluate the reliability of such structures with pitting fatigue. A non-invasive formula consisting of a series of steps is proposed. At a certain size, the height and width of the pit have a great influence on the structural reliability [15].

From the above research, the FL prediction and reliability evaluation of structural parts are conducive to promoting the safe operation and stability of construction machinery. Then the above studies only consider single factor, and the reliability of prediction and evaluation needs to be improved. Therefore, this study considers multiple factors for comprehensive prediction and evaluation.

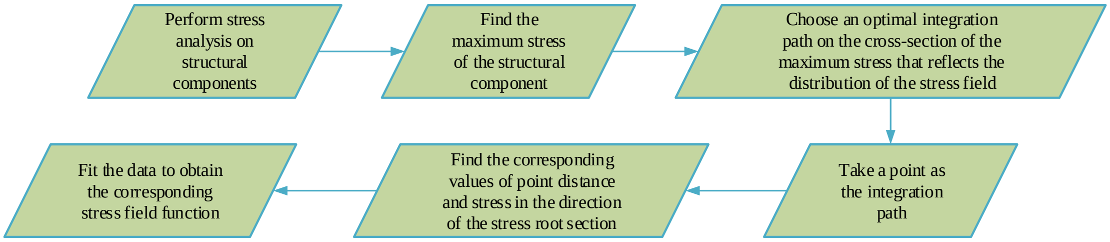
III. Fatigue Life Prediction and Reliability Evaluation of Structural Components Based on Optimized Multi Factor Correction

Through multi factor correction, the fatigue life of structural components is predicted. Based on optimized multi factor correction, the crack propagation of structural components is predicted. According to optimized Bayesian theory, reliability evaluation is carried out to improve the efficiency of FL prediction and reliability evaluation of structural components.

A. *Fatigue Life Prediction Based on Multifactor Correction*

With the continuous progress of science and technology, the understanding of fatigue issues continues to deepen. A series of FL prediction methods have been widely applied, such as nominal stress method, field strength method, etc. However, in practical applications, the nominal stress method and local stress-strain method are commonly used. The traditional nominal stress method mainly analyzes the maximum stress of the structure. Based on the maximum stress and the S-N curve of the material, the FL of the structure is predicted [16]. With the continuous development of finite element technology, the combination of traditional nominal stress method and finite element technology is an important research direction for predicting the FL of structural components under complex loads. This method has simple analysis steps, wide applicability, and strong practical value. However, due to the different fatigue characteristic parameters between structural components and material samples, it is difficult to ensure the accuracy of FL prediction between structural components and material samples. Therefore, starting from the actual characteristics of engineering components, the main controlling factors for the FL of structural components are identified and quantified. Furthermore, a set of FL prediction methods for structural components considering the combined effects of multiple factor corrections is established.

Quantitative research on the impact of multiple factors on the fatigue performance of structural components is the basis for accurately predicting the FL of structural components. Stress concentration has a certain impact on the stress state of load-bearing structural components, which in turn affects the FL of the structure. The stress concentration factor is an important indicator that can distinguish the influence degree of stress concentration. There are two commonly used methods for obtaining stress concentration factors, namely the calculation method and the measurement method [17]. The measurement method is mainly aimed at elemental samples and is not suitable for large-sized components. The finite element method and numerical simulation method are more suitable for calculating the stress concentration coefficient of large-sized structural components. The calculation steps are shown in Fig. 2.



Perform stress analysis on structural components
Find the maximum stress of the structural component
Choose an optimal integration path on the cross-section of the maximum stress that reflects the distribution of the stress field
Take a point as the integration path
Find the corresponding values of point distance and stress in the direction of the stress root section
Fit the data to obtain the corresponding stress field function

Fig. 2. Calculation steps for stress concentration coefficient.

From Fig. 2, stress analysis is first conducted on the structural component to determine the maximum stress. An optimal integration path is selected on the cross-section of the maximum stress that reflects the distribution of the stress field. Then a point is used as the integration path to obtain the corresponding values of point distance L and stress S in the direction of the stress root section. By fitting these data, the corresponding stress field function can be obtained. The stress field function is used for calculation in Eq. (1). The nominal stress corresponding to the stress field is shown in Eq. (1).

$$S_n = \frac{\int_0^L S(L)dL}{L} = \frac{\sum_{i=0}^{n-1}\int_{L_i}^{L_{i+1}} S_i(L)dL}{L} \tag{1}$$

In Eq. (1)， $L=\sum_{i=0}^{n} L_i$. The nominal stress is taken into Eq. (2) for calculation. The stress concentration factor corresponding to the structural component is obtained.

$$K_t = \frac{S_{\max}}{S_n} \tag{2}$$

To evaluate the prediction accuracy of this method, finite element technology is used to analyze the material standard samples. The size factor of structural components is a parameter that reflects the influence of structural component size on FL. The fatigue limit relationship between structural components and materials is shown in Eq. (3) [18].

$$\sigma_{0r} = \frac{\sigma_r}{K_t}\left[f\left(x_1, x_2\right)\right]^{-1} \tag{3}$$

In Eq. (3), σ_{0r} and σ_r represent the fatigue limit of structural members and materials respectively. $f\left(x_1, x_2\right)$ is a function of the stress field near the local maximum stress. x_1 and x_2 are the coordinate parameters of the plane field respectively. The stress field function can also be expressed by the distance $L(i)$ between a point under the stress integration path in the stress field and the root of the maximum local stress, as shown in Eq. (4).

$$f\left(x_1, x_2\right) = \eta_1 + \eta_2 L(i) + \eta_3 L^2(i) + \eta_4 L^3(i) \tag{4}$$

When the materials of two components are consistent, the size factor between the two components that meet the principle of similarity is shown in Eq. (5).

$$\varepsilon = \frac{\sigma_{0r1}}{\sigma_{0r2}} \tag{5}$$

In Eq. (5), ε represents the size factor. By combining Eq. (3), Eq. (4), and Eq. (5), another representation of the size factor can be obtained, as shown in Eq. (6).

$$\varepsilon = \frac{\int_0^l \left(\vartheta_1 + \vartheta_2 L^{'} + \vartheta_3 L^{'2} + \vartheta_4 L^{'3}\right) dL^{'}}{\int_0^l \left(\eta_1 + \eta_2 L + \eta_3 L^2 + \eta_4 L^3\right) dL} \tag{6}$$

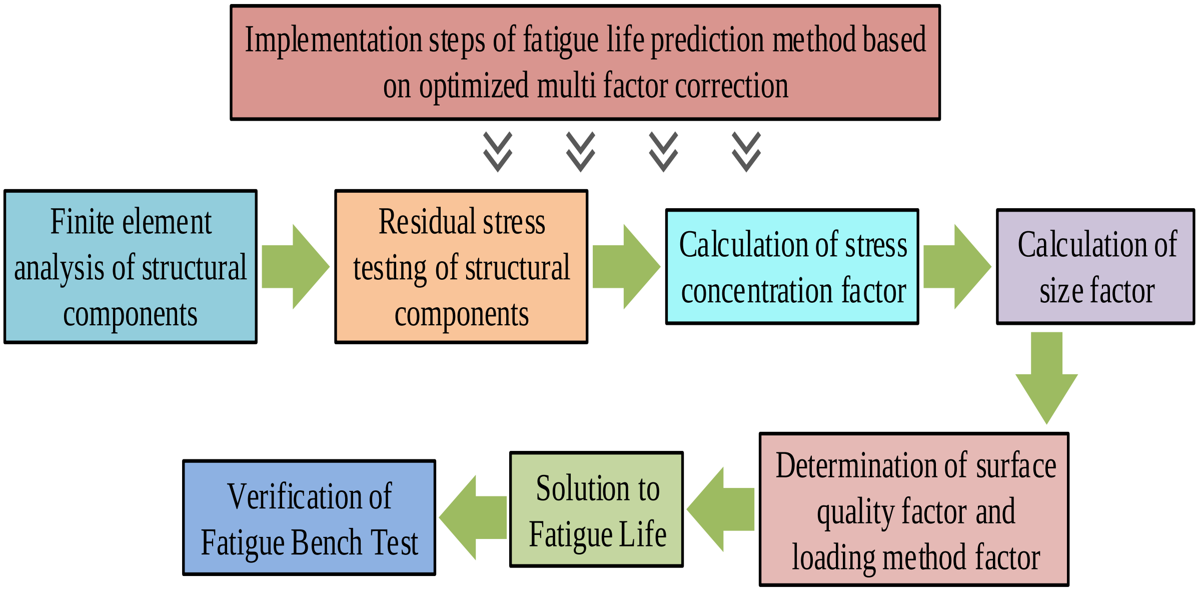
In Eq. (6), $\eta_1, \eta_2, \eta_3, \eta_4$ and $\vartheta_1, \vartheta_2, \vartheta_3, \vartheta_4$ are both coefficients in the fitting function expression. The size factor of a single component can be represented by the integral ratio between the component and the reference sample in the stress field. Different surface treatment methods not only have different effects on the stress state of components, but also have impacts on the FL of components [19]. In addition, the loading method can also affect the FL. The influence of loading method factor on loading form is corrected. The FL prediction expression based on nominal stress is generally shown in Eq. (7).

$$S^m N = C \tag{7}$$

In Eq. (7), S represents stress. N is used to describe the number of loading times for the load. m and C represent parameters related to material and stress ratio. By combining the influence of various factors and Eq. (7), a FL prediction algorithm based on optimized multi factor correction can be obtained, as shown in Eq. (8).

$$\left(\frac{S_{-1}\left[1 - \left(\sigma_m / \sigma_b\right)^2\right]}{K_t} \cdot \varepsilon \cdot \beta \cdot C_L \right)^m N = C \tag{8}$$

In Eq. (8), S_{-1} represents the material fatigue limit under symmetric loading. σ_m is the average stress, $\sigma_m = \frac{\sigma_{\max} + \sigma_{\min}}{2}$. $\sigma_{\max}$ and $\sigma_{\min}$ are the maximum and minimum values of stress, respectively. σ_b represents the tensile strength limit of the material. K_t represents the stress concentration factor. β is the surface quality factor. N represents FL. C_L represents the loading method factor. The implementation steps of the FL prediction method based on optimized multi factor correction are shown in Fig. 3.



Implementation steps of fatigue life prediction method based on optimized multi factor correction
Finite element analysis of structural components
Residual stress testing of structural components
Calculation of stress concentration factor
Calculation of size factor
Determination of surface quality factor and loading method factor
Solution to Fatigue Life
Verification of Fatigue Bench Test

Fig. 3. Implementation steps of fatigue life prediction method based on optimized multi factor correction.

From Fig. 3, during the implementation process, a finite element model of the structural component is first established and analyzed. Residual stresses in the structural components are tested. Then, stress concentration factors and size factors are calculated. Then, the surface quality factor and loading method factor are determined. After solving the FL, the fatigue bench test can be verified.

B. *Crack Propagation Prediction in Structural Components Based on Multi Factor Correction*

Crack propagation information is an important feature in the reliability evaluation of structural components. Accurately predicting crack development is crucial for grasping the reliability of structural components. However, due to structural and other factors, a crack propagation prediction model containing structural and other factors is established to quantitatively correct each influencing factor. Although existing fracture mechanics calculation methods cannot simultaneously correct multiple influencing factors, there is already a method that utilizes multiple factors to correct the S-N curve [20]. The current judgment method is based on the development of cracks to fracture as the basis for determining failure. Therefore, the traditional FL prediction method based on S-N curve cannot be applied to the crack development stage of structural components. The core issue is that it does not include parameters that reflect its development process. The multi factor joint correction method is adopted based on the failure criterion of crack development to fracture. The stress concentration coefficient is introduced to accurately describe the crack length, thereby achieving prediction of crack length. Based on the multi factor correction method for predicting the FL of structural components in the previous section, the structural factors, average stress, and other factors on the FL are quantitatively represented, as shown in Eq. (8). The failure criterion is based on the extension of cracks towards the fracture state. K_t is the only parameter in the algorithm that can be associated with the crack length a, as shown in Eq. (9).

$$K_t = \frac{\sigma_{\max}}{\sigma_n} \tag{9}$$

In Eq. (9), σ_n represents the nominal stress. The expression is shown in Eq. (10).

$$\sigma_n = \frac{\sum_{i=0}^{n-1} \int_{r_i}^{r_{i+1}} \sigma_i dr}{A} = \frac{\int_0^A \sigma_i dr}{A} \tag{10}$$

In Eq. (10), r_i represents the distance between any point in the stress field and the maximum stress position at the crack root, $A = r_{\max}$. σ_i represents the stress value at any point along the stress field path. Combining Eq. (9) and Eq. (10), the expression for the stress concentration factor can be obtained, as shown in Eq. (11).

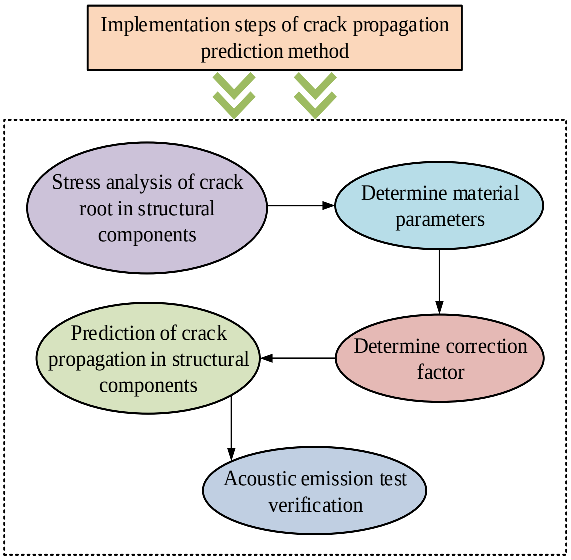
$$K_t = A \Big/ \int_0^A \frac{(a+r)}{\sqrt{2ar+r^2}} dr \tag{11}$$

By combining Eq. (8) and Eq. (9), the crack propagation length can be obtained when the working time N is specified, as shown in Eq. (12) [21].

$$S_{-1} \cdot \left[1-\left(\sigma_m/\sigma_b\right)^2\right] \cdot \left(\frac{C}{N}\right)^{-\frac{1}{m}} \cdot \varepsilon \cdot C_L \cdot \beta = A \Big/ \int_0^A \frac{(a+r)}{\sqrt{2ar+r^2}} dr \tag{12}$$

The implementation process of the crack propagation prediction model based on multi factor correction under constant amplitude load is explained, as shown in Fig. 4.

From Fig. 3, during the implementation process, the stress at the crack root of the structural component is first analyzed. Then the material parameters and correction factors are determined. Then the crack propagation of the structural component is predicted. Finally, the acoustic emission test is verified.



Implementation steps of crack propagation prediction method
Stress analysis of crack root in structural components
Determine material parameters
Determine correction factor
Prediction of crack propagation in structural components
Acoustic emission test verification

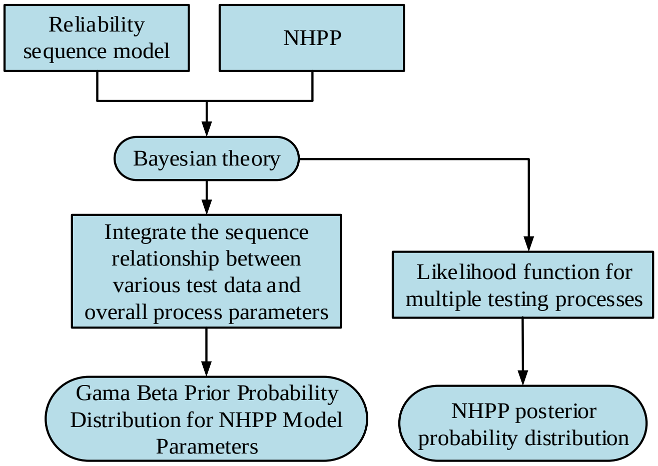
Fig. 4. Implementation steps of crack propagation prediction method.

C. *Reliability Evaluation Method Based on Optimized Bayesian Theory*

In practical applications, due to various uncertain factors, there is a deviation between the predicted results obtained by a single numerical prediction model and the actual situation. Therefore, based on the Bayesian theory of dynamic distribution parameters, existing numerical prediction models and experimental data are organically integrated. Corresponding prior and posterior probability distribution models are constructed to achieve accurate reliability evaluation of structural components. If the initial reliability of different materials is divided according to certain parameters and the ordered reliability between test data is characterized by a certain increasing coefficient, then the NHPP model based on Bayesian theory can be used to evaluate the reliability of components under different initial damage conditions.

The conventional Bayesian theory is no longer applicable to the reliability of components with cracks in different initial crack states, such as non-uniform crack situations. If a parameter based on initial reliability can be established and the ordered reliability between test data can be characterized, an ordered Bayesian model can be used to evaluate the reliability of materials in different initial states. The specific process is shown in Fig. 5.

From Fig. 5, the reliability sequence model is combined with NHPP. The sequence relationship between various test data and overall process parameters is fused through Bayesian theory to obtain a Gama Beta prior probability distribution suitable for NHPP model parameters. Then, Bayesian theory is combined with likelihood functions of multiple test processes to obtain the NHPP posterior probability distribution. Afterwards, the existing measured data is used to predict and evaluate the reliability of component crack development under different initial conditions. In this research, the stress concentration factor is selected as a parameter that reflects the reliability gradient relationship between different data values of structural components, namely the progressive factor.



Reliability sequence model
NHPP
Bayesian theory
Integrate the sequence relationship between various test data and overall process parameters
Likelihood function for multiple testing processes
Gama Beta Prior Probability Distribution for NHPP Model Parameters
NHPP posterior probability distribution

Fig. 5. Specific process of research.

The progressive factor is a very important parameter in establishing the reliability ordering relationship between data. Therefore, data statistics are conducted to determine the discreteness. $\left[\delta_{j,L},\delta_{j,U}\right]$ serves as the value space for the progressive factor to reduce the impact of calculation errors in stress concentration factors on the progressive factor. The corresponding first-order and second-order matrix expressions are shown in Eq. (13).

$$\begin{cases} E\left\{\delta_j\right\}=\dfrac{\delta_{j,U}+\delta_{j,L}}{2} \\ E\left\{\delta_j^2\right\}=\dfrac{\delta_{j,U}^3+\delta_{j,L}^3}{3\left(\delta_{j,U}+\delta_{j,L}\right)} \end{cases} \tag{13}$$

In Eq. (13), $E\left\{\delta_j\right\}$ and $E\left\{\delta_j^2\right\}$ represent the progressive factor value space considering calculation errors. In the prior distribution based on Bayesian theory NHPP, there is no conjugate prior distribution of parameters. Therefore, the main problem is to accurately describe prior information and determine prior distribution. When the initial crack is very small, two methods are usually used to construct an uninformed prior distribution, namely constructing an uninformed prior distribution, or using existing theoretical models to predict prior information. The expression for constructing an uninformed prior distribution using the Box-Tao method is shown in Eq. (14).

$$\pi(\alpha,\beta)\infty\left(\frac{1}{\beta_1\alpha^2}\right),\alpha>0,\beta_1>0 \tag{14}$$

By standardizing the description of prior information and integrating information between different types of data, Bayesian reliability sequences for different cracks are constructed. In posterior reasoning, based on Bayesian theorem and combined with group likelihood function, the posterior distribution of NHPP parameters is obtained. To further verify the feasibility and analytical accuracy of the model, fatigue loading tests were conducted on components with different initial crack lengths. Among them, the ordering relationship is the fundamental condition for the application of the model. Therefore, the sequencing relationship between the analyzed data is verified. The statistical criteria for validation are shown in Eq. (15).

$$F*=\frac{L^*_{N+1,j}-L^*_{N_i,j}}{L^*_{N+1,j+1}-L^*_{N_i,j+1}}\geq 1 \tag{15}$$

In Eq. (15), j and $j+1$ represent two data groups. $F*$ is the test statistic. $L^*_{N+1,j}$ represents the crack propagation length corresponding to the number of N_i load actions in the organized data. After satisfying the serialization relationship in the model assumption, Eq. (12) can be used to predict the crack propagation data under annotated loads.

IV. Application Analysis of Optimized Multi Factor Correction in FL Prediction and Reliability Evaluation of Structural Components

For the prediction and reliability evaluation of FL for structural components, the crack propagation under constant load and the reliability of structures under different initial crack states are analyzed to promote the reliability evaluation and safe operation of engineering machinery structural components.

A. *Prediction Analysis of Crack Propagation Under Constant Load*

The accuracy of predicting crack propagation based on multi factor correction under constant load is verified. A structural component with a crack length of 600mm, a crack width of 100mm, and a crack length of 50mm is selected as the analysis object. The crack propagation model will be calculated according to the parameters calculated in the method to obtain the crack length propagation curve. The results are shown in Fig. 6.

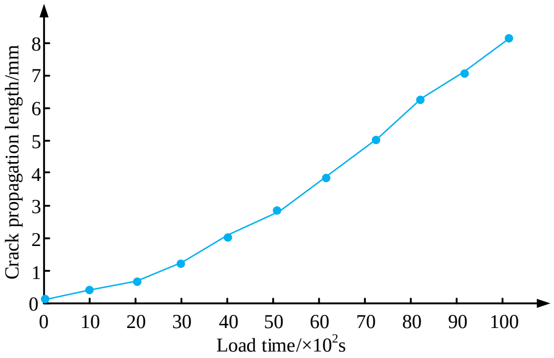


Fig. 6. Crack propagation curve based on multi factor correction.

From Fig. 6, the crack propagation length increases with increasing loading time. When the loading time is 2000s, the crack propagation length is 0.9mm. When the loading time is 10000s, the crack propagation length is 8.5mm. To analyze the accuracy of prediction, crack propagation prediction is carried out based on multi factor correction. The loading times are fixed. The results are shown in Fig. 7.

From Fig. 7(a), (b), (c), (d), and (e) represent the probability density at 2000, 4000, 6000, 8000, and 10000 loading times, respectively. The horizontal axis stands for the crack propagation length, and the vertical axis stands for the probability density. CM represents the correction method. FM stands for fracture mechanics. The curve in the figure represents the probability density distribution corresponding to the acoustic emission test data. Each crack propagation length value corresponds to a probability density value. The probability density values corresponding to the modification method and fracture mechanics method are marked in the figure. The red area represents the difference in probability distribution between the two methods. According to the analysis results, the average probability density of the modified method is 3.628. The probability density of traditional fracture mechanics models is 1.242. Based on the multi factor modified crack propagation prediction model, the accuracy of the predicted data is significantly higher than that of traditional fracture mechanics models. It is consistent with the experimental results. Therefore, a crack propagation prediction model based on multi factor correction can ensure the accuracy of the prediction.

(b) Loading times=4000

(c) Loading times=6000

(d) Loading times=8000

(e) Loading times=10000

Fig. 7. Probability density distribution of predicted data.

B. *Structural Reliability Evaluation Analysis Under Different Initial Crack States Based on Bayesian Theory NHPP*

To further verify the feasibility and accuracy of the model, crack lengths of 5mm, 10mm, and 15mm are prepared. Fatigue loading experiments are conducted on components with different initial crack lengths. The fatigue crack propagation life of the structural components is displayed in Table I. In order to evaluate the generalization ability of the model and verify its accuracy in practical applications, the method of cross-validation is used to retrain and test the model. The performance of the model is evaluated by dividing the raw data into K parts and recycling K-1 of them as training data and the remaining part as test data. In the experiment, the study chose to use 10-fold cross-validation to perform this step. The first group has an initial crack length of 5mm, the second group is 10mm, and the third group is 15mm. The sequencing accuracy is analyzed. In the initial state, the experimental data and maximum probability prediction results of the posterior process model are compared. The prediction accuracy of the test data is obtained. Table II displays the results.

The combination of known critical fracture crack length and predicted data can obtain the predicted reliability gradient process of structural components under different initial crack states. The results are shown in Fig. 8.

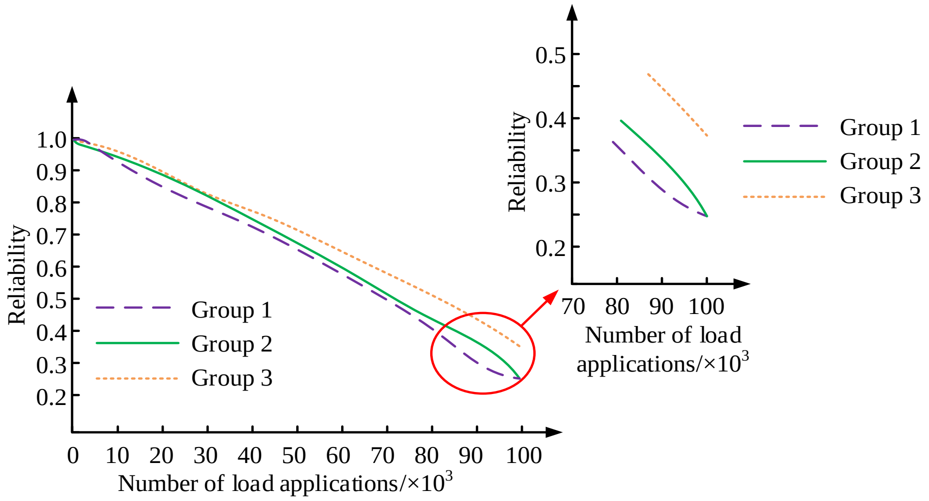

Fig. 8. The gradual process of predictive reliability of structural components under different initial states.

TABLE I. CRACK PROPAGATION INFORMATION OF COMPONENTS IN DIFFERENT INITIAL STATES

Initial crack length=5mm		Initial crack length=10mm		Initial crack length=15mm	
Number of load applications ($\times 10^4$)	Crack propagation length/mm	Number of load applications ($\times 10^4$)	Crack propagation length/mm	Number of load applications ($\times 10^4$)	Crack propagation length/mm
1	4.20	1	4.81	1	5.12
2	8.65	2	9.96	2	10.62
3	13.41	3	15.36	3	16.37
4	18.35	4	21.03	4	22.43
5	22.91	5	26.25	5	27.96
6	28.21	6	32.26	6	34.47
7	33.09	7	37.93	7	40.51
8	38.60	8	44.31	8	47.18
9	43.94	9	50.38	9	53.77
10	51.18	10	58.65	10	62.56

TABLE II. ACCURACY OF PREDICTION RESULTS

Initial crack length(mm)(Group)	Average prediction accuracy (%)
5(Group 1)	91.41
10(Group 2)	92.13
15(Group 3)	92.80

From Fig. 8, the predicted reliability of structural components under three different initial crack states decreases with the increase of load actions. When the load times are 100 ×10^3, the reliability of the first and second group of data is 0.28.

It can be seen that the reliability of the second group of data continues to decline. While the third group of data tends to be stable.

The reliability is ranked from high to low in the third group, the second group, and the first group.

C. *Structural Reliability Evaluation Results Under Different Initial Crack States*

In practical engineering, it is common to face the reliability evaluation of multiple similar structural components. Therefore, fatigue loading experiments are conducted on structural components with different initial crack lengths of 10mm, 25mm, 38mm, and 43mm. The fatigue crack propagation data of structural components are illustrated in Table III.

In Table III, the first group has an initial crack length of 10mm, the second group is 25mm, the third group is 38mm, and the fourth group is 430mm. Similarly, for the data in Table III, a cross-validation approach was adopted to train and test the model. Table IV displays the accuracy of the test data.

Afterwards, the known critical fracture crack length is combined with predicted data to obtain the reliability gradient process of structural components under different initial crack states, as shown in Fig. 9.

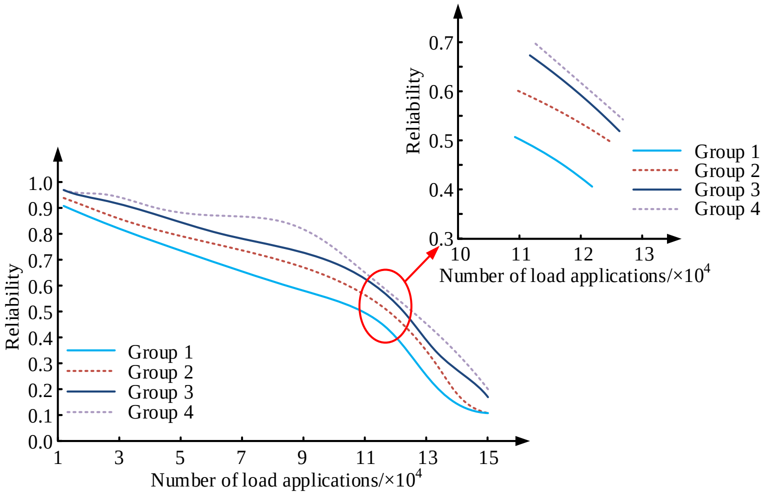

Fig. 9. Gradual process of component reliability under four different initial states of cracks.

TABLE III. CRACK PROPAGATION OF COMPONENTS CORRESPONDING TO DIFFERENT INITIAL CRACK SIZES

Initial crack length=10mm		Initial crack length=25mm		Initial crack length=38mm		Initial crack length=43mm	
Number of load applications (×10^4)	Crack propagation length/mm	Number of load applications (×10^4)	Crack propagation length/mm	Number of load applications (×10^4)	Crack propagation length/mm	Number of load applications (×10^4)	Crack propagation length/mm
1	3.92	1	6.31	1	9.24	1	10.88
2	9.16	2	14.40	2	21.15	2	21.55

13	86.75	13	92.49	13	96.35	13	98.58
14	105.89	14	112.35	14	115.18	14	123.04
15	128.91	15	130.25	15	138.63	15	146.35

TABLE V. ACCURACY OF FOUR SETS OF TEST DATA PREDICTION RESULTS

Initial crack length(mm)(Group)	Average prediction accuracy (%)
10(Group 1)	90.99
25(Group 2)	91.21
38(Group 3)	92.84
43(Group 4)	92.95

From Fig. 9, the predicted reliability of structural components under four different initial crack states decreases with the increase of the load actions. When the load times are 12×10^4, the reliability of the third set of data is almost close to that of the fourth set of data, but it is still lower than that of the fourth set of data after that. The reliability is ranked from high to low in the fourth group, the third group, the second group, and the first group.

The fatigue life prediction and reliability of structural parts are evaluated by considering many complex factors. In order to test the superiority of the multi-factor evaluation method, the performance of the study was compared with that of the single factor evaluation method. The comparative single-factor evaluation methods included initial crack length, material type, loading frequency, and ambient temperature. Under the same experimental conditions, four groups of structural parts with different initial crack lengths were predicted and evaluated by using these four single factor evaluation methods. The experimental results are shown in Table V.

TABLE VI. COMPARISON OF PREDICTION ACCURACY BETWEEN MULTI-FACTOR AND SINGLE-FACTOR EVALUATION METHODS

Initial Crack Length (mm)	Evaluation Method	Average Prediction Accuracy (%)	Evaluation Accuracy (%)
10	Single Factor (Initial Crack Length)	82.35	82.45
	Single Factor (Material Type)	84.02	83.74
	Single Factor (Loading Frequency)	80.47	80.45
	Single Factor (Ambient Temperature)	87.84	87.45
	Multi-Factor Evaluation Method	92.45	92.74
25	Single Factor (Initial Crack Length)	82.45	83.45
	Single Factor (Material Type)	83.97	84.05
	Single Factor (Loading Frequency)	80.42	80.94
	Single Factor (Ambient Temperature)	87.15	87.84
	Multi-Factor Evaluation Method	92.48	93.05
38	Single Factor (Initial Crack Length)	82.48	82.01
	Single Factor (Material Type)	83.89	84.94
	Single Factor (Loading Frequency)	80.74	90.14
	Single Factor (Ambient Temperature)	87.56	85.74
	Multi-Factor Evaluation Method	93.08	94.78
43	Single Factor (Initial Crack Length)	82.84	82.41
	Single Factor (Material Type)	82.97	83.06
	Single Factor (Loading Frequency)	80.15	81.15
	Single Factor (Ambient Temperature)	87.45	88.01
	Multi-Factor Evaluation Method	92.56	92.45

It can be seen from Table V that under any initial crack length, the prediction accuracy of the multi-factor evaluation method is higher than that of the single-factor evaluation method. This shows that considering the combined influence of many factors is very important to accurately predict the fatigue life and reliability of structural parts. Especially in the complex working environment and variable load conditions, the single factor evaluation method often cannot fully reflect the actual state of the structural parts, while the multi-factor evaluation method can more accurately describe the performance change and reliability gradient process of the structural parts.

V. THE RESULTS OF THE RESEARCH

In the process of crack growth prediction analysis under constant load, it is found that the crack growth length increases with the increase of loading time. When the loading time was 2000s, the crack growth length was 0.9mm, and when the loading time was 10000s, the crack growth length was 8.5mm. This indicates that the crack growth rate is not linear, but the crack growth rate is slow at the initial stage of loading, and then gradually accelerates. In order to better understand this nonlinear crack growth process. Under different loading times, the predicted probability density value of CM is significantly higher than that of FM, and the average probability density number of the modified method is 3.628, while the probability density number of the traditional fracture mechanics model is 1.242. Based on the multi-factor modified crack growth prediction model, the predicted data accuracy is significantly higher than that of the traditional fracture mechanics model. In reliability evaluation analysis, the longer the initial crack length, the higher the reliability. In comparison with the experimental results of other methods, the prediction accuracy and reliability evaluation accuracy of the proposed method are both above 90%, which are 92.64% and 93.26%, respectively. In conclusion, the multi-factor evaluation method has obvious superiority and wide application prospect in the fatigue life and reliability evaluation of structural parts.

VI. Conclusion

Construction machinery is important in the "the Belt and Road" initiative. With the advancement of modernization construction, its development prospects are still broad. Continuously improving the safety and reliability of construction machinery can better support national economic development and ensure that it plays a positive role in the application of various industries. The operational safety and stability of construction machinery are crucial for the economic benefits of enterprises and the safety of personnel. For predicting and evaluating the FL of structural components, multiple complex factors need to be considered. It is a challenge that must be faced in practical engineering. Multiple factors are modified for predicting the FL and reliability evaluation of structural components. According to the research results, the crack propagation length increases with increasing loading time. When the loading time is 2000s, the crack propagation length is 0.9mm. When the loading time is 10000s, the length is 8.5mm. In the process of single-factor and multi-factor comparison, the prediction accuracy and evaluation accuracy of multi-factor reached 92.64% and 93.26%, respectively. Moreover, in the comparison experiment between the modified method and the traditional fracture mechanics model, the average probability density number of the modified method is 3.628, while the probability density number of the traditional fracture mechanics model is 1.242. Based on the multi-factor modified crack growth prediction model, the accuracy of the predicted data is significantly higher than that of the traditional fracture mechanics model, and is consistent with the experimental results. The crack propagation prediction model based on multi factor correction can ensure the accuracy of the prediction. Subsequent research will investigate the impact of residual stress on crack propagation patterns.

Recent Advances in Medical Image Classification

Loan Dao, Ngoc Quoc Ly
Dept. of Computer Vision and Cognitive Cybernetics_University of Science, VNUHCM, Ho Chi Minh, Vietnam, Viet Nam
National University, Ho Chi Minh City, Vietnam

Abstract—**Medical image classification is crucial for diagnosis and treatment, benefiting significantly from advancements in artificial intelligence. The paper reviews recent progress in the field, focusing on three levels of solutions: basic, specific, and applied. It highlights advances in traditional methods using deep learning models like Convolutional Neural Networks and Vision Transformers, as well as state-of-the-art approaches with Vision-Language Models. These models tackle the issue of limited labeled data, and enhance and explain predictive results through Explainable Artificial Intelligence.**

Keywords—Medical Image Classification (MIC); Artificial Intelligence (AI); Vision Transformer (ViT); Vision-Language Model (VLM); eXplainable AI (XAI)

I. Introduction

Medical Image Classification (MIC), a crucial integration of Artificial Intelligence (AI) and Computer Vision (CV), is revolutionizing image-based disease diagnosis. By categorizing medical images into specific disease classes, MIC enhances diagnostic accuracy and efficiency. Utilizing various imaging modalities like X-rays, CT scans, MRI, and ultrasound, MIC systems cater to specific clinical needs. Incorporating state-of-the-art technologies, MIC optimizes classification accuracy, leading to precise diagnoses and improved patient care.

1) The importance of MIC: The ability to interpret medical images accurately and efficiently is crucial for timely and effective patient care. However, manual image analysis can be time-consuming and prone to human error. MIC, leveraging AI and CV, offers automated analysis and classification of medical images, leading to several benefits:

a) Improved diagnostic accuracy: MIC systems can detect subtle patterns and features at the pixel level that may be missed by human observers, leading to more accurate diagnoses.

b) Reduced workload for physicians: Automating image analysis frees up valuable time for physicians, allowing them to focus on patient interaction and complex decision-making.

c) Enhanced efficiency: MIC systems can process large volumes of images quickly, leading to faster diagnoses and treatment decisions.

d) Improved patient outcomes: Ultimately, the improved accuracy and efficiency of MIC contribute to better patient outcomes and overall healthcare quality.

2) Challenges and the need for transparency: While MIC offers immense potential, challenges remain. Hospital overload, physician burnout, and the risk of misdiagnosis necessitate robust and reliable MIC systems. Transparency and explainability are crucial for building trust among stakeholders. Explainable AI (XAI) addresses this need by providing insights into the decision-making process of MIC models, allowing physicians to understand the rationale behind classifications and make informed decisions.

3) Advancements in MIC: Recent advancements in MIC have significantly enhanced its capabilities. Large-scale Medical Vision-Language Models (Med-VLMs) trained on extensive datasets of image-caption pairs enable a deeper understanding of visual information, leading to more accurate and generalizable models. Additionally, novel network architectures like transformers and multi-task learning approaches have further improved performance and efficiency. Few-shot and zero-shot learning have also made significant contributions to MIC. Few-shot learning allows models to classify images with minimal labeled examples, beneficial in fields where obtaining large labeled datasets is challenging. Zero-shot learning enables models to classify images from unseen classes by leveraging knowledge transfer from related tasks. Combined with Explainable AI (XAI) techniques, these approaches not only explain results and increase model reliability but also optimize outcomes, enhancing system accuracy and performance. This comprehensive understanding and improved reliability facilitate their integration into clinical practice with high confidence and precision, ultimately leading to better patient outcomes and more efficient healthcare processes.

4) Exploring MIC across three levels of solution: To fully grasp the current state of MIC, this paper delves into three distinct levels:

a) Level 1: Basic Models: This level examines the fundamental theoretical models including MIC, including learning models, basic network architectures, and XAI techniques.

b) Level 2: Task-Specific Models: This level explores specific theoretical models and network architectures tailored to particular MIC tasks, such as single-task and multi-task classification.

c) Level 3: Applications: This level surveys prominent applications of MIC within the medical community, highlighting recent research trends and real-world implementations.

5) Contributions and structure: This article makes several key contributions:

a) Comprehensive review: It provides a thorough and systematic review of recent advancements in MIC, offering valuable insights for researchers and practitioners.

b) Highlighting key developments: It identifies and discusses significant breakthroughs, including VLMs, transformer-based architectures, multitask models, and progress in XAI, which not only explain prediction results but also enhance the performance of MIC. Notably, recent advancements in zero-shot learning and few-shot learning address data scarcity in the medical field and mitigate model overfitting.

c) Addressing challenges and proposing solutions: It explores challenges in MIC and proposes effective solutions to improve classification algorithms and systems.

d) Exploring current issues: It delves into pressing problems surrounding recent advancements in MIC, providing a deeper understanding of the evolving research landscape.

The remainder of the paper is structured as follows (Fig. 1): Section II overviews of recent advancements across three levels. Sections III to V detail each level. Section VI addresses challenges and proposes solutions. Section VII concludes and highlights future research directions. TABLE I. lists the abbreviations used.

By comprehensively exploring recent advancements in MIC, this article aims to contribute to the development of more effective and reliable classification systems, ultimately improving patient care and outcomes.

This comprehensive survey demonstrates the multi-faceted nature of medical image classification across various levels of solutions, providing researchers and practitioners with a holistic view of the field's current state and future directions. By synthesizing recent advancements in MIC across fundamental models, task-specific architectures, and real-world applications, this article not only addresses current challenges but also contributes significantly to the ongoing research in the field, offering valuable insights for future developments.

SOTA	State-of-the-Art
VLM	Vision-Language Model
XAI	eXplainable Artificial Intelligence
ZSL	Zero-shot learning

II. Overview of Recent Advances in MIC Across Three Levels of Classification Systems

This section explores the evolving landscape of MIC through a standard three-level classification system framework. Each level serves a distinct purpose, building upon the foundations of the preceding one. TABLE II. provides a comprehensive overview of recent advancements in MIC across these three levels, highlighting their functionalities and advantages. This structured approach facilitates a deeper understanding of the current SOTA and the interconnected nature of progress within the field.

The proposed methods in this survey address key challenges in MIC:

- Med-VLMs leverage visual and textual data to mitigate limited labeled data issues, enhancing model robustness and generalizability.
- Few-shot and zero-shot learning techniques enable classification of rare conditions with minimal training examples.
- Transformer-based architectures and CNN hybrids capture both local and global features, improving complex medical image comprehension.
- XAI integration enhances interpretability, fostering trust and adoption in clinical settings.

These approaches represent targeted solutions to specific MIC challenges, demonstrating the field's adaptability to clinical needs. By addressing data scarcity, rare condition classification, feature extraction, and interpretability, these methods contribute to advancing AI-driven medical image analysis.

III. Level 1 of MIC (Fundamental Models)

Level 1 includes learning models, fundamental network architectures and backbone DNN, and XAI. This level plays an essential role in developing systems at the subsequent levels.

A. Learning Model

1) Unimodal learning in MIC: The evolution of learning models has significantly impacted the field of MIC, offering solutions to challenges like manual data labeling and limited generalization capacity. TABLE III. provides a concise comparison of various unimodal learning models commonly employed in MIC, highlighting their key characteristics and suitability for different scenarios. Selecting an optimal learning model for MIC tasks (see Table III) requires careful consideration of data availability, labeling costs, privacy requirements, and performance expectations. While supervised learning is powerful when labeled data is abundant, data annotation limitations and privacy concerns necessitate exploring alternative paradigms. Semi-supervised, weakly-supervised, active learning, meta-learning, federated learning, and self-supervised learning offer promising avenues to address these challenges, fostering the development of more efficient and generalizable MIC systems. Leveraging these diverse approaches allows researchers and practitioners can unlock the full potential of MIC, ultimately leading to improved patient care and clinical outcomes.

2) Multimodal learning with med-VLMs in MIC: Bridging the semantic gap between visual and textual information is crucial for effective MIC. VLMs integrate Computer Vision and Natural Language Processing, enabling a comprehensive understanding of medical data. This section explores the role of clinical and paraclinical data in Medical-VLMs (Med-VLMs) and surveys SOTA Med-VLMs for MIC.

a) Clinical and paraclinical data in Med-VLMs: To better understand the distinct roles and characteristics of clinical and paraclinical data within Med-VLMs, TABLE I. It provides a comparative analysis.

Clinical data provides valuable context for interpreting paraclinical images, while paraclinical data offers objective visualizations of potential abnormalities. Med-VLMs leverage both data types to enhance diagnostic accuracy and provide a holistic understanding of patient health.

b) State-of-the-Art (SOTA) Med-VLMs in MIC: Several advanced Med-VLMs have demonstrated remarkable performance in MIC tasks, utilizing sophisticated techniques such as transformer architectures, attention mechanisms, and pre-training on large datasets. TABLE V. summarizes SOTA Med-VLMs for MIC.

TABLE II. Overview of the Three-Level Solution Framework for Medical Image Classification

Level	Content	Specific solutions	Explaination
1	Learning model	• **Unimodal learning:** Supervised learning, unsupervised learning, semi-supervised learning, weakly supervised learning, active learning, meta-learning, federated learning, self-supervised learning. • **Med-VLMs:** BiomedCLIP [1], XrayGPT [2], M-FLAG [3], and MedBLIP [4]. • **Some remarkable methods:** ○ **Few-shot learning**: BioViL-T [5], PM2 [6], and DeViDe [7]. ○ **Zero-shot learning:** MedCLIP [8], CheXZero [9], and MedKLIP [10].	The evolution of learning models **from unimodal to multimodal**, exemplified by the emergence of **Med-VLM**, represents a significant advancement in the field. Few-shot and zero-shot learning models further enhance the ability to classify medical images with minimal or no labeled data, making them effective for rare and novel diseases.
	Architectures of fundamental networks and backbone DNN	• **CNN**: VGGNet [11], GoogleNet [12], ResNet [13], and EfficienNet [14]. • **GNN**: Graph Convolution Networks (GCN) [15], and GAT [16]. • **Transformer**: ViT [17], DeiT [18], TransUnet [19], TransUnet+ [20], and TransUnet++ [21].	Evolution of fundamental network architectures in image classification, including **CNNs, GNNs, and Vision Transformers**, as well as their respective backbone DNNs.
	XAI	• **For CNN:** LIME [22], SHAP [23], CAM-based (CAM [24], GradCAM [25], and GradCAM++ [26]). • **For Transformer:** ProtoPFormer[27], X-Pruner [28], and GradCam for Vision Transformer [29].	XAI is applied for CNN Architecture and Vision Transformer
2	Specific DNN architectures and Med-VLM for single task (classification)	• **CNN:** Unet [30], Unet ++ [31], SNAPSHOT ENSEMBLE [32], and PTRN [33]. • **GNN:** CCF-GNN [34] and GazeGNN [35]. • **Transformer:** SEViT [36] and MedViT [37]. • **Med-VLM:** BERTHop [38], KAD [39], CLIPath [40], and ConVIRT [41].	Specialized network architectures have achieved high performance in MIC. Med-VLMs for MIC.
	Specific DNN architectures and Med-VLM for multitask (classification and segmentation)	• **CNN:** Mask-RCNN-X101 [42] and Cerberus [43]. • **GNN:** MNC-Net [44] and AMTI-GCN [45]. • **Transformer:** TransMT-Net [46] and CNN-VisT-MLP-Mixer [47]. • **Med-VLM:** GLoRIA [48], ASG [49], MeDSLIP [50], SAT [51], CONCH [52], and ECAMP [53].	MIC is advancing with multi-tasking. Classifying disease segments often excels over whole image analysis. The advent of Med-VLMs for multi-tasking enhances precision and depth of analyses.
3	Specific applications	• Breast Cancer [54] [55], tuberculosis [56], eye disease diagnosis [57][58], skin cancer diagnosis [59] [60], bone disease [61] - [63], other pathological [64] [65] • Cancer, brain, tumor, lesion, lung, breast, eye, etc.	Surveying prominent applications significant to the medical community. Recent research trends in MIC (2020 - 2024) and cancer statistics for 2024

TABLE III. COMPARISON OF LEARNING MODELS IN MIC

Learning model	Data Availability	Labeling cost	Operating principles	Balance	Applications
Supervised Learning	Labeled data required	High	Learns input-output mapping from labeled data	High performance with sufficient labeled data	Tumor detection, organ segmentation, classification
Unsupervised Learning	Unlabeled data only	Low	Finds patterns and structures in data without explicit supervision	Lower performance, useful for discovering underlying structures	Clustering similar images, anomaly detection
Semi-supervised Learning	Labeled and unlabeled data	Moderate	Utilizes a combination of labeled and unlabeled data to improve model performance	Higher performance than unsupervised learning with less labeling effort	Classification with limited labeled data
Weakly Supervised Learning	Weak supervision (coarse or image-level labels)	Moderate to low	Learns from partially labeled or noisy data	Scalability with reasonable performance	Image-level diagnosis tasks
Self-supervised Learning	Unlabeled data	Low	Generates supervisory signals from the input data itself	Balances model performance with labeling effort by leveraging unlabeled data	Efficient use of unlabeled data to pre-train models for downstream tasks
Active Learning	Small initial labeled dataset, actively selects informative samples	Initially high, decreases over time	Actively selects the most informative samples to be labeled	Balances model performance with labeling effort	Reducing labeling effort by prioritizing informative images
Meta-Learning	Diverse set of tasks for meta-training	High initially, potentially low for downstream tasks	Learns to learn from different tasks, improving adaptation to new tasks with limited data	Balances adaptation to new tasks with reduced need for extensive labeled data	Efficient adaptation to new imaging modalities or diseases
Federated Learning	Decentralized data across multiple devices/institutions	Varies depending on data distribution	Collaboratively trains a global model while keeping data localized	Balances model performance with data privacy and availability	Collaborative model training across institutions without sharing sensitive data

To summary, Med-VLMs show significant potential for advancing MIC by effectively integrating clinical and paraclinical data. Key takeaways from the surveyed models include the effectiveness of transfer learning, model optimization techniques, integration of medical knowledge, and the development of multi-task models. These advancements pave the way for more accurate, efficient, and comprehensive diagnostic support tools in healthcare.

3) *Some remarkable methods*

a) Few-shot learning in MIC: In the medical imaging domain, few-shot learning (FSL) techniques are crucial due to the scarcity of labeled data and the dynamic nature of disease patterns. FSL enables accurate classification and diagnosis from a limited number of training samples, leveraging meta-learning and transfer-learning principles.

Core Principles:

Meta-learning: Models are trained on diverse medical imaging tasks to learn a shared representation that can be quickly adapted to new tasks with few examples, optimizing for rapid adaptation to new data.

Transfer learning: Pre-trained models on large medical datasets are fine-tuned on smaller, specific datasets to improve performance on the target task, such as disease classification or anomaly detection.

Relevant Med-VLM Models:

- BioViL-T [5] is a self-supervised learning approach that leverages temporal information within longitudinal medical reports and images to enhance performance on medical vision-language tasks. It utilizes a hybrid CNN-Transformer architecture for encoding visual data and a text model pretrained with contrastive and masked language modeling objectives. This approach enables BioViL-T to learn robust representations of medical concepts by capturing both visual and temporal relationships present in longitudinal data. The model's strength lies in its ability to transfer knowledge from diverse sources, leading to improved performance in few-shot settings.
- PM2 [6] introduces a novel multi-modal prompting paradigm for few-shot medical image classification. Its key strength lies in leveraging a pre-trained CLIP model and learnable prompt vectors to effectively bridge visual and textual modalities. This approach enables PM2 to achieve impressive performance in few-shot settings, surpassing existing methods on various medical image classification benchmarks.
- DeViDe [7] is a novel transformer-based approach that leverages open radiology image descriptions to align diverse medical knowledge sources, handling the complexity of associating images with multiple descriptions in multi-label scenarios. It guides medical image-language pretraining using structured medical knowledge, enabling more meaningful image and language representations for improved performance in downstream tasks like medical image classification and captioning.

Advantages:

- Data Efficiency: Reduces the need for large amounts of labeled data, making it feasible to develop models with limited resources.

- Flexibility: Can quickly adapt to new tasks with minimal data, which is crucial in dynamic environments like medical imaging.

Disadvantages:

- Performance: May be less effective compared to models trained on large, fully labelled datasets.
- Complexity: Requires careful design of task sets for training to ensure generalizability and robustness.

b) Zero-shot learning in MIC: Zero-shot learning (ZSL) enables the classification of unseen classes by leveraging semantic relationships between known and unknown classes. ZSL's core principle is to use auxiliary information, such as textual descriptions, to bridge the gap between seen and unseen classes, thereby expanding AI systems' diagnostic capabilities.

Core Principles:

- Semantic Embeddings: Align visual features with semantic representations (e.g., word embeddings) to infer the class of unseen instances by creating a shared space where both visual and semantic data coexist.
- Knowledge Transfer: Utilize knowledge from known classes to predict the properties of unknown classes based on their semantic descriptions, effectively transferring learned information across domains.

Common Models:

- MedCLIP [8] uses contrastive learning from unpaired medical image-text data to improve representation learning and zero-shot prediction, achieving strong performance even with limited data.
- CheXZero [9] is a deep learning model specifically for chest X-ray classification, utilizing pre-trained CNNs and fine-tuning on labelled data to achieve high accuracy in identifying thoracic diseases.
- MedKLIP [10] leverages medical knowledge during language-image pre-training in radiology, enhancing its ability to handle unseen diseases in zero-shot tasks and maintaining strong performance even after fine-tuning.

These models represent significant advancements in medical image classification, demonstrating impressive results and addressing the unique challenges posed by healthcare data.

Advantages:

- Scalability: Enables classification of novel classes without prior training examples, making it highly scalable and versatile.
- Flexibility: Expands the diagnostic capabilities of AI systems to include rare and novel diseases, which are often not well-represented in training datasets.

Disadvantages:

- Accuracy: Performance may be lower compared to models trained specifically on the classes of interest, particularly for highly dissimilar unseen classes.
- Dependency on Semantic Descriptions: Requires accurate and rich semantic information to function effectively, which can be a limitation if such data is not available.

Overall, few-shot and zero-shot learning models address the challenge of limited labeled data in medical image classification. FSL adapts quickly to new tasks with minimal training samples, while ZSL uses semantic relationships to diagnose rare and novel diseases. Each approach has unique advantages and limitations that must be considered when designing MIC systems. Understanding these principles is crucial for developing effective and reliable MIC models.

B. Architectures of Fundamental Networks and Backbone DNN

MIC has significantly shifted from traditional machine learning methods to deep learning approaches. This review focuses on fundamental DL architectures commonly used in MIC, including Convolutional Neural Networks (CNNs), Graph Neural Networks (GNNs), and Transformers. These architectures have shown remarkable efficacy in automatically learning hierarchical feature representations and achieving state-of-the-art performance in various MIC tasks.

1) Convolutional Neural Networks (CNNs): CNNs have become the cornerstone of MIC due to their ability to automatically learn hierarchical feature representations. Inspired by the human visual cortex (Fig. 2 [66]), CNNs excel at capturing local features within images, making them ideal for tasks like disease detection, organ segmentation, and anomaly identification. This section explores the core components of CNNs and their contributions to feature extraction and classification, followed by a review of popular CNN architectures and their advancements in MIC.

a) Core components of CNNs: TABLE VI. summarizes the core components of a CNN and their functions in feature extraction and class prediction.

These components work synergistically to enable CNNs to learn intricate features from medical images, leading to accurate classification.

TABLE IV. COMPARISON OF CLINICAL AND PARACLINICAL DATA

Feature	Clinical Data	Paraclinical Data
Source	Direct interaction with healthcare professionals	Direct interaction with healthcare professionals
Nature	Text-based (medical history, symptoms, physical exam findings)	Image-based (internal body structures)
Role	Subjective assessment of patient condition	Objective visualization of abnormalities
Usage in VLMs	Provides context and complements image interpretation	Serves as primary input for image analysis and classification

TABLE V. PROMINENT MED-VLMS IN MIC

Med-VLMs	Principle	Encoders and fusion method	Pre-trained objectives	Implementation Details	Performance Metrics	Key Contributions
BiomedCLIP [1]	Adapts CLIP for biomedical domains	Language encoder: PubMedBERT Vision encoder: ViT Fusion method: late fusion	Cross-modal global contrastive learning	Toilored batch size and patch dropout strategy for efficiency.	Pcam: 73.41, LC25000 (lung): 65.23, LC25000 (colon): 92.98, TCGA-TIL: 67.04, RSNA: 78.95	Superior zero-shot and few-shot classification. Outperfrms SOTA models on diverse iomedical dataset, robust image encoder.
XrayGPT [2]	Summarizes chest X-rays by aligning MedClip with Vicuna.	Language encoder: Vicuma Vision encoder: MedCLIP Fusion method: early fusion	Hybrid: Image-report matching and mixed objectives	Fine-tuned Vicuna on curated reports	Interactive summaries from radiology reports	Integration of medical knowledge through interactive summaries, enhancing the interpretability and usability of diagnostic results.
M-FLAG [3]	Frozen language model, orthogonality loss for harmonized latent space.	Language encoder: CXR-BERT (frozen) Vision encoder: ResNet50 Fusion method: late fusion	Hybrid: Image-text contrastive learning and language generative	Potential for classification, segmentation, object detection	Outperforms existing MedVLP approaches, 78% parameter reduction	Model optimization and efficiency, achieving high performance with reduced parameters.
MedBLIP [4]	Bootstraps VLP from 3D medical images and texts	Language encoder: BioMedLM Vision encoder: ViT-G14 (EVA-CLIP) Fusion method: late fusion	Global and local contrastive learning	Combines pre-trained vision and language models	SOTA zero-shot classification of Alzheimer's disease	Efficient 3D medical image processing facilitates classifying complex conditions with minimal labeled data.

b) Popular CNN architectures: A Historical Perspective: The evolution of CNN architectures has been driven by continuous innovation in addressing challenges and improving performance. TABLE VII. highlights key milestones:

CNN architectures offer unique advantages and have demonstrably excelled in image classification tasks. Their capacity to learn intricate features and generalize to new data underscores their value in advancing image analysis and related research fields. Ongoing research promises further innovations in CNN architecture and training methodologies, leading to increasingly accurate and efficient image classification systems. This progress holds particular significance for the medical domain, where precise image classification can directly impact diagnosis and patient care.

2) Graph Neural Networks (GNNs): leveraging relationships in image data

GNNs offer a unique approach to image classification by representing images as graphs and exploiting the relationships between pixels or image regions. This allows GNNs to capture contextual information and learn more robust representations compared to traditional CNNs.

a) GNN variants and their advantages: Two prominent Graph Neural Network (GNN) variants demonstrate considerable potential in image classification: Graph Convolutional Networks (GCNs) and Graph Attention Networks (GATs).

TABLE VI. CNN COMPONENTS AND THEIR ROLES IN MIC

Component	Function	Role in MIC
Convolutional Layer	Applies filters to extract local features (edges, textures)	Hierarchical feature extraction, capturing spatial relationships.
Activation Function (e.g., ReLU)	Introduces non-linearity for learning complex patterns.	Enables complex decision boundaries for accurate classification.
Pooling Layer (e.g., Max Pooling)	Down-samples feature maps to reduce dimensionality and improve invariance.	Improves robustness to image variations and reduces computational cost.
Fully-Connected Layer	Integrates local features into global patterns for image understanding.	Combines learned features for final class prediction.
Softmax Layer	Converts outputs into probability distribution over predicted classes.	Provides class probabilities for determining the most likely class.

TABLE VII. POPULAR CNN ARCHITECTURES AND THEIR ADVANCEMENTS

Architecture (Year)	Advancement	Key Technique
VGGNet (2014, [11])	Achieved SOTA performance with increased depth	Small 3x3 filters for deeper networks
GoogleNet (2014, [12])	Further reduced error rates with efficient architecture	Inception modules, 1x1 convolutions, global average pooling
ResNet (2015, [13])	Enabled training of very deep networks	Residual blocks with skip connections to address vanishing gradients
EfficientNet (2019, [14])	SOTA accuracy with fewer parameters	Compound scaling for optimal efficiency and performance

- GCNs [15], by generalizing the convolution operation to graph data, effectively capture the local graph structure and relationships between nodes. This capability allows GCNs to leverage the inherent structural information within images for improved classification.

- GATs [16], on the other hand, introduce an attention mechanism to GNNs. This mechanism enables GATs to focus on relevant features within the graph, leading to improved feature extraction and ultimately, enhanced prediction accuracy. By selectively attending to important features, GATs can make more informed decisions during image classification.

b) Benefits of GNNs for Image Classification

- Modeling complex relationships: GNNs excel at capturing intricate dependencies between image elements, leading to better understanding of image context.

- Improved feature extraction: By considering relationships between nodes, GNNs can extract more informative and discriminative features for classification.

- Enhanced robustness: GNNs are less susceptible to noise and variations in image data due to their focus on structural information.

c) Summary: GNNs offer a valuable complementary approach to CNNs for image classification, particularly when dealing with data where relationships between elements are crucial. Their ability to leverage graph structures and learn contextual representations opens new avenues for improving accuracy and robustness in image classification tasks.

3) Transformers: Expanding Horizons in Image Classification

Transformers, initially designed for NLP, have emerged as powerful contenders in image classification. Unlike CNNs, transformers leverage self-attention mechanisms to capture global context and long-range dependencies within images, leading to richer feature representations.

a) Contributions of transformers to image classification

- Feature extraction: Vision transformers (ViTs [17]) split images into patches, embed them into vectors, and incorporate positional information. Self-attention mechanisms then assess the importance of each patch in relation to others, enabling the capture of global context and intricate features.

- Class prediction: A classification head on top of the final transformer encoder layer predicts the image class based on the learned global context. Parallel processing of patches enhances computational efficiency compared to sequential CNNs.

b) Evolution of transformer architectures

- Vision Transformer (ViT [17]): Introduced the transformer architecture to image classification, achieving impressive performance with patch-based processing and self-attention.

- Data-efficient image Transformers (DeiT [18]): Improved efficiency through knowledge distillation and efficient training strategies, achieving comparable results with fewer resources.

- Specialized variants (e.g., TransUnet [19], TransUnet+ [20], and TransUnet++ [21]): Combine transformers with U-Net architectures for enhanced feature extraction and accurate segmentation in medical imaging tasks.

c) Addressing challenges: Techniques like dropout, regularization, and efficient optimization algorithms mitigate overfitting and manage computational complexity in transformers.

In summation, the choice of architecture depends on the specific task and dataset characteristics. CNNs excel at local feature extraction, GNNs leverage relationships within data, and transformers capture global context and long-range dependencies. Understanding these strengths and weaknesses empowers researchers to select the most appropriate architecture for their MIC tasks.

C. Explainable Artificial Intelligence (XAI) in MIC

XAI techniques are crucial for fostering trust and understanding in MIC systems. Despite achieving human-level accuracy, the integration of automated MIC into clinical practice has been limited due to the lack of explanations for algorithmic decisions. XAI methodologies provide insights into the rationale behind the classification results of DL models, such as CNNs and Transformers, used in MIC tasks. By addressing the '**how**' and '**why'** behind predictive outcomes, XAI enhances the transparency and interpretability of MIC systems, contributing to their improved performance and acceptance in clinical settings.

1) XAI methods in CNNs and transformers: The field of XAI has witnessed significant advancements, particularly in the domain of MIC. This progress is evident in the evolution of XAI methods, transitioning from those primarily designed for CNNs to novel techniques tailored for Transformer architectures. The following tables provide a comparative analysis of recent advancements in XAI methods applied to CNNs (TABLE VIII.), Transformers (TABLE IX.) within the MIC domain, along with techniques used to enhance system performance (TABLE X.).

TABLE VIII. XAI METHODS FOR CNNS IN MIC

Method	Principle	How/Why Explanation	Methodological Approach	System Performance Impact
LIME [22]	Approximates complex models with simpler interpretable ones (e.g., linear regression)	Explains "how" by analyzing feature perturbation impact	Fits a simpler interpretable model to perturbed samples around an instance	Enhances local interpretability but may not capture global model behavior
SHAP [23]	Assigns feature contributions based on game theory principles.	Explains "how" and "why" by quantifying feature importance and interactions	Computes average feature contribution across all possible feature subsets	Provides global and local explanations, valuable for understanding complex models
CAM [24]	Visualizes image regions contributing most to a specific class.	Explains "why" by highlighting relevant regions	Combines feature maps and gradients to create a saliency map	Helps localize important features but lacks fine-grained details
Grad-CAM [25]	Improves CAM by incorporating gradient weights.	Explains "why" through visualization and "how" through contribution values on saliency maps	Computes gradients of class score with respect to feature maps for saliency map creation	Offers better localization and is widely used
Grad-CAM++ [26]	Refines Grad-CAM by addressing negative values and weight stability.	Explains "why" by enhancing visualization quality and "how" through weighted combination of positive and negative partial derivatives	Introduces Shapley values to estimate pixel contributions	Provides improved visual explanations and robustness

TABLE IX. XAI METHODS FOR TRANSFORMERS IN MIC

Method	Principle	How/Why Explanation	Methodological Approach	System Performance Impact
ProtoPFormer [27]	Interpretable image recognition using global and local prototypes	Explains "how" by utilizing prototypes to capture target features and "why" by addressing the need for improved interpretability in ViTs	Employs prototype-based XAI technique to enhance ViT interpretability	Achieves superior performance and visualization results compared to SOTA baselines
X-Pruner [28]	Explainable pruning framework for ViTs	Explains "how" by measuring each unit's contribution to class prediction using an explainability-aware mask	Adaptively searches layer-wise threshold based on explainability-aware mask values	Outperforms SOTA black-box methods with reduced computational costs and slight performance degradation
Grad-CAM for ViTs [29]	Visualization of VT decision-making	Explains "why" by revealing focus areas during ViT decision-making	Generates class activation maps for ViTs	Can enhance ViT model fine-tuning but requires further improvement

TABLE X. XAI TECHNIQUES FOR ENHANCING SYSTEM PERFORMANCE

Technique	Description	Impact on System Performance
Explainable Pruning	Pruning techniques like **X-Pruner** that utilize XAI to guide the **removal of less important** model components.	Reduces computational cost and model complexity while maintaining or improving performance.
Attention Visualization	Visualizing attention mechanisms in Transformers to **understand which parts of the input the model focuses on**.	Provides insights for **model improvement** and **debugging.**
Feature Importance Analysis	Techniques like **SHAP** that quantify **the importance of individual features** for model predictions.	Helps identify **key features and potential biases,** leading to improved model design and feature engineering.
Adversarial Training	Training models with adversarial examples to **improve robustness and generalizability**. XAI methods can be used to analyze the impact of adversarial attacks and guide the development of defense strategies.	Enhances model robustness and performance against adversarial attacks.

2) Discussion: The tables above illustrate the diverse range of XAI methods available for both CNNs and Transformers in MIC. While CNN-based methods like LIME, SHAP, and Grad-CAM variants have been widely explored, the emergence of Transformers has led to the development of novel techniques like ProtoPFormer and X-Pruner. These methods offer unique advantages in terms of interpretability and performance improvement.

a) Key Observations

- Focus on Visual Explanations: Many XAI methods, particularly those applied to CNNs, emphasize visual explanations through saliency maps and other visualization techniques. This is crucial in MIC, where understanding the model's focus on specific image regions is essential for building trust and ensuring reliable diagnoses.
- Evolution from Local to Global Explanations: XAI methods have progressed from providing local explanations for individual predictions (e.g., LIME) to offering global interpretations of model behavior (e.g., SHAP). This allows for a more comprehensive understanding of the decision-making process.
- Integration with Model Optimization: Techniques like X-Pruner demonstrate the potential of integrating XAI with model optimization strategies like pruning. This allows for the development of more efficient and interpretable models.

b) Future directions

- Developing XAI methods specifically tailored for Transformer architectures: While existing techniques like Grad-CAM have been adapted for ViTs, further research is needed to explore methods that fully leverage the unique characteristics of Transformers.
- Combining XAI with other AI advancements: Integrating XAI with areas like federated learning and continual learning can lead to more robust and adaptable medical image classification systems.
- Standardization and Benchmarking: Establishing standardized evaluation metrics and benchmarks for XAI methods will facilitate fair comparisons and accelerate progress in the field.

c) Enhancing performance and accuracy in MIC with XAI: XAI techniques significantly improve the performance and accuracy of MIC systems by providing transparency and facilitating error detection and correction. These techniques help identify and rectify model shortcomings, leading to more reliable and effective MIC systems.

CNN-based XAI Techniques:

- LIME create interpretable models for individual predictions, helping to identify and correct misclassifications by highlighting important features.
- SHAP provide a unified measure of feature importance, allowing for precise identification of influential features and potential sources of errors.
- CAM-based Methods: These methods generate visual explanations by highlighting regions in the input image that influence the model's predictions, making it easier to spot and address inaccuracies.

Transformer-based XAI Techniques:

- ProtoPFormer uses prototypical parts to explain predictions, aiding in the identification of errors by comparing new instances with learned prototypes.
- X-Pruner prunes less important parts of the model, enhancing interpretability and helping to pinpoint and fix model weaknesses.
- GradCam for Vision Transformer adapts GradCAM for transformers, providing visual explanations that help in diagnosing and correcting errors in transformer-based MIC models.

Impact on MIC:

- Error Detection: XAI techniques make it easier to identify misclassifications and understand why they occur, enabling targeted corrections.
- Model Improvement: By revealing which features and regions are most influential, XAI helps refine model training and architecture, leading to better performance.
- Trust and Reliability: Enhanced transparency builds trust among clinicians, ensuring that MIC systems are more likely to be adopted and relied upon in clinical settings.

Some recent XAI techniques:

Recent studies have shown that using XAI methods such as Integrated Gradients can significantly enhance the performance of classification systems.

- A notable study by Apicella et al. (2023, [67]) investigated the application of Integrated Gradients, a technique from XAI, to enhance the performance of classification models. The study focused on three distinct datasets: Fashion-MNIST, CIFAR10, and STL10. Integrated Gradients were employed to identify and quantify the importance of input features contributing to the model's predictions. By analyzing these feature attributions, the researchers were able to pinpoint which features had the most significant impact on the model's output. The insights gained from Integrated Gradients were then used to refine the model. This involved adjusting the model parameters and structure to better capture the critical features identified by the XAI method. The study demonstrated that through this process of feature importance analysis and subsequent model optimization, the classification performance improved significantly across all tested datasets. This approach not only enhanced accuracy but also provided a deeper understanding of the model's decision-making process.

- Additionally, another study by Apicella et al. (2023, [68]) introduced an innovative method that also leveraged Integrated Gradients to boost classification system performance. This study proposed a soft masking scheme, wherein the explanations generated by Integrated Gradients were used to create masks that highlight important features while downplaying less relevant ones. The soft masking approach involved applying these masks during the training phase of the machine learning model. By focusing the model's attention on the most influential features as determined by Integrated Gradients, the training process became more efficient and effective. The experimental results from this study showed a marked improvement in model accuracy across the same datasets: Fashion-MNIST, CIFAR10, and STL10. The use of soft masks helped in reducing noise and enhancing the signal of critical features, thereby leading to better generalization and performance of the classification system.

All in all: XAI explanations enhance both models understanding and classification performance.

Summary of Level 1 Findings:

- Learning models have evolved from traditional supervised learning to advanced techniques like Med-VLMs, few-shot, and zero-shot learning, addressing data scarcity in medical imaging.
- Network architectures have progressed from CNNs to Transformers, with hybrid models showing promise in capturing both local and global features.
- XAI methods have become crucial for enhancing model interpretability and trust in clinical settings, with techniques like Grad-CAM and SHAP leading the way.
- The integration of these advancements has led to more robust, efficient, and interpretable models for medical image classification

IV. Level 2 of MIC (Task-Specific Models)

Expanding on initial network architectures, the second level focuses on specialized architectures for MIC. It takes a comprehensive approach, combining classification with segmentation through multitask learning models. This broad view deepens understanding of MIC network architectures, paving the way for specific applications.

A. Recent Advances in Level 2 for Single Task

1) Specific DNN architectures for single task (classification): This review assesses recent advancements in DNN architectures for single-task classification in medical image analysis. It evaluates specialized architectures across CNNs, GNNs, and Transformers, considering methodology, datasets, effectiveness, advantages, and limitations. The comparative analysis, summarized in Table XITABLE XI. , highlights key developments and their implications for MIC, offering a comprehensive overview of the current state-of-the-art in the field.

Key insights:

a) Adaptability and efficiency: Unet and Unet++ demonstrate adaptability to new tasks and improved segmentation accuracy, though at the cost of increased parameters.

b) Innovative approaches: Snapshot Ensemble and GazeGNN introduce novel methods like GradCAM and eye-gaze data utilization, showcasing the potential of combining different data types and analytical techniques.

c) Challenges in complexity and data requirements: While architectures like PTRN and CCF-GNN show promise in specific tasks, they highlight the ongoing challenges of computational demands and the need for extensive training data.

d) Future directions: The evolution from CNN-based architectures to incorporating GNN and Transformer models indicates a shift towards more complex, yet potentially more effective methods for medical image classification. However, issues such as interpretability, computational efficiency, and data availability remain critical areas for future research.

This summary underscores the dynamic nature of deep learning research in medical image classification, emphasizing the need for continued innovation and exploration of new methodologies.

2) Med-VLMs for MIC: The recent rise of Med-VLMs has greatly influenced MIC. These models utilize NLP and CV to analyze medical images and text reports, enhancing diagnostic accuracy and efficiency. Table XII summarizes key Med-VLMs in MIC, highlighting their performance in zero-shot and few-shot learning scenarios:

Advancements and Impact

Med-VLMs demonstrate remarkable progress in MIC, particularly in scenarios with limited labeled data.

a) Zero-shot learning: Models like KAD showcase the ability to classify images of unseen pathologies without explicit training, highlighting the potential for real-world clinical applications.

b) Few-shot learning: CLIPath and ConVIRT achieve SOTA performance with minimal labeled data, reducing the burden of data annotation in clinical settings.

Future Directions

The field of Med-VLMs is rapidly evolving, with ongoing research exploring:

a) Multi-modal learning: Integrating diverse data modalities (e.g., images, text, genomics) for a more comprehensive understanding of diseases.

b) Explainability and interpretability: Enhancing transparency and trust in model predictions.

c) Domain adaptation: Adapting models to diverse clinical settings and populations.

Summary

Med-VLMs revolutionize MIC, promising improved diagnosis, treatment planning, and patient care. With ongoing research, they have the potential to transform healthcare, enabling more accurate, efficient, and personalized medicine.

B. *Recent Advances in Level 2 for Multitask (Classification and Segmentation)*

Multitask learning (MTL) is vital in MIC tasks, overcoming individual model limitations and boosting overall performance. A recent comprehensive study highlighted the substantial progress made in medical image segmentation using DNNs, leading to more accurate and efficient diagnostic processes [69]. By optimizing image segmentation and classification together, MTL provides numerous advantages:

a) Mitigating data scarcity: MTL leverages knowledge transfer across related tasks, enabling models to learn from complementary data sources and improve performance on the target task, even with limited data availability.

b) Optimizing resource utilization: By sharing feature representations across tasks, MTL optimizes the use of computational resources, leading to more efficient model architectures and reduced computational overhead.

c) Learning robust shared representations: MTL encourages the learning of shared features that are beneficial for both segmentation and classification tasks. These shared representations capture task-agnostic information, leading to improved generalization and performance across multiple MIC tasks.

MTL in MIC tasks effectively tackles challenges like data scarcity, resource constraints, and the necessity for robust, generalizable models. By leveraging synergies between related tasks, MTL enhances MIC systems' performance and efficiency, leading to better clinical decision-making and patient outcomes.

3) Typical architecture for multitasking in MIC: Researchers have investigated different MTL configurations like feature extraction, fine-tuning, and hybrids to match diverse medical imaging contexts and data availability. TABLE XIII. Surveys the latest notable DNN architectures using multitasking to boost MIC performance.

In summary, these MTL-based architectures demonstrate significant advancements in addressing data scarcity, improving resource efficiency, and leveraging shared representations to enhance medical image classification performance across various modalities and disease domains.

TABLE XI. Summary of Key Architectures for Single Task (MIC)

Works	Method	Data	Effectiveness	Advantanges	Limitations
Unet (2015, [30])	Supervised learning with encoder-decoder architecture	PhC-U373: 30 images DIC-HeLa: 35 images	High IOU scores (92% for PhC-U373, 77.5% for DIC-HeLa)	Accurate segmentation with limited data; adaptable to new tasks	Limited in extracting long-range information; lacks explanation for predictions
Unet++ (2018, [31])	Supervised learning with redesigned skip paths	Cell nuclei, colon polyp, liver, lung nodule images	Cell nulei: 92.63, colon polyp: 33.45, liver: 82.90, lung nodule: 77.21 Improved IoU over Unet	Reduces semantic gap; improves accuracy and speed	Increases parameter count; lacks explanation for predictions
Snapshot Ensemble (2021, [32])	Supervised learning with EfficientNet-B0, GradCAM	Malaria Dataset: 27558 erythrocyte images with equal cases of parasitized and uninfected cells. Source: CMC hospital in Bangladesh	High F1 score (99.37%) and AUC (99.57%)	Timely and accurate malaria diagnosis; uses GradCAM for explanations	Focused only on P. falciparum; not other species
PTRN (2022, [33])	Supervised learning with DenseNet-201	CheXpert: 224,316 digital CXRs; CheXphoto: 10,507 CXR	CheXpert: 0.896 CheXphoto-Monitor: 0.880 CheXphoto-Film: 0.802 meanAUC: 0.850	Reduces cost of collecting natural data; eliminates negative impacts of projective transformation	Higher computation costs; untuned hyperparameters
CCF-GNN (2023, [34])	Supervised learning with GNN	TCGA-GBMLGG, BRACS, Bladder Cancer, ExtCRC images	High AUC (0.912 for TCGA-GBMLGG) and accuracy	Effectively analyzes pathology images; represents cancer-relevant cell communities	Requires extensive training data; longer processing time
GazeGNN (2023, [35])	Supervised learning with GNN	Chest X-ray: 1083 images	High accuracy (0.832) and AUC (0.923)	Captures complex relationships via graph learning without pre-generated VAMs	Needs eye-tracking devices for gaze data collection
SEViT (2022, [36])	Supervised learning with Transformer	Chest X-ray: 7000 chest X-ray images (Normal or Tuberculosis) Fundoscopy (APTOS2019): diabetic retinopathy (DR) 3662 retina images (5 classes)	High accuracy (94.64% for Chest X-ray) and AUC	Detects adversarial samples by assessing prediction consistency	Full white-box settings not evaluated in natural image contexts
MedViT (2023, [37])	Supervised learning with hybrid CNN-Transformer.	MedMNIST-2D: 12 biomedical datasets (CT, X-ray, Ultrasound, and OCT images)	Average accuracy of 0.851 and AUC of 0.942	Reduces computational complexity; high generalization ability	Lacks precise hyperparameter tuning; employs two CNNs.

TABLE XII. PERFORMANCE OF MED-VLMS IN MIC

Model	Modality	Zero-shot Learning	Few-Shot Learning	Encoders and fusion method	Pre-trained objective	Key Features
BERTHop [38]	Chest X-ray	AUC: 98.12%	None	Language encoder: BlueBERT Vision encoder: PixelHop++ Fusion method: Early fusion	Hybrid: matching and masking (masked language modelling)	Combines PixelHop++ and BlueBERT for effective visual-language fusion.
KAD [39]	Chest X-ray	Outperforms expert radiologists on multiple pathologies	Excels with few-shot annotations	Language encoder: PubMedBERT Vision encoder: ResNet-50, ViT-16 Fusion method: Late fusion	Cross-modal global contrastive learning and hybrid with additional classification objective	Leverages medical knowledge graphs for improved zero-shot performance and auto-diagnosis.
CLIPath [40]	Pathology	Strong transferability	Efficient adaptation with limited data	Language encoder: BERT Vision encoder: ResNet-50 or ViT Fusion method: Early fusion	Contrastive learning	Fine-tunes CLIP using Residual Feature Connection for pathology image classification
ConVIRT [41]	Chest X-ray	Competitive performance	SOTA with few-shot annotations	Language encoder: BERT Vision encoder: ResNet50 Fusion method: No fusion	Global contrastive learning	SOTA with few-shot annotations

TABLE XIII. SUMMARY OF KEY ARCHITECTURES FOR MULTITASK LEARNING (MIC)

Works	Method	Data	Effectiveness	Advantages	Limitations
Mask-RCNN-X101 (2021, [42])	Supervised learning, Mask-RCNN-X101 architecture	934 radiographs (667 benign, 267 malignant bone tumors)	Classification of bone tumors: 80.2% accuracy, 62.9% sensitivity, and 88.2% specificity. Bounding box placements: IoU of 0.52 Segmentation: mean Dice score 0.60.	Assists in diagnostic workflow by accurately placing bounding boxes, segmenting, and classifying primary bone tumors	Selection bias, inability to predict other diseases, fixed image resolution, lack of bone metastases and density information
Cerberus (2023, [43])	Supervised learning, shared encoder (ResNet34) and independent decoders (U-Net)	Gland: (1602 GlaS + 3209 CRAG + 46346 generated), Lumen: 56358, Nuclei: 495179	Segmentation: Nuclei 0.774, 0.560; Gland 0.908, 0.640; Lumen 0.666, 0.525; Classification: mAP 0.948, mF1 0.883	Simultaneously predicts multiple tasks without compromising performance, publishes processed TCGA dataset	Performance enhancement in new tasks yet to be explored
MNC-Net (2023, [44])	Supervised learning, graph encoder and cluster-layer	Parkinson's Progression Markers Initiative (PPMI) MRI data	ACC 95.50%, F1 95.49%, Prec 97.00%, Rec 94.42%	Early diagnosis of Parkinson's disease using clinical scores and brain regions, manages brain network complexity effectively	Limited to node-level tasks, does not capture all Parkinson's-related information
AMTI-GCN (2024, [45])	Supervised learning, interpretation, feature sharing, and task-specific modules	AD-NC, AD-MCI, NC-MCI, MCIn-MCIp (186-393 samples)	NC-MCI: ACC 70.1, SEN 69.3, SPE 70.8, AUC 70.6, ADAS-Cog CC 0.477, MMSE CC 0.498; MCIn-MCIp: ACC 71.9, SEN 73.2, SPE 71.1, AUC 72.5, ADAS-Cog CC 0.485, MMSE CC 0.522	Addresses limitations in binary Alzheimer's diagnosis and ignores task correlation	Did not explore potential correlations between ADAS-Cog, MMSE, and other factors like education level
TransMT-Net (2023, [46])	Active learning, hybrid CNN-Transformer architecture	Polyp: 1,645 images	**Seg.:** DSC 77.76%, IoU 67.40%, 95% HD 21.62 mm **Class:** Acc 96.94%, Pre 96.56%, Rec 96.52%, F1 96.54%;	Effectively addresses lesion classification and segmentation in GI tract endoscopic images	Slightly higher computational complexity, inferior segmentation performance with 70% training set, varied processing speed
CNN-VisT-MLP-Mixer (2024, [47])	Supervised learning, hybrid CNN-ViT architecture and MLP-Mixer	BUSI: 789, UDIAT: 163	**Seg:** BUSI (Acc 94.04, DC 83.42, IoU 72.56, Sen 80.10); UDIAT (Acc 97.88, DC 81.52, IoU 70.32, Sen 90.32); **Class:** Acc 86.00, Prec 86.11, Rec 86.02, F1 85.93, Sen 89.42, Spec 85.26	Effectively captures local and high-level features in breast ultrasound images, enhances feature integration	Inability to monitor tumor's surrounding environment during diagnosis

4) Med-VLMs for multitask (classification and segmentation): Recent advancements in Med-VLMs have significantly improved the accuracy and efficiency of MIC by leveraging the power of multimodal AI. These models excel at handling multitask challenges, such as simultaneous classification and segmentation, leading to a more comprehensive understanding of medical images. Table XIV summarizes key Med-VLMs and their contributions to MIC. These Med-VLMs demonstrate several key advancements in MIC:

a) Enhanced medical knowledge: Models like MedKLIP incorporate medical knowledge bases and text extraction techniques to improve understanding of medical images.

b) Improved representation learning: Techniques like attention mechanisms and contrastive learning enable models like GLoRIA and CONCH to learn more robust and efficient representations of medical images.

c) Anatomical structure guidance: ASG (IRA) and MeDSLIP leverage anatomical information to improve interpretability and clinical relevance, leading to more accurate classifications.

d) Multitask capabilities: Many of these models excel at both classification and segmentation tasks, providing a more comprehensive analysis of medical images.

e) Zero-Shot and few-shot learning: Several models, including GLoRIA and SAT, demonstrate strong performance even with limited labeled data, making them valuable in scenarios with scarce data resources.

Significantly, Med-VLMs are revolutionizing MIC by leveraging the power of multimodal AI and multitask learning. These models offer enhanced diagnostic precision, efficiency, and interpretability, ultimately leading to improved patient care and outcomes. As research in this area continues, we can expect even more powerful and versatile Med-VLMs to emerge, further transforming the field of medical imaging and healthcare as a whole.

TABLE XIV. COMPARISON OF MED-VLMS FOR MULTITASK MEDICAL IMAGE ANALYSIS

Model	Encoders and fusion method	Pre-trained objective	Key innovations	Strengths
GLoRIA [48]	Language encoder: BioClinicalBERT Vision encoder: ResNet-50 Fusion method: late fusion	Global and local contrastive learning	Multimodal global-local approach, attention-weighted image regions	Data efficiency, zero-shot capabilities, excels in limited-label settings
ASG (IRA) [49]	Language encoder: BioClinicalBERT Vision encoder: ResNet-50 and ViT-B/16 Fusion method: late fusion	Contrastive learning and image tag recognition	Anatomical structure guidance, image-report alignment	Improved interpretability and clinical relevance, enhanced representation learning
MeDSLIP [50]	Language encoder: BioClinicalBERT Vision encoder: ResNet-50 Fusion method: late fusion	Hybrid: Prototypical contrastive learning and intra-image contrastive learning	Dual-stream architecture for disentangling anatomical and pathological information	Precise vision-language associations, improved performance in medical image captioning and report generation
SAT [51]	Language encoder: BioClinicalBERT Vision encoder: ResNet-50 Fusion method: late fusion	Contrastive learning	Semantic-aware transformer for integrating semantic information	Effective representation learning, excels in data/no-data recognition tasks
CONCH [52]	Language encoder: GPT-style Transformer Vision encoder: ViT-Base Fusion method: early fusion	Hybrid: Contrastive learning and captioning objective	Contrastive learning from captions for histopathology images	SOTA performance in histology image classification, segmentation, and retrieval tasks
ECAMP [53]	Language encoder: BERT Vision encoder: ViT-B/16 Fusion method: early fusion (multi-scale context fusion)	Hybrid: masked image modeling, masked language modeling, and context-guided super-resolution	Entity-centered context-aware pre-training, multi-scale context fusion	Enhanced text-image interplay, improved performance in downstream medical imaging tasks

V. RECENT ADVANCES IN LEVEL 3 OF MIC (SPECIFIC APPLICATIONS)

A. Medical Image Data

1) Medical imaging modalities: Medical imaging plays a critical role in modern healthcare, offering non-invasive visualization of the human body for diagnosis and treatment planning. Various modalities, including X-ray, CT, MRI, ultrasound, PET, and SPECT, provide unique insights into different organs and tissues (Fig. 3 [70]; Fig. 4 [71] illustrates the diverse applications of these modalities across various anatomical structures.

The Medical Segmentation Decathlon dataset [72] exemplifies this diversity, encompassing 2,633 3D images spanning ten different organs (Fig. 5). Each modality possesses distinct characteristics, advantages, and limitations, necessitating careful selection based on the specific clinical scenario. Understanding these nuances is crucial for optimal utilization of medical imaging technology. A concise comparison of imaging techniques reveals their unique advantages and limitations is presented in Table XV.

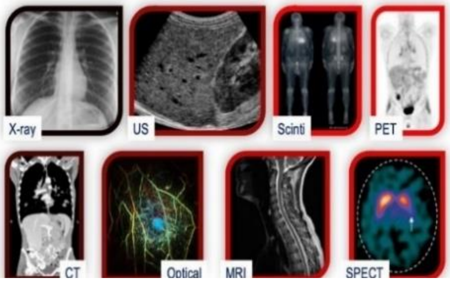

Fig. 3. Illustration of the diverse imaging techniques [70].

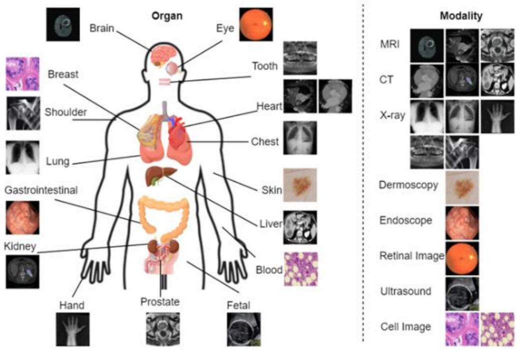

Fig. 4. An overview of the organs and corresponding medical imaging modalities [71].

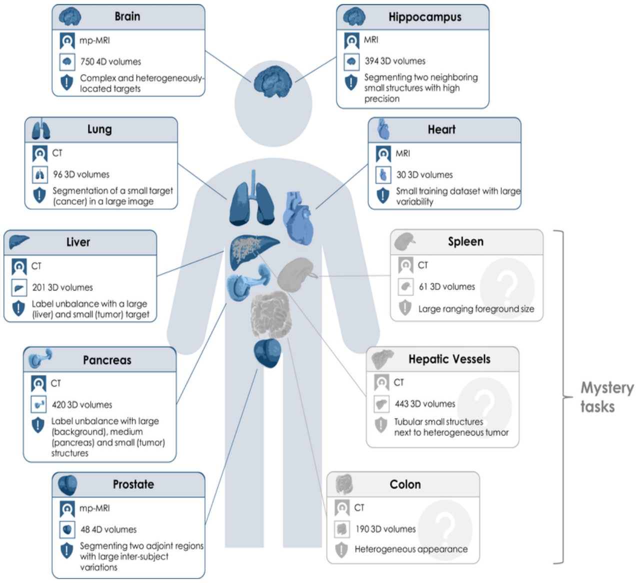

Brain

2) Public databases in medical imaging research: The growth of public medical image databases has been crucial in advancing disease classification research. Noteworthy databases include:

- ChestX-ray14[1]: Over 100,000 chest X-ray images.
- MURA[2]: More than 40,000 X-ray images of bones and joints.
- NIH Clinical Center’s dataset: [3] A diverse range of modalities.
- ISIC [4]: Skin image collection for lesion detection.
- DeepLesion[5]: Nearly 10,600 CT scans.
- CheXpert:[6] Over 224,000 chest radiographs.
- MIMIC-CXR[7]: over 377,000 chest radiographs

Platforms like the World Health Data Hub of the WHO[8], Medical ImageNet[9], Kaggle[10], and PaperswithCode[11], offer extensive resources for machine learning research in medical imaging, showcasing the collaborative and open nature of contemporary scientific inquiry.

3) Advanced techniques in medical imaging research: Innovative computational techniques such as augmentation, transfer learning, Generative Adversarial Networks (GANs), and Federated Learning are pushing the boundaries of medical imaging research. These methods improve model performance, generate new data, and enable decentralized learning, thus enhancing the robustness and diversity of medical imaging applications.

4) Summary: Medical imaging is a cornerstone of modern medical diagnostics, with each modality serving specific purposes based on clinical needs. The advent of AI and machine learning, alongside the proliferation of public datasets, is revolutionizing medical imaging research, promising more accurate disease detection and personalized medicine. The future of medical imaging lies in harnessing these technological advancements to improve healthcare outcomes.
General comment

- Ionizing radiation (X-ray and CT) can be harmful, especially for pregnant women.
- MRI offers the highest detail without radiation but is expensive and not suitable for everyone.
- Ultrasound is safe and widely available but offers less detail.
- PET and SPECT provide functional information but involve radioactive materials.

B. *Advancements in Medical Imaging Diagnosis: From CAD to AI-CAD*

AI integration has profoundly transformed various domains, notably evident in medical diagnostic imaging. This shift marks a significant departure from conventional Computer-Aided Diagnosis (CAD) to AI-driven CAD systems, ushering in a new era of diagnostic capabilities,

The evolution began in the 1960s with CAD systems aiming to automate diagnostic processes. A significant milestone was the FDA's approval of a mammography CAD device by R2 Technology, Inc., in 1998, marking the start of the "CAD era." Endorsement for reimbursement by the Centers for Medicare and Medicaid Services in 2002 further accelerated CAD's adoption across modalities like chest radiographs and CT scans.

CAD systems encompass three categories based on their role in image interpretation: second-reader, concurrent-reader, and first-reader types (Fig. 6 [73]). Notably, interactive CAD falls under the first-reader type. The evolution of CAD architecture has transitioned from sequential interpretation (seen in second-reader CAD Fig. 6(a)) to simultaneous interpretation (concurrent-reader CAD Fig. 6(b)), streamlining the diagnostic process by integrating CAD results from the outset. The advent of first-reader CAD (Fig. 6(c)) presents a novel approach where CAD autonomously conducts initial interpretation, guiding the physician's analysis solely on CAD-marked images, showing promise for mass screenings like mammography.

TABLE XV. COMPARISON OF MEDICAL IMAGING MODALITIES IN MIC

Technique	Description	Pros	Cons	Safety and Image Detail
X-ray	Examines bones, detects fractures, tumors, and infections.	Quick, painless, cost-effective, immediate results, widely available.	Limited soft tissue contrast, ionizing radiation exposure. Not suitable for detailed organ visualization.	Radiation risk: Moderate. Image detail: Low. Best for bone visualization.
CT	Detailed cross-sectional images of the body. Examines organs, blood vessels, and detects abnormalities.	High-resolution images, fast acquisition time, useful for diagnosing trauma, differentiates tissue densities.	Ionizing radiation exposure. Limited soft tissue contrast compared to MRI. Not suitable for pregnant women due to radiation risks.	Radiation risk: High. Image detail: High. Excellent for visualizing organs and bone.
MRI	Detailed images of internal structures. Assesses brain, spinal cord, joints, and organs.	Superior soft tissue contrast, no ionizing radiation. Multiplanar imaging, detects subtle abnormalities.	Expensive, long scan times, contraindicated for patients with certain metallic implants.	Radiation risk: None. Image detail: Very High. Best for soft tissue and organ visualization.
Ultrasound	Uses sound waves to produce real-time images. Examines abdomen, pelvis, heart, and monitors fetal development.	Real-time imaging, non-invasive, safe, portable, widely available, no ionizing radiation.	Operator-dependent, limited penetration in obese patients, less detailed images compared to other modalities.	Radiation risk: None. Image detail: Moderate. Best for real-time imaging and pregnancy monitoring.
PET	Visualizes metabolic processes. Detects cancer, assesses treatment response, evaluates brain disorders.	Provides functional information, detects diseases early, helps in personalized medicine.	Expensive, limited spatial resolution, radioactive material involved.	Radiation risk: Low. Image detail: Moderate. Best for visualizing metabolic activity.
SPECT	Detects gamma rays emitted by a tracer. Assesses blood flow, detects myocardial infarctions, and evaluates brain disorders.	Non-invasive, provides functional information, good spatial resolution.	Longer acquisition time than PET, lower sensitivity than PET, radioactive material involved.	Radiation risk: Low. Image detail: Moderate. Best for visualizing blood flow and brain function.

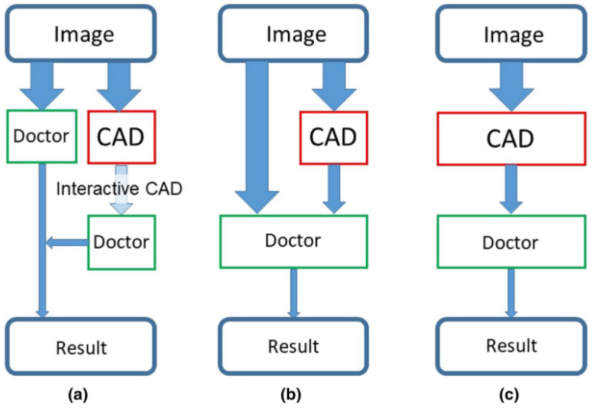

Fig. 6. Categorization of CAD systems in medical imaging interpretation: a) Second-reader, b) Concurrent-reader, and c) First-reader types [73].

Despite CAD's acknowledged utility, persistent challenges include high development costs, elevated false-positive rates leading to increased recalls and biopsies, and limited clinical efficacy. These challenges are well-documented in clinical studies, emphasizing the need for AI-driven solutions.

The recent introduction of AI-CAD, primarily employing deep learning methodologies, signifies a significant advancement. Deep learning algorithms have proven effective in reducing interpretation time and improving diagnostic accuracy, as demonstrated by studies like Kyono et al., which explored deep learning's potential to ease radiologists' workload in mammography screenings. AI-CAD's reliance on deep learning adopts a data-driven approach, benefiting from extensive datasets to enhance performance. Fig. 7 illustrates the superior performance of deep learning-based AI-CAD compared to traditional CAD systems, particularly with increasing data volume.

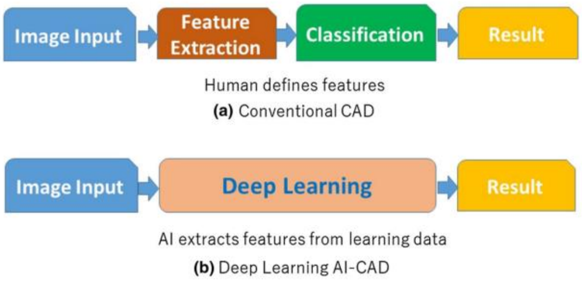

Fig. 7. Development processes: a) Conventional CAD vs. b) Deep learning-based AI-CAD [73].

In conclusion, the shift from CAD to AI-CAD represents a significant advancement in medical imaging diagnosis, offering increased accuracy, efficiency, and versatility. As AI matures, its integration has the potential to revolutionize healthcare delivery, providing clinicians with sophisticated diagnostic tools for precise and timely patient care.

Remarkable Applications of AI-CAD

- Breast Cancer: AI-CAD systems have demonstrated significant potential in breast cancer screening and mammography interpretation. Systems like cmAssist [54] can reduce false-positive markings by up to 69%, minimizing unnecessary follow-up procedures and patient anxiety. Deep learning models have shown accuracy comparable to experienced radiologists, with some hybrid models outperforming human experts. The AI-STREAM study [55] aims to generate real-world evidence on the benefits and drawbacks of AI-based computer-aided detection/diagnosis (CADe/x) for breast cancer screening.

- Tuberculosis Detection: AI-based CAD systems can assist in community-based active case finding for tuberculosis, especially in areas with limited access to experienced physicians. Okada et al. [56] demonstrated the applicability of AI-CAD for pulmonary tuberculosis in community-based active case findings, showing performance levels nearing human experts. This approach holds promise in triaging and screening tuberculosis, with significant implications for addressing healthcare professional shortages in low- and middle-income countries. Such advancements contribute to the World Health Organization's goal of "Ending tuberculosis" by 2030.

- Eye Disease Diagnosis: Google's deep learning analysis [57] achieved a detection sensitivity of about 98% in diagnosing eye diseases. AI analysis of fundus photographs [58] can assist in diagnosing not only eye diseases but also systemic conditions like heart disease, surpassing human capabilities.

- Skin Cancer Diagnosis: AI demonstrates accuracy equivalent to or higher than dermatologists in diagnosing skin cancer, utilizing deep learning on large datasets of skin lesions. Studies have shown AI achieving diagnostic accuracy comparable to dermatologists [59] and even outperforming them in differentiating melanoma [60].

- Bone diseases: The use of AI, particularly deep learning, is gaining traction in the medical community for diagnosing and treating bone diseases. Recent applications focus on segmentation and classification of bone tumors and lesions in medical images. For instance, Zhan et al. [61] developed SEAGNET, a novel framework for segmenting malignant bone tumors. Yildiz Potter et al. [62] explored a multi-task learning approach for automated bone tumor segmentation and classification. Additionally, Ye et al. [63] investigated an ensemble multi-task deep learning framework for the detection, segmentation, and classification of bone tumors and infections using multi-parametric MRI. These studies highlight the potential of deep learning to significantly improve the accuracy and efficiency of diagnosing and treating bone diseases.

- Other Pathological Applications: AI has demonstrated superior performance in detecting lymph node metastasis of breast cancer [64] and detecting diabetes from fundus photographs [65] with high sensitivity and specificity. These applications underscore AI's potential in enhancing the accuracy and efficiency of medical imaging diagnosis, ultimately improving patient outcomes and healthcare delivery.

Overall, AI-CAD systems have shown remarkable potential in various medical imaging applications, from breast cancer screening to tuberculosis detection, eye disease diagnosis, skin cancer diagnosis, and other pathological conditions. By leveraging the power of deep learning and large datasets, these systems can augment and enhance human expertise, leading to improved diagnostic accuracy, efficiency, and accessibility in healthcare.

C. *Recent Research Trends in Medical Image Classification and Cancer Statistics (2020-2024)*

Recent statistics from representative journals using keywords related to medical image classification cover the latest advancements from 2020 to 2024. In addition, the 2024 Cancer Statistics [74] indicate a 33% decrease in cancer deaths in the U.S. since 1991, attributed to reduced smoking, earlier detection, and improved treatments. However, the incidence of six major cancers continues to rise, with colorectal cancer becoming a leading cause of death among men under 50. Efforts like the Persistent Poverty Initiative aim to mitigate cancer outcomes' impact of poverty, emphasizing the need for increased investment in prevention and disparity reduction.

The document concludes with a projection of the top ten cancer types for new cases and deaths in the United States for 2024, underscoring the ongoing challenge and importance of advancements in medical imaging diagnosis.

VI. Challenges and Advancements in MIC

While MIC has experienced significant progress, challenges remain in data limitations, algorithm development, and healthcare integration. This section explores these challenges and proposes innovative solutions to advance the field.

TABLE XVI. Five-Year Statistics of Medical Image Classification Research in Four Representative Journals (2020-2024)

	Classes	Springer	Sciencedirect	IEEE	PubMed
1	cancer	4064	3474	748	291

Fig. 8. Projected top ten cancer types for new cases and deaths in the United States for 2024, by gender [74].

A. Challenges and Solutions in MIC

1) Medical image data:

a) Limited labeled data: Transfer learning has shown promise in addressing the scarcity of labeled data. Kim et al. [75] provide a comprehensive review of transfer learning methods for MIC. Additionally, FSL, ZSL, and Med-VLM have been explored as potential solutions, as mentioned in previous sections. Fig. 8 shows the projected top ten cancer types for new cases and deaths in the United States.

b) Inter-class similarity and imbalanced datasets: Islam et al. [76] introduced CosSIF, a cosine similarity-based image filtering method for synthetic medical image datasets to improve accuracy when dealing with high inter-class similarity. For imbalanced datasets, Huynh et al. [77] propose a semi-supervised learning approach for MIC.

c) Large image sizes and domain shift: Sreenivasulu and Varadarajan [78] present an efficient lossless ROI image compression technique to address computational challenges posed by large image dimensions. Guan and Liu [79] provide a survey on domain adaptation methods for medical image analysis, highlighting techniques to improve model generalizability across different datasets and populations.

2) Clinical data:

a) Data privacy, security, and accessibility: Kaissis et al. [80] discuss secure, privacy-preserving, and federated machine learning approaches in medical imaging, addressing crucial aspects of protecting patient data while improving access to clinical data.

3) Practical application challenges

a) Model interpretability: Alam et al. [81] explore LRP and Grad-CAM visualization techniques to interpret multi-label-multi-class pathology prediction using chest radiography, enhancing model interpretability.

b) Model validation: Ramezan et al. [82] evaluate sampling and cross-validation tuning strategies for regional-scale machine learning classification, ensuring model performance and generalizability.

c) Regulatory approval: Joshi and Bhandari [83] provide an updated landscape of FDA-approved AI/ML-enabled medical devices, offering insights into navigating regulatory requirements.

Future Directions and Research Opportunities:

This review highlights various challenges in medical image classification and presents potential solutions based on recent research. However, it's important to note that these solutions require further validation in specific clinical contexts. To advance the field, researchers should consider:

- Conducting comparative studies of different approaches to address each challenge.
- Validating the proposed solutions in diverse clinical settings and with larger datasets.
- Investigating the integration of multiple solutions to address complex, real-world scenarios in medical image classification.
- Exploring the ethical implications and potential biases of AI systems in healthcare**.**

B. Key Advancements in MIC Techniques

a) Transformers vs. CNNs: Evidence suggests Transformers like ViT and DeiT demonstrate promising results compared to traditional CNNs, especially in capturing global context and long-range dependencies.

b) Synergy of transformers and CNNs: Hybrid models like MedViT and TransMT-Net leverage the strengths of both architectures, achieving superior performance in classification and segmentation tasks.

c) Med-VLMs for multitask MIC: Integrating Med-VLMs into multitask learning frameworks improves performance by effectively aligning visual and textual information.

d) AI for tumor classification: AI models demonstrate impressive accuracy in distinguishing between benign and malignant tumors, with potential to augment clinical decision-making.

e) FSL addresses the challenge of limited labeled data by enabling models to generalize effectively from a small number of examples. Researchs have demonstrated that FSL can achieve high accuracy in tasks such as tumor detection with minimal data, highlighting its potential in clinical applications.

f) ZSL tackles the issue of classifying unseen categories by leveraging semantic relationships. ZSL has shown promising results in identifying rare diseases and novel medical conditions, significantly aiding in early diagnosis and treatment planning.

g) XAI techniques enhance the interpretability and trustworthiness of MIC systems, making them more acceptable in clinical practice. Additionally, XAI contributes to optimizing model performance and accuracy by providing insights that allow for iterative model adjustments.

C. Summary

Addressing data challenges, refining algorithms, and ensuring responsible implementation are crucial for advancing MIC. The integration of Transformers, CNNs, Med-VLMs, and XAI techniques holds immense potential for improving healthcare delivery and patient outcomes. With the increasing focus on explainability and trustworthiness in AI models, further breakthroughs in MIC and its transformative impact on healthcare can be anticipated.

VII. Conclusion and Future Directions

The paper outlines the development of medical image classification through three solution levels: basic, specific, and applied. It discusses traditional high-performance deep learning models and highlights the promising vision-language models that can explain predictions. The paper also emphasizes the potential of multimodal models combining clinical and paraclinical data for disease diagnosis and treatment. It notes the research community's growing interest in early prediction to reduce risks and the role of Explainable Artificial Intelligence in improving predictive results. The application of AI in Computer Vision for medical purposes consistently surpasses expectations, indicating a future focus on integrating AI advancements into diagnostic and treatment-related problems using multimodal data.

Revolutionizing Esophageal Cancer Diagnosis: A Deep Learning-Based Method in Endoscopic Images

Shincy P Kunjumon, S Felix Stephen
Department of Electronics and Instrumentation Engineering,
Noorul Islam Centre for Higher Education, Tamil Nadu, India

Abstract—**Esophageal cancer (EC) is a severe and commonly increasing disease due to the uncontrolled growth in the esophagus. It is the sixth leading cause of cancer-related deaths worldwide. The traditional methods for the diagnosis of EC are not only time-consuming but also suffer from inconsistencies due to human factors such as experience and fatigue. This paper proposes a deep learning (DL) approach for the detection of EC from endoscopic images to improve efficiency and accuracy. The study utilizes an endoscopic image dataset of 2000 images evenly split into cancerous and non-cancerous cases. After image preprocessing and augmentation, these images are fed into the proposed Inception ResNet V2 model. The extracted features were processed by the final classification layers and produced class probabilities. The simulation results revealed that the suggested model attained 98.50% of accuracy, 97.50% of precision, 98.75% of recall and 98.00% of F1 score after fine-tuning. These results underscore the model's capability to accurately identify EC, minimizing false positives and enhancing diagnostic reliability. The proposed DL framework for automated EC detection, promising advancements in clinical workflows and patient care.**

Keywords—Deep learning; esophagus cancer; transfer learning; endoscopic images; inception ResNet V2; fine tuning

I. Introduction

Cancer involves a range of illnesses caused by the uncontrolled growth of cells, which can impact any part of the body. Over the past century, the number of new cancer cases diagnosed within a specific period of time and mortality rates have significantly increased worldwide. This rise can be attributed to several factors, including changes in lifestyle, an aging population, genetic tendencies, and environmental influences such as pollution and dietary habits. Among the many types of cancer, EC is the 6th leading cause of cancer-related deaths worldwide, highlighting its severity and significant impact on public health [1]. In less developed regions the impact of EC is significantly greater, where 80% of cases arise. About 70% of these cases are diagnosed in males, with new diagnosis and mortality rates being two to five times greater in men compared to women, increasing with age. The frequency of EC is rising due to factors such as population growth and increased life expectancy. Risk factors like smoking and excessive alcohol consumption also play a role in the increase of EC, as depicted in Fig. 1 [2]. It begins within the mucosal layer of the esophagus and gradually extends outwards, making early identification more challenging. As a result, individuals might postpone seeking medical help until the cancer has reached an advanced stage. Therefore, it's crucial to raise awareness about risk factors and encourage early screening, particularly for individuals with specific demographics, lifestyle habits, or medical conditions [3].

EC can be broadly divided into 4 categories based on the type of cells from which the cancer originates as shown in Fig. 2. Squamous cell carcinoma (SCC) develops from the thin, flat cells lining the esophagus, with risk factors including smoking, excessive alcohol consumption, and specific dietary factors. Adenocarcinoma develops from glandular cells located in the lower part of the esophagus, close to the junction with the stomach. Risk factors for this type of cancer include obesity and smoking. Sarcomas, which develops from connective tissues such as muscle or cartilage in the esophagus, are rare and consist of only a small fraction of EC cases. Lymphoma, a cancer of the lymphatic system, can occur in the esophagus but is rare compared to other types of EC.

The TNM (Tumor, Node, Metastasis) staging system is employed in clinical practice to examine the extent of EC. It categorizes tumors on the basis of three factors: Tumor (T), assessing the size and invasion of the primary tumor; Node (N), indicating lymph node involvement; and Metastasis (M), evaluating distant organ spread [4]. Combining T, N, and M categories allows clinicians to stage EC (I-IV), assisting treatment decisions and providing prediction data. Conventional EC detection and classification involve manual inspection of endoscopic images by trained professionals, which is time-consuming and subjective. This approach results in variability in diagnoses and missed detections. Human interpretation can be influenced by factors like observer experience, tiredness, and personal opinion, affecting diagnostic accuracy and consistency. Thus, there's a demand for more objective and streamlined approaches to detect and classify EC, enhancing diagnostic accuracy, enabling early intervention, and improving patient outcomes [5].

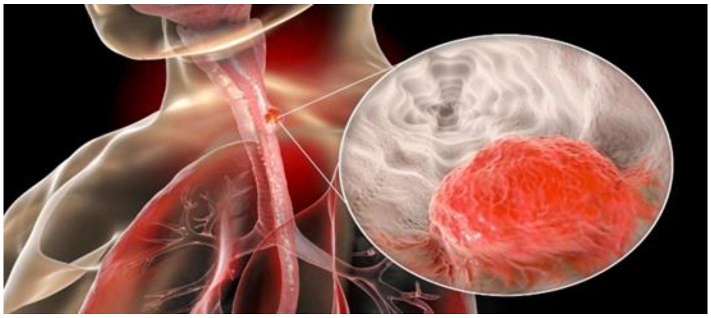

Fig. 1. Esophagus cancer.

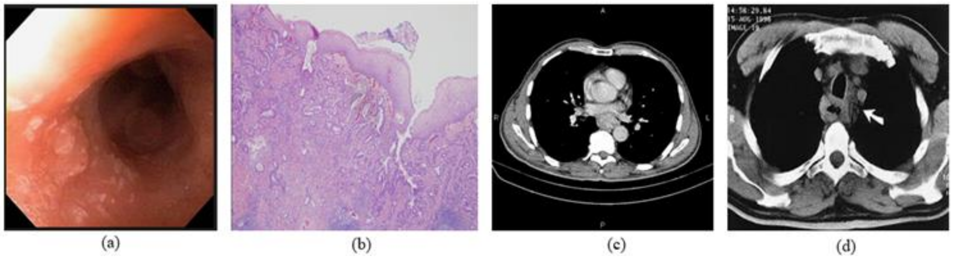

Fig. 2. Types of esophagus cancer: (a) Squamous cell carcinoma, (b) Adenocarcinoma (c) Sarcoma and (d) Lymphoma.

Deep learning, a subset of machine learning (ML) has shown impressive performances in extracting complex patterns and features from large datasets. This has resulted in notable progress in tasks like recognizing, classifying, and segmenting images. In medical imaging, such as endoscopic images for EC detection and classification, DL has shown immense potential. These algorithms can efficiently analyze vast amounts of medical images, accurately identifying diseases that are hidden. For example, DL models can distinguish between normal and abnormal tissue, detect early signs of cancerous lesions, and even predict disease progression based on imaging data [6]. Moreover, DL algorithms can be integrated into clinical workflows to help healthcare professionals in making more accurate and timely diagnoses. Automating the analysis of medical images can help lessen the burden on endoscopists and radiologists, enabling them to concentrate on cases requiring more complex interpretation. However, the use of DL in medical image analysis shows certain challenges including the need for large, high-quality labeled datasets, robust validation methods, and interpretability of model predictions. Addressing these challenges is crucial to ensure the reliability and safety of AI-assisted medical diagnosis and treatment. In this study, an effective DL approach for detecting the EC from endoscopic images is proposed. The method uses an Inception ResNet V2 model to categorize the endoscopic images accurately as “EC” or “No_EC”. The work proposed offers the following key contributions:

- To develop a DL-based model for the detection and classification of EC form endoscopic images.
- To improve the diagnosis of EC from endoscopic images and obtain an optimum accuracy.
- To compare and analyze the performance of the method suggested with the existing methods.

The paper proceeds as follows: Section II reviews previous methods relevant to the current study. Section III outlines the proposed approach. Section IV presents the experimental results and their interpretation. Finally, Section V provides the study's conclusion.

II. Literature Review

Chin et al. (2024) [7] aimed to develop a diagnostic system using DL to differentiate EC from non-contrast CT images of chests. They studied 398 people with EC and 255 healthy individuals without esophageal tumors. They employed a technique called nnU-Net for segmenting the esophagus and used a decision tree (DT) to determine the presence or absence of cancer. Their DL-based method demonstrated strong diagnostic performance, achieving 0.900 of sensitivity, 0.882 of accuracy, 0.880 of specificity, 0.890 of AUC and an 0.891 of F-score. Similarly, the study faced certain limitations, including difficulty in identifying all early-stage cancers and also the number of patients involved in this study is limited.

Li et al. (2024) [8] presented a deep-learning approach for segmenting EEC lesions. They utilized the YOHO framework, as it depends only on a single image from each patient to ensure complete patient privacy. This "one-image-one-network" learning strategy avoided the generalization issues by training the network exclusively on the input image itself, without using data from other patients. The YOHO framework was evaluated on an EEC dataset, attaining a mean Dice score of 0.888.

Yasaka et al. (2023) [9] studied the efficacy of a DL model in detecting EC on contrast-enhanced CT images. Their study comprised 252 patients with EC and 25 patients with No EC. They developed a DL model using data from patients with EC for training and validation. Then, they applied the developed model to a test dataset containing patients with and without EC, achieving AUCs of 0.98 and 0.95 for image-based and patient-based analyses, respectively. Also, the study shown certain limitations, including a training dataset of relatively small size and the restriction to patients with EC visible on CT images.

In their study, Fang et al. (2022) [10] used a semantic segmentation method to predict and label early-stage EC. They utilized a combination of ResNet and U-Net as the fundamental artificial neural network (ANN) architecture to extract the feature maps used in classifying and predicting the cancer's location. A total of 90 narrow-band images (NBI) and 75 white-light images (WLI) were used. The research found that, on average, it took 111 ms to make predictions for each image in the test set. NBI showed 84.724% of high accuracy rate compared to WLI, which achieved 82.377%. These findings indicate that the proposed method is suitable for EC detection.

In their study, Tsai et al. (2022) [11] introduced a new method that integrate hyperspectral imaging (HSI) through band selection. They transformed WLIs into NBIs and developed a single-shot multi-box detector (SSD) model to predict the location and stage of EC, using a total of 1780 EC images. The outcomes shows that the mean average precision (mAP) for WLIs was 80%, for HSI images was 84% and for NBIs was 85%.

In their research, Zhang et al. (2022) [12] proposed an automated DL system for detecting esophageal cancer on barium esophagram. They employed five datasets derived from barium esophagram to progressively train, validate, and test the DLS. The method was evaluated and achieved a specificity, accuracy and sensitivity of 88.7%, 90.3% and 92.5%, respectively, in detecting EC. The study notes some limitations, such as the data collected only from a single medical center and the use of high-quality barium esophagram images for both testing and training purposes.

Mohammed (2022) [13] aimed to create a computer system utilizing modern image processing techniques and algorithms for the early identification of EC. The study employed the Fuzzy C-Means (FCM) algorithm for segmentation and clustering, and utilized a convolutional neural network (CNN) algorithm for detection. When tested on 100 color esophagogastroduodenoscopy (EGD) images, the proposed system achieved an accuracy of 95%. Observations indicated that combining these two algorithms enhanced the detection of EC.

Gong et al. (2022) [14] conducted a study where they developed a DL model capable of diagnosing ECs, non-neoplasms, and precursor lesions using endoscopic images. A total of 5163 (WLIs) were used to train and test the model. They utilized a no-code DL tool to build the model. It achieved an internal test accuracy of 95.6%, with precision at 78.0%, F1 Score at 85.2%, and recall at 93.9%. Furthermore, the external test accuracy reached 93.9%. However, a limitation of the study was that the established model's diagnostic performance was comparatively lower in comparison to other classes.

Chen et al. (2021) [15] introduced an EC detection model based on DL. They employed the Faster RCNN method, incorporating a technique called online hard example mining (OHEM), for detecting objects in EC images. The experiment included 1525 gastrointestinal CT images collected from 420 patients. The improved Faster RCNN's performance was examined by evaluating its mAP, F-1 measure and detection time. The experimental results indicated that the improved Faster RCNN outperformed the other two networks. The proposed method achieved a mAP of 92.15%, an F-1 measure of 95.17%, and a detection time per CT of only 5.3 seconds.

Takeuchi et al. (2021) [16] proposed a system based on AI for diagnosing EC from CT images, employing a group of 458 patients with primary EC in their study. A DL based image recognition model VGG16, was fine-tuned specifically for detecting EC. The CNN's diagnostic accuracy was examined using a test dataset comprising 46 cancerous images from CT scans and 100 non-cancerous images. The CNN-based system demonstrated an F-value of 0.742, a diagnostic accuracy of 84.2%, a specificity of 90.0% and a sensitivity of 71.7%. The study's limitations include insufficient datasets, which limits the model's performance.

Tsai et al. (2021) [17] employed an HSI and a DL model to determine the stage of EC and mark their positions. The study generated spectral data from the images using a special algorithm developed for this purpose. An SSD system was used in DL methods for the diagnosis and classification of EC. The prediction model for EC was evaluated using WLI and NBI images. The accuracy in detecting EC was 88% for WLI and 91% for NBI. Additionally, the algorithm required 19 seconds for result prediction.

Sui et al. (2021) [18] aimed to develop a DL model using the thickness of esophagus for detecting EC from unenhanced CT images. They identified 141 patients with EC and 273 without EC for the model training. A CNN model was created by collecting unenhanced CT images for diagnosing EC. Specifically, in this study, CNN utilized a VB-Net segmentation model, designed to separate the esophagus in images, measure the thickness of the mucosal layer of the esophagus and identify any lesions in the esophagus. The model's results demonstrated an average specificity of 74.33%, an average sensitivity of 77.67% and an average accuracy of 76%. The study's limitation highlighted that the developed DL model depended only on the thickness of the mucosal layer of the esophagus and couldn't identify the texture and other radiomic features.

There are several gaps in current research related to the detection and segmentation of esophageal tumors from unenhanced CT images. Firstly, it's challenging to identify these images and tumors specifically around the esophagogastric junction. Secondly, the detection performance is said to be weak when dealing with low-quality images. Additionally, the model's performance can heavily depend on the size of the learning rate used during training. Moreover, if the initial weight vector of a neuron is too distant from the input vector, it can lead to a decrease in the performance. Also, there's a poor prediction performance when generating depth maps. Tumors at different stages vary significantly in its shape, volume, and complexity, which affects the accuracy of automated segmentation. Finally, the use of limited and biased datasets during training may have limited the overall performance of DL-based models.

III. Materials and Methods

Detecting EC from endoscopic images is crucial for medical diagnosis. In this study, a DL model incorporating an Inception ResNet V2 is utilized for the precise detection and classification of EC. An outline of the work suggested is illustrated in Fig. 3. The model takes endoscopic images from the dataset as input. These images undergo further preprocessing and augmentation. Subsequently, the preprocessed images are given as an input to the pretrained Inception ResNet V2 model to identify the features and classifies the images into two categories: "EC" or "No_EC".

A. Dataset Description

The dataset for detecting EC from endoscopic images was obtained from the Kaggle repository [19]. It comprises 2000 endoscopic images, with 1000 images depicting EC and 1000 images showing no EC. These images are stored in "jpg" format, ensuring ease of access and compatibility. Fig. 4 displays sample images from the endoscopic image dataset.

B. Data Preprocessing and Augmentation

In the proposed framework for detecting EC from endoscopic images, preprocessing plays a crucial role in improving image quality by reducing noise and improving the contrast. This involves resizing the images and normalization. To enhance training efficiency, OpenCV was employed to standardize all images to 224x224 pixels. Data augmentation increases dataset sizes by applying random alterations to existing images. Techniques such as rotation, flipping, shearing, and zooming create varied versions of the original images enhancing the model's ability to generalize and recognize cancerous patterns under different conditions [20]. Following data augmentation, the dataset is split into training and testing sets with a ratio of 80:20.

C. Proposed Methodology

1) Convolutional Neural Network (CNN): A CNN network is a DL model designed specifically for processing and analyzing visual data. It comprises various layers, such as pooling layers, convolutional layers and fully connected layers. The CNNs architecture is illustrated in Fig. 5. In this architecture, features from input images are extracted by the convolutional layers by applying filters or kernels across the image. These layers capture patterns such as textures edges and shapes. The feature maps produced from convolutional layers are subsequently down-sampled by pooling layers, which lowers the spatial dimensions of the data without losing important information. Finally, the fully connected layers process the features extracted and carry out regression or classification tasks. CNNs are efficient at recognizing objects in images due to their ability to share parameters and connect nearby pixels. This helps them learn patterns at different levels, like shapes and textures. Consequently, CNNs are valuable for tasks such as object detection, image classification and segmentation [21].

2) Inception ResNet V2: Inception ResNet V2 is a deep CNN architecture that merges the principles of the Inception and ResNet models [22]. This hybrid model is employed for detecting EC. The basic architecture of the Inception ResNet V2 model, is shown in Fig. 6, which includes the inception modules, convolutional layers and residual connections.

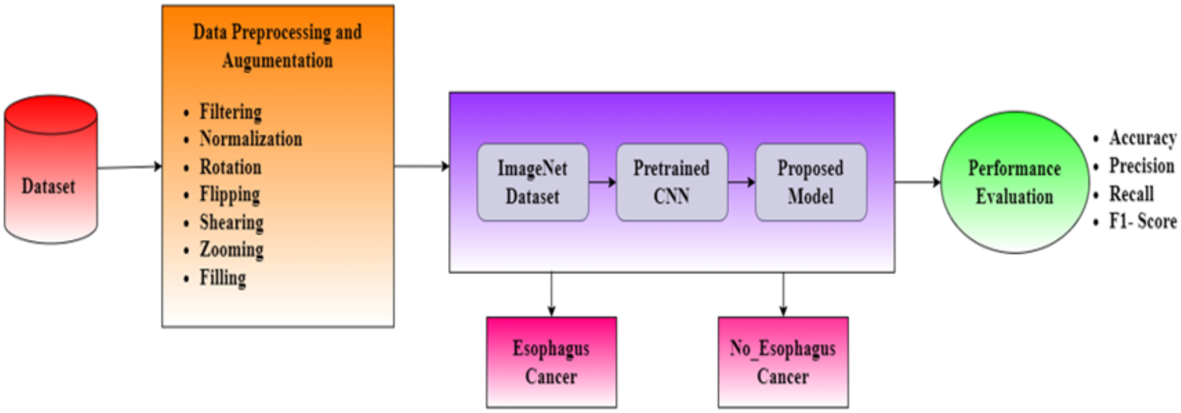

Fig. 3. Block diagram of the proposed methodology.

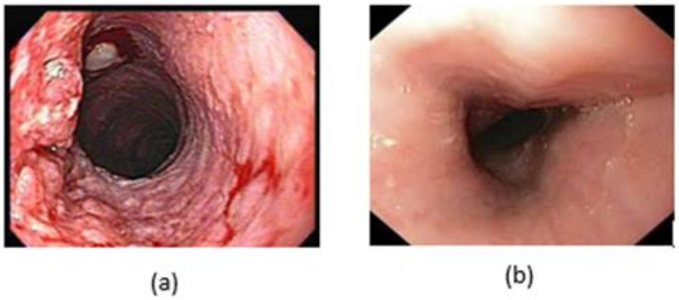

Fig. 4. Sample endoscopic images of (a) Esophagus cancer (b) Normal.

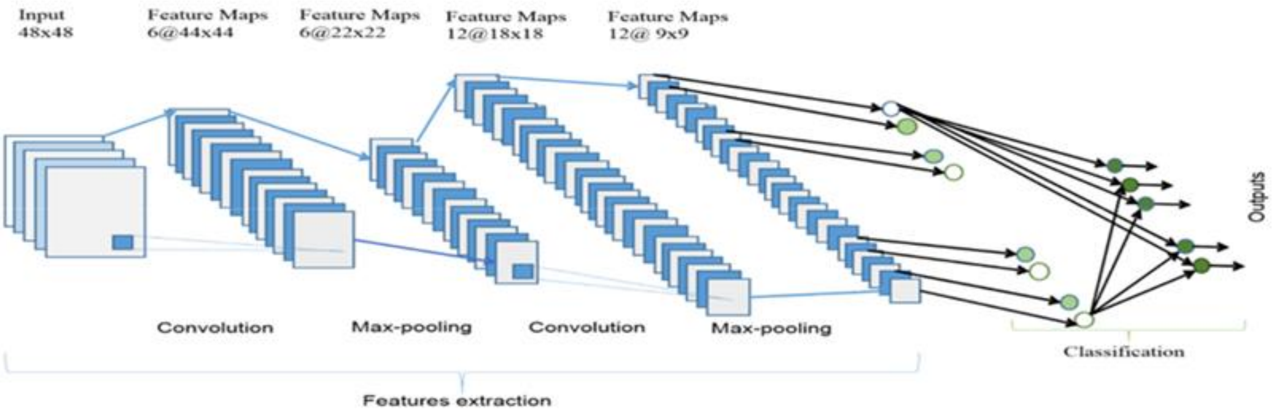

Fig. 5. Basic block diagram of CNN.

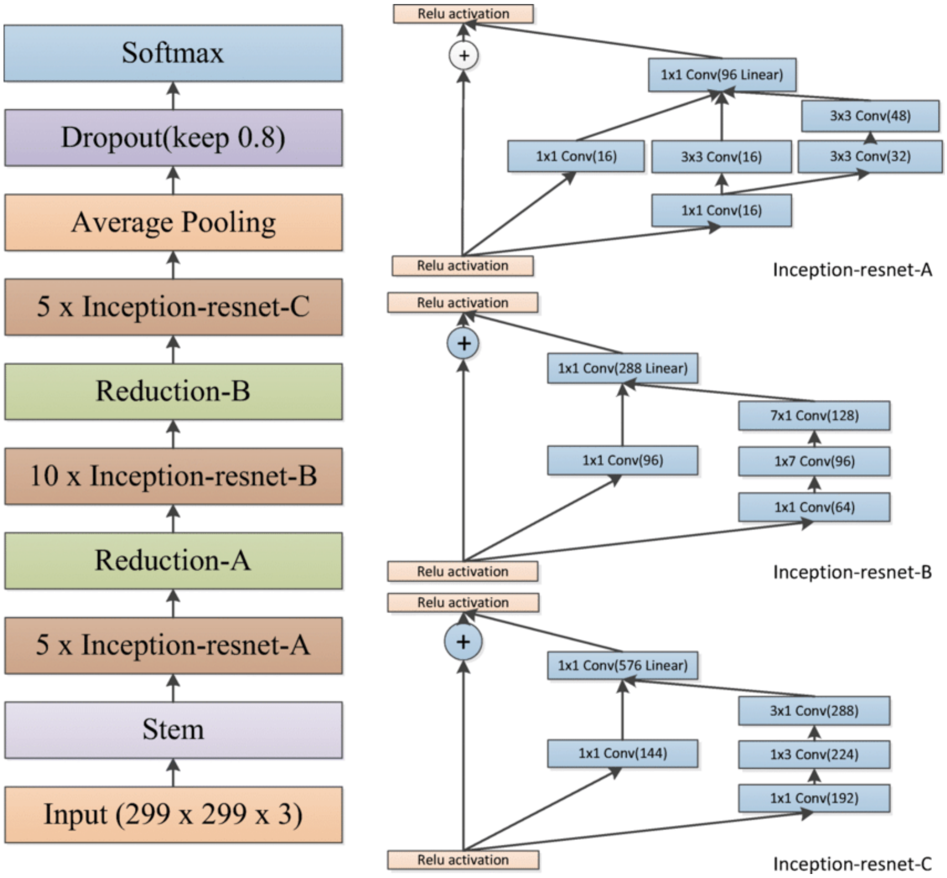

Fig. 6. Basic architecture of inception ResNet V2 model.

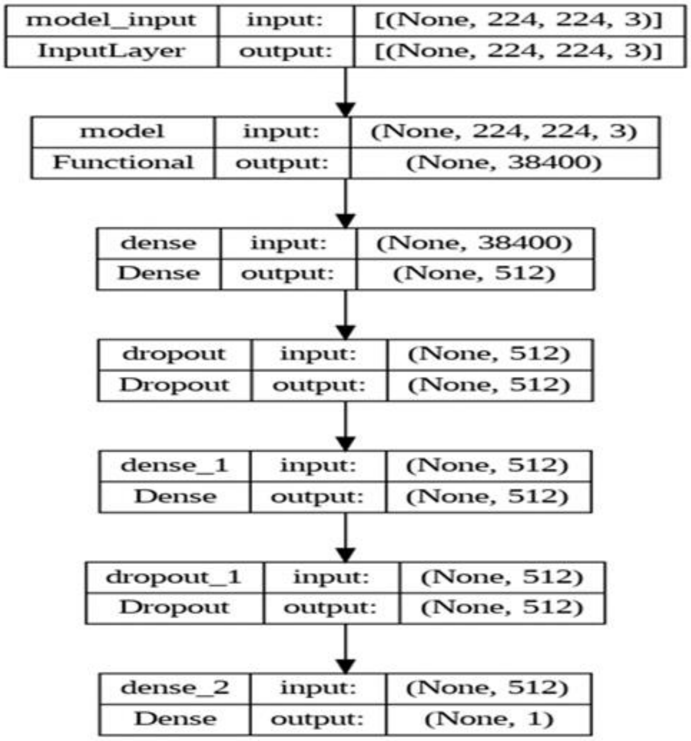
The endoscopic images are given as input to the Inception ResNet V2 model, functioning as a feature extractor. This allows the model to capture the features from the input image, including textures, shapes, and patterns associated with EC. The inception modules within the architecture conduct parallel convolutions at different scales, facilitating the model in capturing multi-scale features. The residual connections within each block facilitates gradient propagation. By combining the advantages of inception modules and ResNet's skip connections, Inception-ResNet V2 achieves high accuracy and computational efficiency in deep network training. In the proposed fine-tuned model, a pre-trained Inception ResNet V2 functions as a feature extractor, extracting significant features from the input endoscopic images. These features extracted are subsequently fed into dense layers comprising fully connected neural network layers for classification. The proposed framework architecture is depicted in Fig. 7.



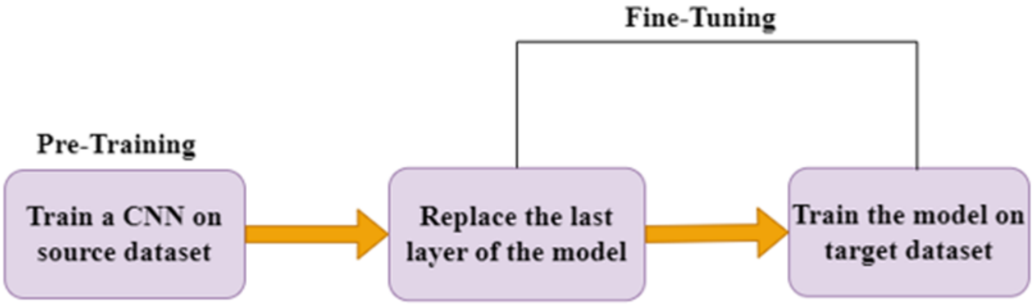
model_input | input: | [(None, 224, 224, 3)]
InputLayer | output: | [(None, 224, 224, 3)]
model | input: | (None, 224, 224, 3)
Functional | output: | (None, 38400)
dense | input: | (None, 38400)
Dense | output: | (None, 512)
dropout | input: | (None, 512)
Dropout | output: | (None, 512)
dense_1 | input: | (None, 512)
Dense | output: | (None, 512)
dropout_1 | input: | (None, 512)
Dropout | output: | (None, 512)
dense_2 | input: | (None, 512)
Dense | output: | (None, 1)

Fig. 7. Proposed model architecture.

The initial dense layer comprises 512 units and employs the ReLU activation function, introducing non-linear characteristics to the model, enables to learn more complex patterns and relationships within the data. To reduce the issue related to overfitting, a dropout layer with a dropout rate of 0.3 is applied after the initial dense layer. Following, another dense layer with 512 units and ReLU activation, similar to that of the previous layer, captures high-level representations and patterns from the data, while a dropout of 0.3 is applied again to prevent overfitting. At last, the output layer of the model consists of a single neuron with sigmoid activation. This configuration is well-suited for binary classification, effectively distinguishing between endoscopic images depicting “EC’’ or “No_EC”.

Fine-tuning is a specific approach within the TL where the pretrained model's parameters are fine-tuned using the new dataset as shown in Fig. 8 [23].

In endoscopic image-based EC detection, fine-tuning involves in adapting a pretrained deep learning model, such as Inception-ResNet V2, that has previously been trained on a large dataset. During fine-tuning, the initial layers of the pretrained model, which capture general features are kept fixed or "frozen" to preserve the knowledge gained during the original training. This ensures that the model retains its ability to recognize basic patterns and structures. Next, the model is trained on the new dataset of endoscopic images depicting EC. This model adjusts the weight of the latter layers to extract features specific to the EC detection. These later layers, starting from the 600th layer onwards in this case, are responsible for capturing more specific features relevant to the new task or dataset. Applying a low learning rate during fine-tuning allows the later layers of the model to adapt slowly to the new dataset. As the training progresses, the model learns to extract task-specific features from the endoscopic images, such as shapes, textures, and patterns associated with EC for accurate predictions. Finally, the dense layers at the end of the model are used for classification, detecting whether the endoscopic images depict EC or not. Table I provides a summary of the proposed model, both before and after fine-tuning.



Fine-Tuning
Pre-Training
Train a CNN on source dataset
Replace the last layer of the model
Train the model on target dataset

Fig. 8. Block diagram of fine-tuning.

TABLE I. SUMMRY OF THE DESIGNED MODEL

	Before Fine-tuning	**After Fine-tuning**
Total Parameters	74,261,217	74,261,217
Trainable Parameters	19,924,481	46,509,569
Non-Trainable Parameters	54,336,736	27,751,648

The algorithm for the proposed model is outlined below:

```
Algorithm
Input: Endoscopic image dataset, labels determine Esophagus cancer or No_Esophagus cancer.
Output: Predictions of whether the input image contains esophagus cancer or not
Begin:
Load and preprocess data:
    1. Collect dataset: S= {($M_i$,$n_i$), where $M_i$ is an endoscopic image and $n_i \in \{0,1\}$ $n_i i \in \{0,1\}$ (1: No_EC, 0: EC).
    2. Preprocess:
        • Resize: $M_i \rightarrow M_i' \in R^{224\times224}$
        • Normalize: $M_i' \rightarrow \frac{M_i'-\mu}{\sigma}$
        • Data Augmentation: $M_i' \rightarrow \{M_i''\}$ (Shear, Zoom, Flipp, Rotation)

Define Base Models:
    1. Load Inception ResNet V2
    2. Input: $224 \times 224 \times 3$
            Dense (512, activation='relu')
            Dropout (0.3)
            Dense (512, activation='relu')
            Dropout (0.3)
            Dense (1, activation='sigmoid')
    3. Weight Initialization: Random initialization for new layers.

Fine tune the Model:
    1. Compile Modified Model:
       model. Compile (loss='binary_crossentropy', optimizer='Adam')
    2. Fine-tuning from the 600th Layer Onwards:
           for l≥600, layer. trainable=True
           for l<600, layer. trainable=False
    3. Train the Model with Fine-tuning Hyperparameters:
           Base_learning_rate= $\eta$
           Lower_layer_learning_rate= $\frac{\eta}{10}$
           Optimizer_higher_layers= Adam(learning_rate= $\eta$)
           Optimizer_higher_layers= Adam(learning_rate= $\frac{\eta}{10}$)
       history = model.fit (train_data, epochs=num_epochs, validation_data= (val_data, val_labels))
    4. Update the Lower Layers:

Model Evaluation:
    1. Evaluate:
           metrics=M.evaluate( $X_{test}$ , $y_{test}$ ), where metrics include accuracy, precision, recall and f1- score.
    2. Adjust Hyperparameters:
       if test_accuracy < desired_accuracy: adjust hyperparameters and retrain

Save the Model
End
```

D. Hardware and Software Setup

The method proposed for detecting EC from endoscopic images is implemented and evaluated on the Google Colaboratory platform. Two different learning rates, 0.0001 and 0.00001, are selected for the training process. The Adam optimizer is chosen for its effectiveness in optimizing DL models by adapting the learning rate during training. Additionally, the binary crossentropy loss function is employed which is commonly used for the binary classification distinguishing "EC" and "No EC". A batch size of 8 samples per iteration is utilized during training such that the model processes eight images at a time before updating its parameters. The training process is conducted over 10 and 20 epochs, with each epoch representing one complete pass through the entire training dataset. The hyperparameters of deep neural networks are determined empirically and have a notable impact on the learning process, as detailed in Table II.

TABLE II. HYPERPARAMETERS

Parameters	**Value**
Image Size	224*224
Batch Size	8
Optimizer	Adam
Learning rate	0.0001, 0.00001
Number of epochs	10,20
Activation function	Relu, Sigmoid
Loss	Binary crossentropy
Class mode	Binary

IV. RESULTS AND DISCUSSION

A. Evaluation Metrics

Evaluation metrics offer a quantitative assessment of performance of the model, facilitating a structured and a comprehensive evaluation of its effectiveness. Table III shows several key evaluation criteria from the proposed study.

Table IV shows the classification report of the proposed models for EC detection from endoscopic images, revealing significant performance improvements after fine-tuning. Initially, the model achieved 94.49% accuracy, which is increased to 98.50% after fine-tuning. Precision improved from 95.99% to 97.50%, while recall rise from 96.24% to 98.75%. The F1-score also increased substantially from 94.99% to 98.00%. These enhancements demonstrate that fine-tuning the model led to a more accurate and precise classification performance, effectively identifying positive instances while minimizing false positives.

TABLE III. EVALUATION METRICS

$Accuracy = (T_P + T_N)/(T_P + T_N + F_P + F_N)$	(1)
$Recall = (T_P)/(T_P + F_N)$	(2)
$Precision = (T_P)/(T_P + F_P)$	(3)
$F1 - Score = 2[(Recall * Precision)/(Recall + Precision)]$	(4)
$T_P = True\ Positive, T_N = True\ Negative, F_P = False\ Positive, F_N = False\ Negative$	

TABLE IV. CLASSIFICATION REPORT OF PROPOSED METHOD

Metrics	Before Fine-tuning	After Fine-tuning
Accuracy	94.49 %	98.50 %
Precision	95.99 %	97.50 %
Recall	96.24 %	98.75 %
F1-score	94.99 %	98.00 %

Plots, such as accuracy and loss plots, are utilized in EC detection using endoscopic images to visualize the performance of ML models during training. The accuracy plot displays how well the model performs in terms of correctly predicting the target variable over each epoch of training. Conversely, the loss plot illustrates the value of the loss function across each epoch, representing how well the predictions of the model match with the actual target values. As training progresses, the accuracy tends to increase while the loss decreases, indicating that the model is learning to make more accurate predictions.

Fig. 9 illustrates the accuracy plot and loss plot of the model before fine-tuning. Initially, in Epoch 1, the proposed model attained an accuracy of around 83.36% on the training dataset and 91.87% on validation dataset, indicating a good performance at the start of training. With each epoch, the accuracy gradually improves. By the final epoch (Epoch 10), the accuracy increases to approximately 96.02% on the training dataset and 96.25% on the validation dataset. Regarding loss of the model, it begins with a relatively high value of 0.7302 in the initial epoch and progressively decreases over subsequent epochs. By the final epoch, the loss reduces to 0.1039, indicating that the model's predictions become more accurate as training progresses.

Fig. 10 illustrates the accuracy plot and loss plot of the model after fine-tuning. Initially, in Epoch 1, the proposed model attained an accuracy of about 90.39% on the training dataset and 96.25% on the validation dataset. As training progressed, the accuracy is improved, reaching approximately 98.83% on the training dataset and 99.06% on the validation dataset at Epoch 30. Regarding the loss, the initial epoch (Epoch 10) showed high loss around 0.2356, indicating initial errors in prediction. However, as training continued, the loss slowly decreased, reaching approximately 0.0304 by the final epoch (Epoch 30). This decrease indicates that the model's predictive accuracy results in more precise classification as "EC" or "No EC".

A randomly selected image from the dataset is subjected to classification using the proposed model, accurately identifying it as either "EC" or "No EC." This successful classification, depicted in Fig. 11, underscores the model's effectiveness and reliability in accurately identifying and categorizing images within the dataset. Table V presents a comparison of the accuracy between the proposed and current techniques.

TABLE V. COMPARISON BETWEEN THE PROPOSED METHOD AND EXISTING METHODS

SL. No:	Author	Methodology	Accuracy (%)
1.	Chong Lin et al. [7]	nnU-Net	88.20
2.	Fang et al. [10]	U-Net & ResNet	84.724 (NBI), 82.377 (WLI)
3.	Zhang et al. [12]	Two-stage DLS	90.3
4.	Mohammed [13]	FCM & CNN	95
5.	Gong et al. [14]	DL	95.6
6.	Chen et al. [15]	Faster RCNN	93.53
7.	Takeuchi et al. [16]	VGG16 CNN	84.2
8.	**Proposed Methodology**	**Inception ResNet V2 with Fine tuning**	**98.50**

The following table presents the comparison of the proposed method for EC diagnosis from endoscopic images with existing approaches. The proposed methodology which uses Inception ResNet V2 with fine-tuning, achieved the highest accuracy at 98.50%. This outperforms the performance of other methods, such as nnU-Net by Chong Lin et al. with 88.20% accuracy, U-Net & ResNet by Fang et al. with 84.724% (NBI) and 82.377% (WLI), and the two-stage DLS by Zhang et al. with 90.3%. Other notable methods include FCM & CNN by Mohammed at 95%, DL by Gong et al. at 95.6%, Faster RCNN by Chen et al. at 93.53%, and VGG16 CNN by Takeuchi et al. at 84.2%. The results indicate that the proposed method significantly outperforms existing approaches, highlighting its potential effectiveness in accurately diagnosing esophageal cancer from endoscopic images. Fig. 12 shows the graphical representation of the comparison of the proposed and existing approaches.

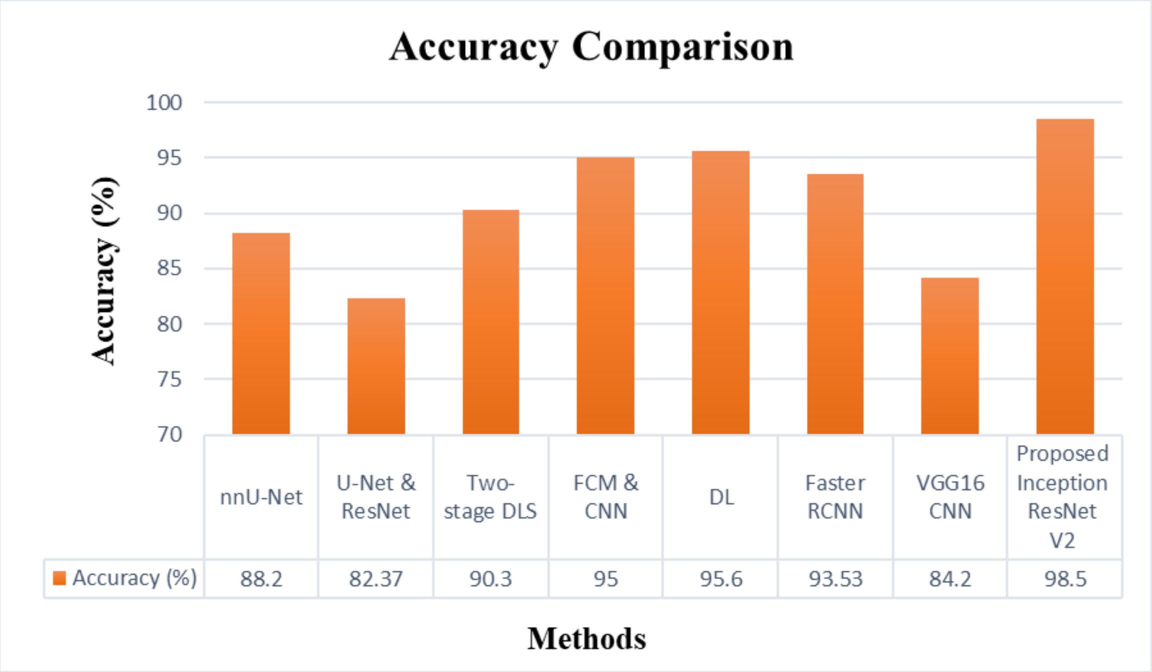

Fig. 12. Accuracy comparison of existing and proposed methods.

V. Conclusion

The early identification of EC is essential in enhancing treatment effectiveness and improving patient outcomes. This study proposes an effective DL method for detecting EC from endoscopic images. The methodology employed a deep CNN architecture, specifically the Inception ResNet V2 model. Preprocessed images are fed into the Inception ResNet V2 model, which serves as a feature extractor. TL was used to enhance the model for EC diagnosis. Through fine-tuning, the model successfully classified images depicting EC or not. The results show the efficacy of the suggested model showing significant improvements in the model exhibiting 98.50% of accuracy, 97.50% of precision, 98.75% of recall and 98.00% of F1 score. These improvements show that the model can accurately identify positive instances while minimizing the false positives which is crucial for the cancer diagnosis. Thus, the study presents a robust DL approach for EC detection from endoscopic images, providing exciting opportunities for enhancing treatment efficiency. One of the major limitations of the proposed work is its computational complexity.

Acknowledgment

I would like to express my sincere gratitude to all those who contributed to the completion of this research paper. I extend my heartfelt thanks to my supervisor, my family, my colleagues and fellow researchers for their encouragement and understanding during the demanding phases of this work.

Information Systems Dept.-Faculty of Computer Science and Artificial Intelligence, Beni-Suef University, Beni-Suef, Egypt[3]

***Abstract*—This paper proposes a framework to solve academic certificate fraud by implementing a blockchain network. A permissioned Hyperledger fabric network is deployed to store students' information and allows the proper access to guarantee the system security. The paper discusses several studies that introduce variants of solutions for the academic certification tampering problem by using blockchain technology. It finds Hyperledger Fabric secure, performant with higher TPS than Bitcoin and Ethereum; latency increases with participant number.**

Keywords—Academic certificates; tampering; security; blockchain; hyperledger fabric; Ethereum; channels; nodes; peers; chaincode

I. Introduction

Education in the era of industry 4.0 is different from the old days, Nowadays, Technology becomes a part of everything, especially, one of the most important pillars of nations' development. Thus, technologies like the Blockchain had been employed to help developing education in many forms; education systems management, Institutional Accreditation, Academic records, academic credits, and degrees' verification. Hence, no wonder, Blockchain is a promising technology that had been adopted by a variety of industries such as health records, manufacturing, tourism, supply chain & logistics, financing & banking, and education [1], which is because of the immutable ledger that made it secured, decentralized, transparent, and accountable networking technology [2].

Credential fraud is one of the challenges that had been an obstacle for the education systems around the world, particularly, as it affects the education quality, trustworthiness, and creditability, thus, the country's education ranking. For instance, The United Kingdom was known for hosting the biggest amount of Diploma mills [3] while investigations resulted in the University of Wales shutting down its degree validation system and the registrar resigning [4]. Furthermore, one in every nine politicians in the lower house of the Russian Duma held a fake academic degree as per a study was conducted in 2015 [5]. Pakistan was not any far from that, where regulatory bodies were easily able to fake degrees of high-standard officials and it was discovered by the Federal Investigation Agency in January 2018 [6]. And when it comes to our Arab world, we can mention the 450.000.000$ revenues that were gained by an American-operated diploma mill that had offices in Europe and the Middle East [7].

As it was mentioned, the Credentials fraud is prevalent all over the world, however some recent project started to counter this, thanks to the new Blockchain network helps to store students' data safely and allow appropriate access to their records [8], Moreover, it supports the management system of the academic degrees and the learning outcomes [9]. That is why integrating a degree verification system for higher education can be a noted step in achieving the education development goals in Egypt.

Blockchain-based education solutions had been proposed and implemented in many higher institutions; in Massachusetts institute of technology in the United States of America has implemented a project named "Blockcert" that is an open-source developing platform that allows developers to develop certifications' validation applications for academic records [10]. Also, in Maribor University in Slovenia where the EDUCTX project was first introduced to be a peer-to-peer student and university network that allows students credit for fees payments [11].

This study is of utmost importance as it tackles the urgent requirement for secure and tamper-resistant validation of academic qualifications. Through Hyperledger fabric technology, this framework guarantees transparency, diminishes fraudulent activities, and strengthens confidence in the educational field. It holds substantial practical implications for educational institutions and employers globally, simplifying the validation procedure. Furthermore, it lays the groundwork for future progressions in digital credentialing and decentralized authentication systems.

Researchers opt for the blockchain-suggested framework to verify academic certificates because it effectively tackles the problem of certificate tampering for several compelling reasons:

1) Firstly, the immutability of the blockchain ensures that once academic certificates are recorded, they become tamper-proof, making it virtually impossible to alter certificate data without detection. Additionally, the blockchain's consensus mechanism maintains the integrity of the certificates by validating any changes to the records.

2) Furthermore, the transparency and auditability provided by the blockchain play a crucial role in addressing the problem of certificate tampering. The transparent ledger allows authorized participants to view all transactions related to certificates, aiding in the identification and tracking of any unauthorized changes. Moreover, comprehensive audit trails enable easy verification of certificate authenticity and detection of tampering attempts.

3) The decentralized verification offered by the blockchain framework also contributes to addressing the issue of certificate tampering. The use of a distributed network ensures that no single entity controls the certificate data, reducing the risk of tampering by internal or external actors. Additionally, consensus protocols used in blockchain ensure that changes are only accepted if agreed upon by multiple network participants, further mitigating tampering risks.

However, evaluating the security of this framework through penetration testing is valuable, but it has limitations. These limitations encompass its limited scope, the possibility of overlooking untested areas, time and resource constraints, and reliance on the testers' knowledge. Furthermore, the constantly changing threat landscape means that new vulnerabilities may arise after the testing process. Ethical and legal factors can also limit the extent of testing, and live system tests may cause disruptions in operations. Lastly, penetration testing may fail to identify certain issues, such as insider threats or subtle logical flaws, highlighting the necessity of a comprehensive, multifaceted security assessment approach.

II. Background

Blockchain was defined by (Wang) [12] as "an essentially a distributed database of records, or public ledger of all transactions or digital events that have been executed and shared among participating parties", originally, Bitcoin was first introduced and developed in 2008 as the base stone for Blockchain technology [13]. Simply, Blockchain is a series of blocks linked together using encrypted links or "Hashes", similarly, each of these blocks represents a database record and the Hash is the link between these blocks. Deenmohamed [14] explained the Blockchain that needs to contain at least "three constituents"; "Data" which is the record stored. "Previous hash" and its value of the preceding block hash, and "Hash" which is a calculated value of the block-stored data, and the "Previous hash" that references it.

The decentralized nature of a blockchain, along with its immutability, data encryption, and change transparency, are the key factors that contribute to its exceptional level of security [15].

Conventional client-server systems, such as centralized systems, store all data in a single repository, which exposes the system to potential hacking threats. Also, when maintenance or downtime occurs, the entire system becomes inaccessible; however, in the worst-case scenario, if the system becomes corrupted or irreparable, all the data will be permanently lost. On the other hand, blockchain, as a decentralized network, offers significantly higher security against hacking attempts as it operates without the control of any central authority or third-party controller, ensuring enhanced security measures. Moreover, blockchain technology ensures data immutability, making it tamper-proof once stored through the utilization of cryptographic hash functions. While blockchain maintains transparency by recording every transaction, it also safeguards user privacy by encrypting usernames, thereby protecting the user's identity [16].

Blockchain networks can be permissioned or permissionless. Aswin & Kuriakose [17] explained that Permissioned blockchains differ in that they are exclusively open to a specific group of verified participants. These participants operate within a governance model that fosters partial trust among them. Permissioned block chains serve as a means to secure interactions between entities that share a common objective but cannot fully trust one another. Unlike permissionless blockchains, permissioned blockchains do not require costly mining processes, and implementing a native currency is not obligatory. On the other hand, Permissionless networks stand out in blockchain networks as they are accessible to all individuals, with the added benefit of participant anonymity. This inclusive nature allows virtually anyone to partake in the network, ensuring anonymity for all involved. Trust within permissionless blockchains solely relies on the state of the blockchain itself, as no external factors influence participants' trust. Additionally, permissionless blockchains typically incorporate a native cryptocurrency, which necessitates either mining or transaction fees.

III. Related Work

Based on many studies, Blockchain proved its ability to overcome most of the security issues any other database technology faced before. Especially when the related field is education, as the educational process outcomes is meant to be certified to guarantee and authenticate students' qualification of specific study track. The following studies discussed the deployment of the blockchain in some educational areas in term of certifications' security and validity.

In [1]: The study of Huynh [18] was conducted to set a solution for the global spread of fake certificates which are becoming difficult to be managed or controlled. Today many institutions issue unlicensed certificates, this prolongs the validation process of certificates, especially with the increase in the number of certificate holders.

Thus, the author benefited from the advantages of blockchain and the potentials of Blockcert that can solve the problem of fake certificates more easily and securely. A blockchain called UniCert is deployed to issue and verify certificates which, in the future, will prevent the issuance of any fake certificates based on the author's mention.

The UniCert standard makes it possible to issue multiple certificates simultaneously by committing to the recipient list file format a certain way that each column is used to distinguish recipients. The recipient's UniCoin address is used to retrieve issued certificates. That title is called PubKey. After issuance, the certificate identification number issued to the recipient will be added.

The Merkle root algorithm (hash tree) is designed to be used in cryptocurrency to assure the data blocks' safety when passing through peer-to-peer networks, to be undamaged, complete, and unaltered.

After the target certificate is being hashed, all of those certificate hashes are merged into the Merkle root, and the evidence of this is the trend of Merkle Root that returns at Target Hash. As a result, UniCert Signature is a trust guarantee that every batch of certificates is secure.

In [2]: Problems related to the forgery of certificates lead to dire consequences on society. Certainly, the traditional method of printing paper certificates encourages forgery. It leads to a long wait for the certificate to be issued and then received. To avoid these issues, El-Dorry [19] proposed a digital certificate system that is based on the blockchain with the basic characteristics of consensus, source, immutability, and finality.

This study aims to develop a decentralized system for issuing digital certificates using the blockchain and according to the Hyperledger Fabric framework. This system is characterized by being able to prevent certificate fraud and reduce costs and time taken to issue those certificates. Blockchain was chosen because it is a trackable system that is maintained across synchronized ledgers. It is also a completely tamper-proof system. The use of Hyperledger Fabric is based on its privacy, scalability, and smart contract support.

A decentralized blockchain system consists of a network of participants, in our case, it consists of four organizations: public universities, private universities, corporations, and the MOHESR (Ministry of Higher Education and Scientific Research) in Egypt. As well as graduates with specific roles who represent their universities. All persons within the network, whether participants or actors have their permissions. Graduates query their degree through synchronized ledgers also called ledgers.

As for the Ministry of Higher Education, it can inquire about synchronized books and can issue certificates to graduates of private universities. Also, Companies have the right to verify the authenticity of the certificate, so they are considered actors where companies have access to the verification portal. Graduate certificates will have a period during which they will be valid.

This model was the result of this study where the network configured to accept MOHESR as network administration center, and the ordering service is a solo node for ordering transactions which is just used for development.

The solution consists of three applications, each is connected to the peer organizations to allow actors to interact with the blockchain network to issue, request, and verify a certificate, each according to the allowed permissions.

In [3], on the other hand, the study of Hasan [20] aimed to develop a proposal for a theoretical system to verify graduate certificates. It is a blockchain-based system on the cloud that can issue academic certificates, verify their validity, and block cryptocurrencies.

The study deals with the Blockchain (BC) technology used to solve these problems. It showed that the proposed “DistB-CVS” system found that banned cryptocurrencies can benefit from this BC technology. The research proposed a system model to verify the certificates according to the BC located in the cloud database.

The authors suggested the DistB-CVS architecture based primarily on BC as it is the most suitable solution for countries with crypto-bans.

The paper proposed a consensus algorithm that has a major role in improving the block validation mechanism. This study was able to enhance security by relying on a multi-signature scheme. (Block chain without cryptocurrencies). The research evaluated the performance of the displayed architecture while adding various criteria such as increased throughput and latency change.

It has been observed that the proposed “DistBCVS” architecture shows much better performance after a certain time. That's because of the strong authentication and privacy performance of the current model. Data becomes more secure when using a multi-signature scheme.

In [4], Gayathiri [13] discussed the validation of academic and sports certificates as it is tedious for organizations, and indicated how important it is to convert everything related to diplomas to a digital format. It is known that it is difficult for students to keep their academic degrees, but, in the digital world, SSLC, HSC, and Academic Certificates can become digital, easy-to-obtain, and validated for the students in educational institutions.

The suggested application can work even if it is disconnected from the network. Through it, the authenticity of the certificate and the accuracy of the documented information are quickly verified.

Through the proposed system, it is easy to convert academic and sports certificates to another type called digital certificates. The samples and quantity of the digital certificates are then added, hashed, and stored in blocks. The chaotic algorithm is used to generate the hash value as it takes input in various sizes and produces a fixed-size output. For blocks, each block consists of three sections which are the hash value, timestamp, and the hash value of the previous block. All those blocks are connected in the form of a blockchain.

In the proposed application, the administrator login is via the first page using their login ID and password, on the next page, the student and the certificate are added, and the last page allows validation of the certificate. After login, the administrator can add the student's data and certificates by clicking on the button designated for that. Later, the auditor or the employer can validate the certificate using the auditor's login ID and password. This method provides the student login ID and selects the type of certificate and validates the authenticity of the original certificates by clicking the Verify button.

In [5], Khandelwal [21] argued the certification fraud from a consequence perspective, as he mentioned that people who have worked hard and obtained legitimate degrees suffer from those who have fake degrees.

The system has three main users which are: the user, the organization, and the company that verifies. The user is the person who has the certificates and who can share them with the companies. Institutions are responsible for issuing original certificates. An auditor is an individual or company that verifies the authenticity of certifications.

Once a user has completed a particular course, diploma, or degree, the organization will make a digital copy of the certificate. The organization converts the digital certificate to a base-64 string, then, it hashes the certificate using the SHA-512 algorithm. This hash is sent to the blockchain using the enterprise's private key signature, so the blockchain automatically verifies that signature before a transaction is triggered to add the hash to the blockchain.

Then, the transaction ID is generated successfully. It sends the user the transaction ID obtained and the digital certificate. When the user is in the system, it becomes visible on their control panel. It will also be uploaded to the portal via the user's account. The user can send a digital copy of the certificate to the company through the system. Thus, the company can view and verify all the certificates received from the user on the dashboard.

The system is secure and is a guarantee of the original identity of each of the three entities concerned which are the user, the organization, and the auditor.

In [6], from another view, monitoring personal fraudulent activities can help to detect certificates fraud as discussed by Priya [22] who proposed a system that is able to deploy unique monitoring by updating all personal identity activities and illegal activities carried out against a person. The whole personality and behavioral activities of a person can be monitored by the modification process.

The proposed system was developed on Ethereum platform and being run on Ethereum virtual machine (EVM), and it consists of multiple modules; user interface, verification, building block, android-based QR code generation.

The user can view his certificates after completing the correct authentication, if a third person scans the QR code beyond the allowed limit, that person's location will be sent to the authorized user with the permission link. Also, the user can allow or reject that person through this link.

The system has a transparency that allows the process of requesting and granting the certificate automatically. Thus, companies and organizations will be able to verify the data of any certificate from the system.

In [7], Bousaba & Anderson [23] highlighted the case when a student is going through requesting procedures of requesting an official copy of the certificate or validation of grade after graduation which can be demanded various reasons such as seeking a job or higher education. Usually, people who request verification of grades are bound by a specific time limit. The traditional methods of validating scores are very complex which makes them very time-consuming. It is known that these methods require human labor to maintain them. They often have security or privacy issues.

To solve this system problem, the study provided a solution via Ethereum smart contracts and using a decentralized application (DApp). Via a user profile application, the user is enabled to use the functionality of the Ethereum Smart Contract with a provided web graphical interface. The application allows the programming of transaction logic into the blockchain by connecting the Ethereum blockchain technology to the EVM (Ethereum Virtual Machine) using the Solidity programming language.

Students, universities, and trusted parties can retrieve student information after accessing the requestor's information and then using the private key to decrypt.

However, student data is not subject to change unless it has been intentionally modified and with a specific date for the modified data on the blockchain.

The results of the tests showed that the cost of gas remained constant even though the number of users increased. Another test was done using a third-party account which turns out that he was only able to view the students' profile information but not to edit it. All tests passed and were able to embrace the application's initial use cases.

In [8], another study highlighted that obtaining a fake graduation certificate has become easy due to the lack of an anti-counterfeiting system. This made tracking and validating those certificates in the traditional way arduous.

Devdoot [24] study proposed a system to solve this problem based on smart contracts and IPFS. The list of participants who can interact with our smart contract are university/College, students, and the company.

The certificate data will be collected and appended in a bit matrix then it will be given to IPFS. After it applies the hash algorithm, that hash will be stored with the original certificate.

IPFS will pass that data to the Blockchain. Then, the issuer will be approved for the generation fee in MetaMask. This hash will be stored in the Blockchain and is not subject to change under normal circumstances. The student will be able to send his digital certificate to different institutions and companies.

The issuer will be able to load that certificate or write the hash key. The system will be able to provide a response whether the document is legitimate or illegitimate.

In [9], also, Liu & Guo [25] proposed a scheme that can store certificates, validate scores and combine the properties of the blockchain. The study demonstrated the scheme as follows:

Platform: The front-end system of a web service through which the user of the system can interact with the blockchain. The platform user is mainly divided into three: system administrators, users, and auditors.

Sections. System administrators can manage and assign user rights. The users are the students. They are responsible for submitting, querying, and updating transaction requests for certificate registrations if necessary. The auditors refer primarily to the user of the colleges and to those responsible for checking the validity of certificates.

The system consists of the application layer, the business layer, the smart contract, and the Hyperledger Fabric.

The results of the tests showed that the system is characterized by a faster transaction processing rate than other blockchain systems. Based on this scheme, the transfer rate of transactions of this system is maintained at 180-250 tps. But the Bitcoin-based scheme makes seven transactions per second. And Ethereum is capable of doing dozens of transactions per second. The Hyperledger Fabric-based scheme has the highest transaction throughput.

In [10], the study of Tariq [26] discussed the credential data fraud that has become a common practice and negatively affects investment and trust in higher education systems. This study proposed a blockchain-based solution that provides a comprehensive solution for validating certified data. It is the most influential Cerberus in the fight against fraud as it is connected to the existing validation ecosystem.

The accredited body works in partnership with multiple parties such as universities, and monitoring entities, such as organizations and citizen groups as it maintains the authorized blockchain network. The authorized body can periodically aggregate these transactions into blocks that are then added to the blockchain.

The university issues an academic paper certificate and a digital copy of it when the student graduates. The Registrar digitally signs that accredited certificate and then publishes it on the Cerberus network. Next, the authorized body verifies the digital certificate by the nodes mined in the block which are added to the blockchain. The certified certificate is then issued and certified digitally.

The university issues the student's degree certificate that includes a QR code. The business owner can verify the original certificates by scanning the code using the web portal or smartphone application.

The search prototype was implemented on Parity, an Ethereum client, version 1.10.4-fixed. Parity insists that it is the fastest and most advanced Ethereum client (89).

Cerberus is scalable because it is batch version dependent. It also maintains the privacy of user data.

The authors mentioned that one of the direct additions is to link several approved documents or student qualifications to the system. This ensures that you can check the most recent and that all data is also original. The system can easily integrate this by including the hashes of the previous original data in the parameters of the recently approved data.

In [11], further, the study of Hammi [27] spotted the light on the public key (PKI), as it has a primary function of the infrastructure which is revocation management as this mission is essential to the security of the PKI.

The study relies on the use of a public blockchain to store and publish data for revoked certificates. The proposal uses the same principles as the CRL distribution points to support scalability. When the certificate authority (CA) revokes the certificate, it recalculates the corresponding Bloom filter. It also provides a new transaction to store in the blockchain.

The proposal includes four entities; certificate authority (CA), blockchain (BC), server, and the client.

The Namecoin blockchain was used. Its role is to implement the bit top-level domain. It is also independent of the Internet Corporation for Assigned Names and Numbers (ICANN).

A mechanism based on bloom filters has been proposed because it reduces the time required to provide invalidation information. The study uses the same principles as the CRL distribution points. Each distribution point served by a Bloom filter is filled with revoked certificates. Then, Bloom filters and cancellation information are shared and published using the public blockchain.

Standard deviations calculated on the results of each trial were very low (<0.08 ms), however after the evaluation, it became clear that the revocation system was able to meet the security requirements in addition to its ability to outperform the current systems.

Focusing on the worst-case scenario of our solution, that is when the filter provides a positive response. The challenge is to provide an alternative solution that avoids the downloading of all the LRSIs from the server.

In [12], furthermore, Chengv [28] discussed distance education as it has become one of the most important educational means for students. Despite its advantages, online education makes it difficult to track student activities. There are also difficulties in managing the verification of paper documents and digital files. In this study, a digital education certification prototype is designed based on the use of blockchain, and the abstract algorithm.

Education data can currently be verified by the system, universities, and employers using the certification authorities as to the regulatory nodes of the blockchain consortium.

The student can use the application to issue a digital certificate. Next, a digital certificate is generated and then hashed into a digital fingerprint. The certificate is stored in an immutable position on the blockchain.

Employers are allowed to recognize the authenticity of the digital student certificate.

The mobile terminal software allows students to apply to the school to generate a digital certificate via a specific application. Students can authorize stakeholders to search for their original data.

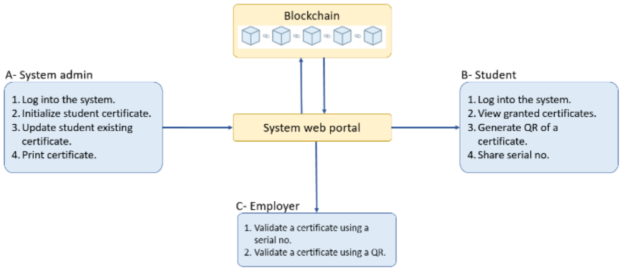
In this prototype, the study considers that the Macau University of Science and Technology will serve as the university's participating node responsible for issuing digital documents. The test environment for Hyperledger Fabric V1.4 is configured with the goal of creating a blockchain framework. The model allows for the virtual deployment of blockchain nodes to three organizations and to share with two peers. To measure the performance of the educational blockchain platform, the Hyperledger Caliper tool is used. This tool also uses scalability and stability.

As a result, the creation of a new transaction recorded a transfer rate of 263.9 tps and a query of 1982.6 tps which verifies the efficiency and the superiority of the proposal over the traditional method.

The mentioned studies illustrate the characteristics and capabilities of the blockchain, which the researchers recommend for building a secure certificate ledger. Blockchain characteristics as revealed are: (1) Immutability, (2) Privacy, (3) Confidentiality, (4) Auditability, (5) Accountability, (6) Interoperability, (7) Data sharing, (8) Tractability, and (9) Data integrity.

IV. The Proposed Framework

The researcher proposes a framework that links the qualifications taken by the student under one account in a blockchain system. Fig. 1 summarizes the general workflow of the proposed framework.



Blockchain
A- System admin
1. Log into the system.
2. Initialize student certificate.
3. Update student existing certificate.
4. Print certificate.
System web portal
B- Student
1. Log into the system.
2. View granted certificates.
3. Generate QR of a certificate.
4. Share serial no.
C- Employer
1. Validate a certificate using a serial no.
2. Validate a certificate using a QR.

Fig. 1. System framework.

The system admin represents the graduation affairs administration in the faculty of commerce and business administration at Helwan University in Egypt. The admin can log into the system using a provided unique username and password to initiate or update an academic certificate of a student. The student account holds all academic certificates related to the concerned student that can be of graduation, masters, or doctorate certificate type.

To add a student's new certificate, the system admin needs to create a new student account by inserting basic information such as student ID, Name, birth place, birth date, nationality, national ID, gender, contact number, email, account user name, and the password.

The admin can add a new certificate by inserting details such as university and faculty name, degree type, degree name, specialization, general percentage, general grade, graduation project grade, total credit hours, the CGPA, graduation season, date of certificate initialization, date of certificate confirmation, thesis title, and the number of prints.

Once a certificate is saved, it is viewable in the student's account, so the student can generate a QR code and share the serial number with the employer. On the other hand, the employer can access the portal to validate a certificate using the certificate serial number provided by the graduate.

V. Framework Implementation

Aswin & Kuriakose [17] revealed that Ethereum operates as a public blockchain, making all data publicly accessible. Consequently, it is well-suited for applications that require interaction with a global audience, such as insurance and peer-to-peer gambling. On the other hand, Hyperledger Fabric is specifically designed for private use cases, particularly in supply chain scenarios where participants should only have access to relevant data. For instance, it allows selling goods at different prices without disclosing this information to all participants. Furthermore, the study found that Ethereum, the more popular framework, offers a diverse ecosystem of development tools. However, it lacks well-established support for various programming languages, resulting in limited options. Conversely, Hyperledger Fabric provides essential tools but supports widely used languages with extensive libraries, facilitating development [17].

The Hyperledger Fabric has been identified by researchers as an optimal choice for implementing the authentication framework for academic certificates due to a variety of key advantages. These advantages include:

1) A permissioned network that ensures controlled access and heightened security by permitting only authorized participants.

2) The modular architecture of the Hyperledger Fabric allows for the customization of components to align with specific requirements, including the integration of pluggable consensus mechanisms.

3) Hyperledger Fabric boasts scalability and performance capabilities, supporting parallel transaction execution to achieve high throughput and low latency, thereby enhancing its scalability.

4) In addition, the platform offers privacy and confidentiality features such as private channels and fine-grained access controls to safeguard sensitive data within the academic certificate authentication framework.

5) The rich query language of Hyperledger Fabric enables flexible and efficient data retrieval and verification processes, enhancing the overall functionality of the system.

6) Furthermore, the platform promotes interoperability by seamlessly integrating with existing systems and supporting cross-platform compatibility, ensuring smooth operation within diverse technological environments.

7) Hyperledger Fabric benefits from a strong community and support system, with an active development community and comprehensive documentation to assist users in navigating the platform effectively.

8) The platform provides features that aid in regulatory compliance, including audit logs and privacy controls, to help meet the necessary regulatory requirements for the authentication of academic certificates.

These combined benefits establish Hyperledger Fabric as a robust, secure, and scalable solution for the authentication framework of academic certificates.

Hyperledger fabric implemented system consists of:

1) Organizations (Peers): are the entities which the transactions are being transferred among, such as graduation affairs administration, student, and the employer, and each of them has its own ledger.

2) Chain code: is the smart contract that contains the transaction code – instructions- that is required to be executed, such as inserting student data, insert a new certification, and retrieve student's data, etc.

3) Consensus mechanism: serves as the validation principle through which all participating organizations reach an agreement on the data that is generated as a result of executing the Chaincode.

4) Endorsement policy: the agreement policy which verifies user authentication, creates a version of the asset that allows read and write operations, and has the authority to either accept or reject the proposal.

5) *Channels*: between the peers to execute transactions.

The Hyperledger Fabric network is deployed using single-organization model for executing the following Chaincode (a simplified textual representation):

Chaincode:

```
Procedure CreateAccount(ctx, studentID, Name, birthplace, birthdate, nationality, nationalID, gender, contactnumber, email, accountusername, password)
    studentExists = Call StudentExists(ctx, studentID)

    if studentExists
        return "Student already exists"

    student = {
        studentID, Name,  birthplace,  birthdate,  nationality,
        national_ID,  gender, contactnumber, email,
        accountusername,  password}

    Call PutState(ctx.stub, studentID, Buffer.from(JSON.stringify(student)))
    return "Student account created successfully"

Procedure InsertCertificate(ctx, studentID, universityname, facultyname, degreename, specialization, generalpercentage, generalgrade, graduationprojectgrade, totalcredithours, CGPA, graduationseason, dateofcertificateinitialization, dateofcertificateconfirmation, numberofprints)
    studentExists = Call StudentExists(ctx, studentID)

    if not studentExists
        return "No student account found"

    degreeExists = Call DegreeExists(ctx, degreename)

    if degreeExists
        return "Degree already exists"

    certificateID = Call GenerateRandomCertificateID()
    certificate = {
        certificateID, studentID, universityname, facultyname,
        degree_name, specialization, generalpercentage, generalgrade,
        graduationprojectgrade, totalcredithours, CGPA,
        graduationseason,
        dateofcertificateinitialization, dateofcertificateconfirmation,
        numberofprints       }
    Call PutState(ctx.stub, degreename, Buffer.from(JSON.stringify(certificate)))
    return "Student account created successfully. Certificate ID: " + certificateID

Procedure RetrieveCertificates(ctx, studentID)
    studentExists = Call StudentExists(ctx, studentID)

    if not studentExists
        return "No student account found"
    certificates = []
    iterator = Call GetStateByPartialCompositeKey(ctx.stub, 'certificate', [studentID])

    for each (key, value) in iterator
        certificates.push(JSON.parse(value.toString('utf8')))

    return if certificates.length > 0 then certificates else "No certificates found for this student"

Procedure StudentExists(ctx, studentID)
    studentData = Call GetState(ctx.stub, studentID)
    return bool(studentData and length(studentData) > 0)

Procedure DegreeExists(ctx, degreename)
    certificateData = Call GetState(ctx.stub, degreename)
    return bool(certificateData and length(certificateData) > 0)

Procedure GenerateRandomCertificateID()
    min = 1000
    max = 9999
    return random(min, max)
```

VI. Application Procedures

The process of inserting student data into the HLF network involves the following procedures:

1) The system admin initiates a request (proposal) to carry out the insertion transaction for the student's data.

2) The endorsing peer emulates the proposal by applying the endorsement policy, so it can either accept or reject the proposal.

3) If the proposal is approved, system sends the required transaction to the ordering service node.

4) The ordering service node maintains process concurrency and integrity by generating a batch (block) comprising the requested transactions and guarantees their sequential placement in the correct order.

5) Then it passes all the approved transactions to all peer to insert the data into their ledgers.

6) Peers validate each transaction by validating; the endorsement policy and the read/ write version.

7) Then the peers commit the transactions block to the blockchain, therefore, all peers will see the new inserted data.

In the realm of blockchain, the current data is stored in the world state ledger, which is constantly updated. Simultaneously, the log information ledger documents the historical transactions. This divergence in ledger functionality distinguishes hyper ledger fabric from Ethereum.

VII. Results

The study places utmost importance on ensuring the security of the Hyperledger fabric network. However, the process of gauging the security of a Hyperledger Fabric network is all-encompassing, involving a thorough examination of technical aspects, policy considerations, and ongoing monitoring. To effectively address the ever-evolving threats and vulnerabilities, it is crucial to conduct regular security audits and implement necessary updates. Engaging with security experts and staying well-informed about the latest developments in blockchain security is of utmost importance in order to maintain a secure Hyperledger Fabric network. This highlights the role of security measures as a type of technological limitation.

Linux's security assessment of Fabric reveals that it is a robust and well-designed platform with a strong implementation. The platform has demonstrated a high level of security and functionality, positioning it well for future updates and addressing any potential flaws in the industry-standard cryptography [29].

Performance measurement of a blockchain network is as crucial as its security. To evaluating the read-write throughput of the network constructed, we utilized the Hyperledger caliper tool and conducted a comparative analysis with Ethereum and Bitcoin.

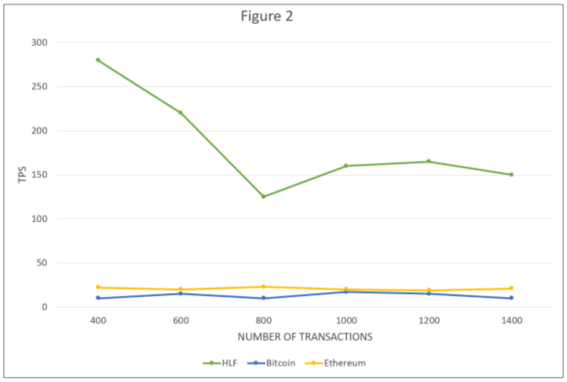


Fig. 2. No. of transactions HLF vs Bitcoin and Ethereum.

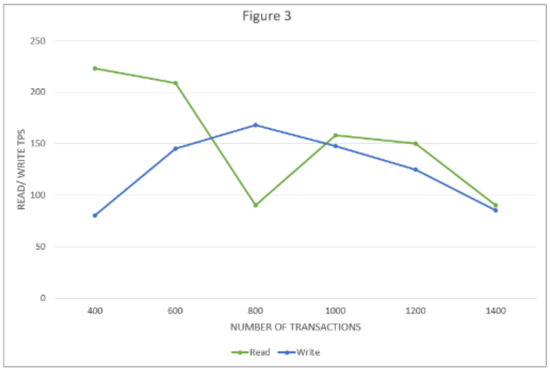

Fig. 3. Transactions read / write speed per second.

The outcomes of the tests are illustrated in Fig. 2 and Fig. 3. Notably, the Hyperledger network exhibited a higher TPS (Transactions per Second) compared to Bitcoin and Ethereum. This discrepancy can be attributed to the fact that the latter two are public blockchains, involving the issuance of coins and utilizing different consensus protocols. As the number of transactions increases, the reading performance surpasses the writing performance, primarily due to the requirement of consensus for writing. Consequently, the read and write performance of the blockchain is influenced as the transaction volume rises.

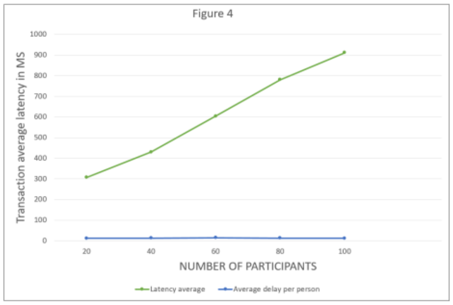

Fig. 4. Network latency test result.

The data in Fig. 4 clearly demonstrates the network latency test results (Time taken for a transaction to be committed). As the number of participants' increases, both the average delay and the average delay per person also increase. This relationship is evident when examining the results for 20, 40, 60, 80, and 100 participants, where the average delay values are 306.5ms, 430ms, 603.7ms, 780.9, and 911.3ms, respectively. It is worth noting that the average delay per person ranges from approximately 12-14ms.

VIII. Conclusion

In our research article, we presented a secure database for academic certificates utilizing Hyperledger Fabric. This innovative approach effectively addresses the issues of fraud and tampering associated with academic certifications. The framework showcased in our study emphasizes the significance of safeguarding academic data, particularly within a multi-peer network. The utilization of Hyperledger Fabric technology proves to be paramount in this context. Moving forward, our future investigations will focus on further enhancing academic accreditation through the integration of blockchain technology.

Acknowledgment

We sincerely appreciate the financial support from Watan First Digital, which played a crucial role in enabling this study. Their generous funding allowed us to carry out the essential research and bring this project to fruition.

DGA Domain Name Detection and Classification Using Deep Learning Models

Ranjana B Nadagoudar[1], M Ramakrishna[2]
Dept. of Computer Science and Engineering, Visvesvaraya Technological University, Belagavi, India[1]
Dept. of Computer Science and Engineering, Vemana Institute of Technology, Bangalore, India[2]

***Abstract*—In today's cyber environment, modern botnets and malware are increasingly employing domain generation mechanisms to circumvent conventional detection solutions reliant on blacklisting or statistical methods for malicious domains. These outdated methods prove inadequate against algorithmically generated domain names, presenting significant challenges for cyber security. Domain Generation Algorithms (DGAs) have become essential tools for many malware families, allowing them to create numerous DGA domain names to establish communication with C&C servers. Consequently, detecting such malware has become a formidable task in cyber security. Traditional approaches to domain name detection rely heavily on manual feature engineering and statistical analysis, with classifiers designed to differentiate between legitimate and DGA domain names. In this study, we propose a novel approach to classify and detect algorithmically generated domain names. The deep learning architectures, including LSTM, RNN and GRU are trained and evaluated for their effectiveness in distinguishing between legitimate and malicious domain names. The performance of each model is evaluated using standard metrics such as precision, recall, and F1-score. The findings of this research have significant implications for cyber security defense strategies. Our experimental findings illustrate that the proposed model outperforms current state-of-the-art methods in both DGA domain name classification and detection. Our proposed model achieved 99% accuracy for DGA classification. By integrating additional feature extraction and knowledge-based methods our proposed model surpasses existing models. The experimental outcomes suggest that our proposed model gated recurrent unit can achieve 99% accuracy, a 94% recall rate, and a 98% F1-score for the detection and classification of DGA-generated domain names.**

Keywords—Botnet; cyber security; Domain Generation Algorithms (DGAs); gated recurrent unit; Domain Name System (DNS)

I. INTRODUCTION

With rapid advancement in the information technology and development of mobile Internet, there is increase in the Internet connected devices, detecting malicious domain names is of great importance for network security. The rapid evolution of the Internet has revolutionized daily life with unprecedented convenience, yet it also presents a formidable threat to network security. A constant stream of malicious attacks continues to emerge, with botnet-based attacks standing out as a major concern [1]. Botnets consist of a chain of malware-infected hosts, where a central machine commands these compromised hosts remotely via a C&C server to carry out malicious activities. Utilizing the Domain Generation Algorithm (DGA), botnets exploit algorithmic characteristics to generate pseudo-random strings and dynamically select connected hosts, significantly enhancing their stealth and resilience [2]. Consequently, detecting DGA domain names with high accuracy and minimal cost is crucial for safeguarding network security.

Conventional methods for detecting domain names primarily rely on extracting artificial features from Domain Name Server (DNS) traffic or statistical characteristics of domain name language. Machine learning is then applied to analyze these features for the classification and identification of domain names [4]. However, accurately identifying the appropriate type of DGA is a challenging task. Each DGA family typically represents a cluster of similar algorithms, and various types of DGAs exhibit distinct DNS traffic patterns and statistical characteristics of domain names. Consequently, detection strategies that hinge on artificial feature extraction are costly and lack adaptability, rendering them inadequate for handling the intricacies of DGA types [5]. Therefore, the development of a DGA detection model using deep learning has garnered research attention as an enhanced detection approach compared to traditional methods.

Developing cyber security solutions remains a formidable challenge. Traditional signature-based detection systems rely on human involvement in continuously oversee and revise signatures, making them ineffective against emerging forms of cyber threats and emerging malware. Recent advances in optimization and parallel/distributed computing technologies have enabled the efficient training of large-scale datasets. Deep learning, a subset of artificial intelligence, has significantly improved performance across various domains [6]. Architectures like LSTM, RNN and GRU have demonstrated superior performance in cyber security applications compared to classical machine learning algorithms.

Real-time approaches for detecting Domain Generation Algorithms (DGAs) aim to classify domains as either benign or generated by a DGA [7]. Retrospective methods have shown poor performance in this regard. Early detection techniques likely employed machine learning methods. Classical approaches to machine learning-based DGA detection heavily emphasize feature engineering, which results in performance of these methods are dependent on domain specific features [8]. Recently the deep learning architectures have been considered for DGA classification and detection, these methods perform better over the traditional ML algorithms, which circumvent feature engineering and shows significant performance improvement [12].

In this paper, our intent is to evaluate the effectiveness of deep learning models for algorithmically generated domain detection. We suggest a deep learning technique called gated recurrent unit for DGA classification and detection. Initially this model performs the binary classification, which gives the probability of being benign or DGA generated. Further it detects whether the domains are legitimate or DGA generated, if the domain name is generated by a DGA then it will categorize the domain into respective DGA family it belongs.

The structure of this paper is as follows. Section II examines algorithmically generated domain names and reviews related work on DGA domain detection. Section III provides an explanation of the domain generation algorithm. Section IV covers the theoretical background of deep learning methods. Section V outlines the overall procedure for DGA domain classification and detection, while Section VI describes the dataset used. Section VII evaluates the detection performance of the proposed deep learning models through experimentation. Results and discussion is given in Section VIII. Finally, Section IX presents the conclusions drawn from the study.

II. Related Work

In recent years, many malware families have shifted their approach to communicating with remote servers. To distinguish DGA-generated domains from normal ones, researchers have identified distinct features associated with DGA-generated domain names. Consequently, numerous studies focus on blocking these DGA domain names as a defensive measure [2]. Traditional malware control methods, such as blacklisting, static string-matching approaches, and hashing schemes, are insufficient for addressing DGA threats. Several researchers have worked on algorithmically generated domain name detection some of these research papers are discussed below.

Mathew [3] devised a classification system for domain generation algorithms based on DNS traffic, along with presenting various detection techniques for DGA botnets. Among these techniques, the genetic algorithm for DGA detection was proposed. However, this method is hindered by computational complexity and high implementation costs.

Daniel Plohmann [4] presented a comprehensive study of domain generation algorithms as they are used by modern botnets. This study uses the reverse engineering of the DGAs of 43 malware families and their variants [5]. The author performed an analysis on domain registrations, utilizing historic WHOIS data. They have characterized the registration behavior of bot masters and sink holes and examined the effectiveness of domain mitigations [6]. The author explained the complexity of word list-based DGA families and their detection.

Tong and Nguyen [7] employed semantic indicators like entropy, domain level, frequency of N-grams and Mahalanobis distance were utilized in domain classification [8] for detecting DGA domain names. They proposed resampling as a preventive measure at the data level, categorizing it into oversampling, under sampling, and hybrid sampling combining both approaches.

K. Alieyan [9] introduced a rule-based schema for the domain name system designed to identify inconsistencies within it. The results of the study demonstrated an accuracy of 99.35% in detecting botnets, accompanied by a low false positive rate of 0.25. It should be noted that this approach is specifically tailored for DNS-based traffic flows.

Kheir et al. [11] introduced the Mentor method, which gathers statistical features from suspicious domain names and employs supervised machine learning to distinguish between benign and suspicious domains. This method was tested against an extensive collection of public botnet blacklists. The results indicate that the Mentor system effectively detects malicious bots while maintaining a low false positive rate by filtering out benign domain names.

The author's Woodbridge et al. [12] presented a method that makes use of LSTM to categorize the DGA-generated and legitimate domains. LSTMs have benefits over other approaches as they are not dependent on features and make use of raw domain names as their input [14]. The experimental results show that LSTM outperformed as compared with random forest with manually engineered features and logistic regression with bigram features [16]. These approaches can perform real-time detection but they are sensitive to the imbalanced dataset which makes it difficult to detect domains from minority families.

Cheng [18] conducted an analysis comparing legal domains with DGA domain names, identifying significant deviations in domain name construction rules. They utilized domain name length and character information entropy as classification features for detecting DGA domain names. Y. Li et al. [19] investigated the distribution of alphanumeric characters and bigrams across domains sharing the same set of IP addresses to analyze the statistical characteristics of domain name language. They also evaluated the efficacy of various distance metrics in this context.

Lison et al. [25] similarly adopted an approach where they substituted the LSTM layer with a GRU layer, achieving an AUC of 0.996. Meanwhile, Mac et al. [26] employed additional embedding and integrated an LSTM with an SVM, as well as a bidirectional LSTM, achieving AUCs of 0.9969 and 0.9964, respectively, on comparable datasets.

To address the constraints of machine learning techniques in the aforementioned scenarios Curtin et al. [30] designed a framework for detecting DGA domains with recurrent neural networks. The author has presented a complexity for domain name families called the smash word score; it quantifies how much DGA domain is to English words. Further, the DGA families having higher smash word scores will usually pose greater difficulty for detection [29]. The author used a recurrent neural network model with logistic regression for DGA detection which outperforms the existing approaches of DGA detection. The limitation of this study is results are not up to the mark and this is not adoptable for corporate use.

However, while these studies have demonstrated high detection rates for specific DGA families, machine learning-based detection systems often perform poorly against new DGA variants when trained on unrepresentative or imbalanced datasets. Addressing this issue, Anderson et al. [31] employed a Generative Adversarial Network (GAN) to create domain names that traditional DGA classifiers struggle to identify. The generator produced synthetic data used to train new models. Initially, an auto-encoder was pre-trained on approximately 256,000 domains and subsequently fine-tuned. The new models were then trained and evaluated using these newly generated domain names [32]. As a result, models trained on the newly generated domains exhibited an overall improvement in True Positive Rate (TPR) from 68% to 70%.

Chin et al. [33] devised a machine learning-based framework for identifying and detecting domains generated by DGAs. Further they have applied the proposed ML techniques to investigate the DGA-based modern malware. The proposed model comprises two levels containing the classification as first level operation and the clustering method as a second-level operation. These methods are to detect and identify the algorithmically generated domains. In this work ML-based methods apply DNS blacklist for detecting DGA-generated domains.

Vinayakumar et al. [34], the author developed a model that gathers traffic data of DNS at the ISP level. Further, it identifies the DGA-based domains in real-time. They also used many deep learning models such as LSTM, CNN, CNN-LSTM and RNN for modern botnet detection. These methods have performed well compared to classical ML approaches and also give better classification accuracy rate.

Vinayakumar et al. [35], the author had designed and developed scalable architecture called Apache spark. The proposed model gathers DNS logs data and performed the analysis. The deep learning techniques are being used to detect and gives alert for suspicious domains.

The literature survey shows that recent methods for DGA domain name detection and classification based on machine learning performed better results and most importantly deep learning specifically recurrent based models. In this work, we apply enhanced model of LSTM called as GRU for DGA domain name detection and classification.

III. Domain Generation Algorithm

A Domain Generation Algorithm (DGA) operates by utilizing available sources of randomness within malware to generate hundreds or even thousands of domains automatically. DGAs enable malware to constantly switch between these domains during attacks, complicating efforts to block and remove them [3]. Cybercriminals and botnet operators exploit DGAs to deliver malware, ensuring continuous communication with Command and Control (C&C) servers through dynamically generated domains [5]. The malware attempts to query each domain against its local DNS server, vital for translating domain names into IP addresses on the Internet [9]. Only domains registered by the botmaster yield valid IP addresses for C&C communication; unregistered domains return resolution errors and are disregarded [10]. One prominent example is Banjori, widely recognized for targeting online banking users to steal information [11]. According to NSFOCUS, Banjori was first identified in 2013, and as of in 2019, a total of 1,499 botnets related to this issue were detected.

2019, a total of 1,499 related botnets had been detected, with numbers continuing to rise. Other DGAs, such as Tinba and Ramnit, specialize in financial theft and worm infections [12]. Given the diversity of DGA types, precise classification of these domains is crucial.

The algorithm takes DNS queries or domain names as input. If a domain is broken down into words or letters, it can be viewed as a sequence akin to a sentence. Certain words serve as the core components, representing key features of the domain name. Domain names within the same DGA botnet family exhibit similar characteristics based on shared keyword sets [13]. Consequently, domains from different families differ significantly in their specific keywords.

Domains within the same family create a consistent context based on the characteristic keyword sets used to generate them [15]. These contextual differences are essential in the classification process. Initially, query domains are processed through a trained binary classification model to distinguish between malicious and benign domains [17]. Domains identified as malicious then undergo multiclass classification to accurately determine their DGA botnet family, as illustrated in Fig. 1. The binary classification distinguishes between benign and malicious domain names, while the multiclass classification identifies the specific botnet family associated with malicious domains.

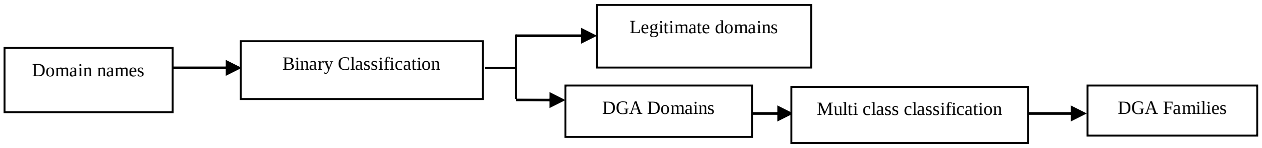

Fig. 1. Steps involved in the DGA botnet detection.

IV. Deep Learning Models

A. Gated Recurrent Unit

The Gated Recurrent Unit (GRU) is acknowledged as an enhanced version of the standard recurrent neural network, first introduced by Cho et al. in 2014. It addresses the issue of the vanishing gradient that commonly affects traditional RNNs. GRU shares similarities with LSTM (Long Short-Term Memory) networks in design and often yields comparable performance.

GRU incorporates gating mechanisms and a hidden state to regulate information flow [20]. It tackles RNN issues by employing two gates: the update gate and the reset gate. These gates act as vector components (0, 1) capable of performing a convex combination. This mechanism determines whether to update (retain) or reset the hidden state based on incoming information [21]. Consequently, the network learns to disregard irrelevant temporal details.

GRUs are effective for enhancing the memory capabilities of recurrent neural networks and facilitating easier model training. They are widely applicable in diverse fields such as speech signal modeling, machine translation, and handwriting recognition.

The basic RNN suffers from short-term memory problems. GRU is a modified or lightweight version of LSTM, where it combines long and short-term memory into its hidden states [22]. LSTM has two attributes cell state and hidden state; here it has only a hidden state which can combine both long and short-term memory. The GRU (Gated Recurrent Unit) is characterized by its two primary gates: the update gate and the reset gate. The update gate plays a crucial role in memory retention, determining how much past information should be preserved. In contrast, the reset gate decides how much past information to discard.

The update gate is pivotal in allowing the model to selectively retain relevant earlier information across time steps. This capability is particularly advantageous as it enables the model to potentially retain all pertinent details from the past, thus mitigating the issue of vanishing gradients.

Conversely, the reset gate determines the degree to which past information should be forgotten. Similar to the Forget gate in LSTM, the reset gate identifies and disregards irrelevant data, facilitating the model's ability to progress without unnecessary baggage from previous computations. Both gates contribute significantly to the GRU's architecture and function. While their formulas are similar, their respective roles and weights within the model are distinct, as elaborated in subsequent sections.

In the GRU architecture, two key gates play crucial roles: the reset gate and the update gate. These gates are responsible for dynamically adjusting how much information each hidden unit retains or discards as it processes a sequence. In the figure illustrating the Gated Recurrent Unit, denoted as GRU, the symbols r and z represent the reset and update gates respectively, while h and h' correspond to the activations and candidate activations. This configuration is discussed in reference [23].

During operation, when the reset gate r approaches zero, the hidden state disregards the previous state and resets based on the current input. This mechanism allows the model to efficiently discard irrelevant data, leading to a more streamlined representation. Conversely, the update gate z regulates how much information from the previous hidden state is transferred to the current hidden state. This process resembles the function of a memory cell in LSTM networks, facilitating the retention of long-term dependencies.

At any given time step, the activation of the GRU is determined through a linear interpolation between the previous activation and the candidate activation. The update gate z dictates the extent to which the unit updates its activation or content, thereby influencing the flow of information throughout the network.

V. Proposed Architecture

The proposed method includes the domain names as an input which contains series of characters, later it transforms these characters into a series of vectors. In our proposed work we have adopted Keras character level embedding. After translating the character representation into a series of vectors in the next step series of vectors are provided for deep learning layers [24]. Further, it processes the series of vectors in the sequential order and at each step it updates the hidden vector state information. Finally, the model will be able to perform the binary classification task to categorize the domains as either benign or DGA generated, where as in multi-classification task initially it detects either the domain name is benign or DGA generated. If it is DGA generated then it classifies into the corresponding malware families.

The outline of our proposed approach for detecting DGA domains using deep learning model is shown in Fig. 2. The model represents three stages of operation, first one is character encoding here it maps each character into real-valued vector and the second one is feature representation and lastly, the fully connected layer and softmax function differentiates between DGA classes, including a category for non-DGA instances. The proposed model is evaluated on both binary classification and multi-class classification that classifies whether domains are benign or DGA generated. Deep learning models are educated and evaluated on the dataset for DGA Detection.

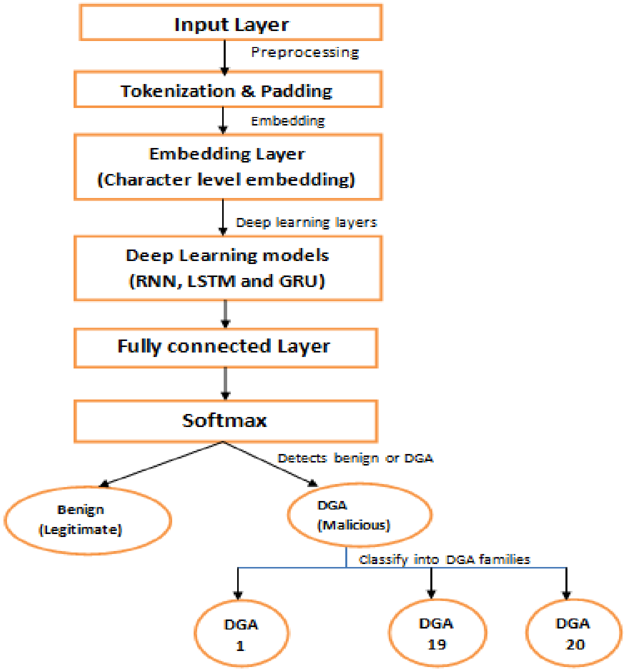

Fig. 2. Proposed deep learning architecture for DGA detection.

A. Domain Name Character Embedding

The Keras framework includes an embedding layer that translates character-level domain names into dense vectors representation shown in Fig. 3. The embedding is also learned independently during training. In this paper we have utilized keras for DGA detection [27]. In the initial phase of the operation weights are going to be assigned and later these weights will learn all the characters in the dataset. Further these embedding layer tries to maps each one of character in the dataset to a 128 length of real value represented in the vector. The domain name character level embedding makes use of recurrent neural network to determine numerical value representation by looking at their character level compositions.

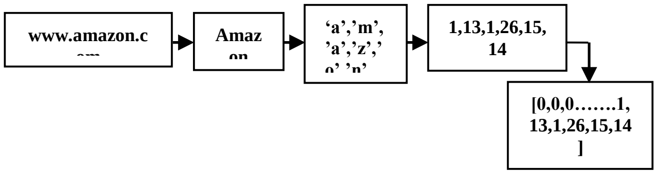

Fig. 3. Domain name character level embedding.

B. Domain Name Feature Extraction

For representing the features various deep layers have been used such as LSTM, RNN and GRU. These structures will capture the sequential information. The pattern-matching approach along with the deep learning layer looks effective and efficient compared with regular expression [28]. The regular expression outputs a binary value but the deep learning models produce a continuous value which in turn represents how much the pattern is matched.

C. Recurrent Layers

We have used many recurrent networks including LSTM, RNN and GRU. Here the number of recurrent units is set to 128 based on the knowledge acquired. These recurrent network layers primarily capture the sequential data from the output of the embedding layer. Each unit in a recurrent neural network employs an activation function with values ranging from [-1, 1]. The gate uses a logistic sigmoid function, which produces values in the range of [1, 0].

D. Deep Learning for the Binary Class Classification Task

Binary classification task involves distinguishing between two classes: benign and DGA (malicious). In our approach, benign domains are designated with a label of 0, whereas DGAs carry a label of 1. To tackle this task, we trained several deep neural network models, such as LSTM, RNN, and GRU, drawing on existing research in deep learning for character-based text classification. To optimize these neural networks for classifying domain names as either benign or malicious, we refer to the detailed descriptions of the model architectures provided in previous studies. When applying these trained neural models to a test dataset, a domain is labelled as benign if the probability is less than 0.5 and malicious if it is 0.5 or higher.

Deep Learning for the Multiclass Classification Task. The dataset used for multiclass classification contains domains from both the "benign family" and 20 distinct DGA families, totaling 21 families. For this task, we employed a model architecture similar to that used for binary classification. However, instead of two prediction classes, the models now predict among 21 classes (one class per family). Therefore, the output layer of the models from reference [18] was adjusted to use the "softmax" activation function. This ensures that the output values range between 0 and 1, representing predicted probabilities. To facilitate this, we applied one-hot encoding, resulting in 21 output values, each corresponding to a class. The class with the highest probability is selected as the final prediction made by the model.

VI. Dataset Description

The proposed domain name detection model was assessed on AmritaDGA dataset for identifying malwares/botnets from the DNS traffic [12]. AmritaDGA is a benchmark dataset publically available for research purpose. This database was used in DMD-2018 shared task and after the shared task this database has been used for benchmark purpose by various researchers for DGA detection [13]. Following, in this work, the AmritaDGA database was used for DGA domains detection. The domain name in the dataset is labeled as benign or DGA family. The dataset is further divided into training and testing respectively.

All deep learning models are trained using the training dataset. Further the dataset is comprised of training, validation and testing dataset. The training, validation and testing domain name samples are shown in below Table I.

TABLE I. Detailed Information of the Dataset

Label	Domain Type	Training	Testing	Validation
0	benign	25574	6414	8079
1	banjori	3779	1021	1165

VII. Performance Metrics

We have adopted performance measures to compare the accuracy of various DGA classification models. Further the various metrics have been used to determine the quality of DGA classification models. AUC, recall, precision, F1 score, and ROC performance evaluation metrics are used to compare the GRU with other deep learning classification techniques.

True Positive: It represents the number of domains classified as legitimate and which is indicated with class 0.

True Negative: This represents the number of domains classified as DGA generated and which is indicated with class 1.

False Positive: It represents the number of domains wrongly classified as legitimate.

False Negative: It represents the number of domains wrongly classified as DGA generated.

$$Precision \ = \frac{TP}{(TP+FP)} \tag{1}$$

Recall: Measures the completeness of correctly labeled features.

$$Recall \ = \frac{TP}{(TP+FN)} \tag{2}$$

F1-score: Defines the harmonic mean between precision and recall measures.

$$F1 - Score = 2 \times \frac{(Recall*Precision)}{(Recall+Precision)} \tag{3}$$

Receiver operating characteristic measures the trade-off of the TPR to FPR where,

$$TPR = \frac{True\ Positive}{TruePositive+FalseNegative)} \tag{4}$$

$$FPR = \frac{FalsePositive}{(FalsePositive+TrueNegative)} \tag{5}$$

The ROC curve established with recall and false positive rate. It also shows the capability of the binary classifiers. The ROC curve also measures the competence of the classifier in differentiating the classes as either DGA or legitimate. The graph is plotted between the two metrics recall and false positive rate.

$$AUC = \int_0^1 \frac{TP}{(TP+FN)} d \frac{FP}{TN+FP} \tag{6}$$

The macro avg. and weighted avg. are used to average the results over the classes. The Macro avg. computes the elements independently and finally, it takes the average over all classes. In this paper, the weighted averaging considers as a significant performance indicator.

VIII. Results and Discussion

The deep learning techniques were executed utilizing Tensor Flow and Keras. The performance of the trained models was evaluated on a per-epoch basis using testing samples. For baseline comparison, we applied a logistic regression model to bigrams in the character-level representation of domain names, as well as other deep learning methods such as RNN, LSTM, and GRU. The experimental results demonstrate that these methods effectively classify domain names as either benign or DGA-generated in binary classification and further categorize algorithmically generated domain names into their respective malware families, based on metrics such as accuracy, precision, recall, and F1-score.

The performance of our trained model is assessed using testing samples on an epoch-by-epoch basis, as shown in Fig. 4. The baseline model showed good performance till epoch 27 and this model gives AUC of 0.988. LSTM model is evaluated using testing samples on epoch 9 which is shown in Fig. 5, whereas the RNN model performed well till epoch 11.

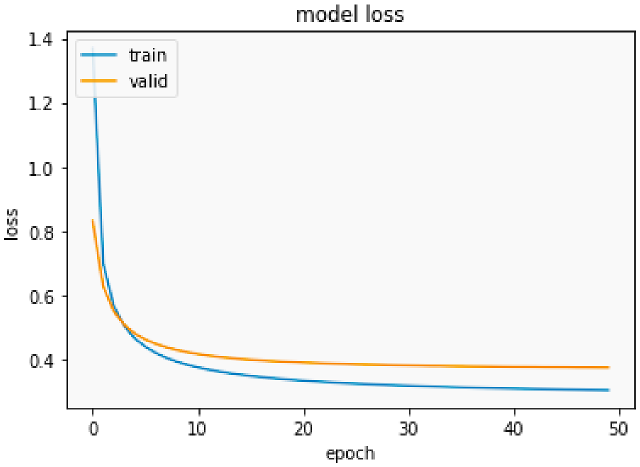

Fig. 4. Training and validation loss curve for baseline model with LR.

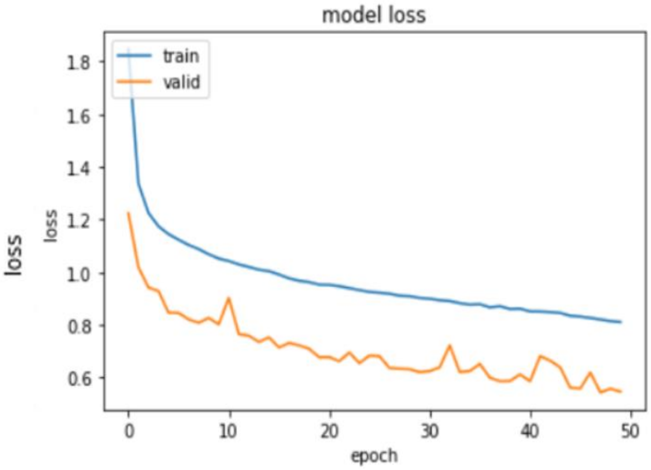

Fig. 5. The validation and training loss curve for LSTM.

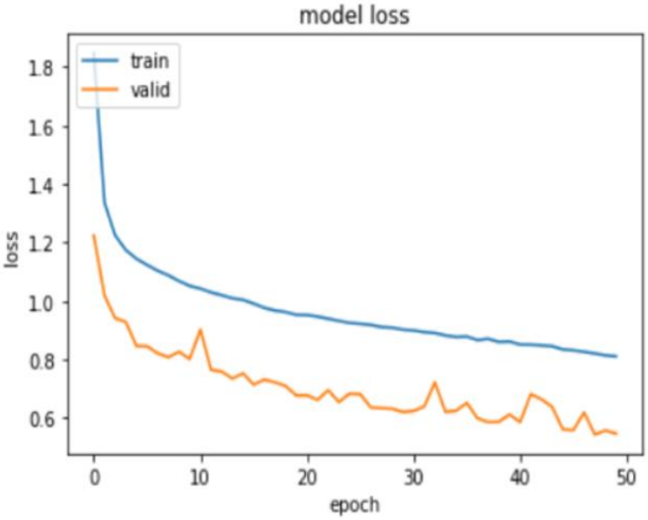

Fig. 6. Training and validation loss curve for RNN.

The proposed deep learning model gated recurrent unit has showed better performance till epochs 14 shown in Fig. 6. After that point, the performance began to decline due to over fitting. This indicates that 15 epochs are sufficient to capture the dependencies of domain names at the character level. For baseline comparison, we applied a logistic regression model to bigrams in the character-level representation of domain names.

The performance of the deep learning models is evaluated using two types of averages: weighted average and macro average. The weighted average takes into account the total number of samples by calculating the performance for each class and then averaging these performances, weighted by the sample distribution across classes. This method allows us to assess the overall performance across the entire dataset. The macro average, in contrast, involves calculating the performance for each class separately and then averaging these values, treating all classes as if they have the same number of samples. This provides the average performance per class. In cases of class imbalance in multiclass classification, the weighted average is often more representative than the macro average. Nevertheless, to obtain a comprehensive understanding of the models' performance, we compare the results of both the weighted average and macro average.

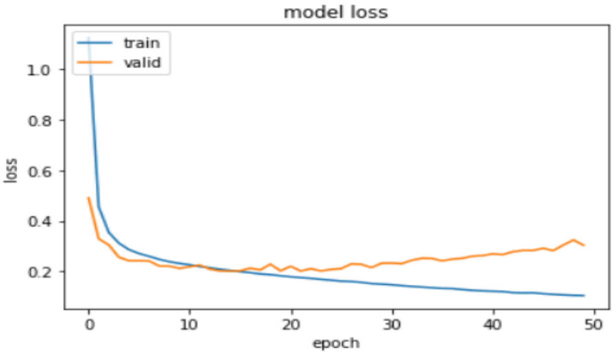

Fig. 7. The validation and training loss curve GRU.

Initially, various test experiments were run to identify various parameters for GRU model. In the proposed GRU model, the first layer is embedding and it contains the embedding length parameter. We run experiments with 32, 64, 128, and 256. The performance with 128 was good compared to others and when we increased 128 to 256, the performance remained same. Thus we decided to set the embedding length as 128. Each character of the domain will be transformed into 128 length vector. Next embedding layer follows GRU layer and again similar experiments were done and 128 units were set to GRU layer shown in Fig. 7. GRU layer follows the classification or output layer. Also, dropout was added in between the output layer and GRU layer.

The results of the models are represented in the form of a PRC curve by differentiating two parameters, such as precision and recall. The ROC curve is represented with false positive rate and recall value. Deep learning model outperforms the N-gram derived features with huge size of domain names. The PRC curves for the Bigram baseline model, LSTM, RNN and GRU are presented in Fig. 8. The performance metrics of various methods are displayed in precision recall curve which shows that the gated recurrent unit results with higher precision and recall value compared with other approaches such as RNN and LSTM, the GRU model gives in better precision and recall value shown in Fig. 9. The green line represented the Fig. 10 indicates gated recurrent unit, red line indicates LSTM and blue line indicates the baseline model. The calibration performance metrics was used to assess the performance of classifier and also to tune its parameter shown in Fig. 10. The ROC curve is represented with false positive rate and recall value shown in Fig. 11. The gated recurrent unit gives the performance with an AUC of 0.999 shown in Fig. 12.

Table II represents the experimental results of recurrent neural network for multiclass classification of DGA domains to classify the domain name into a family of malwares in terms of accuracy, precision, recall, and f1-score.

Table III shows experimental results of deep learning approaches for multiclass classification of domain names into a family of malwares. The proposed detection model gated recurrent unit significantly outperforms in comparison with other deep learning models like LSTM and RNN in all measurements, in which our model produces accuracy of 99%, F1-score of 98%, macro avg. of 91% and weighted avg. of 92% and also provides significantly reduced false positive rate (FPR) and false negative rate (FNR). Whereas the LSTM produces accuracy of 92%, F1-score of 98%, macro avg. of 90% and weighted avg. of 91% and RNN models produces accuracy of 83%, recall of 94%, precision of 98%, macro avg. of 80% and weighted avg. of 84%. The baseline model for logistic regression produces accuracy of 87%, f1-score of 99%, precision of 98% and macro avg. of 84% and weighted avg. of 87%.

IX. Conclusion

In this paper we propose a novel deep learning framework for the detection of malicious domain names, achieving superior performance accuracy for both binary and multiclass classification tasks. Our proposed model uses deep learning techniques with Keras embedding and it has the capability to detect the domain names to a particular malware family. Further the domain names are differentiated as either legitimate or DGA generated by training the domain names within the character level by automatically extracting the necessary features. Detecting DGAs presents a significant challenge in cyber security. These algorithms are typically employed by attackers to establish communication with diverse servers. This paper introduces deep learning architectures designed to mitigate DGA threats. The proposed framework includes a feature extractor and preprocessing model tailored for classifying and detecting malicious domain names. As the volume of data grows, deep learning models offer superior performance compared to traditional machine learning algorithms. This study examines the efficacy of different approaches in detecting DGAs and categorizing domain names into respective families, utilizing a dataset encompassing 20 malware families. Specifically, in the GRU model, domain names are vectorized through a Keras embedding technique, where each domain character is mapped to a vector in a defined dictionary. Future work could explore training with more complex models and adding additional layers for enhanced accuracy. Experimentation with different preprocessing techniques, embeddings, hyper parameter fine-tuning, and increased epochs may further refine the model's accuracy.

***Abstract*—People in areas affected by natural disasters and use social media websites such as Facebook, Twitter (also known as "X") and Instagram tend to post images of damage to their surroundings. These social media sites have become vital sources of immediate and highly available data for providing situational awareness and organisation for natural disaster response. A few previous attempts at classifying the level of natural disaster damage in these images using image processing techniques had noted the challenge in producing robust classification models due to the effect of overfitting caused by a lack of observations and data imbalance in annotated datasets. This article shows an attempt to improve a training strategy within the data level for deep learning models such as VGG16, ResNetV2 and EffecientNetV2, used to estimate the level of disaster damage in images by training them with data generated using image data augmentation with data balancing, oversampling up to eight times and combining the oversampled image data collections. The F-1 score achieved for classifying damage on earthquake images and images from the Hurricane Matthew data collection by training EfficientNetV2 on a generated dataset made with a combination of oversampled data surpassed previous benchmark results. These results show that using data balancing and oversampling on the dataset prior to training deep learning models on these datasets result in increased robustness.**

Keywords*—Deep learning; image processing; oversampling; image data augmentation

I. Introduction

Natural disasters that have occurred from 1998 to 2017 have caused $2.9 trillion US in monetary damage and have cost the lives of 1.3 million people [4]. Worldwide insured losses from natural and man-made disasters in 2017 alone are estimated to cost $144 billion US according to a report by the Swiss Re [32]. Damages caused by Hurricane Ian in 2022 have been projected to cost exceeding $45 billion USD [10].

During the disaster response process, an assessment of damage done is made typically by door-to-door survey. This approach may cause a "cold start" issue to obtain and analyse the data. The time required to acquire and the complexity of annotating the data for damage assessment may also take several days to weeks when using the traditional "boots-on-the-ground" method.

Victims of natural disasters have been using social media posts, including image posts, to communicate and update their status during a disaster event [13]. The information extracted from these social posts have been useful in providing situational awareness in disaster response [27].

Data from social media websites are multi-dimensional; they are generally represented in four dimensions which are space, time, content and network [2]. Image data from within the content dimension in addition to the spatial and temporal dimensions may contribute to gaining situational awareness regarding ongoing natural disasters. Endsley [31] defined situational awareness as "the perception of elements in the environment within a volume of time and space, the comprehension of their meaning, and the projection of their status in the near future".

Frameworks for collecting and annotating information regarding ongoing disaster events such as Artificial Intelligence for Disaster Response (AIDR) have been developed to collect data that can be used to combine human intelligence with Natural Language Processing (NLP) and Machine Learning (ML) models [26]. A system for collecting and annotating images with natural disaster damage from social media had been integrated into AIDR [35].

Deep Neural Networks (DNNs) such as Convolutional Neural Networks (CNNs) have been used to process digital images in various tasks such as image classification and object detection. VGG16 is a CNN that has been implemented to classify images from social media in the ImageNet challenge [9]. An adaptation of the VGG16 image classification model had been used to classify the level of disaster damage in images from social media based on intensity [15]. Other models such as ResNet50, InceptionNet, EfficientNet and MobileNet have been explored as replacements for VGG16 for classifying the severity of natural disaster damage [34].

This article explores the use of data balancing and oversampling in conjunction with image augmentation on a labelled image dataset containing images of natural disaster damage in various levels. This article aims to investigate the effects of using these data manipulation techniques with the goal of improving a training strategy for training image DNN disaster damage level image classifiers.

The rest of this paper is organized as follows. Section II details the works relating to DNNs, image processing methods used in disaster management, image data augmentation methods for oversampling, and issues in using image classification in disaster management. Section III presents the methodology

Spatial Big Data and IoT for coastal erosion and floods mitigation and prediction [grant number TUFR/2017/004/03].

aimed to improve the performance of current models. Section IV shows the results gained from this study, its limitations and discusses the achievements of this study. Lastly, Section V concludes this article and shows recommendations for further study.

II. Related Work

This section relays related work regarding literature on deep neural networks, their use within natural disaster response and current issues.

A. *Deep Neural Networks*

DNNs are a type of Artificial Neural Network (ANN) with many hidden layers, where in each layer the aggregation of input or activation signals of the prior layer is transformed [12]. DNNs have been used to implement image recognition and detection of intricate structures [21].

CNNs are a type of DNN which includes layers which use convolutions to transform the input. CNNs are often used in image processing tasks such as optical character recognition, image classification and object detection.

The addition of backpropagation to CNNs allows for the neural network to learn convolutional kernel coefficients from the dataset [20]. Prior to this, weights in CNN had to be designed manually. This led to the development of the LeNet model [19].

VGG16 is a relatively modern CNN which won second place in the ImageNet Large Scale Visual Recognition Challenge in 2012. This model uses groups of CNNs followed by fully connected layers to extract and classify combinations of features to classify images. Compared to other competitors, VGG16 was designed with smaller receptive fields (starting with 3x3) convoluted by a stride of 1 pixel and had a greater “depth” by increasing the number of convolutional weight layers [9].

ResNet is an image classification deep residual network consisting of a network of “residual units” where each of these units consists of skip networks [29]. An improved version known as ResNetV2 adds full pre-activation to the skipping vertices prior to addition [28]. Both ResNet and ResNetV2 have 50, 101 and 152 layer versions.

EfficientNet is an image classification deep neural network made as an attempt to create a scalable convolutional neural network [6]. EffecentNet’s architecture is based on MnasNet which uses successive MBConv layers. The modification made by the authors of EfficientNet were that they had proposed a compound scaling method that scales the width, depth and resolution of these layers. An updated version of EfficientNet known as EfficientNetV2 which replaced MBConv layers with Fused-MBConv layers which resulted in faster and smaller models [5].

B. *Data Collection and Annotation Methods in Natural Disaster Response*

Disaster response is the second stage of natural disaster management carried out immediately after a natural disaster event. Traditional methods for collecting data for natural disaster response typically uses remote sensing or optical imagery from satellites but may be susceptible to noise from the effects of weather while being costly and time consuming to setup [25]. Social media provides an easy and immediate source of data to collect from. This allows for a quicker start to disaster response by collecting data from social media sites. This data includes text, images, videos, geospatial and temporal data [2]. Images of natural disaster damage are often uploaded to social media sites during and immediately after natural disaster events [13].

Image analysis for natural disaster response starts in the collection of image data. Image data is either scraped from social media sites or captured via aerial photography. This data is then annotated, based the parameters of the intended image processing method. For example, the AIDR [26] platform collects image data from Twitter (also known as “X”), uses volunteers to annotate the image data to form a dataset, then splits the data into a training set, validation set and a testing set, with the goal of developing a machine learning model that classifies the level of disaster damage shown in image data collected in the future. This platform has been used to gather and annotate data from social media on the regarding natural disasters events [14], [15], [16], [33], [34], [35].

Studies using data collected using AIDR have explored using various machine learning tasks such as NLP, computer vision tasks, and multi-modal learning [33]. For example, data collected during various natural disaster events were used to train machine learning models to detect natural disaster damage [14], classify the level of natural disaster damage [15], [35], classify the type of damage caused by natural disasters [16], [34].

C. *Detection of Natural Disaster Damage in Images*

There are multiple methods to detect natural disaster damage in images, often through the use of deep learning models trained as a binary classifier to detect the presence natural disaster damage in images.

A natural disaster damage image detector was used in [14] to filter posts based on the presence of natural disaster related content in conjunction with perceptual hashing with the intention of reducing the workload of human annotators. This classifier was implemented using a pre-trained VGG-16 CNN that has been fine-tuned to classify images that are relevant to disaster damage and achieved an almost perfect F-1 score of 0.98.

Another approach to detecting natural disaster damage in images is to use a (Single Shot-MultiBox Detector) SSD to detect natural disaster damage in images. A two-part SSD based on VGG-16 was used to detect natural disaster damage in aerial images [17]. This SSD was trained with a dataset that had been oversampled with augmented images.

Detection of urban flooding in crowd-sourced image data has been used to locate occurrences of urban flooding using the Clarifai object recognition model as a way to monitor urban flooding and to validate urban flooding models [3]. The Clarifai object recognition model was developed as a contender in the 2013 ImageNet LSVR challenge. This object recognition model was used via an online API and was used to provide a list of tags relevant to each image fed to the model as well as the probability of each tag.

Another effort relating to floods explored the use of InceptionNetv3 and DenseNet to classify images of flood based on severity as part of an image sorting system [24]. Both models used had an F-1 score of 0.82.

D. Classification of Natural Disaster Damage in Images

Damage depicted in image can classified into their respective classes following one or more taxonomies. Classification of posts often use modified versions deep learning models used to implement detection of damage depicted in social media posts. Social media posts that depict damage have been categorised by damage intensity, relevance, type of damage, or within a multi-dimensional taxonomy which may include a combination of the prior categorisation schemes.

Hence, image processing models have been used to classify disaster damage in images collected from social media. CNNs such as VGG16, InceptionNetV3, InceptionNetV4 and InceptionResNet have been used to classify the severity of disaster damage shown in the image into either the severe damage, mild damage or no damage classes. These models have been found to have comparable performance in various use-cases such as in classification of natural disaster damage levels [15], and classification of the types of natural disaster damage.

Earlier explorations at classifying images of natural disaster damage included training a VBoW model against an annotated disaster damage dataset but it was found that using pre-trained CNNs such as VGG16 pretrained on the ImageNet dataset performed better. Fine tuning this pre-trained VGG16 model with the same training data further increased the F-1 score [15].

TABLE I. PERFORMANCE OF BOVW AND VGG16 AGAINST DISASTER DAMAGE DATA COLLECTIONS

Event	Model	Accuracy	Precision	Recall
Nepal Earthquake	BoVW	0.78	0.77	0.78
	VGG-16-fc7	0.76	0.76	0.78
	VGG-16-fine-tuned	0.84	0.82	0.84
Ecuador Earthquake	BoVW	0.82	0.81	0.82
	VGG-16-fc7	0.82	0.82	0.84
	VGG-16-fine-tuned	0.87	0.86	0.87
Hurricane Matthew	BoVW	0.64	0.64	0.64
	VGG-16-fc7	0.63	0.63	0.64
	VGG-16-fine-tuned	0.74	0.73	0.74
Typhoon Ruby	BoVW	0.73	0.74	0.73
	VGG-16-fc7	0.79	0.80	0.80
	VGG-16-fine-tuned	0.81	0.81	0.80
Google images	BoVW	0.57	0.53	0.56
	VGG-16-fc7	0.60	0.63	0.64
	VGG-16-fine-tuned	0.67	0.67	0.67

According to study [1], training the last layer of a pre-trained model allows the use of a smaller dataset to transfer the capabilities of the model to train for a different task. This method also reduces the time spent on training the model as a smaller dataset is used. This technique is also known as transfer learning [1].

Table I compares the accuracy, precision, recall rate, and F-1 score (balance between precision and accuracy) of Bag-of-Visual-Words, VGG16-fc7 and the fine-tuned VGG16 models when trained with single event datasets with image data collected from social media related Nepal earthquake, Ecuador earthquake, Hurricane Matthew, Typhoon Ruby and images of damaged buildings from Google Images. The table shows that in some cases (e.g., Nepal earthquake, Ecuador earthquake), VGG16 without fine-tuning was comparable to visual bag-of-words for three of the image collections but surpassed the BoVW model's performance for the Typhoon Ruby and Google Images collections. The fine-tuned model achieved a higher F-1 score on all image collections.

A similar dataset was included in a benchmark image dataset compiled by [34] to benchmark various image classification models on various tasks. The F-1 scores obtained for classifying images of disaster damage levels using EfficientNetB1 was 0.758 compared to an F-1 score of 0.753 for VGG16.

Another notable implementation by [16] of a classifier for identifying damage in a social media post analysed both text and image data collected from Instagram posts via a fusion of image and text classifiers using a multi-modal approach. This multi-modal classifier was described using the Inception architecture to classify images in social media by several InceptionNet models to classify the type of disaster damage in images from social media. These classes were named: Infrastructure, Nature, Fires, Floods, Human and Non-Damage.

The inception network used was described as a layered stack of "Inception modules" with each layer consisting of multiple convolution filters with a variety of sizes. The Inception Network models have been described to have near state-of-the-art accuracies with the ImageNet dataset while having a relatively smaller model compared to other CNN models.

Mouzannar et al. [16] compared the performance of four DNN models which were InceptionNetv4, InceptionNetv3, VGG16 and InceptionResNet. InceptionNetv4 scored a higher validation accuracy while InceptionNetv3 scored a higher test accuracy. The higher validation accuracy of the InceptionNetv3 model led to its selection as a component for a multi-modal classifier.

The disaster damage severity task was revisited by [34] as part of an effort to build a consolidated benchmark dataset. A subset of this benchmark dataset includes the dataset by [15]. The F-1 score for classifying damage severity using EfficientNetB1 is 0.758, slightly higher compared to the F-1 score obtained using VGG16 which is 0.753.

Classification of natural disaster damage in images can also be used in image segmentation. Class activated mapping can be carried out via CNNs to classify areas of mild damage, severe damage or no damage done to an area depicted within these images [18]. This information can be used to generate a heatmap visualisation of damage shown within a given image by finding gradients between segments of the image with damage, and segments without damage. This heatmap can then be used to calculate a Damage Assessment Value for each image.

E. Issues with Classifying Natural Disaster Damage Levels in Images

The research in [15] used a fine-tuned VGG16 model to classify image data by the level of disaster damage with a dataset that had a small amount of image data. The amount of image data in the dataset was limited due to the issues caused by the complexity of data annotation tasks, unintended collection of irrelevant data, the subjectivity of the data annotation tasks and time limitations when collecting and annotating the data. The dataset used is imbalanced; there are far fewer images labelled as mild within the dataset than images with other labels.

This issue was also highlighted by [34] when training other deep learning models with the same classification task. Alam had noted that the number of images labelled as “mild” was lower and that models trained for the damage severity task tend confuse images with this label as images with other labels. Efforts to overcome limitations in the robustness of deep learning models for various disaster informatics tasks was noted by [33].

The study in [14] revisited this and trained a fine-tuned VGG16 model to filter posts that are not related to natural disasters. This model is then combined with a perceptual hash function to filter posts that were irrelevant or duplicates. This filtering task reduced the amount of image data in the dataset by 62%. Training a model with a dataset that has a low amount of data can cause overfitting [11]. The dataset that was used by [15] was noted to be imbalanced such that the recall rate for minority classes was much lower than majority classes leading to many false negatives.

Training with imbalanced data can also increase the overfitting issue [23]. Overfitting is a phenomenon that causes deep learning models to strictly conform with a training dataset as a result of training with a training dataset that has a low amount of data. This causes the model to have a lower validation score, causing the number of false positives and false negatives to increase. The resulting trained VGG16 models by [15] achieved precision-recall rates for the minority class that were significantly lower compared to other classes and identified that the lack of labelled training data was the cause of this issue. [7] had shown that the effect of overfitting in CNNs used in image classification decreases as the number of observations increases. The VGG16 deep learning model uses dropout layers as a way to reduce this overfitting [9]. Dropout layers regulate overfitting by removing connections between layers [8].

F. Image Data Augmentation

Image Data Augmentation refers to the use of one or more image manipulation techniques, often used in conjunction with image data oversampling with the goal of reducing the effect of overfitting when training deep learning models. Overfitting is a phenomenon where a deep learning model is trained such that it has a high variance to fit the training data [11]. Overfitting can cause a stall in validation accuracy when training deep learning models to generalise the dataset. Larger datasets have been regarded as resulting in deep learning models with higher overall qualitative performance [7].

Transformations on images in the dataset include geometric, colour space manipulations and noise injection. Various geometric transformations can be applied to images in data augmentation. These geometric transformations include flipping, cropping, rotating and shifting. Colour space manipulations include applying a coloured tint or filters commonly found within photo editing applications. For example, training a classifier with the ImageNet or CIFAR-10 datasets would yield better results when vertical axis flipping is used while slight rotations can help in training with text recognition datasets such as MNIST [11].

The research in [30] used image data augmentation in combination with weight decay an various tasks and found it had significantly improved the performance of InceptionNetv3.

G. Oversampling

Oversampling is a data level technique which inflates the number of samples in a given dataset. Oversampling is often used to increase the signal to noise value by adding samples augmented with unrelated noise to the dataset before using any processing method. In the case of image processing, the dataset is inflated with augmented images [11]. Random oversampling can significantly improve classification of images and was found to have the best performance against other data-level methods such as undersampling, two phase training and thresholding [23].

H. Combining Data-Level Techniques

Data level techniques such as image data augmentation combined with oversampling can be used to improve the validity and robustness of social media image classification models especially within the limitations in natural disaster management. Image data augmentation utilises a collection of image manipulation techniques used as a technique for oversampling in image datasets which could play an important role in reducing the effect of overfitting brought about by training DNNs with smaller datasets. The next section discusses the methodology used in combining image data augmentation with image data oversampling.

III. Methodology

This section details the methodology in pre-processing a labelled dataset by oversampling it with augmented images, followed by training VGG16 with the pre-processed dataset, and testing the trained model and analysis of the results.

A. Experiments Carried Out

Three sequences of deep learning experiments are carried out. The initial sequence of experiments consists of a grid search of oversampling levels for each data collection using VGG16. This first sequence of experiments is also used to search for “early stopping” parameters.

The second sequence of experiments compares the performance of deep learning models selected after training each of theses models against the Nepal data collection. The deep learning models used in this sequence are VGG16, ResNet50V2 and EfficientNetV2B0.

The last of these experiments uses the optimal datasets acquired form the first experiment to train best performing model in the second experiment. The performance of the resulting trained model is then compared with the published performance of state-of-the-art models.

B. Equipment and Software used

The training of the image classification models was carried out on a computer with a graphics card capable of training deep learning models. This computer was built around an NVidia RTX2060 SUPER graphics card which has 8 GDDR6 RAM and 272 tensor cores.

As for the software, Ubuntu Server 20.04 LTS was installed without any desktop environment such that the computer can be operated headlessly (without a desktop GUI) to reduce GPU RAM usage. Python 3.7, TensorFlow version 2.2.0 and the included Keras library was used together with Jupyter Notebooks to implement image data augmentation, oversampling, model training, and model testing.

C. Dataset Details

The dataset used in this study is a data collection containing images collected from social media regarding several disaster events including the 2015 Nepal earthquake, the 2016 Ecuador earthquake, Hurricane Matthew in 2016 and Typhoon Ruby in 2014. These images were collected and annotated using the AIDR platform [26] which was modified to work with images [35].

This data collection contained three comma-separated value (CSV) files labelling 1,584 images with no natural disaster damage, 451 images showing mild natural disaster damage, and 1,785 images showing severe natural disaster damage together with these images. Each CSV file also divided the images into training (60%), cross-validation (20%) and testing (20%) sets. This data split is a common arrangement for training with cross-validation.

The dataset that contains this image collection can be downloaded from https://crisisnlp.qcri.org/ under Resource # 9. This dataset is also included in a benchmark dataset published by [34] from the same website under Resource #15.

D. Pre-Processing

During pre-processing, the images were first sorted based on their label to respective directories and split into either the training, validation or testing data split using the CSV files included such that the data collection can used with the ImageDataGenerator object from Keras.

After sorting the images, image data augmentation and various levels of oversampling were applied to generate augmented and oversampled datasets. The bulleted lists below show the augmentations applied to the training datasets and to validation datasets, while images in the testing data was rescaled to 1/255 only. These augmentations were selected to generate a variety of augmented images to prevent overfitting. The effect of these augmentations can be seen in Fig. 1.

List of Image Data Augmentations Used To Generate Training Data:

- Rescale values to 1/255.
- Random rotation range of -15° to 15°.
- Random width shift range of 10%.
- Random height shift range of 10%.
- Horizontal flipping.

List of Image Data Augmentations Used To Generate Training Data:

- Rescale values to 1/255.
- Horizontal flipping.

Table II shows the number of images after oversampling the images with augmented images. The control dataset does not contain any images with augmentations and does not contain any images generated for balancing or oversampling. The dataset with augmentations only contains augmented images but is not balanced or oversampled, preserving the same number of images as the control dataset. The balanced dataset contains images that have been augmented and balanced by oversampling images from the minority classes such that each class has the same number of images. The remaining datasets contain augmented images and were generated with two times, four times, and six times the number of images compared to the balanced dataset.

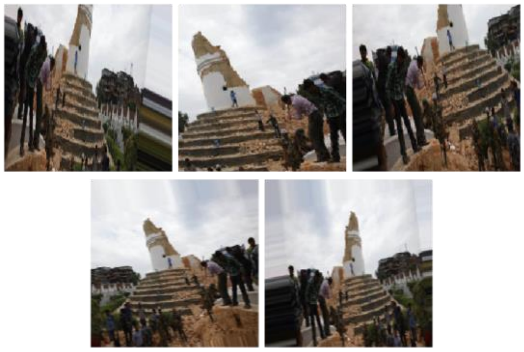

Fig. 1. Five augmented images were generated from an image from the Nepal Earthquake data collection.

TABLE II. NUMBER OF IMAGES IN EACH GENERATED DATASET AFTER PRE-PROCESSING THE NEPAL DATA COLLECTION

Name	Images labelled None	Images labelled Mild	Images labelled Severe	Total Images
No Augmentations (control)	4752	1354	5357	14463
With Augmentations	4752	1354	5357	14463
Augmented and Balanced	5357	5357	5357	16071
2X Oversampled	10714	10714	10714	32142
4X Oversampled	21428	21428	21428	64282
6X Oversampled	32142	32142	32142	96424

E. Deep Learning Model Implementation

This study will involve three deep learning models namely VGG16, ResNet50v2, and EfficientNetv2B0. The configuration of the VGG16 model used includes 224 pixel by 224 pixel inputs with three channels. This model was constructed using a pre-trained version of VGG16 supplied by the Keras software library which did not include dropout layers. The model was pre-trained with the ImageNet ILSVRC 2015 challenge dataset. Dropout layers were added back to the model as specified in the original implementation of VGG16 [9] with a dropout rate of 0.5 inserted before the FC1 and FC2 layers. These dropout layers were used for preventing overfitting by randomly dropping units during training [8].

The model was further modified by replacing the output layer which was originally used to classify 1000 classes in the ImageNet ILSVRC 2015 challenge, with a “dense” layer of three outputs with each output corresponding to each class found in the dataset. The L2 Kernel regularization rate for the output layer is set to 0.0005. The last layer was set to be trainable while the other layers were set to be not trainable.

The ResNet50V2 and EfficientNetV2B0 models were pre-trained with the ImageNet Dataset [22]. The ResNet50v2 model had its “head” replaced with a GlobalAveragePooling2D layer, followed by a Dropout layer with a dropout rate initially set to 0.5, and finally a Dense layer with three outputs. The head of the EfficientNetV2B0 model was replaced with a GlobalAveragePooling2D layer, followed by a BatchNormalization layer, then a Dropout layer with a dropout rate of 0.5, and finally a Dense layer with three outputs (see Fig. 2).

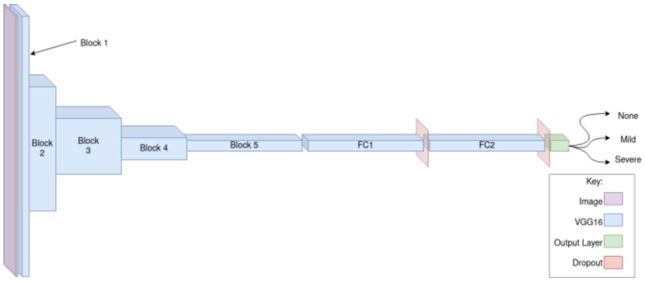

Fig. 2. VGG16 with three outputs and dropout layers.

F. Training, Validation and Testing

For the first round of training, VGG16 was initially selected as a control model. For each dataset generated in the prepossessing steps, an instance of this modified VGG16 model was trained on the dataset for up to 100 epochs. After each epoch, if the validation loss is lower than in all prior epochs, the weights of the model are saved.

During testing, the weights of each trained VGG16 instance was loaded, then tested by classifying images from the test set. The number of “true” and “predicted” occurrences is collected to calculate the precision, recall rate, F-1 score and to plot a confusion matrix. A “combined” F-1 score is also calculated to measure the overall performance of the trained model. Fig. 3 shows an activity diagram summarizing the process of training, validation and testing.

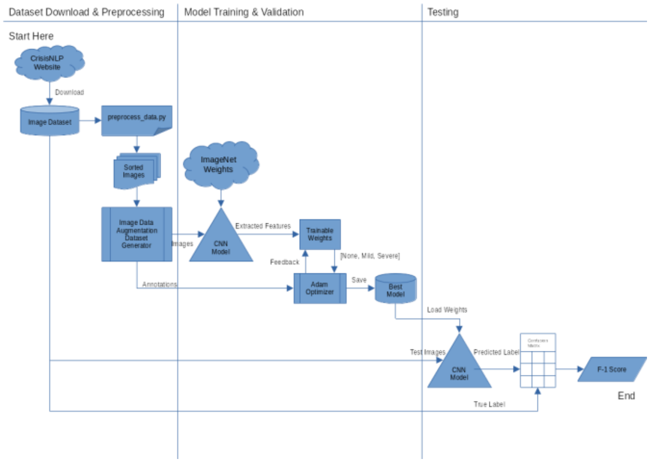

Fig. 3. Activity Diagram for training a CNN.

The second round of training, validation and testing involves ResNet50V2 and EfficientNetV2B0, the results of which are used to compare against each other (including VGG16) to determine which model achieves a higher F-1 score. This effort uses a similar process to the first round.

The third and final round of training involves the model selected from the second round of training against a dataset built by combining generated datasets that have obtained the highest combined F-1 score within each of the image data collections. This endeavour also uses a similar process to the first two rounds but has the addition of including a grid search of the dropout rate. The range of this dropout rate grid search starts from a dropout rate of 0.3 through 0.7 with a resolution of 0.1.

IV. Results, Limitations and Discussion

A. Results on VGG16 Single Event Tasks

Table III shows the F-1 scores for each class and the overall “combined” F-1 score obtained from testing VGG16 trained on single event generated datasets. The results in Table III demonstrate the effect of oversampling with image augmentations in training VGG16. With the exception of the Ruby image collection, models trained with generated datasets that had more oversampling tends to have a higher F-1 score.

Generated datasets that led to a higher combined F-1 score were selected to form a a combined dataset. An exception was made for the Nepal 6X generated dataset as combining it with the other selected datasets made it too large such that it caused an out-of-memory error. The final combined dataset included the balanced Nepal, Ecuador 8X, Matthew 8X, Ruby 2X datasets.

B. VGG16, ResNet50V2 and EffecientNetV2B0 against Nepal6X Dataset

Table IV shows the F-1 score obtained from testing VGG16, ResNet50V2 and EfficientNetV2B0 against the Nepal6X generated dataset. These three models were trained without a grid search of the dropout rate.

TABLE III. F-1 SCORE OF VGG16 AGAINST SINGLE-EVENT TASKS

Event	Generated Dataset	F-1 Score			
		None	*Mild*	*Severe*	*Combined*
Nepal	No Augmentations	0.76	0.02	0.80	0.53
	With Augmentations	0.75	0.05	0.79	0.53
	Balanced[a]	0.74	0.25	0.79	0.59
	2X Augmentations	0.72	0.18	0.76	0.55
	4X Augmentations	0.69	0.28	0.71	0.56
	6X Augmentations[b]	0.73	0.29	0.74	0.59
Ecuador	No Augmentations	0.80	0.00	0.85	0.55
	With Augmentations	0.78	0.00	0.84	0.54
	Balanced	0.72	0.19	0.81	0.57
	2X Augmentations	0.75	0.13	0.83	0.57
	4X Augmentations	0.73	0.18	0.79	0.57
	6X Augmentations	0.71	0.14	0.59	0.48
	8X Augmentations[a]	0.76	0.20	0.80	0.59
Matthew	No Augmentations	0.77	0.43	0.63	0.61
	With Augmentations	0.76	0.21	0.60	0.52
	Balanced	0.69	0.48	0.58	0.58
	2X Augmentations	0.73	0.45	0.59	0.59
	4X Augmentations	0.73	0.52	0.50	0.58
	6X Augmentations	0.70	0.46	0.61	0.59
	8X Augmentations[a]	0.67	0.54	0.62	0.61
Ruby	No Augmentations	0.74	0.73	0.11	0.53
	With Augmentations	0.77	0.72	0.36	0.62
	Balanced	0.72	0.64	0.47	0.61
	2X Augmentations[a]	0.75	0.66	0.46	0.62
	4X Augmentations	0.78	0.55	0.41	0.58
	6X Augmentations	0.74	0.67	0.38	0.60
	8X Augmentations	0.78	0.62	0.42	0.61

[a] Generated datasets selected.

[b] Too large to be combined with other datasets (causes out-of-memory error).

EfficientNetV2B obtained the highest F-1 score leading ResNet50V2 by 0.04 and VGG16 by 0.14. Both EfficientNetV2B and ResNet50V2 had significantly higher F-1 scores for all classes compared to VGG16. These results led to the selection of EfficientNetV2B0 for the next step.

TABLE IV. F-1 SCORE COMPARING VGG16 RESNET50V2 AND EFFICIENTNETV2B0

Model	F-1 Score			
	None	*Mild*	*Severe*	*Combined*
VGG16	0.73	0.29	0.74	0.59
ResNet50V2	0.82	0.40	0.84	0.69
EfficientNetV2B0	0.85	0.45	0.89	0.73

C. *EfficientNetV2B0 against the Combined Dataset*

The final model has managed to outperform state-of-the-art models in classifying the severity of damage in the Nepal, Ecuador and Matthew data collections which makes up the bulk of the damage severity dataset. Compared to [15], the F-1 score has increased from 0.76 to 0.782 for the Nepal data collection, 0.82 to 0.837 for the Ecuador data collection, and from 0.63 to 0.68 for the Matthew data collection. The combined overall F-1 score in the EfficientNetV2B0 model is close to the performance obtained with VGG16-fc7 by [34].

TABLE V. F-1 SCORE COMPARING VGG16 RESNET50V2 AND EFFICIENTNETV2B0

Data Collection	VGG16-fc7[cd]	EfficientNetV1B1[d]	EfficientNetV2B0
Nepal	0.76[c]	-	**0.782**
Ecuador	0.82[c]	-	**0.837**
Matthew	0.63[c]	-	**0.682**
Ruby	0.80[c]	-	0.709
Google Images	0.63[c]	-	0.576
Combined	0.753[d]	**0.758[d]**	0.752

[d] from [34]

D. *Limitations*

This study contains various technical limitations and time constraints which caused the scope of this study to be reduced.

This study was carried out using a single consumer grade Nvidia GPU with 8 Gigabytes of video RAM, namely an RTX 2060 Super. The computer used in this study had a solid state drive (SSD, not to be confused with Single Shot-MultiBox Detector) with a capacity of 256GB limiting the amount of generated image datasets that can be generated. This limits the size of both the model and the dataset that it can be trained on. These technical constraints restricted the scope of this study to models with 224 by 224 pixel inputs. There was not enough disk space to expand the study to include models with 240 by 240 input with this setup. These technical limitations also contributed to encountering an out-of-memory error when combining the six times oversampled Nepal dataset with other chosen generated datasets.

Another limitation is the amount of time needed to carry out model training. Training a deep learning model on one generated image dataset would take between three to six hours with the current setup assuming that the early stopping callback did not trigger. Each data collection would have seven generated datasets. Expanding the current scope to include the “CrisisMMD” dataset (containing 7 data collections) and “Damage Multimodal Dataset” dataset (treated as one data collection) would require an additional 56 single-event training and testing sessions, increasing the amount of time needed to include these. It is preferred that a data assessment task in response to the event of natural disasters takes place within 72 hours [25]. In the interest of time, the dataset used was limited to the “ASONAM2017” dataset.

This study did not explore fine-tuning as there is a lack of benchmarks for fine-tuned models trained on similar tasks to compare against.

E. Discussion

This paper shows a significant advancement in training deep learning models for classifying the level of natural disaster damage in images. The EfficientNetV2B0 model trained on the novel oversampling strategy was able to out-perform existing published benchmarks on classifying the level of disaster damage in the Nepal, Ecuador and Matthew data collections as seen in Table V.

These improvements were made possible using a combination of image data preprocessing techniques including a novel oversampling search strategy. This combination of techniques involve the use of image augmentation, data balancing and oversampling to address ongoing challenges in faced in data collection for disaster informatics leading to data imbalance and limited sample size for tasks involving image classification of disaster damage severity. The methods in order to obtain these results are:

1) For each image data collection, generate image datasets oversampled with augmented images ranging from balanced sampling to oversampling up to eight times the original sample size.

2) Use VGG16 to carry out a grid search of oversampling levels to identify which generated image dataset provides the highest F-1 score for each image data collection.

3) Combine the datasets identified in step 2 to create an optimized comprehensive dataset for training EfficientNetV2B0.

These steps have allowed for the creation of a dataset for training EfficientNetV2B0 such that it produces a more robust model with superior classification performance across various natural disaster scenarios.

These methods have demonstrated an importance in strategising the use of data preparation methods in machine learning when faced against situations caused by the nature of natural disaster events creating limitations that affect data collection. By using these image augmentation, balancing and oversampling methods, these issues that historically cause class imbalance and low sample size of images in this domain have been mitigated.

The findings in this study have shown several implications regarding disaster damage assessment through the classification of images. This study has demonstrated that the proposed training strategy improved the robustness and F-1 score of EfficienNetV2B0 in classifying the level of disaster damage. This in turn could increase the reliability of deep learning models used in the aftermath of a disaster event, potentially improving future efforts undertaken during disaster response and disaster resource allocation.

The proposed methodology in this paper could potentially be applied or be developed further in deep learning tasks facing similar issues on data imbalance and data scarcity. This combination of image data augmentation, data balancing and strategic data oversampling grid search could be implemented improve deep learning image classification tasks to counter the effects of imbalanced or scarce data.

V. Conclusion

This study has shown a novel strategy in countering the issue of data imbalance and data scarcity in classifying the level of disaster damage in images using deep learning models. By applying a mixture of techniques such as image data augmentation and image data oversampling, a trained EfficientNetV2B0 model that surpasses the performance of current models of similar input size in classifying the severity of natural disaster damage in some image collections has been obtained.

The methods in this study involved generating datasets of varying oversampling levels on different image data collections, ranging from balanced oversampling up to eight times the sample size. A search of an optimal amount of oversampling using VGG16 was carried out. The generated datasets with the optimal amount of oversampling were then combined to train the EfficentNetV2B0 model.

This success has netted a trained EfficentNetV2B0 model with improved F-1 scores of 0.782 on the Nepal data collection, 0.837 on the Ecuador data collection and a notable 0.683 on the Matthew data collection while maintaining a robust overall F-1 score of 0.752. These results show a major improvement on the classification of natural disaster damage levels in images, particularly on the Matthew data collection with some improvements on the Nepal and Ecuador data collections.

The findings in this study suggests that applying a combination of image data augmentation and oversampling techniques prior to model training helps in improving the robustness of deep learning classification models for classifying natural disaster damage. These methods have the potential to solve the challenges of data imbalance and data scarcity in image classification tasks involving natural disasters and offers a solution to improve the reliability and efficacy of natural disaster damage level classification in disaster response efforts.

Large-Scale Image Indexing and Retrieval Methods: A PRISMA-Based Review

Abdelkrim Saouabe[1], Said Tkatek[2], Hicham Oualla[3], Carlos SOSA Henriquez[4]
Computer Science Research Laboratory, Faculty of Sciences, IbnTofail University Kenitra, Morocco[1, 2]
AKKODIS Research, Paris, France[1, 3, 4]

***Abstract*—Large-scale image indexing and retrieval are pivotal in artificial intelligence, especially within computer vision, for efficiently organizing and accessing extensive image databases. This systematic literature review employs the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) methodology to thoroughly analyze and synthesise the current research landscape in this domain. Through meticulous research and a stringent selection process, this study uncovers significant trends, pioneering methodologies, and ongoing challenges in large-scale image indexing and retrieval. Key findings reveal a growing adoption of deep learning techniques, the integration of multimodal data to improve retrieval accuracy, and persistent challenges related to scalability and real-time processing. These insights offer a valuable resource for researchers and practitioners striving to enhance the efficiency and effectiveness of image indexing and retrieval systems.**

Keywords—Image indexing; image retrieval; similarity; PRISMA, computer vision

I. Introduction

In the aim of big data, the proliferation of digital images has created a need for efficient methods of indexing and retrieving large-scale visual information. With the rapid proliferation of digital content, it is estimated that by 2025, over 160 zettabytes of data will be generated annually, with a significant portion being image and video data. This exponential growth underscores the necessity for advanced indexing and retrieval systems. Large-scale image indexing and retrieval systems play an essential role in different contexts like image search algorithms, content-based image retrieval and multimedia data management. The rapid growth of image data from diverse sources such as social media, surveillance systems and scientific imagery has underlined the importance of robust and scalable techniques for organizing and accessing this vast visual content.

This systematic literature review uses the PRISMA method - a widely recognized approach for systematic reviews in healthcare and the social sciences - to carry out a comprehensive survey of existing literature in the field of large-scale image indexing and retrieval. The PRISMA method guarantees transparency, reproducibility and rigor in the synthesis of evidence from a wide range of studies. By adhering to this methodology, our review aims to provide an unbiased assessment of state-of-the-art techniques, identify gaps in current research and propose future directions for advancing this vital area of computer vision and information retrieval.

The remainder of this review document is organized as follows: Section II outlines the methodology utilized in the systematic literature review, detailing the search approach, criteria for study selection, and the process of extracting data. Section III discusses the outcomes of our analysis, emphasizing key discoveries, patterns, and obstacles uncovered in the chosen studies. Section IV examines the implications of these findings and suggests avenues for future research. Finally, Section V concludes the analysis with a summary of contributions and key lessons.

By synthesizing and analyzing the collective knowledge of large-scale image indexing and retrieval, this journal aims to inform researchers, developers and practitioners engaged in image-based information systems, offering insights to accelerate progress in this dynamic and rapidly evolving field.

II. Methodology of PRISMA

The research methodology used in this study, particularly the use of the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) model, is of crucial importance in ensuring the rigor and transparency of the analysis of existing studies on large-scale image indexing and retrieval. The PRISMA process is based on specific guidelines that guide each stage of the systematic review, from initial planning to synthesis of results.

First, the PRISMA methodology requires a clear definition of the review's objectives, including the formulation of precise research questions. These questions guide the selection of relevant studies to be included in the analysis. Next, a detailed search protocol is drawn up, describing the inclusion and exclusion criteria for studies and the literature search strategy used to identify relevant articles.

The systematic search is carried out through academic databases and specialized search engines, using keywords and search terms appropriate to the field of large-scale indexing and image retrieval. The selected articles are then subjected to independent evaluation by two or more reviewers to ensure the quality and consistency of the selection, the methodology is presented in Fig. 1.

Once the included studies have been identified, relevant data are systematically extracted from each selected article. This includes information on the methodologies employed, the results obtained and the authors' conclusions. The extracted data is then synthesized and analyzed to identify trends, gaps and emerging recommendations in the field of large-scale image indexing and retrieval.

Fig. 1. Selection process based on PRISMA.

Therefore, the selection has been carried out by applying the search results for the combinations selected. The inclusion and exclusion criteria are described as follows:

- Inclusion criteria: The articles dealing with "Large-Scale Image Processing" and "Large-Scale Image indexing and retrieval", the contribution of the article, the approach, and the metric.
- Exclusion criteria: The document types other than scientific, the language other than French and English, the duplicates, and the articles which are not directly dealing with the research object, excluding the research subject.

III. Exploring Contemporary Image Indexing and Retrieval Families

This section is dedicated to the state of the art of image indexing and retrieval methods. We can distinguish four families of approaches, which are described in the following sections. Section A presents for Deep Learning-Based Image Indexing and Retrieval family. Section B presents the family of Hybrid Image Retrieval Systems. Section C describes the set of methods dedicated to Image Indexing with Textual Information. Section D the family of Large-Scale Image Retrieval and Indexing. The approaches listed below are presented in chronological order.

A. Deep Learning-Based Image Indexing and Retrieval

The first approach in this category is the one presented in [1] in 2012, which introduces a novel framework for attribute-based image retrieval, allowing users to describe search objects using intuitive attributes. It explores various research aspects related to this method, highlighting recent advances and challenges encountered. This framework extends existing search models to handle relationships between query attributes and weak attributes, improving expressiveness and scalability. To efficiently learn this dependency model without overfitting, the paper proposes a semi-supervised graphical model. This model uses latent trees to represent the joint distributions of query and weak attributes at each level and uses an alternating inference algorithm to estimate the conditional probability.

The approach in study [1] presents a comprehensive dataset for multi-attribute image retrieval, called a-TRECVID, comprising 126 fully labeled query attributes and 6,000 weak attributes of 0.26 million images. The evaluation is based on mean AUC (Area Under Curve), which is commonly used to evaluate the performance of binary classification task, using a different dataset, like a-TRECVID, a-Yahoo and a-PASCAL dataset. The experimental results demonstrate significant performance improvements over state-of-the-art techniques, with a higher AUC equal to 85% compared with other approaches. The semi-supervised model significantly improves the generalizability of the proposed method for cross-dataset searching and searching with a very small training dataset.

The paper in [2] focuses on large-scale partially duplicated image retrieval. Provided a reference image, the goal is to identify pictures featuring the identical object or scene within an extensive database instantly. The approach concerns the development of a coupled binary embedding method for large-scale image retrieval. Multi-index binary indexing is used to combine SIFT visual words with binary features at the indexing level. The correlations are modeled between different features, proposing the concept multi-IDF, which represents a weighted sum of the individual IDFs of each merged feature. The study also explores the integration of the local color descriptor into the retrieval process. The framework is extended to include a binary color feature, using binary features to check visual word match pairs and enhance discrimination capability. This method uses heterogeneous binary features, such as color features, and extends to other binary features. It also incorporates the Multiple Assignment (MA) technique to improve recall of candidate images. Databases used for evaluation include Ukbench (10,200 images), Holidays (1,491 images), DupImage (1,104 images) and MIR Flickr (1 million images).

The performance evaluation in study [2] is based on different metrics depending on the database. For UKBench, performance is measured by recall for the top 4 candidates, while for Holidays and DupImage, mAP (mean Average Precision) is used to assess the quality of image retrieval. In the Holidays dataset, the inverted SIFT files achieve a mAP of 73.9%, while the CN files yield a mAP of 50.5%. The article also analyzes the impact of different parameters on retrieval precision, such as the weighting parameter σ and the Hamming distance threshold κ. In addition, it compares the proposed method with other image retrieval approaches using metrics such as the N-S score for UKBench and the mAP for the Holidays and DupImage datasets.

Deep convolutional neural networks (CNNs) have been effectively utilized for image classification tasks. However, when utilized for image retrieval, the conventional assumption that the last layers of CNNs yield optimal performance, as observed in classification tasks, is often challenged. The Research presented in study [3] demonstrates that, for instance-level image retrieval, lower layers of CNNs frequently outperform the final layers. The presented methodology involves obtaining convolutional features from various layers of CNNs, specifically employing the OxfordNet and GoogLeNet architectures. These features are then encoded into a compact representation using Vector of Locally Aggregated

Descriptors (VLAD) encoding. The diverse layers and dimensions of input images are assessed for their impact on the effectiveness of convolutional features in image retrieval tasks. The experiments were conducted on three datasets for retrieving images at the instance level: Holidays, Oxford, and Paris. The Holidays dataset comprises 1491 personal holiday photos across 500 categories, with the first image of each category used as a query. The Oxford and Paris datasets contain images of famous landmarks, each with specified regions of interest for retrieval. Oxford includes 5062 images, while Paris includes 6412 images, both with multiple queries per landmark. The approach of [3] emphasizes on:

- Utilization of Deep Neural Networks: By employing the OxfordNet and GoogLeNet for feature extraction, exploring various layers to identify optimal performance for image retrieval.
- Feature Extraction: Convolutional features are extracted from selected layers of the networks, considering different dimensions of input images.
- Encoding with VLAD: Features are compressed into compact representations using VLAD encoding to facilitate efficient retrieval.

The experimental results show that middle or deeper layers with more refined resolutions often yield better outcomes in image retrieval when contrasted with using the final layer. Specifically, when employing compressed 128-dimensional VLAD descriptors, the method achieves state-of-the-art performance and outperforms existing VLAD and CNN-based approaches on two of the three test datasets (Holidays, Oxford and Paris). Computing times between 0.4 and 3.5 seconds depending on the sparsity of the user sketch have bene reported, for a database of 1.5 million images. Following the standard evaluation protocol, mAP is used to evaluate the performance of the proposed approach. The mAP initially increases as you move deeper into the network. The variation in mAP varies from one base to another, between 10% and 75%, and increases with the layers.

The adoption of Deep Learning for content-based image retrieval has surged in recent years. In the research presented in [4], a method for indexing Deep Convolutional Neural Network Features to facilitate efficient retrieval from extensive image databases has been introduced. The approach involves encoding these features into text representations, allowing the utilization of a text retrieval engine for image similarity searches. This led to the development of LuQ (name of the approach), a robust retrieval system that integrates full-text search with content-based image retrieval capabilities. The main idea behind LuQ is to index DCNN features using a text encoding that allows us to use a text search engine to perform an image similarity search. To enhance index efficiency and query response time, they conducted evaluations on various tuning parameters for text encoding. As a result, a web-based prototype capable of efficiently searching through a dataset containing 100 million images was developed.

To evaluate the efficiency of LuQ, the Yahoo Flickr Creative Commons 100 million (YFCC100M) dataset was employed [4]. This dataset was established in 2014 under the Yahoo Webscope program. YFCC100M comprises 99.2 million photos and 0.8 million videos that were uploaded to Flickr between 2004 and 2014. The authors have reported an average query time of less than four seconds, without parallelization, for the configuration LuQ and Cur = 10. This approach is 10 magnitudes quicker than the sequential scan using L2. The mAP is assessed based on the quantization factor Q. The findings indicate that a high mAP is achieved when Q is set to 30, yielding a value of 62%.

The paper in [5] discusses the development of a new method based on CNNs to improve the performance of content-based image retrieval (CBIR). This innovative approach uses deep CNN models, exploiting class information available in the data, as well as information provided by distractors, to improve search accuracy. It uses a deep CNN model to extract meaningful features from images, adjusting its weights to bring each image closer to its relevant representations and further away from those that are irrelevant. The experimental results are presented on public datasets for image retrieval, demonstrating its effectiveness. Its main contributions include the integration of multiple relevant and irrelevant samples in the training phase for each sample, as well as the definition of representation objectives for training samples and regression on hidden layers.

For the future, the authors of [5] plan to extend their approach to the use of cropped queries in the Oxford and Paris datasets for research. Evaluations were carried out on the Oxford 5k, Paris 6k, UKBench and UKBench-2 databases, containing 5062, 6412, 10200 and 7650 images respectively. The presented approach also uses the BVLC Reference CaffeNet model and re-train the pre-trained CNN on the dataset. It refines the distance between distractor representations and each specific image using Euclidean loss during training. Adjustments are made to the CaffeNet model, such as removing certain layers and replacing them with PReLU layers, making this method apply to all layers except FC6 and FC7. The performance is evaluated using the mAP for 55 queries, the mAP results vary from 22% to 98% depending on the database and Feature Representation. The approach is compared to other CNN-based methods as well as to manually designed methods on the Oxford 5k, Paris 6k, UKBench and UKBench-2 datasets in terms of precision and recall. It also compares this method to other approaches.

The approach presented in the paper [6], addresses the optimization of large-scale similarity search using matrix factorization. The method presented reformulates the image search problem into a matrix factorization problem, which can be solved by eigenvalue decomposition or dictionary learning. The database used includes various datasets such as Oxford5k, Paris6k, 100,000 Flickr distracting images, Oxford105k, Paris106k, Yahoo Flickr Creative Commons 100M, Holidays and UKB.

The performance is assessed by measuring retrieval performance, mainly mAP for most datasets, except for UKB where performance is measured by 4×recall@4. The mAP increases as a function of Complexity Ratio and reaches values between 60% and 80% depending on dataset used. A comparison is made between the eigenvalue decomposition method, Dictionary Learning (DL) and locality-sensitive hashing (LSH). Dictionary learning shows better performance, especially with large datasets such as Paris6k, Oxford5k, Oxford105k and Paris106k, using complexity ratio and mAP as performance measures [6]. The approach offers an efficient alternative for large-scale similarity search by reducing the number of vector operations required, while maintaining search performance comparable to exhaustive search.

The research presented in study [7], presents the DELF (DEep Local Feature), an attentive local feature descriptor designed specifically for large-scale image retrieval tasks. DELF is based on convolutional neural networks trained solely with image-level annotations from a landmark image dataset. To identify semantically meaningful local features for image retrieval, an attention mechanism for keypoint selection is incorporated, which shares most network layers with the descriptor. DELF can seamlessly replace existing keypoint detectors and descriptors in image retrieval systems, leading to improved feature matching and geometric verification. The approach provides reliable confidence scores to mitigate false positives, particularly excelling in scenarios where query images lack correct matches in the database. To assess the effectiveness of DELF, the Google-Landmarks dataset was introduced, a comprehensive large-scale dataset designed to challenge image retrieval systems with diverse scenarios including background clutter, partial occlusion, multiple landmarks, and objects at varying scales. The framework presented in this work represents a significant advancement in local feature descriptors for image retrieval, demonstrating robust performance across challenging real-world scenarios through the integration of CNN-based learning and attention mechanisms. In the first stage, the performance is evaluated using a modified precision (PRE) and Recall. In the second stage, the performance was evaluated using mAP on the Oxf5k, Oxf105k, Par6k and Par106K databases. The results show satisfactory values for the proposed approach, with mAP values equal to 90%, 88,5%, 95,7% and 92,8% for the four databases used.

Instance Search (INS) presents a significant challenge compared to traditional image search, as relevancy is defined at the instance level rather than image-wide. Prior research has relied on complex ensemble systems involving object proposal generation and subsequent feature extraction for matching, often resulting in a disjointed approach with decreased effectiveness [8]. Moreover, the sheer volume of proposals has hindered the matching speed, limiting these methods scalability to large datasets. To address these shortcomings, the paper presented by [8] introduces Deep Region Hashing (DRH), a novel approach for large-scale INS using image patches as queries. DRH is an end-to-end, deep neural network integrating object proposal, feature extraction, and hash code generation. Notably, it shares the full-image convolutional feature map with the region proposal network, making region proposals practically cost-free. Furthermore, it maps high-dimensional, real-valued region features into compact binary codes for efficient object-level matching in large-scale datasets.

The experimental results in study [8] across four datasets, Oxford5K, Oxford106k, Paris6k and Paris 106k, demonstrate that DRH outperforms state-of-the-art methods in terms of mAP while achieving an approximate 85% increase in efficiency for all the datasets. The algorithm performance is evaluated on the instance search task by studying the impact of different components within the presented framework. A comparative analysis is then conducted between DRH and existing algorithms, focusing on both efficiency and effectiveness, using two standard datasets as benchmarks. For the lDRH, the INS is improved by approximately 3% for the Oxford datasets, while the gQE improves the performance of DRH by 85% on the Oxford 5k dataset.

The paper in [9] discusses the development of a large-scale image hashing method called Semi-supervised Deep Hashing (SSDH), aimed at improving the efficiency of image retrieval. Firstly, it proposes a semi-supervised loss that simultaneously minimizes the empirical error on labeled data and the embedding error on labeled and unlabeled data, to preserve semantic similarity and capture meaningful relationships between data for efficient hashing. Secondly, a semi-supervised deep hashing network is designed to fully exploit both labeled and unlabeled data, enabling the simultaneous learning of hash functions and image representations in a semi-supervised manner. In addition, an online graph construction method is proposed to take advantage of deep features evolving during training, to better capture semantic relationships between images.

The experiments in study [9] are carried out on several datasets, including CIFAR-10, MNIST, NUS-WIDE and MIRFLICKR. Evaluation of the SSDH method is based on various metrics such as mAP, precision-recall curves, accuracy @ topk and accuracy @ top500. This evaluation compares SSDH to eight state-of-the-art methods, including unsupervised, semi-supervised and supervised approaches. The proposed method had a high recall value of 78% and a minimal retrieval time of 980 ms, which is in the order of 10% more satisfactory than the comparative methods. The mAP varies between 70% and 98% depending on different hash code lengths and dataset.

The paper in [10] discusses large-scale image retrieval using transductive support vector machines (TSVMs) combined with hierarchical binary trees (BHTs). This innovative approach comprises several key components. Firstly, it exploits TSVMs in combination with BHTs to facilitate efficient large-scale image retrieval. Secondly, it involves the creation of multiple binary hierarchical trees based on the separability of visual object classes, which contributes to a better organization of data for search. In addition, the TSVM classifier is trained using a stochastic gradient-based solver, enabling efficient scaling with large datasets. Finally, the approach includes a method for learning class hierarchies, using graph cutting and hierarchical binary trees, to ensure a meaningful margin between samples of different classes.

The experiments of [10] are conducted on various datasets including Cifar100, CLEF 2013 Dataset, NUS-WIDE dataset, Cifar10 dataset and MNIST 3-digit dataset. The evaluation of the proposed method, TSVMH-BHT, is done compared with other supervised and unsupervised hashing methods. Measures used for this evaluation include the mAP and Euclidean distance metrics. The mAP results range from 24.46% to

37.27% for Fisher vectors (FVs) and 41.48% to 46.78% for CNN. In addition, the approach's effectiveness is also evaluated against other large-scale image search methods, particularly on specific datasets such as Cifar100.

In the paper [11], other novel image indexing systems are introduced based on the composition of an inverted file index (IVF) and a structured binary encoding mechanism termed SUBIC (Structured Unifying Binary Encoding). Unlike traditional approaches that rely on unsupervised clustering for indexing, the proposed system leverages a unified neural framework to learn both indexing components. The IVF system partitions the dataset using Vector Quantization (VQ), facilitating efficient retrieval by restricting searches to relevant subsets. Concurrently, the SUBIC encoder embeds image features into a structured binary space, enabling rapid approximate distance computations during retrieval.

The approximate distance computation methods in the framework encompass hashing techniques and structured variants of VQ. The methodology in study [11] extends supervised learning approaches to enhance the efficiency and accuracy of distance computations. To evaluate the efficacy of the feature encoder, the performance of SUBIC encoding is compared against unsupervised Vector Quantization (VQ) on various test datasets. Furthermore, the baseline indexing systems (IVF-PQ, IMI-PQ, DSH-SUBIC) are assessed by comparing metrics such as the average number of retrieved images and mean Average Precision across the first T responses. mAP results vary between 46% and 93% depending on the dataset and method used. The evaluations are conducted against established benchmarks including Oxford5K, Oxford5K, Paris6K, Holidays, Oxford105K, and Paris106K. The presented study aims to demonstrate the superiority of the proposed indexing system over traditional approaches, highlighting improvements in retrieval performance across diverse datasets through the integration of supervised learning techniques into the indexing pipeline.

The study referenced in study [12] explores the creation of a system that can efficiently retrieve images instantaneously from extensive repositories, focusing on scalability and computational power. It specifically targets applications in remote detection and botany. The method involves processing images independently without considering relationships between subsets of images. A deep Convolutional Neural Network (CNN) is used to extract features and generate deep representations from the image data. Additionally, an optimized data structure is introduced to improve query speed by employing a structure organized in hierarchical levels and recursive similarity assessments. The study includes a comprehensive series of trials to assess the precision and computational effectiveness of the suggested image retrieval approach, which is tailored for botanical identification and high definition remotely detecting data. Comparative analysis is conducted against traditional content-based image retrieval (CBIR) methods like the bag of visual words (BOVW) and integrating multiple features (MFF) methods.

The experiments in study [12] aimed to assess fundamental aspects of Content-Based Image Retrieval (CBIR), focusing on accuracy and computational efficiency. Feature extraction was conducted using the Keras API in Python within a deep learning framework, while MATLAB was employed for feature indexing. The accuracy of the proposed method was evaluated against BOVW and MFF, traditional feature-based methods. Additionally, computational efficiency and retrieval time were compared with inverted index organization and flat structure search strategies. The experiments utilized the University of California Merced (UCM) Dataset, which includes 21 land cover classes with large-scale aerial images sourced from the USGS national map urban area imagery. Each class comprised of 100 images sized at 256 × 256 pixels, with a spatial resolution of 30 cm per pixel in RGB spectral space for assessing the effectiveness of high-resolution remotely detecting image scene classification.

The evaluation assesses performance using mean Average Precision (mAP) and average retrieval time metrics. The proposed approach achieves maximum precision exceeding 90% in mAP scores. On the MalayaKew (MK) and UCM image datasets, RL-CNN utilizing a hierarchical indexing scheme achieved average retrieval times of 0.039 and 0.025 seconds, respectively. In comparison, RL-CNN employing sequential searching ranked second with retrieval times of 0.164 and 0.142 seconds on the same datasets. It's important to highlight that sequential searching operates with an O (N) linear complexity, resulting in significantly longer execution times as the image count rises to hundreds of thousands or even millions, contrasting techniques such as BOVW using inverted index and BOVW without indexing showed slower retrieval times-0.29 and 1.8 seconds for the MK dataset, and 0.66 and 3.9 seconds for the UCM dataset, respectively. Moreover, RL-CNN employing sequential searching exhibited better efficiency compared to BOW with a comparable framework [11].

The development of the DSLL (Distribution Structure Learning Loss) algorithm for image retrieval based on deep metric learning is discussed in study [13]. DSLL preserves the structural information of positive samples by learning a hyperplane for each query sample in the model, while using the structural distribution-based entropy weight to assess the spatial relationship between negative samples and their environment. This method combines the eigenvectors with the weights to train the network, improving retrieval accuracy by preserving the structure of the image feature vectors and the consistency of the structural similarity ranking.

The DSLL performance is evaluated from different aspects by study [13], including the impact of choosing different selections of the boundary τ, comparing performance based on non-ranking, ED (Euclidean distance) and structural consistency methods, as well as the impact of choosing different selections of the threshold β. These evaluations are carried out with the AlexNet and VGG architectures on the Oxford 5k and Paris 6k datasets. In addition, the performance mAP of DSLL is compared with that of state-of-the-art image retrieval methods under VGG and ResNet deep networks on various datasets. The result of the evolution of mAP depending on training epoch shows that the mAP increases and achieves 59% for Oxford5K and 70% for Paris5k.

The proposed method by study [14], named OS2OS (Score Objects in Scene for Objects in Scene), aims to model object-level regions using image key points from an image index, enabling small significant objects to be accurately weighted in the results, without requiring costly object detections. Several datasets are used, including Oxford 5k, Paris 6k, Google-Landmarks, the NIST Media Forensics Challenge 2018 (MFC2018) and the Reddit dataset.

The evaluation of the method uses features such as SURF and DELF, as well as indexing techniques such as Optimized Product Quantization (OPQ) for nearest neighbor search. Performance is assessed by comparing the OS2OS score with other spatial verification methods. The OS2OS scoring provides competitive or superior performance, without the need for bounding boxes to pre-select regions of interest. The mAP varies between 74% and 86% depending on the techniques used and the Paris or Oxford dataset. The recall scores confirm the effectiveness of the approach comparing to other methods with higher values 47,9%, 54 ,8% and 59,3% respectively for top-50, 100, and 200 most related retrieved images.

The paper in [15] presents a new image retrieval method called CBIR-Similarity Measure through Artificial Neural Network Interpolation (CBIR-SMANN), aimed at improving image retrieval using artificial neural network (ANN) interpolation. The process involves resizing images, applying Gaussian filtering as pre-processing, and identifying key points using a Hessian detector. Features such as mean, kurtosis and standard deviation are extracted and fed to an artificial neural network for interpolation. The interpolated data are then stored in a database for later retrieval. The main contributions of this method are as follows:

- Acquisition and verification of image data including information on objects, colors, spatial information, textures, and shapes, leading to maximum retrieval rates and accuracy.
- Introduction of a weightless feature description and detection model that efficiently recovers appropriate results from complex and cluttered datasets.
- Introduction of a method to implement semantic variation with a similarity measure and color matching to highlight objects.
- Ability of the technique to extract only important image information from the anchor translation instead of iterating over complete images.
- Deploying a retrieval system optimized for storage, processing speed, and computational efficiency, ensuring search results are obtained within seconds.

The future perspective suggested in the article is to integrate the convolution network to obtain improved results. The experiments were carried out on a public dataset containing 1000 images divided into 15 classes. Evaluation metrics used included recovery time, accuracy, false positive rate, false negative rate, specificity, F1 score, error, precision, recall and negative predictive value [15]. The results indicate that CBIR-SMANN achieved a high recall rate of 78% with minimum retrieval time of 980ms has given a high precision with 82% compared to other approaches that were cited in the paper.

The paper in [16] presents the Super Global method, which transforms the conventional two-stage image retrieval model. This approach exclusively relies on global features for both initial retrieval and reranking, thereby improving efficiency without sacrificing accuracy. The method utilizes only global image features for both retrieval phases, eliminating the necessity for local features and implementing advancements in global feature extraction and reranking processes.

The scalability issues are addressed in image retrieval systems, specifically the substantial storage and computational costs associated with local feature matching during reranking. The effectiveness of the proposed method is evaluated using standard image retrieval benchmarks, demonstrating significant improvements over existing approaches. Notably, on the Revisited Oxford+1M Hard dataset, the single-stage performance improves by 7.1%, while the two-stage approach achieves a gain of 3.7% with a remarkable speedup of 64,865 times. The two-stage system outperforms the current single-stage state-of-the-art by 16.3% [16]. The mAP Results were performed on the ROxford and RParis datasets (and their large-scale versions ROxf+1M and RPar+1M), with Medium and Hard evaluation protocols. The best mAP results are obtained for RN50 and RN101 and vary between 68% and 90% depending on the database used.

The paper in [17] discusses image-based patent searching, highlighting its growing importance in the fields of intellectual property and information retrieval. The proposed method focuses on a simple yet robust approach, using a lightweight structure for feature extraction and a neck structure to obtain a low-dimensional representation to facilitate patent search. The network is trained with classification loss in a geometric angular space, accompanied by data augmentation specifically tailored to patent drawings, without scaling. The database used, DeepPatent, comprises a total of 45,000 different design patents and 350,000 drawing images, with a training set of 254,787 images from 33,364 patents and a validation set of 44,815 images from 5,888 patents.

The performance is evaluated using mAP and Rank-N metrics [17]. The results show that the proposed method outperforms traditional and deep learning methods, highlighting its robustness and scalability, for mAP the result obtained is the higher, with value equal to 71%, comparing with some other approaches, the same for Rank-1, Rank-5, Rank-20, the experiments show the performances of the proposed approach which equal respectively to 88,9, 95,8 and 98,1 and higher than the values obtained for other existing approaches in the literature. These results also suggest promising directions for exploring more robust loss functions in the context of image-based patent search, paving the way for future advances in this field.

B. Hybrid Image Retrieval Systems

In this family the first approach is the one presented in study [18] in 1996 which is the oldest approach in this state of art. A novel approach to object recognition in image databases is presented in study [18], focusing on a process of progressive clustering of coherent image regions that satisfy increasingly stringent constraints. This method is based on the aggregation of coherent image regions satisfying increasing color and texture criteria. It incorporates hierarchical clustering and learning techniques for classification, enabling general objects to be processed in uncontrolled environments. The results are evaluated using different metrics such as precision and recall measuring the method's effectiveness in retrieving objects from large image collections, with databases including QBIC and Photobook without mentioning their specific size.

The system's effectiveness was assessed using 4289 training images and 565 images for testing purposes. The evaluation was implemented in various configuration system and using a different metric (Precision, Recall, Response ratio, Test response….). The result of precision varies between 48% and 61%, recall varies also between 7% and 79% depending on the system configurations used.

In the presented work in study [19], a novel incremental and parallel Correspondence Factor Analysis (CFA) algorithm optimized for large-scale image retrieval using GPU processing was introduced. The CFA algorithm is adapted specifically for content-based image retrieval employing local image descriptors such as SIFT (Scale-Invariant Feature Transform). The primary objectives of this approach include dimensionality reduction and theme discovery to streamline image search processes and reduce query response times. To accommodate very large image databases, an incremental and parallelized version of the AFC algorithm has been presented. This adapted version is leveraged to construct inverse files based on extracted indicators, facilitating the identification of images sharing similar themes with the query image. Notably, this indexing step is also optimized for parallel execution on GPU hardware to achieve rapid query responses.

Experimental results in study [19] conducted on the Nister-Stewenius image database integrated with 1 million Flickr images demonstrate the substantial performance gains of the incremental and parallel algorithm compared to the standard version of AFC. To assess the scalability of the presented methods, the Nistér Stewénius database was extended by merging it with additional Flickr images (100,000, 200,000, 500,000, and one million). The vocabulary size was set of 5000 words. The algorithms were implemented in C++ utilizing LAPACK and ATLAS libraries for efficient computation and optimization. These experiments underscore the effectiveness and scalability of the proposed incremental and parallel CFA algorithm for large-scale image retrieval, offering significant improvements in retrieval speed and efficiency across expansive image datasets. The response time and precision are used to study the performance of the proposed method. The response time is the lowest (7.53ms) compared with other methods. In terms of precision, the results obtained show the quality of the proposed method, with a value equal to 62.5%.

As the volume of multimedia content grows rapidly, there is an increasing demand for efficient image retrieval systems. Content-based image retrieval (CBIR) systems are pivotal in addressing this challenge [20]. However, retrieving specific images from vast databases can be time-consuming. To address this challenge, methods for image organization are utilized to speed up how quickly images can be found. The study outlined by [3] highlights the advancement of a proficient image retrieval system that integrates various organizing methods to decrease retrieval time. The emphasis lies in developing a hybrid image retrieval system that utilizes texture, color, and shape characteristics of images. Particularly, the gray level co-occurrence matrix (GLCM) is employed to capture texture details, color moments are used for extracting color attributes, and the region props procedure is applied to shape feature extraction. By combining these diverse image attributes, the proposed system aims to enhance retrieval efficiency and enable faster access to relevant images within large databases. Following the feature fusion process using texture, color, and shape attributes, principal component analysis (PCA) is applied to optimize the selection of fused features. Next, two indexing methods—similarity-based indexing and cluster-based indexing—are evaluated in the hybrid image retrieval system to gauge their efficacy.

The study in [20] reveals that the hybrid color descriptor combined with cluster-based indexing yields significant improvements. The findings show mean precision percentages of 93.8%, 79.6%, 70%, 98.7%, 93.5%, and 79.5% across different datasets, such as Corel-1K, Corel-5K, Corel-10K, COIL-100, GHIM-10, and ZUBUD. These findings demonstrate the efficacy of the proposed hybrid image retrieval system, particularly when utilizing cluster-based indexing, in achieving enhanced retrieval performance across diverse datasets. The utilization of PCA for feature optimization further contributes to the system’s effectiveness in retrieving relevant images efficiently from large repositories.

C. *Image Indexing with Textual Information*

The paper in [21] presents an automatic image text alignment algorithm aimed at improving the indexing and retrieval of large-scale web images by aligning them with relevant auxiliary text terms or phrases. The algorithm operates in several stages:

- Web Crawling and Segmentation: A large collection of cross-media web pages containing both web images and associated text is crawled and segmented to create image‑text pairs. These pairs consist of informative web images and their corresponding text terms or phrases.

- Near-Duplicate Image Clustering: The web images are grouped into clusters of near duplicates based on visual similarities. Images within the same cluster share similar semantics and are associated with similar auxiliary text terms or phrases that frequently co-occur in relevant text blocks. This clustering process helps reduce uncertainty in determining the relationship between image semantics and auxiliary text.

- Random Walk on Phrase Correlation Network: A random walk is performed on a phrase correlation network to refine relevance scores between web images and their associated text terms or phrases. This step enhances the precision of image‑text alignment. The algorithm effectiveness is validated through experiments on large-scale cross-media web pages, demonstrating positive results in terms of image retrieval and indexing.

As a result of the [21] methodology, a database containing 5,000,000 image – text pairs are curated. This approach enhances the capability of image retrieval systems by leveraging text information associated with web images, thereby improving the accuracy and effectiveness of indexing and retrieval tasks on a large scale.

D. Large-Scale Image Retrieval and Indexing

The challenges posed by the rapid growth of online image repositories like Flickr, which house vast quantities of images requiring efficient indexing, searching, and browsing capabilities has been assessed by [22]. The presented approach leverages image content as valuable information for image retrieval. The Latent Dirichlet Allocation (LDA) models are adopted to represent images for content-based retrieval, involving learning image representations in an unsupervised manner, where each image is characterized as a mixture of topics or object parts depicted within the image. This modeling enables the placement of images into subspaces for higher-level reasoning, facilitating the discovery of similar images. The various similarity measures are explored based on this image representation to enhance retrieval accuracy. To validate the presented approach, it is evaluated on a real-world image database comprising over 246,000 images and compare it against image models based on probabilistic Latent Semantic Analysis (pLSA). The results demonstrate the effectiveness and scalability of the proposed LDA-based approach for large-scale image databases.

The active learning is integrated by [22] with user relevance feedback into our framework to further enhance retrieval performance. This incorporation of user feedback allows for iterative refinement of the retrieval process, adapting to user preferences and improving the relevance of retrieved images. Overall, the work presents the potential of LDA-based image representation for content-based retrieval, particularly in managing large-scale image datasets, and underscores the benefits of incorporating active learning mechanisms to optimize retrieval outcomes based on user interaction and feedback.

Large-scale image retrieval has demonstrated significant potential for real-life applications. The conventional method relies on Inverted Indexing, where images are represented using a Bag-of- Words model. However, a key drawback of this approach is the neglect of spatial information associated with visual words during image representation and comparison. This oversight leads to reduced retrieval accuracy. Earlier researchers in [23] investigated a technique for integrating spatial data into the Inverted Index, aiming to boost precision without compromising retrieval speed. Their methodology was tested on established datasets (Oxford Building 5K, Oxford Building 5K+100K, and Paris 6K), demonstrating the efficacy of their proposed method.

To evaluate the accuracy of the retrieval system, the study in [23] compared the mAP and processing time (in seconds) of four methods (Baseline 1, Baseline 2, II+SPM, II+SPM*) across three datasets: Oxford 5K, Oxford 105K, and Paris 6K. The method II+SPM* improves the mAP of the Baseline 2 by about 2.31%, 4.21% and 3.31% on Oxford 5K, Oxford 105K and Paris 6K, respectively. Furthermore, the study investigates the impact of background visual word weighting on the final mAP of the retrieval system across the three datasets. Additionally, the II+SPM* presents lower processing times than Baseline 2 and comparable magnitudes with Baseline 1 and II+SPM.

The exponential growth of online images necessitates efficient indexing for large-scale digital image retrieval. Designing a compact yet highly efficient image indexing system remains challenging, primarily due to the semantic gap between user queries and the complex semantics of vast datasets. In the paper [24], a novel approach that constructs a joint semantic-visual space by integrating visual descriptors and semantic attributes was presented. This integration aims to bridge the semantic gap by combining attributes and indexing within a unified framework. The proposed joint space enables coherent semantic-visual indexing, leveraging binary codes to enhance retrieval speed while preserving accuracy. To address this, the following contributions are made:

- Interactive Optimization Method: Proposed by an interactive optimization approach to discover the joint semantic and visual descriptor space efficiently.
- Convergence Analysis: Proved by the convergence of the optimization algorithm, ensuring convergence to a good solution after a finite number of iterations.
- Integration with Spectral Hashing: By integrating the semantic-visual joint space with spectral hashing, providing an efficient solution for searching billion-scale datasets.
- Online Cloud Service Design: By developing an online cloud service to deliver more efficient multimedia services based on the proposed indexing system.

Experimental evaluations on standard retrieval datasets (Holidays1M, Oxford5K) demonstrate the effectiveness of the presented method compared to state-of-the-art approaches. Moreover, the cloud system significantly enhances performance, presenting the practical utility and scalability of the presented semantic-visual joint space indexing framework. Overall, the presented work [24] contributes to advancing efficient image retrieval systems by addressing the semantic gap through a unified semantic-visual space, optimizing retrieval speed and accuracy, and facilitating scalable multimedia services in cloud environments.

The paper in [25] discusses the development of a large-scale image retrieval system for everyday scenery with typical items. This system uses advances in deep learning and natural language processing (NLP) to gain deeper insights into images by capturing the interconnections between objects within an image. The goal is to empower users to access highly pertinent images and receive recommendations for analogous image searches to delve deeper into the repository. The proposed method, named QIK (Querying Images Using Contextual Knowledge), utilizes forecasts generated by deep networks for tasks related to interpreting images, such as generating descriptions for images and identifying objects, instead of creating local/global image descriptors using CNN-based features. QIK uses contemporary natural language processing (NLP) frameworks for effective and precise image retrieval in daily situations. The QIK's structure comprises two primary elements: the Indexing module and the Query Handler. The Indexer creates a probabilistic image understanding (PIU) for each image in the database, employing cutting-edge captioning and object detection algorithms. There is an exhaustive survey of all the image contextualization methods mentioned in [26]. A PIU comprises the most probable descriptions and identifies items in an image, enabling the contextualization of ordinary scenarios and comprehension of the connections between items. The Query Handler can employ either image descriptions or identified items for image retrieval.

The method evaluation is based on metrics such as retrieval time, accuracy, false positive rate, false negative rate, specificity, F1 score, etc. The tests in study [25] were carried out on datasets including images of daily scenes from MSCOCO and Unsplash.

The Progressive Distributed and Parallel Similarity Retrieval (DPRS) method addresses the search for similarity between computed tomography (CTI) image sequences in resource-constrained cell phone networks (MTNs), while preserving the confidentiality of medical data. DPRS relies on four key techniques: a PCTI-based similarity measure, a lightweight privacy-preserving strategy, an SSL-based data distribution scheme, and a UDI framework. Various experiments [27] following these techniques have been conducted on a database comprising 50,000 CTIS used to diagnose various types of lesions. The experimental results show a significant improvement in response time compared to the state-of-the-art, using metrics such as response time, precision and recall evaluating the effectiveness of the DPRS method. In conclusion, DPRS represents a promising approach for similarity search in medical information systems, combining innovative techniques to optimize similarity between CTISs, preserve data confidentiality, distribute data efficiently and provide effective indexing for fast search.

E. Other Works

There are numerous other works addressing the issue of image indexing that we have not included in this article. These works were excluded because they did not meet the specific inclusion criteria defined by the PRISMA framework we employed. Our criteria were stringent to ensure the relevance and quality of the studies reviewed, focusing on specific methodologies, contexts, and outcomes pertinent to our research objectives. Some of the excluded studies, such as those cited in references [28], [29], [30], [31], [32], [33], [34], [35], [36], [37], [38], [39], [40], [41], [42], [43], [44], [45], [46], [47], [48], [49], [50], [51], [52], [53], [54], [55], [56], [57], [58], [59] and [60], provide valuable insights and contributions to the field but fell outside our defined scope. These studies might focus on different aspects of image indexing, employ alternative methodologies, or address broader contexts that, while important, were not directly aligned with our research parameters. By acknowledging these works, we recognize the breadth and diversity of research in image indexing, even though they were not part of our systematic review.

IV. Discussion

The systematic review conducted using the PRISMA method has provided a comprehensive synthesis and analysis of the literature on large-scale image indexing and retrieval. The results of this review highlight several important trends, methods, and challenges in this rapidly evolving field of image processing research.

One of the most significant trends identified in the review is the strong advance in deep learning-based approaches, particularly the use of convolutional neural networks (CNNs). These techniques have substantially improved the performance of image retrieval systems, offering superior accuracy and efficiency compared to traditional methods. The ability of CNNs to automatically learn hierarchical feature representations has been a key factor in their success.

Despite these advancements, several challenges remain. One of the primary issues is the generalization of these models to more diverse datasets. Current models often perform well on specific, well-curated datasets but struggle with variability in real-world data. This includes variations in scale, viewpoint, lighting conditions, and occlusions. Additionally, the efficient management of large volumes of data remains a significant hurdle. The storage, retrieval, and processing of massive datasets require robust and scalable solutions.

To address these challenges, promising avenues of research have emerged. Integrating semantic and contextual knowledge into image retrieval systems is one such direction. By understanding the context and semantics of images, retrieval systems can provide more accurate and relevant search results. For instance, combining visual information with textual data or metadata can enhance the retrieval process by adding another layer of information.

Another area of interest is the development of models that are robust to variations in scale and perspective. Techniques such as data augmentation, multi-scale feature extraction, and the use of generative adversarial networks (GANs) for synthetic data generation are being explored to improve model robustness.

The review also highlights the importance of interdisciplinary collaborations to advance research in large-scale image indexing and retrieval. Collaborations between computer scientists, data engineers, domain experts, and industry practitioners can drive innovation and address practical challenges. Such collaborations can lead to the development of more effective and efficient retrieval systems that are applicable to a wide range of real-world scenarios.

Looking ahead, the practical applications of advanced image retrieval systems are vast. From medical imaging and remote sensing to e-commerce and social media, the ability to efficiently and accurately retrieve images has significant implications. Future research should focus on creating more adaptable, robust, and scalable systems that can handle the complexities of real-world data.

We have structured our state-of-the-art in the form of tables to summarize the different approaches, techniques, databases and metrics used in image indexing. This organization makes it possible to present the essential information clearly and concisely, facilitating comparison and analysis of the various methods employed. By detailing the characteristics and performance of the techniques studied, we can better understand their respective advantages and disadvantages, helping us to identify the solutions best suited to our specific image indexing needs.

The summarized Table I provides an overview of various techniques, datasets, and evaluation metrics employed in image retrieval and recognition research, particularly within the family of deep learning-based image indexing and retrieval. The techniques covered include CNNs, DELF, binary encoding, VLAD encoding, DRH, SIFT, FV, among others. Commonly used datasets are Oxford 5k, Oxford 105k, Paris6k, Paris106k, Holiday, and Flickr. The primary evaluation metric is mean average precision (mAP), typically ranging from 70% to over 90%. Additionally, metrics such as retrieval time, precision (PRE), recall (REC), F1 score, Rank-N, and others are also utilized.

Table II offers a thorough summary of the methods, techniques, datasets, and metrics employed in various studies on hybrid image retrieval systems family, image indexing with textual information family, and large-scale image retrieval and indexing family. The table highlights several techniques such as SIFT, PCA, GLCM, DOM, SVM, NLP, and CTI, along with additional techniques mentioned in certain studies, showcasing a broad spectrum of methodologies applied in this field. The studies utilize diverse datasets including Nister-Stewenius, Corel, COIL, ZUBUD, Paris6K, Oxford5K, Oxford105K, Holidays, MSCOCO, and Unsplash, as well as other datasets unique to individual research projects. The evaluation metrics featured in these studies encompass retrieval time, mean Average Precision (mAP), recall (REC), and Rank-N, with mAP being the most frequently cited metric.

Most of these approaches concentrate on the family of Deep Learning-Based Image Indexing and Retrieval, highlighting the significance of deep learning architecture in this field. The decision to choose between these different families depends on the specific problem at hand, as well as various factors such as datasets, image quality, hardware resources, and more.

V. CONCLUSION

The systematic review using the PRISMA method has comprehensively synthesized and analyzed the literature on large-scale image indexing and retrieval. The results highlight current trends, methods, and challenges in this dynamic area of image processing research. We have seen a strong advance in deep learning-based approaches, notably convolutional neural networks, which have significantly improved the performance of image retrieval systems. However, challenges remain, such as generalization to more diverse datasets, robustness to variations in scale and view, and efficient management of large volumes of data. Promising avenues of research include the integration of semantic and contextual knowledge to improve the accuracy and relevance of search results.

Finally, while significant progress has been made in the field of large-scale image indexing and retrieval, this review underscores the importance of ongoing research and interdisciplinary collaborations to overcome existing challenges and drive further advancements. Highlighting the necessity of such collaborative efforts, this review provides a foundation for future work aimed at improving the accuracy, efficiency, and applicability of image retrieval systems, with a focus on practical applications and substantial progress in this constantly evolving field.

Semi-Supervised Clustering Algorithms Through Active Constraints

Abdulwahab Ali Almazroi, Walid Atwa
Department of Information Technology-College of Computing and Information Technology at Khulais,
University of Jeddah, Jeddah, Saudi Arabia

***Abstract*—Pairwise constraints improve clustering performance in constraint-based clustering issues, especially since they are applicable. However, randomly choosing these constraints may be adverse and minimize accuracy. To address the problem of random choosing pairwise constraints, an active learning method is used to identify the most informative constraints, which are then selected by the active learning technique. In this research, we replaced random selection with an active learning strategy. We provide a semi-supervised selective affinity propagation clustering approach with active constraints, which combines the affinity propagation (AP) clustering algorithm with prior information to improve semi-supervised clustering performance. Based on the neighborhood concept, we select the most informative constraints where neighborhoods include labelled examples of various clusters. The experimental results on eight real datasets demonstrate that the proposed method in this paper outperforms other baseline methods and that it can improve clustering performance significantly.**

***Keywords*—Semi-supervised; pairwise constraints; affinity propagation; active learning**

I. Introduction

In data mining, clustering is an unsupervised learning technique that divides a data collection into *k* clusters based on how similar or dissimilar data examples are within a cluster and outside of it. Clustering with restrictions, or semi-supervised clustering, has drawn a lot of attention from researchers in the past few years. By utilizing user-provided side information, semi-supervised clustering seeks to enhance clustering performance. Pairwise restrictions, or must-links (*ML*) and cannot-links (*CL*), are the most often utilized information in semi-supervised clustering. Instances x_i and x_j must be assigned to the same cluster according to the constraint $ML(x_i, x_j)$, but a $CL(x_i, x_j)$ specifies that they must be assigned to separate clusters [1, 2].

Constraints have been shown in several earlier research to improve clustering performance. However, incorrect constraint selection can also degrade the clustering performance [3-5]. Furthermore, getting pairwise constraints usually necessitates a user to examine the relevant data points by hand, which can be expensive and time-consuming. Most semi-supervised clustering techniques already in use choose all of their constraints at random. Therefore, these methods are unable to predict the impact of a particular constraint on the algorithm [6-8].

The affinity propagation (AP) method is a highly effective clustering method for data mining. Compared to standard clustering methods, the AP method is capable of clustering large-scale and multi-cluster datasets quickly. Furthermore, the AP method does not need to predetermine the initial centres of the cluster and cluster number, which allows it to avoid getting locked in the local optimal setting [15]. Thus, utilizing the AP technique is preferable since the clustering algorithm may provide higher-quality component clusters [9].

In this paper, we maximize the pairwise constraint selection for semi-supervised clustering by combining the affinity propagation (AP) clustering algorithm with prior information based on the neighborhood notion. A neighborhood is a collection of data items that must-link constraints have determined to belong to the same class. It is well known that distinct neighborhoods belong to different classes since they are connected by cannot-link constraints. Our goal is to choose the most educational point to incorporate into the neighborhoods. After a point is chosen, its neighborhood is ascertained by querying the chosen point against the list of neighborhoods. Utilizing the neighborhood ideas has the major benefit of allowing us to obtain constraints by utilizing the neighborhood knowledge.

On UCI datasets, extensive research has been done with the MPCK-means semi-supervised clustering technique. According to experimental results, MPCK-means performs better when subjected to AML and ACL restrictions than when subjected to random selection constraints.

The rest of the paper is structured as follows. A concise overview of relevant research on active learning techniques is given in Section II. We present our suggested active learning algorithm in Section III. Section IV presents the outcomes of the experiment. In Section V, we finally wrap up the paper and talk about future directions.

II. Related Work

Semi-supervised clustering algorithms are proposed in recent years [10]. These algorithms are an extension of known unsupervised clustering algorithms [11, 12]. The methods utilized constraints in adapted clustering procedure for learning similarity metrics. In recent years, various constraint-based methods were proposed for clustering, specifically in clustering algorithms like spectral clustering and *K*-means [11].

Basu et al. proposed a pairwise constrained clustering framework and a new method for selecting information pairwise constraints for enhance clustering performance [13]. These two methods, as indicated by the authors, can handle large and high dimensional datasets. The result shows an improvement in clustering accuracy with little supervision required.

Shental et al. proposed a framework for the composition of side information in the form of equivalence constraints into the model estimation procedure [14]. The authors further introduce EM procedure and generalized EM procedure that handles both positive constraints (for the former), and negative constraints (for the latter). The algorithm shows significant improvements. In another study by Bilenko et al., a new clustering algorithm was proposed that integrates two methods, which are the constraint-based method and distance-function learning methods for semi-supervised clustering [15]. Based on an experimental study, the result revealed that the proposed algorithm provides better clusters.

In a study by Wagstaff et al., a constrained k-means clustering algorithm was proposed with background knowledge [11]. The experiment was conducted with artificial constraints on various datasets, the result shows a significant improvement. Rangapuram and Hein proposed a clustering method that is based on tight relaxation of constraint normalized cut [12]. The proposed method guarantees the satisfy all constrained. The method further allows the optimization of the trade-off between the number of violated constraints and normalized cut. The result shows some improvements.

In the last decades, active learning has been studied for supervised classification problem. Xiong et al., introduced a method that incorporates a neighborhood concept. Hence, each neighborhood is composed of labeled examples of distinct clusters based on pairwise constraints [16]. An evaluation of benchmark datasets shows that the proposed method outperforms the existing state-of-the-art.

Fernandes et al. proposed four active learning strategies for an evolutionary constrained clustering algorithm coined FIECE-EM. The proposed strategies utilizes key information from multitudes of sources like partition, population, and so on [17]. An empirical evaluation result shows that the proposed strategies attain a better result in comparison to various state-of-the-art. Based on the knowledge that choosing a constraint is critical because choosing it improperly may result in low clustering precision, a new active query mechanism was proposed by Kumar et al. The proposed mechanism selects queries by utilizing min-max criterion. Hence, the authors specifically focused on constraints selection to enhance clustering performance. The experimental result indicates that the proposed outperforms the existing state-of-the-art [18].

In another study by Nguyen and Smeulders, an algorithm was developed to construct classifier in a group of cluster representatives and further propagates the conducted classification to other samples through a local noise model [19]. The developed algorithm initially selects the most active samples for the avoidance of repeatable samples labels. In the active learning process, the algorithm adjusts the clustering by utilizing coarse-to-fine strategy. This is purposely to balance between large clusters merit and data representation accuracy. The result demonstrates the performance of the proposed algorithm.

Another study by Vu et al. proposed an efficient algorithm for active seeds selection [20]. The proposed algorithm depends on min-max approach which permits the coverage of large dataset and the selection of useful user queries. The result shows that the proposed algorithm performs very well. A semi-supervised clustering algorithm with a new method for selecting information instance-level constraints was proposed to enhance clustering accuracy [21]. The proposed algorithm is coined Constrained DBSCAN. The algorithm is aimed at selecting informative document pairs to retrieve user feedback. Hence, the authors used two kinds of instance-level constraints, which are cannot-link and must-link. For the former, it means that document pairs must always be placed in distinct groups, while for the latter, the document pairs must be in the same cluster. The result shows that a good clustering performance was achieved.

Wang and Davidson proposed a spectral clustering algorithm with active learning and further investigates active learning [22]. The authors also allow for the utilization of cannot-link and must-link constraints in the proposed algorithm. However, in distinction, their constraints are identified incrementally through oracle querying. Hence, the outline advantages of their proposed algorithm are the process of constraints querying that reduces error, and the combination of both soft and hard constraints. The results based on an experiment on existing benchmark show that the proposed algorithm outperforms existing baseline approaches [23].

Although many studies have investigated active constraints, there is limited research on leveraging existing information to identify the most informative constraints in ensemble clustering or on integrating active constraints with selective ensemble clustering results [24-26]. To address this gap, this paper introduces a semi-supervised selective affinity propagation clustering approach that incorporates active constraints, aiming to enhance the performance of semi-supervised clustering.

III. Active Affinity Propagation

Affinity propagation (AP) [9] is a clustering technique that groups data points into clusters according to their similarities. Messages are sent between data points iteratively via affinity propagation. These messages show how each data point is ideally suited to serve as a cluster center for additional data points. High affinity data points eventually become cluster centers, to which other points are allocated. There are two kinds of messages exchanged between data items the responsibility $r(i, k)$ and the availability massage $a(i, k)$, that reflects the accumulated evidence for how well-suited item x_k is to serve as the exemplar for item x_i, and reflects the accumulated evidence for how appropriate it would be for item x_i to choose item x_k as its exemplar.

$$r(i,k) = S(x_i, x_k) - \max_{j \neq k}\{S(x_i, x_j) + a(i,j)\} \quad (1)$$

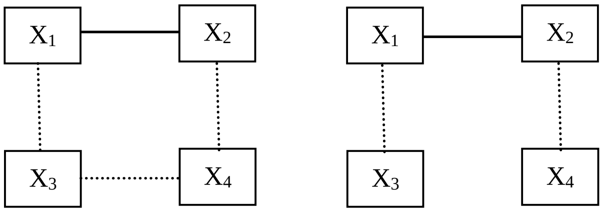
$$a(i,k) = \begin{cases} \sum_{i' \neq k} \max[0, r(i',k)] & i = k \\ \min\left[0, r(k,k) + \sum_{i' \notin \{i,k\}} \max[0, r(i',k)]\right] & i \neq k \end{cases} \quad (2)$$

where, $S(x_i, x_j)$ denote the similarity between the data items x_i and x_j , with $i \neq j$.

Affinity propagation is an unsupervised clustering method. Semi-supervised clustering algorithms make use of the partially labeled data by using a limited number of constraints. The issue of selecting pairwise queries wisely to provide a precise clustering assignment is covered in this section. Using the neighborhood concept—where neighborhoods include labeled examples of various clusters depending on pairwise constraints—we choose the active constraints. By picking the most illuminating examples and investigating their connections to the communities, we broaden the neighborhoods. We summarize our strategy in Algorithm 1.

In order to create C clusters from a set of data points $X=\{x_1,..., x_n\}$, we can find a set of m neighborhoods $N = \{N_1, \cdot \cdot \cdot ,N_m\}$, where $m \leq C$. Imagine the data represented as a graph, with edges denoting must-link restrictions and vertices representing data instances. The neighborhoods are just the connected parts of the graph with cannot-link constraints between them. They are represented by the notation $N_i \subset X$, $i \in \{1, \cdot \cdot \cdot , m\}$.

Two examples that clarify how the neighborhoods can be formed from a set of pairwise constraints are shown in Fig. 1. Data instances are represented by nodes, must-link constraints are shown by solid lines, and cannot-link constraints are shown by dashed lines. Take note that there must be a cannot-link constraint between every neighborhood and every other neighborhood. Therefore, Fig. 1(b) only has two known neighborhoods, which might be either $\{x_1, x_2\}$, $\{x_3\}$ or $\{x_1, x_2\}$, $\{x_4\}$, but Fig. 1(a) has three neighborhoods: $\{x_1, x_2\}$, $\{x_3\}$, and $\{x_4\}$.



(a) (b)

Fig. 1. Two examples of neighborhoods based on pairwise constraints.

To determine the most informative points, let's consider a labeled dataset L consisting of pairs $\{(x_1, y_1), (x_2, y_2), . . . , (x_l, y_l)\}$, where y_l represents the cluster label of the data item x_l, along with an unlabeled set U containing data items $x_{l+1}, x_{l+2}, . . . , x_{l+u}$. Let E denote the set of exemplars in the dataset. Given a labeled sample x_i $(1 \leq i \leq l)$ and an unlabeled data item x_j $(l + 1 \leq j \leq u)$, we can identify two scenarios where the labeled sample might be associated with the unlabeled data item following execution of the AP algorithm:

1) If the unlabeled data item x_j adopts the labeled sample x_i as its cluster exemplar, and the message $a(x_i, x_i) + r(x_i, x_i)$ is positive (indicating $x_i \in E$), and x_i is the $\max\{a(x_j, x_k) + r(x_j, x_k)\}$ for each $k = \{1, 2, . . .,n\}$.

2) If the labeled sample x_i selects the unlabeled data item x_j as its cluster exemplar, and the message $a(x_i, x_i) + r(x_i, x_i)$ is negative (indicating $x_i \notin E$), and x_j is the $\max\{a(x_i, x_k) + r(x_i, x_k)\}$ for each $k = \{1, 2, . . .,n\}$.

If either of these conditions is met, the unlabeled data item x_j is deemed most similar to the labeled sample x_i. Consequently, x_j is chosen and assigned the label of x_i, effectively selecting the most similar unlabeled data item x_j as follows:

$$x^* = \begin{cases} x_j & if\ x_i = \max_{1\leq k\leq n}\{a(x_j,x_k)+ r(x_j,x_k)\}\ and\ x_i \in E \\ & if\ x_j = \max_{1\leq k\leq n}\{a(x_i,x_k)+ r(x_i,x_k)\}\ and\ x_i \notin E \end{cases} \tag{3}$$

where, x^* is the selection of the unlabeled point from the set U follows the operational principles of the AP algorithm

Once the most informative point is chosen, it is queried against the existing neighborhoods to ascertain its membership. To optimize query efficiency, the initial query is directed towards the neighborhood with the highest likelihood of containing x^*. This approach minimizes the overall number of queries required. The determination of a point x^* likelihood of belonging to a specific neighborhood N_i is based solely on its interactions with labeled points. This likelihood is estimated by averaging the similarities between x and the instances within N_i, as expressed by the formula:

$$p(x \in N_i) = \frac{\frac{1}{|N_i|} \sum_{x_j \in N_i} S(x,x_j)}{\sum_{p=1}^{l} \frac{1}{|N_p|} \sum_{x_j \in N_p} S(x,x_j)} \tag{4}$$

Here $S(x, x_j)$ represents the degree of similarity between point x and point x_j, $|N_i|$ denotes the amount of points in the neighborhood N_i, and l signifies the overall amount of neighborhoods.

Line 4 traverses the neighborhoods in decreasing order based on $p(x^* \in Ni)$, $i \in \{1, \cdot \cdot \cdot, l\}$, or the likelihood of x^* belonging to each neighborhood. We can find the neighborhood of x^* with the fewest number of searches by using this query order. With just one query, we can end if a must-link is returned. If not, the following question should be directed towards the neighborhood with the next highest likelihood of having x^*. A new neighborhood will be generated using x^* (lines 4–15) once this procedure is repeated until a must-link constraint is returned or we have a cannot-link constraint against all neighborhoods.

Algorithm 1. Affinity Propagation with Active Constraints

```
Start with a single neighborhood $N_1$ containing a randomly chosen instance $x$ and set the number of queries $q$ to 0.
While $q<Q$
    Select the most informative point $x^*$ to query using Equation 3;
    For $N_i \in N$ ordered by decreasing probability of $x^*$ belonging to $Ni$;
        Query $x^*$ against any data point $x_i$ belonging to $N_i$;
        $q$++;
        Update the set of constraints according to the results of the queries;
        If $ML(x^*, x_i)$ exist
            $N_i = N_i \cup x^*$
            Break;
        else
            make a new neighborhood containing the point $x^*$;
        End if
End while
```

IV. Experimental Results

This section presents the datasets, evaluation metrics, Constraint selection strategies, and outcomes of the study. The effectiveness of the proposed method is explained through comparisons with several state-of-the-art algorithms across different scenarios to highlight its superiority.

A. Datasets

In this section, the datasets utilized are presented. For our experiments, real datasets were utilized. Hence, these datasets are labelled with instances, attributes, and numbers of clusters as described in Table I.

TABLE I. The Data Sets Used in the Experiments

Dataset	# Instances	#Attributes	#Clusters
Glass	214	10	6
Ecoli	336	8	8
Ionosphere	351	34	2
Liver	345	6	2
Breast	683	9	2
Yeast	1484	8	10
Segment	2310	19	7
Magic	19020	10	2

B. Evaluation Metrics

We used pairwise F-measure and Normalized Mutual Information (NMI) as clustering validation metrics to evaluate the effectiveness of the approaches. NMI evaluation metric takes into consideration the clustering assignment and class label as random variable. Hence, the metric measures the common information between dual random variables. Therefore, this information will be normalized to zero-to-one range by the metric. *NMI* is computed as follows:

$$NMI = \frac{I(X;Y)}{\big(H(X)+H(Y)\big)/2}$$

In this context, $H(Y)$ represents Shannon entropy of Y, $H(Y|X)$ denotes conditional entropy of Y given X, and $I(X;Y)$ signifies the mutual information shared between the variables X and Y.

Pairwise F-measure was assessed in order to gauge clustering performance even more. Recall and precision were the sources of this statistic [16]. By comparing the predicted pairwise relationship between instance pairs to the ground truth class labels relationship comparison, the measure assesses one's predictive ability. Therefore, the harmonic mean of precision and recall is the common definition of F-measure. Thus, after obtaining a clustering result, we calculate the F-measure in the manner mentioned below:

$$Precision = \frac{n_c}{n_s}$$

$$Recall = \frac{n_c}{n_f}$$

$$F-measure = \frac{2 \times Precision \times Recall}{Precision + Recall}$$

C. Constraint Selection Strategies

In all experiments, the following strategies are considered for selecting constraints:

- Random: This strategy entails a completely arbitrary selection of constraints. It involves generating a set of Must-Link (*ML*) and Cannot-Link (*CL*) constraints by comparing the labels of randomly chosen objects.
- Min-Max: This method follows a neighborhood-based approach and operates in two phases [18]. First, it creates a set of disjoint neighborhoods, Then, it incrementally expands these neighborhoods using a distance-based criterion.
- ASC: this method utilizing the neighborhood graph and formulating queries based on the constraint utility function. ASC relies on a pair of parameters, namely the threshold (θ) and the number of nearest neighbors (k). In accordance with their method, these parameters are set to $\lfloor (k/2) + 1 \rfloor$ and 6 respectively [8].
- NPU: This method is grounded in the uncertainty-based principle, employing a neighborhood-based strategy [16].

D. Performance Analysis Based on NMI

For the performance evaluation in this section, four algorithms were utilized for cross-comparison with our proposed algorithm. These algorithms are Random, min-max, ASC, and NPU. All these algorithms are active learning algorithms. Hence, the four datasets which are Glass, Ecoli, Segment, and Magic are used for the experiment. From Fig. 2, with 150 constraints on Glass dataset, the proposed algorithm performed better with 0.8 NMI, followed by ASC, NPU, Min-Max, and Random, respectively. The result is quit the same on Ecoli, Segment, and Magic datasets. One of the things worth noting is that the proposed algorithm is consistently effective. Meaning, it persistently outperformed all the algorithms compared with in all experiments. This conclusion is driven based on our general observation of Fig. 2.

In general, with respect to NMI evaluation, the proposed algorithm is more effective by large. It is important to also note that Random is the least effective algorithm. This is particularly due to the random selection of constraints by the algorithm in contrast to the other algorithms.

E. Performance Analysis Based on F-measure

The result in this section is given based on our evaluation using F-measure. Hence, the result is given of the comparison with other methods with respect to the datasets in Fig. 3. Hence, from Fig. 3, with focus on Glass datasets, the reader can see that the proposed algorithm surpasses the compared algorithms on all constraints. With respect to Ecoli dataset, our proposed algorithm also outperformed the compared algorithms with great margin. We observed that the proposed algorithm is does not have a good performance in large dataset like Magic with small number of constraints. However, the proposed algorithm achieves better performance result when we have a large number of constraints.

However, on Segment dataset, our proposed algorithm was outperformed by NPU algorithm 25, 125, and 150 constraints. Hence, looking at the result carefully, on 50, 75, and 100 constraints, the proposed algorithm outperformed all the compared algorithms. Furthermore, on Magic dataset, NPU and ASC outperformed the proposed algorithm on 25 and 50 constraints. However, from 75 constraints and above, the proposed algorithm outperformed all the compared algorithms as presented in Fig. 3.

V. Conclusion and Future Work

In this study, we introduced an approach to improve the semi-supervised clustering algorithms that select the active pairwise constrained with affinity propagation clustering algorithm. Initially, the most informative points are generated using the AP algorithm, and subsequently, only the points are chosen to compose the neighborhoods and generate the final clustering outcomes. Additionally, in acquiring pairwise constraints, we replaced random selection with an active learning strategy, resulting in more representative constraints. Our algorithm was applied to eight datasets from UCI datasets, with the performance evaluated using NMI and F-measure metrics. The experimental findings demonstrate the superiority of our proposed method over other clustering algorithms. In future work, we would like to work on the problem of incremental growing constraint set for streaming data. To address this problem, we are interested to apply an incremental semi-supervised clustering method.

***Abstract*—Diabetic retinopathy (DR) is a leading cause of blindness worldwide, particularly among working-age individuals. With the increasing prevalence of diabetes, there is an urgent need to address the public health burden posed by DR. This research paper aims to develop a clinical decision support approach that integrates automated DR detection and classifying the grade of severity in DR. A three-stage deep learning model for DR detection is proposed. First, incorporating preprocessing, image enhancement, and augmenting the DR images using three different color space transformations and a filtering technique: BGR to RGB, RGR to LAB, and Gaussian Blur Filter. Secondly, feature extraction and representation learning are based on CNN with various layers. Thirdly, classification is based on SVM. The implementation and evaluation of the proposed model on a dataset containing five stages of DR are essential steps towards validating its performance and assessing its potential for clinical applications. Through thorough dataset preprocessing, model training, performance analysis, comparison with baseline methods, and generalization tests, we can gain insights into the model's classification and staging capabilities. This research makes a significant contribution to the field of DR severity detection, ultimately leading to enhanced diagnostic capabilities. The developed models demonstrated an accuracy rate of 94.72%, indicating their efficacy in accurately assessing the severity of the condition.**

Keywords*—Deep learning; diabetic retinopathy (DR); Gaussian Blur Filter; support vector machine (SVM); color space; performance evaluations

I. Introduction

Diabetic Retinopathy (DR) is an ocular disorder that can lead to visual impairment and complete blindness in individuals with diabetes. This condition specifically impacts the blood vessels located in the retina, which is the light-sensitive tissue situated at the rear of the eye. Early intervention in the treatment of DR can significantly alleviate the burden of vision loss attributed to this condition, so making it a crucial area of study, particularly in light of the creation of new diagnostic instruments [1].

Several studies aimed at detecting Parkinson's disease early were presented. Yasashvini R. et al. [2] presented DR Classification using convolution neural network (CNN), hybrid CNN with DenseNet 2.1, and hybrid CNN with ResNet are utilized to extract the features of the eye. The author’s model used 3662 train images and 1928 test images after applying the image augmentation technique, divided into 5-classes. Sayan Das and Sanjoy Kumar Saha [3] introduced DR detection model using CNN based on genetic algorithm for extract features and support vector machine (SVM) for classification. The model was tested on a dataset that contains 1200 retinal fundus images divided into 4- classes. Raja Chandrasekaran and Balaji Loganathan [4] presented an approach that combines deep learning techniques with wavelet analysis with Hyper-analyticWavelet phase activations. The reported results in DR classification offer better generalization ability and improved learning of feature maps from wavelet sub-bands.

Thippa Reddy Gadekallu et al. [5] used DNN based on Principal Component Analysis (PCA) for dimensonality reduction used firefly optimization algorithm. The DenseNet architecture has demonstrated exceptional performance in the task of image feature extraction, resulting in optimal accuracy for image classification tasks [6]. Mohamed M. Farag et al. [7], presented a severity detection model based on DenseNet169's encoder that was used for feature extraction then followed by Convolutional Block Attention Module (CBAM) for feature refinement. The author model used 3296 training and 366 testing images, divided into 5-classes. Gergo Bogacsovics et al. [8], presented a model based on hand-crafted features sequentially AlexNet, MobileNetv3, and Resnet-50, respectively, in automated fundus image classification. The authors applied their model to three datasets: the IDRiD, Kaggle DR, and Messidor datasets. Fernando C. Monteiro [9] proposed blended Deep Learing (DL) model by training several DL models (VGG16, VGG19, ResNet50, ResNet101, Inception-V3, Incep.ResNet, Xception, DenseNet201, DarkNet53, and EfficientNetB0) using 5-f) using validation that mean 50 (10 architectures x 5 folds).

Zongyun Gu. et al. [10] proposed a classification model of fundus images for DR stages. The author’s model used a transformer encoder for feature extraction, and multiple fractional tensors were generated via different 1 × 1 convolutions that were used for grading prediction. The author’s model was applied to DDR dataset consisting of 13,673 fundus images with 6835 training, 2733 validation, and 4105 testing, divided into 6 classes. Ghadah Alwakid et al. [11] presented two RD classification models, one without and one with image augmentation. Auther models used DenseNet-121 that were applied on APTOS and DDR datasets, divided into 5-classes. Isoon Kanjanasurat et al. [12] introduced DR fundus grading model. In a single training session, the author's model employed 27 pre-trained CNNs and divided the DR Dataset into two groups (no DR and DR). The author’s used (APTOS2019) dataset consists of 3662 color retinal images, divided into 5-classes.

*Corresponding Author

Zhan Wu et al. [13] proposed CF-DRNet model consists of two stage, first of them is Coarse Network performs that was used to classify data into two-class including No DR and DR. Second of them is Fine network is proposed to classify four-stage DR severity grades of the grade DR. Rajaa, and L. Balajib [14] presented diabetic detection in retinal images, which used adaptive histogram equalization (AHE) for preprocessing followed by CNN and fuzzy c-means clustering (FCM), respectively. The author's model was applied on a dataset containing 76 retinal images which includes normal and abnormal retinal images. Angel Ayala et al. [15], introduced a convolutional neural network model to process a fundus oculi image to recognize the eyeball structure and determine the presence of DR.

Our contribution to this research is: 1) Utilizing efficient image preprocessing including BGR to RGB color space conversion, RGB to LAB color space transformation, and Gaussian blur filtering to preprocess and enhance the (DR) images, 2) designing a CNN-based architecture that can automatically learn and extract relevant features from the preprocessed DR images, capturing the intricate patterns and anomalies associated with different stages of the disease, 3) classifying and staging diabetic retinopathy using SVM and DNN models in accordance with the CNN-extracted features, 4) comparing and investigating the optimal model according to the evaluation metrics, and compare the results with datasets that have higher accuracy, as the dataset used in this research has a lower accuracy.

The subsequent sections of this paper will be structured as follows: Section II briefly introduces the preprocessing operation and CCN layers which were used in the proposed model. Section III explains the research methodology (dataset description and architecture of the proposed model), the experimental environment, and the procedure of the proposed model are illustrated in Section IV. In Section V. Comparative study and discussion of results. Sections VI and VII serve as the concluding section of the paper, summarizing the key findings and insights obtained throughout the research. Additionally, it outlines the scope and potential avenues for future activities and investigations in the field.

II. Preliminaries

This section introduces three image processing techniques utilized for dataset augmentation, along with an overview of different types of CNN layers.

A. *Preprocessing Operation*

The input image undergoes various preprocessing procedures before the feature extraction stage. Image processing plays a crucial role in enhancing the quality and diversity of the images, leading to improved performance of machine learning models. In this subsection three preprocessing techniques are discussed.

- BGR Color Space to RGB: The default color space used in many image processing applications, is the BGR color space [16]. However, most computer vision tasks and deep learning models utilize the RGB color space. Therefore, converting images from BGR to RGB is a fundamental step in preprocessing. By performing this conversion, we ensure compatibility with various algorithms and frameworks, facilitating seamless integration into deep learning architectures. Additionally, RGB images often exhibit better visual interpretability and can capture more accurate color information, enhancing the overall quality of the dataset.
- RGR Color Space to the LAB: Another preprocessing operation involves converting images from the RGB color space to the LAB color space, the LAB color space separates the luminance (L) component from the color information [16]. This separation provides a perceptually uniform color representation, enabling better discrimination of color variations. By incorporating LAB images into the dataset additional diversity is introduced, as the model can learn to extract meaningful features from different color channels independently.
- Gaussian Blur Filter (GBF): GBF is a widely used technique in image processing [17]. It applies a convolution operation using a Gaussian kernel, resulting in a blurring effect on the image. This filter introduces controlled levels of blurriness to the images, simulating different degrees of focus and sharpness. By incorporating blurred images into the dataset, the model can learn to handle and generalize better to such instances, improving its overall performance.

B. *CNN and Layer Types*

Convolutional Neural Networks (CNNs) create a network architecture in a more reasonable way by utilizing the structure of the input image. Three dimensions; width, height, and depth—are used to organize the layers of a CNN in a 3D volume; depth is the third dimension of the volume, which can be the number of channels in an image or the number of filters in a layer [18].

CNNs are composed of various layers, each serving a specific purpose in the network's architecture. Convolutional Layer (CONV) is the fundamental building block of a CNN. It performs a mathematical operation known as convolution, which involves applying a set of filters to the input data. These filters help to extract relevant features from the input image, such as edges, textures, and shapes. The output of this layer is a feature map, which represents the learned features. Pooling layers are used to reduce the spatial dimensions of the feature maps generated by previous layers. They achieve this by downsampling the feature maps, effectively reducing the amount of information to be processed in subsequent layers. Activation layers help the network to learn complex patterns and make predictions such as Rectified Linear Unit (ReLU) [19].

Fully connected layers, also known as dense layers are responsible for making predictions based on the learned features. Dropout layers are used to prevent overfitting in CNNs. Batch normalization layers are used to improve the training speed and stability of CNNs [20]. The softmax layer is often used as the final layer in CNNs for classification tasks. Fig.1 shows the fundamental architecture of CNN.

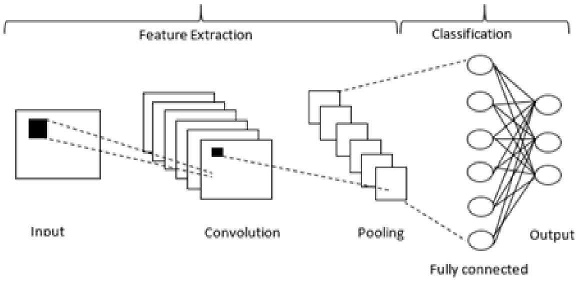

Fig. 1. The fundamental architecture of CNN.

The template is used to format your paper and style the text. All margins, column widths, line spaces, and text fonts are prescribed; please do not alter them. You may note peculiarities. For example, the head margin in this template measures proportionately more than is customary. This measurement and others are deliberate, using specifications that anticipate your paper as one part of the entire proceedings, and not as an independent document. Please do not revise any of the current designations.

III. Research Methodology

A. Dataset Description

All the experimental work conducted in this research utilized the DR Dataset as the primary test bed [21]. It encompasses five distinct classes, namely Healthy, Mild DR, Moderate DR, Proliferative DR, and Severe DR. The distribution of images across these classes is presented in Table I. The dataset provides a comprehensive representation of different stages of DR, ranging from healthy retinas to severe cases. The availability of images across various classes allows for a thorough analysis and evaluation of the proposed model's performance in detecting and classifying DR [22].

TABLE I. Distribution of Images in DR Dataset

Class	# Original Images
Healthy	1000
Mild DR	370
Moderate DR	900
Proliferative DR	290
Severe DR	190

B. Architecture of the Proposed Model

In this section, we present the architecture of the proposed model for classifying the severity of DR. The model's architecture plays a critical role in its ability to extract relevant features from retinal images and make accurate predictions regarding the severity levels of DR. As shown in Fig. 2. a general overview of the proposed model for DR classification is provided.

1) Preprocessing operation and dataset augmentation: The proposed methodology of image processing is based on enhancing the contrast of images, it consists of two stages aimed at increasing the number of images and introducing diversity into the dataset.

The first stage focuses on augmenting the DR images by converting them from the default BGR color space to RGB. This conversion effectively doubles the number of images available for analysis or training.

In the second stage, the original images are transformed from the RGB color space to the LAB color space, generating a new set of images. By introducing LAB images into the dataset, a broader range of variations is incorporated, enhancing the diversity of the data. This augmentation technique benefits the model by enabling it to capture subtle color variations more effectively, thus improving its performance in accurately detecting and classifying different stages of DR. To further enhance the diversity of the dataset, a Gaussian Blur filter is applied to the augmented images. Table II shows the number of images in each class after augmentation.

TABLE II. Distribution of Augmented Images in each Class

Class	# original images+ RGB	# original images+ RGB +LAB
Healthy	2000	3000
Mild DR	740	1110
Moderate DR	1800	2700
Proliferative DR	580	870
Severe DR	380	570

2) Proposed learning model: To prepare the dataset, the enhanced input image dimensions are standardized to 224 x 224 pixels, and the corresponding category is assigned to each image. Table III presents the proposed model for classifying the severity of DR adopts a CNN-based architecture. The image classification stage consists of six convolutional layers, activation functions, pooling layers, and fully connected layers, the model effectively extracts and learns meaningful features from retinal images. This architecture enables the model to make accurate predictions regarding the severity levels of DR, contributing to improved diagnosis and management of this condition. The architecture, illustrated in Table III consists of CNN layers that play a crucial role in extracting relevant features from retinal images. The table also provides names for the operations performed in each layer, providing a clear understanding of the network's structure. The model is compiled using the Adam optimizer with a learning rate of 0.001 and the categorical cross-entropy loss function is utilized to measure the difference between the predicted class probabilities and the true labels. It undergoes 100 epochs of training, with a batch size of 32.

TABLE III. CNN MODEL ARCHITECTURE

Layer No.	Operation Name	Name	Setting
1	Convolutional	conv2d	Filter 32, kernel size (3x3), activation(ReLU)
1	Convolutional	conv2d	Filter 32, kernel size (3x3), activation(ReLU)
2	Batch Normalization	batch_normalization	Maintains the mean output close to 0 and the output standard deviation close to 1.
3	Convolutional	conv2d_1	Filter 32, kernel size (3x3), activation(ReLU)
4	Batch Normalization	batch_normalization_1	Maintains the mean output close to 0 and the output standard deviation close to 1.
5	MaxPooling2D	max_pooling2d	pool_size=(2, 2) to reduce the spatial dimensions of the feature maps.
6	Dropout	dropout	Rate=0.25
7	Convolutional	conv2d_2	Filter 64, kernel size (3x3), activation(ReLU)
8	Batch Normalization	batch_normalization_2	Maintains the mean output close to 0 and the output standard deviation close to 1.
9	Convolutional	conv2d_3	Filter 64, kernel size (3x3), activation(ReLU)
10	Batch Normalization	batch_normalization_3	Maintains the mean output close to 0 and the output standard deviation close to 1.
11	MaxPooling2D	max_pooling2d_1	pool_size=(2, 2)
12	Dropout	Dropout_1	Rate=0.25
13	Convolutional	conv2d_4	Filter 128, kernel size (3x3), activation(ReLU)
14	Batch Normalization	batch_normalization_4	Maintains the mean output close to 0 and the output standard deviation close to 1.
15	Convolutional	conv2d_5	Filter 128, kernel size (3x3), activation(ReLU)
16	Batch Normalization	batch_normalization_5	Maintains the mean output close to 0 and the output standard deviation close to 1.
17	MaxPooling2D	max_pooling2d_2	pool_size=(2, 2)
18	Dropout	Dropout_2	Rate=0.25
19	Flatten	flatten	adds an extra channel dimension and output shape is (batch, 1).
20	Dense	dense	Units=256, activation(ReLU)
21	Batch Normalization	batch_normalization_6	Maintains the mean output close to 0 and the output standard deviation close to 1.
22	Dropout	dropout_3	Rate=0.5
23	Dense	dense_1	Units=5, activation(Softmax)

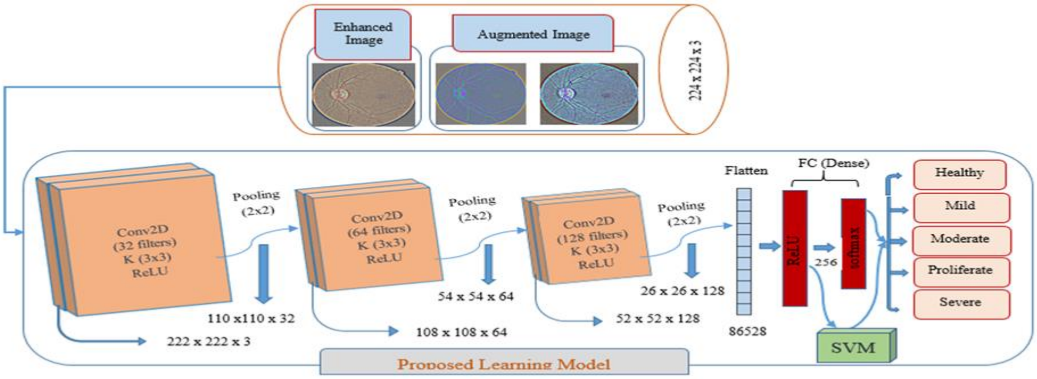

Fig. 2. Architecture of proposed learning model.

IV. EXPERIMENTAL RESULTS

The experimental setup utilized an Intel(R) Core i7 processor running at 2 GHz, with 8GB of RAM. The system operated on a 64-bit architecture. The dataset is split into training and testing sets, with a test size of 20% and the validation set was assigned 20% of the training set. This ensures a separate and unbiased dataset for evaluating the model's performance.

A. Deep Learning Model for Classifying Severity of DR Dataset

In this section, we present the evaluation results of the proposed model for classifying the severity of DR using Softmax and SVM classifiers. The original DR dataset as shown in Table I, comprising a collection of retinal images, is utilized for this evaluation. The objective is to assess the performance of the proposed model when employing these two commonly used classifiers in the field of deep learning. Table IV presents the distribution of samples used for training, validation, and testing in the experimental setup. Additionally, we provide insights into the performance of the CNN model by analyzing the classification accuracy and loss for the training and validation images across different numbers of epochs as shows in Fig. 3 and 4.

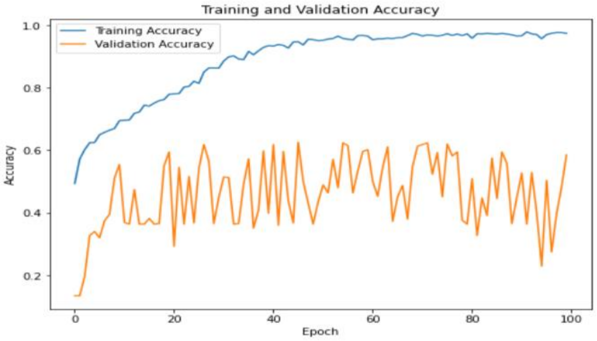

Fig. 3. Classification accuracy for CNN model on an orginal DR dataset with different no. of epochs.

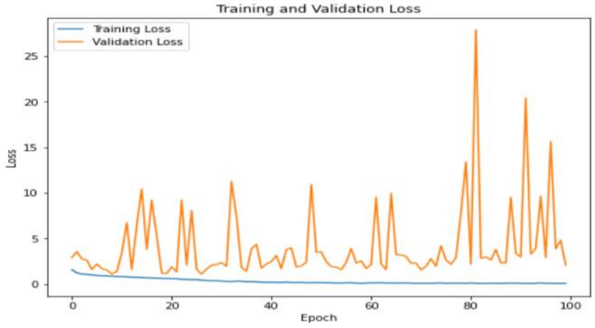

Fig. 4. Loss for CNN model on an orginal DR dataset with different no. of epochs.

TABLE IV. THE DISTRIBUTION OF SAMPLES

Class Name	Training	Validation	Testing
Healthy	640	160	200
Mild DR	237	59	74
Moderate DR	576	144	180
Proliferative DR	186	46	58
Severe DR	121	31	38

Table V and VI presents the performance measures obtained by applying the Softmax and SVM classification methods on the extracted features from the original DR test images using a CNN model.

TABLE V. THE PERFORMANCE MEASURES OBTAINED BY APPLYING A CNN MODEL ON THE ORIGINAL DR DATASET

Class Name	Accuracy %	Precision%	Recall%	F1 Score%
Healthy	90.55	91	82	86
Mild DR	84	41	43	42
Moderate DR	70.73	55	59	57
Proliferative DR	80.91	16	19	17
Severe DR	90.91	27	18	38

TABLE VI. THE PERFORMANCE MEASURES OBTAINED BY APPLYING A CNN MODEL AND SVM CLASSIFIER ON THE ORIGINAL DR DATASET

Class Name	Accuracy %	Precision %	Recall %	F1 Score %
Healthy	94	90	94	92
Mild DR	85.27	44	34	38
Moderate DR	72.18	57	61	59
Proliferative DR	83.82	22	21	21
Severe DR	88.73	18	18	18

B. Improving DL Model for Classifying Severity of DR based on Enhancement Technique

In this section, we employed the DR dataset as the test bed after applying enhancement preprocessing operations. We applied a contrast enhancement technique by multiplying the pixel intensities by a factor of 1.5, thereby effectively increasing the image's contrast. The distribution of samples after applying the enactment technique used for training, validation, and testing in the experimental setup as in Table IV. Fig. 5 and 6 illustrate respectively the classification accuracy and loss of the CNN model for the training and validation images across different numbers of epochs. It provides insights into how the accuracy improves or stabilizes as the training progresses. Table VII and VIII present the performance measures obtained by applying the Softmax and SVM classification methods on the extracted features from the DR test images using a CNN model based on enhancement technique.

TABLE VII. THE PERFORMANCE MEASURES OBTAINED BY APPLYING A CNN MODEL ON THE DR DATASET BASED ON ENHANCEMENT TECHNIQUE

Class Name	Accuracy %	Precision %	Recall %	F1 Score %
Healthy	87.09	74	98	85
Mild DR	87.64	60	24	35

C. Improving Feature Extraction using DL Model based on Augmented BGR2RGB

In this paper, we investigate the impact of using an augmented BGR2RGB color space on the feature extraction capabilities of deep learning models. BGR2RGB color space conversion refers to converting an image from the BGR (Blue, Green, Red) color space commonly used in computer vision applications to the RGB (Red, Green, Blue) color space, often used in other domains. Table IX presents the distribution of samples used for training, validation, and testing in the experimental setup after an augmented BGR2RGB. Fig. 7 is the plot visually demonstrates the performance of the model as the number of epochs increases. It shows how well the model learns from the training data and its ability to generalize to unseen validation data. Fig. 8 demonstrates the reduction in loss as the model optimizes its parameters during training. The validation loss, demonstrates how the loss changes on unseen validation data as the model undergoes training.

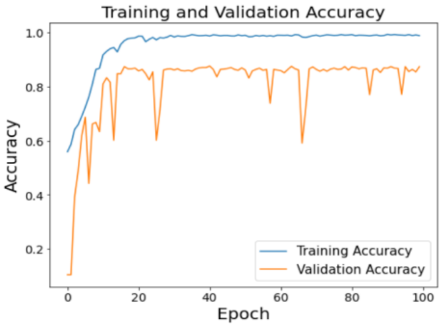

Fig. 7. Classification accuracy for CNN model based on augmented BGR2RGB with different no. of epochs.

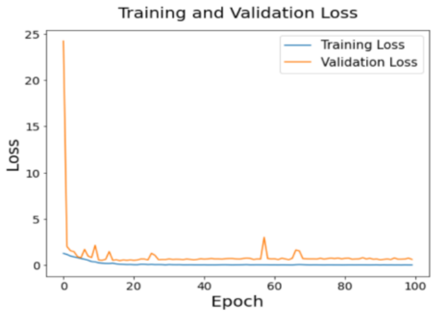

Fig. 8. Loss for CNN model based on augmented BGR2RGB with different no. of epochs.

TABLE IX. THE DISTRIBUTION OF SAMPLES USING AN AUGMENTED BGR2RGB

Class Name	Training	Validation	Testing
Healthy	1280	320	400
Mild DR	474	118	148
Moderate DR	1152	288	360
Proliferative DR	273	92	116
Severe DR	242	62	76

Healthy	97.27	94	99	96
Mild DR	94.18	82	73	77
Moderate DR	89.09	81	87	84
Proliferative DR	94.36	76	67	72
Severe DR	96.55	84	62	71

D. Improving Feature Extraction using DL Models based on Augmented BGR2RGB and RGB2LAB Color Space Conversions

We investigate the efficacy of improving feature extraction using DL models based on augmented BGR2RGB and RGB2LAB color space conversions. RGB2LAB conversion converts images from the RGB color space to the LAB color space, which separates color information from brightness. We hypothesize that leveraging these augmented color space conversions can enhance the models' ability to capture meaningful patterns and improve generalization performance. Table XI. the distribution of samples used for training, validation, and testing in our experimental setup after applying both augmented BGR2RGB and RGB2LAB color space conversions. Fig. 9 and 10 would present the classification accuracy and loss for the CNN model based on augmented BGR2RGB and RGB2LAB color space conversions during the training and validation stages.

TABLE XI. THE DISTRIBUTION OF SAMPLES USING AN AUGMENTED BGR2RGB AND RGB2LAB

Class Name	Training	Validation	Testing
Healthy	1920	480	600
Mild DR	711	177	222
Moderate DR	1728	432	540
Proliferative DR	558	138	174
Severe DR	363	93	114

Table XII and Table X display the performance measures obtained by applying the Softmax and SVM classification methods on the extracted features after utilizing an augmented BGR2RGB color space conversion on the DR test images using a CNN model. The performance measures include accuracy, precision, recall, and F1-score.

TABLE XII. THE PERFORMANCE MEASURES OBTAINED BY APPLYING A CNN MODEL ON THE DR DATASET AFTER UTILIZING AN AUGMENTED BGR2RGB

Class Name	Accuracy %	Precision%	Recall %	F1 Score %
Healthy	96.73	93	99	96
Mild DR	94.36	86	69	77
Moderate DR	89.09	80	89	84
Proliferative DR	94.55	79	66	72
Severe DR	96.36	81	62	70

In Tables XIII and XIV, we present the performance measures obtained by applying the Softmax and SVM classification methods on the extracted features, following the utilization of an augmented BGR2RGB and RGB2LAB color space conversion on the DR test images using a CNN model.

TABLE XIII. THE PERFORMANCE MEASURES OBTAINED BY APPLYING A CNN MODEL ON THE DR DATASET AFTER UTILIZING AN AUGMENTED BGR2RGB AND RGB2LAB

Class Name	Accuracy (%)	Precision (%)	Recall (%)	F1 Score %
Healthy	98.79	97	97	98
Mild DR	97.94	92	92	92
Moderate DR	95.33	91	95	93
Proliferative DR	96.73	89	78	83
Severe DR	98.12	94	78	85

TABLE XIV. THE PERFORMANCE MEASURES OBTAINED BY APPLYING A CNN MODEL AND SVM CLASSIFIER ON THE DR DATASET AFTER UTILIZING AN AUGMENTED BGR2RGB AND RGB2LAB

Class Name	Accuracy (%)	Precision (%)	Recall (%)	F1 Score %
Healthy	99.45	99	99	99
Mild DR	98.12	93	93	93
Moderate DR	96.42	94	95	95
Proliferative DR	97.33	88	87	87
Severe DR	98.12	90	82	86

V. COMPARATIVE STUDY AND DISCUSSION OF RESULTS

To gain deeper insights into the effectiveness of the proposed model, a comparative analysis is conducted by evaluating different architectures commonly adopted for DR detection and classification. Each architecture is trained, validation and tested using the same dataset and evaluation metrics as the proposed model. Table XV and XVI the training and testing overall accuracy of the CNN and the proposed model using original, enhanced, an augmented BGR2RGB and an augmented BGR2RGB +RGB2LAB datasets. These tables allow for a comparative analysis of the models' performance, providing insights into the effectiveness of the proposed model and the impact of preprocessing stage on the overall accuracy for DR detection and classification. The proposed model using SoftMax and SVM classifiers achieved an overall accuracy of approximately 93.45% and 94.72% respectively for testing and 96.6% and 99.36% for training DR classification. The confusion matrices obtained from different techniques on the DR Dataset are analyzed and compared in Table XIX. These findings contribute to the understanding of the proposed model's effectiveness and can guide future improvements in the classification of DR severity.

TABLE XV. THE OVERALL ACCURACY FOR TRAINING OF THE PROPOSED MODEL AND COMPARATIVE RESULTS ON THE DR

Techniques	Overall Accuracy for Training			
	CNN based on an original dataset	CNN based on an enhancement technique	CNN based on an augmented BGR2RGB	CNN based on an augmented BGR2RGB and RGB2LAB
CNN Model	88.7%	93.9%	95.6%	96.6%
CNN+SVM (Proposed)	99%	68%	95.3%	99.36%

TABLE XVI. THE OVERALL ACCURACY FOR TESTING OF THE PROPOSED MODEL AND COMPARATIVE RESULTS ON THE DR

Techniques	Overall Accuracy for Testing			
	CNN based on an original dataset	CNN based on an enhancement technique	CNN based on an augmented BGR2RGB	CNN based on an augmented BGR2RGB and RGB2LAB
CNN Model	58.5%	62%	85.55%	93.45%
CNN+SVM (Proposed)	62%	68%	85.73%	94.72%

Table XVII presents the loss values obtained during the testing process of the CNN model and the SVM classifier on the DR dataset. These loss values serve as crucial indicators of convergence and performance for each classifier.

TABLE XVII. THE LOSS VALUES OF THE PROPOSED MODEL AND COMPARATIVE RESULTS ON THE DR

Techniques	Loss Values for Testing			
	CNN based on an original dataset	CNN based on an enhancement technique	CNN based on an augmented BGR2RGB	CNN based on an augmented BGR2RGB and RGB2LAB
CNN Model	2.1	1.8	0.7104	0.2131
CNN+SVM (Proposed)	0.9	0.32	0.1427	0.1199

Table XVIII illustrates the overall accuracy values of the proposed model, considering the enhancement technique, in comparison with a related approach. In study [2], the authors employed a CNN with DenseNet 2.1 to extract eye features for effective classification. When applied to the DR Dataset, as shown in Fig. 11(a), they reported an overall accuracy of 66.9%. However, when utilizing the dataset depicted in Fig.

11(b) as per study [2], they achieved an overall accuracy of 93.18%. This difference in accuracy can be attributed to variations in image resolution between the two datasets.

The overall accuracy attained by the proposed model serves as a crucial indicator of its effectiveness in classifying the severity of DR. A higher overall accuracy value of 94.72% demonstrates the model's ability to make accurate predictions, thereby providing valuable assistance to healthcare professionals in diagnosing and managing this condition as show in Table XVI.

TABLE XVIII. OVERALL ACCURACIES FOR THE MODEL BASED ON ENHANCEMENT AND SOME RELATED ONES BASED ON DR DATASET (A)

Techniques	Classifier	Overall Accuracy
CNN + DenseNet [2]	SoftMax	66.9%
CNN based on an enhancement technique	SoftMax	62%
	SVM	68%

TABLE XIX. COMPARATIVE ANALYSIS OF CONFUSION MATRICES ON THE DR DATASET USING DIFFERENT TECHNIQUES

<table>
<tr><th>Techniques</th><th>SoftMax</th><th>SVM</th></tr>
<tr><td>CNN based on an original dataset</td><td></td><td></td></tr>

VI. Recommended Prototype

Fig. 12 illustrates the recommended prototype for effectively classifying new DR images using a proposed learning model. The process begins by enhancing the contrast of the input image, as depicted in figure. This enhancement step aims to improve the visual quality and highlight important features in the image. Then, additional transformation is performed including applying BGR2RGB and RGB2LAB conversions, which further augment the image and help extract relevant information for classification purposes. Finally, the enhanced and the augmented images are passed to the proposed learning model for classification.

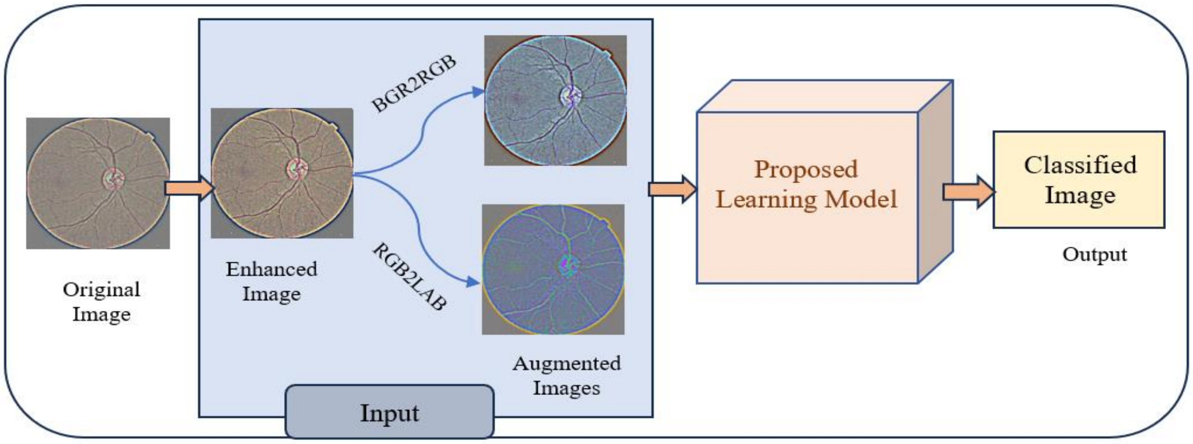

Fig. 12. Recommended prototype.

VII. CONCLUSION

In conclusion, DR has a significant global burden that requires immediate attention, as a primary cause of blindness among working-age populations globally. The main objective of this study was to develop a robust CDSS that combines automatic DR diagnosis and multistage classification module to make CDSS a comprehensive tool for ophthalmologists and help them make an accurate diagnosis. The proposed three-stage deep learning model for DR analysis encompasses several key steps. Firstly, preprocessing techniques, including image enhancement and augmentation, were implemented. In particular, the Gaussian Blur Filter was applied to augment the DR images, alongside the conversion from BGR to RGB and from RGB to LAB color spaces. Secondly, feature extraction and representation learning were performed using a CNN with various layers. This step allowed the model to learn discriminative features from the enhanced images dataset, including the augmented images from BGR to RGB and further augmented images from RGB to LAB. Lastly, by testing the SVM and deep learning models on different versions dataset iterations, the classification outcomes were determined. These versions included the enhanced images dataset, the enhanced images dataset combined with augmentation from BGR to RGB, and the enhanced images dataset augmented from BGR to RGB and further augmented from RGB to LAB. The evaluation metrics were employed to compare the performance of the models. Notably, the enhanced images dataset combined with augmentation from BGR to RGB and augmentation from RGB to LAB demonstrated superior results, achieving an overall accuracy about 95% by SVM classifier. This finding highlights the effectiveness of the proposed approach in accurately classifying and staging DR. While the proposed three-stage deep learning framework has demonstrated promising results in automated diabetic retinopathy grading, future research directions may include the exploration of more advanced neural network architectures to further enhance the feature extraction and classification capabilities.

An Efficient and Secure Access Authorization Policy for Cloud Storage Resources Based on Fuzzy Searchable Encryption

Jun Fu
Guangdong Open University, Guangzhou 510091, China

Abstract—**When fuzzy searchable encrypted cloud storage resources are available, keywords are allowed to have a certain range of changes. Even if there are slight differences in the spelling, word order, or spacing between words, the correct data can be matched. Therefore, it does not have the effect of fine-grained access control (FGAC). Consequently, to satisfy the security demands of cloud storage assets and the ease of resource retrieval through fuzzy searchable encryption, CP-ABE employs attribute and policy definitions to introduce a novel, effective security access authorization approach for cloud storage assets utilizing fuzzy searchable encryption technology. Encrypt cloud storage resources after keyword preprocessing through initialization, file encryption and decryption, index generation encryption, search, and other steps; use the wildcard-based method to generate indexes; and use the Bloom filter to generate security traps to achieve Pail lier-based asymmetric fuzzy searchable encryption of resources. In combination with the CP-ABE-based access control method, authorized users are assigned private keys in the authorization center to ensure that unauthorized users cannot obtain cloud storage resources and complete the fuzzy searchable encryption access authorization of cloud storage resources. The experiment shows that the search index generation of this strategy greatly reduces the resource utilization rate and effectively improves the fuzzy search speed. Moreover, the combination of fuzzy searchable encryption and CP-ABE can better ensure full cloud storage resources.**

Keywords—Fuzzy search encryption; cloud storage; security access; CP-ABE (Ciphertext-Policy Attribute-Based Encryption); access control; authorization policy

I. INTRODUCTION

With the rapid development of information technology and the wide application of cloud computing, cloud storage has become an important choice to satisfy the data storage needs of enterprises and individuals due to its convenient, dynamic, easy-to-scale, and on-demand low-cost characteristics [1]. However, data security issues in cloud storage are becoming more and more prominent, including the risks of privacy leakage, data tampering, and illegal access [2], [3]. To secure data in cloud storage, a common practice is to encrypt the data locally before uploading. However, this approach may lead to a loss of the ability to access the data [4]. Therefore, researchers have proposed methods of searchable encryption and setting secure access control policies to protect user privacy while ensuring that only authorized users can access the information allowed by the authorization, thus balancing the security and accessibility of data [5], [6]. In cloud storage environments, data searching using traditional single encryption techniques can face huge time complexity challenges due to the massive nature and high dimensionality of resources. To solve this problem, researchers have started to explore more efficient and flexible encrypted search methods.

Sivas elvan N. and others proposed a security-unified authentication strategy based on the ability of the Internet of Things [7]. In this policy, it is a token that can authorize the entity's access rights. This token is used to ensure authorization and control access to the limited resources on the Internet of Things. In this method, lightweight elliptic curve symmetric key encryption and decryption, message authentication code, and encryption hash primitives are used to complete the access protection of data. This method uses tokens or keys to achieve access control over data. However, if an attacker can obtain or forge these tokens or keys, it is possible to bypass the authentication and authorization mechanisms and gain unauthorized access rights. The privacy protection key aggregation proposed by Padhya M. et al. can search for encryption and access control policies [8]. First, an attacker can intercept the aggregation key or query the trap gate from an insecure communication channel involving the ECS and impersonate an authorized user of the server to access data. Secondly, fine-grained multi-delegation is allowed; that is, if the delegated attributes meet the hidden access policy (defined by the data holder), the delegated can delegate the permissions it receives to another user without compromising data privacy. This method involves ECS, but if the communication channel is not secure, an attacker may be able to intercept the communication and obtain the aggregation key or query information. This may lead to an attacker using the identity of an authorized user to access data. Huso I and others proposed a privacy protection data propagation scheme based on searchable encryption, a publish-subscribe model, and edge computing [9]. The customized edge server is deployed at the edge of the network. It completes searchable encryption of data through four steps: (1) collects subscription requests encoded by a searchable encryption trapdoor; (2) receives data publishing; (3) encrypts through an attribute-based searchable encryption scheme; (3) implements keyword search on encrypted data; and (4) only provides encrypted data to authorized requesters. This method uses searchable encryption technology, which may expose sensitive information related to data when decrypting and searching data. This may lead to the disclosure of data privacy. Chaudhari, P., and others proposed a scheme called Key Sea, which is a keyword-based search for attribute-based encrypted data when the receiver is anonymous [10]. When searching for documents related to target keywords, keeping the anonymity of recipients and ensuring data privacy are important functions of applications such as healthcare, bureaucracy, and social engineering. The Key Sea scheme uses hidden access policies for attribute-based searchable encryption. However, in practical applications, this method may have the risk of cross-anonymous data association when dealing with large-scale data sets, which will lead to threats to data privacy. Based on the analysis of existing research, it is known that current research faces multiple challenges in IoT security and cloud service access control, including the security of tokens or keys, the security of communication channels, data privacy leakage, the balance between anonymity and data privacy, the complexity of fine-grained access control, and performance and efficiency issues in practical applications.

Pail lier-based asymmetric fuzzy searchable encryption has strong data confidentiality and privacy protection, ensures the safe storage and transmission of data in the cloud, supports asymmetric encryption, improves data security and encryption efficiency, enables fuzzy keyword search, and facilitates users to quickly find the required data. CP-ABE-based access control can provide FGAC [11], reduce key management costs, facilitate large-scale system deployment, enhance data security and privacy protection, and prevent unauthorized access and data disclosure. According to the above advantages, this paper proposes an efficient and secure access authorization strategy for cloud storage resources based on fuzzy searchable encryption technology, which can quickly and effectively encrypt cloud storage resources and achieve efficient access control to ensure the security of cloud storage resources. The implementation process is summarized as follows: Firstly, the cloud storage resources are encrypted using fuzzy searchable encryption technology to ensure accurate matching of data even in cases of slight differences in keywords, reducing the exposure of sensitive information and thus reducing the risk of data privacy leakage. Next, a wildcard-based method is used to generate indexes, and a Bloom filter is used to generate security trapdoors to prevent attackers from intercepting communication and obtaining aggregation keys or query information, thereby protecting the identity of authorized users from being impersonated. Implement asymmetric fuzzy searchable encryption based on Paillier. In order to solve the access control problem, combined with the CP-ABE (Attribute Based Access Control) access control method, the authorization center allocates private keys to authorized users, ensuring that unauthorized users cannot access cloud storage resources. At the same time, through the definition of attributes and policies in this process, it ensures that even if an attacker obtains or forges a token or key, they cannot bypass authentication and authorization mechanisms, because access permissions depend on the user's attributes rather than simple tokens or keys, avoiding the risk of cross anonymous data association in large-scale dataset processing, and protecting data privacy from threats.

II. Efficient and Secure Access Authorization Policy for Cloud Storage Resources

A. *Secure Access Authorization Policy Based on Fuzzy Searchable Encryption*

Data stored in cloud storage may contain sensitive information, and data privacy and security need to be ensured. In cloud storage environments, there are usually requirements for multiple users and different permission levels. Efficient and secure access authorization needs to be able to flexibly manage the permissions of different users, including read, write, edit, delete, and other operations. Therefore, efficient and secure access authorization to data can be achieved in the cloud storage environment to ensure the privacy and security of data while maintaining flexibility and efficiency to meet the needs of large-scale data storage. This paper combines the CP-ABE algorithm [12] based on fuzzy searchable encryption to achieve the purpose of fuzzy searchable cloud storage resources and secure access authorization. The overall structure of this strategy is shown in Fig. 1.

As can be seen from Fig. 1, the overall strategy of this paper is composed of four parts, namely, the authorized institution, ECS, data holder, and authorized user. The working process of this method is to generate the master key and public key for the authorized authority and distribute the private key to each user. The data holder generates a security index for local storage resources and uploads the ciphertext and security index to the ECS. Generate authorization credentials for each resource and upload them to the authorization authority. The authorized users generate security traps based on the keywords to be searched and upload them to the ECS with their search tokens. The ECS first matches the security index with the security trap door to obtain a highly relevant resource ID and then requests the authorization authority to audit the access rights of the resource. After the audit is passed, the ciphertext and key are returned to the user. The user obtains the key through calculation and decrypts the ciphertext to obtain the plaintext data. In the overall structure, fuzzy searchable encryption technology uses the proposed method to realize the search and encryption of ciphertext [13], and access authorization uses the control based on CP-ABE scope [14].

The implementation of the whole policy can also be divided into four main parts, which are the system management part, resource processing part, ciphertext search part, and access right authentication part.

The system management part is mainly done by the authorization authority, which realizes the overall management operation of the system. As a trusted third party, the authorization authority is the only fully reliable part, i.e., the authorization center in Fig. 1.

The resource processing part is responsible for the encryption and decryption of resources, and the ciphertext search part realizes the fuzzy search of multiple keywords on the ciphertext, which is mainly realized by the fuzzy searchable encryption technology.

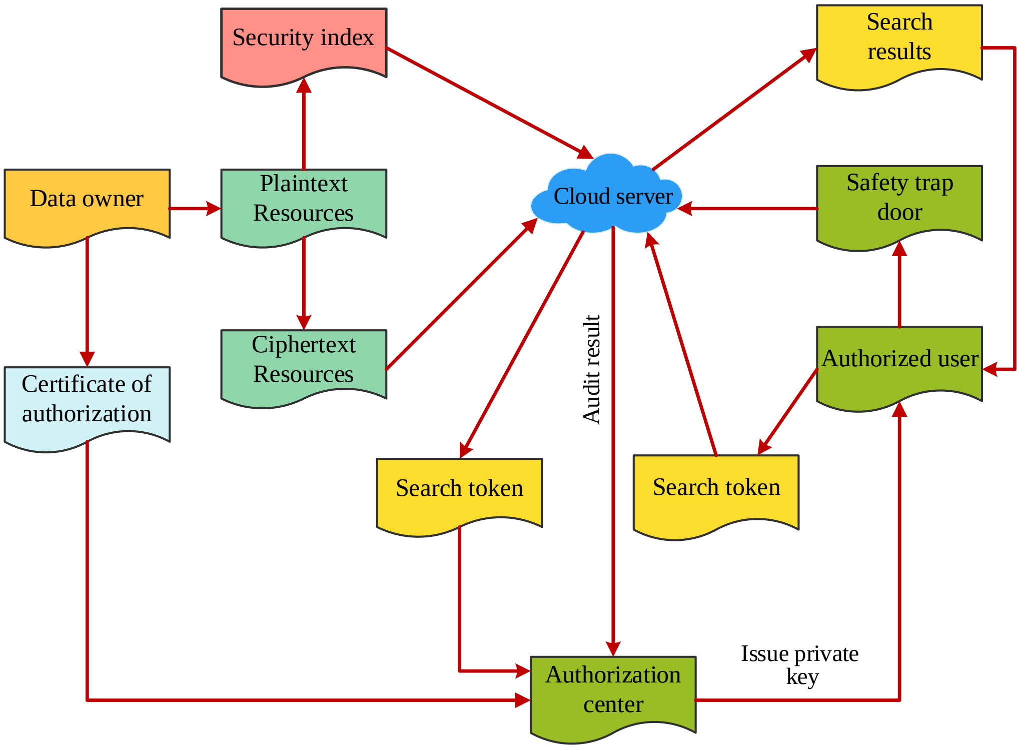

Fig. 1. Overall structure.

Access authority authentication is the core part of authorization search, which is implemented by CP-ABE-based access control.

B. Design of Asymmetric Fuzzy Searchable Encryption Scheme Based on Pail Lier

The access demand for data in cloud storage may change dynamically, and efficient and secure access authorization needs to support dynamic access control policy adjustments to adapt to the change in business requirements. In this context, to safeguard the security and privacy of cloud storage resources and at the same time provide efficient data access control and search functions to adapt to the needs of multi-user, multi-privilege, and dynamic access control, to ensure the security and availability of the system, this paper proposes a secure access authorization strategy based on fuzzy, searchable encryption. The strategy is designed to consider several aspects, including initialization, file encryption and decryption, index generation encryption, and search steps. The key factors in fuzzy searchable encryption are edit distance, fuzzy keyword letting, and keyword trapdoor.

1) Edit distance: Edit distance is used to quantitatively measure the similarity of strings. For a given two keywords, the$\mathrm{w}_1$and w_2, the editorial distanceed $(\mathrm{w}_1, \mathrm{w}_2)$ between them means the minimum number of operations required to change from$\mathrm{w}_1$tow_2. The three basic operations are: (1) Replacement: replacing one letter in a word with another. (2) Delete: delete a letter in the word. (3) Insert: insert a letter into a word. Given a specific keywordw, collection$\mathrm{S}_{\mathrm{w,d}}$represents each word in the set w' that all satisfied the edit distance $\mathrm{ed}(\mathrm{w}, \mathrm{w}' \leq \mathrm{d})$betweenw′andw. Heredis a given integer.

2) Fuzzy keyword letting: On the basis of editing distance, fuzzy keyword searching is defined as the following process: Given the collection $C = \{F_1, F_2, \cdots, F_N\}$ containing n encrypted documents stored on the cloud server, a collection of mutually exclusive keywords $W = \{w_1, w_2, \cdots, w_p\}$, a predetermined edit distance$d$, and the search input$(w, k)$of the coded distances$k (k < d)$. The execution result of the fuzzy keyword returns an ID set of all documents that may contain the keyword W isFID_w: if $w = w_i \in W$, return FID_w; if$w_i \notin W$, return$\{FID_w\}$, here$ed(w, w_i) \leq k$.

3) Keyword traps: Using bloom filters and locally sensitive hash functions with P-stable distributions to construct index vectors and search trap vectors, keyword traps act as pseudo-random functions, allowing fuzzy keyword-letting schemes to achieve search request privacy and index privacy.

a) Keyword pre-processing: This paper uses a Pail lier-based encryption method to complete fuzzy searchable encryption of cloud storage resources [15]. To Pail lier encrypt the keywords of cloud storage resources, first convert the keywords to an integer. Specific steps: first convert each character in the cloud storage resource keyword to ASC II code, then convert the hexadecimal ASC II code to the decimal integer, and finally accumulate these integers to get a large integer, as shown in Fig. 2.

Pail lier fuzzy searchable encryption also has four parts, namely initialization, file encryption and decryption, index generation encryption, and search. Index generation encryption and search are the core of fuzzy searchable encryption. Different steps will be designed as follows.

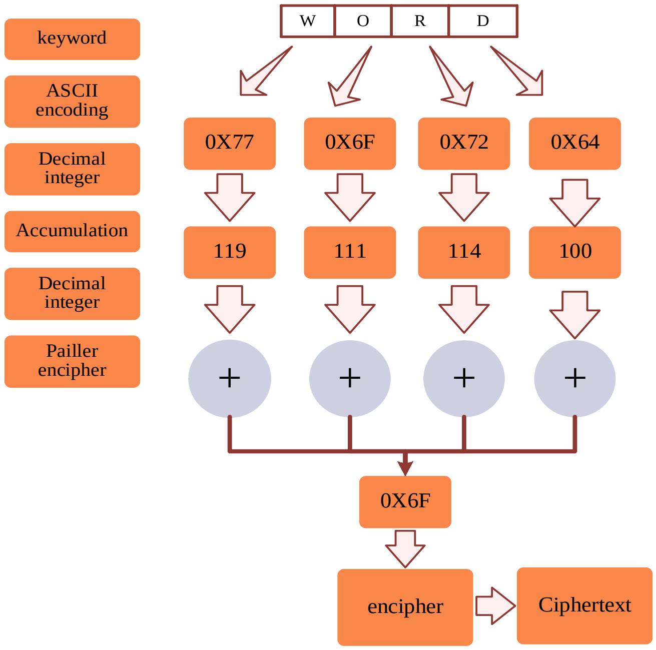

Fig. 2. Keyword conversion process.

b) Fuzzy searchable encryption initialization: For fuzzy searchable encryption, the initialization can be divided into two phases: key initialization and resource initialization [16].

- Key initialization phase: The data holder sets the cloud storage data encryption fuzzy value acc, which is taken by default $acc = 1$ (i.e., the resource edit distance between the two keywords is 1); the data holder enters the security parameter that a, outputs a string of length with a, i.e., the key K, used for AES encryption and decryption; the data holder inputs security parameters λ, and output a pair of public and private keys pk and sk for Paillier encryption, the steps are as follows:
    - ○ Randomly select two large prime numbers $0 < p < 2^{\lambda}$ and $0 < q < 2^{\lambda}$, calculate $n = p \times q$.
    - ○ b. Calculate $\mu = e^{-1}\, mod\, n$, the least common multiple * of p and q, which is e, is expressed as $e = 1cm(p-1, q-1)$.
    - ○ c. To generate the public key pk for (n), private key sk is (e, μ).
- Document initialization phase:
    - ○ a. Extract several keywords from each document in the document collection FS to form a keyword dictionary w'.
    - ○ b. Remove the repeated keywords in the keyword dictionary w', and get the dictionary w containing n keywords.

c) Fuzzy searchable encryption: This section contains two tasks: the resource encryption phase and the resource decryption phase.

- Resource encryption phase.
    - ○ a. The data holder encrypts each resource F_j by AES using the key K, to obtain ciphertext resources CF_j, and generate a ciphertext resource set CFS.
    - ○ b. For each resource CF_j in the ciphertext resource set CFS, setting a unique identifier ID_j.
    - ○ c. Upload the ciphertext resource set CCFS and the corresponding ID_j to a cloud server.
- Resource decryption phase: after the authorized user obtains the key K through the authorization of the data holder, the CFS of the ciphertext resource returned from the search is decrypted by AES to obtain the plaintext resource F_j.

d) Index generation encryption

This section contains two tasks: index generation and index encryption.

- In this paper, a wildcard-based fuzzy set construction is chosen for the index of fuzzy search, which is to say, a keyword fuzzy set. Let the edit distance be d, keywords w based on a wildcard fuzzy set can be expressed as $S_{w,d} = \{S'_{w,0}, S'_{w,1}, \cdots S'_{w,\tau}, \cdots, S'_{w,d}\}$. Here $S'_{w,\tau}$ denotes a keyword w' have number of τ $*$ (wildcard). For example, for the keyword CASTLE, edit the distance $d = 1$, which has a wildcard-based fuzzy set of:

$$S_{CASTLE,1} = \{CASTLE, *CASTLE, *ASTLE, C*ASTLE, C*STLE, \cdots, CASTLE*\{\}\} \quad (1)$$

All the keywords in the set are $13 + 1$iinstead of $13 \times 26 + 1$. Generally, for the keyword w_i of length l, the set $S_{w_i,1}$ constructed by this method has a size of $2l + 1 + 1$, the full keyword of the traditional direct construction method is $(2l + 1) * 26 + 1$. For the direct construction method, the storage capacity will be reduced from 30GB to about 40MB by using the fuzzy set construction based on wildcards.

- Index encryption: Using a public key pk perform bitwise encryption to $S_{w,d} = \{S'_{w,0}, S'_{w,1}, \cdots S'_{w,\tau}, \cdots, S'_{w,d}\}$ to get $CIw_i\{[w_i]_{pk} \| [w_{i1}]_{pk}, [w_{i2}]_{pk}, \cdots, [w_{id}]_{pk}\}$ which ultimately generates a collection of ciphertext indexes $CIS\{CI_{w_1}, CI_{w2}, \cdots, CI_{w_d}\}$. The ciphertext index collection is then sent to the cloud server.

e) Search schemes for fuzzy keywords: Indexed list-based search is a fuzzy keyword search scheme [17], the specific steps of this scheme are as follows:

Step 1: Indexing. In this stage, the data holder encrypts the resources to be stored in the cloud and generates the index of the fuzzy set of keywords, and then uploads both of them to the cloud server, the specific process is as follows: for each keyword $w_i \in W$, the data holder with the key sk computes its gate value for all $w' \in S_{w_i,d}$; the data holder then computes the encrypted address of the corresponding keyword resource store, the

$TEnc\{sk, FID_{w_i}\|w_i\}$, and finally the encrypted resource sets and the list of indexes $\left\{\left\{T_{w_i'}\right\}_{w_i'\in S_{w_i,d}}, Enc\left(sk, FID_{w_i}\|w_i\right)\right\}$sent together to the cloud server.

Step 2: Request a search. The user wants to search for keywords containing w resources, first at a predefined search distance k under which keyword fuzzy sets $S_{w,k}$are generated; then for each element $w' \in S_{w_i,d}$in the fuzzy set, calculate its trapdoor value and send it to the server.

Step 3: Document search. After the cloud server receives the user's letting request, it performs letting on the index list and returns the corresponding encrypted resource address to the user as the search result. The user decrypts the resource address to obtain the corresponding ciphertext resource, downloads it to the local area for decryption, and ultimately obtains the plaintext resource.

f)Keyword trapdoor: Keywords for querying must be submitted when making a query, and the server cannot obtain this keyword information through the query itself. Authorized users need to generate local security trapdoors for the Chinese keywords to be queried and submit them to the cloud server for querying. The specific steps are as follows:

- Convert keywords into pinyin strings and construct binary vectors. A Bloom filter is constructed, and the LSH function is used to map the binary vector corresponding to each pinyin string to the Bloom filter to obtain the query vector as shown in Fig. 3.

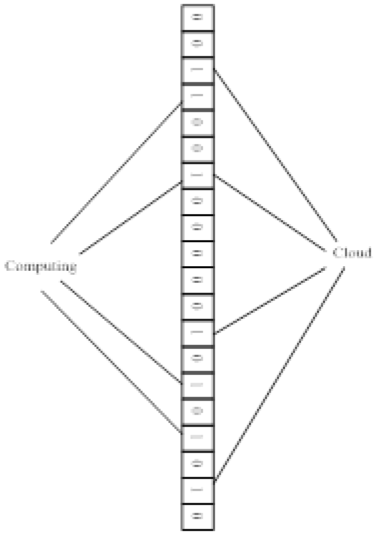

Fig. 3. Example of bloom filter.

- The invertible matrix encrypts the query vector to obtain a secure trapdoor.

Bloom filter: Bloom filter is an efficient data structure that can quickly determine whether an element belongs to the set. It is an array containing m -bits, and initialize each bit to 0 . Usually, Bloom filters are used that r individual hash functions h_t: $\{0,1\}^* \rightarrow [1, n]$, of which, $t \in [1, r]$, and each hash function is mapped to a bit in the array. As shown in Fig. 3, map the words cloud and computing to the Bloom filter, were, $m = 20, r = 4$. The cloud mapped to four positions of $P = \{3,7,12,19\}$by a hash function, computing mapped to 4 positions of $P = \{4,7,15,17\}$by a hash function. So set the value of 7 positions of the Bloom Filter $P = \{3,4,7,13,15,17,19\}$ to 1. When a user submits a search request, the keyword is also hashed. When the value of all hash maps is 1, true is returned. Otherwise, false is returned. The Bloom filter has high time and space efficiency, and when using the Bloom filter as an index to search documents, the required documents will not be missed, which can provide search integrity verification for the system.

C. *Access Control of Cloud Storage Resources Based on CP-ABE*

The above asymmetric fuzzy searchable encryption scheme based on Pail lier is a form of imprecise keyword searchable encryption, which solves the problem of inconsistent keyword word order and word spacing and improves the fault tolerance and robustness of retrieval conditions. However, it allows keywords to have a certain range of changes. Even if there are slight differences in the spelling, word order, or spacing of keywords, the correct data can be matched. This process tends to reduce the security of cloud storage resource access control. To ensure that only legitimate users can access the corresponding data and ensure the operating efficiency of the system. The CP-ABE algorithm is used to formulate complex access policies, conduct FGAC on data, meet the access needs of different users to data, and ensure the security of data.

The data holder uses the CP-ABE algorithm to connect the cloud storage resources with the access control structure [18], to attain FGAC over the resources saved in CSP, prevent the ECS and unauthorized users from obtaining access rights to cloud storage resources, help manage access rights, and not disclose information about keys or cloud storage resources. In addition, the scheme also meets the following safety requirements:

- Fine-grained access control (FGAC): Authorized users can only access their authorized resources.
- Obfuscation resistance: Authorized users cannot access unauthorized cloud storage resources by sharing keys.
- Privacy protection: The cloud server does not save the user's private information.

CP-ABE algorithm is based on bilinear mapping structure [19], set $G_1$and G_2be two multiplicative cycle groups of the order of prime p the $g$is the generating element of G_1, the $e$is a bilinear mapping, the$e$: $G_1 \times G_1 \rightarrow G_2$, the bilinear mapping e can be described as below:

- Bilinear: $\forall u, v \in G_1, a, b \in Z_p$, makes $e(u^a, v^b) = e(u, v)^{a,b}$;
- Non-degradation: $e(g, g) \neq 1$;
- Computability: for any $y, z \in G_1$, there exist given polynomial time algorithms to compute $e(y, z) \in G_2$.

CP-ABE data is described by an attribute set [20], which is used to build an access control tree and will then be allocated to cloud storage resources. Authorized users have attribute sets (this task has been assigned by the data holder) and special IDs that describe their access rights. A novel key is allocated to every account associated with a user. If the attribute set held by the authorized user meets the access control tree of the corresponding cloud storage resource, the authorized user can decrypt the cloud storage resource. The scheme is divided into four steps: parameter initialization, encryption operation, generating key, and decrypting operation. In the parameter initialization phase, select the attributes used according to the holder and generate system parameters for each attribute. In the encryption operation phase, the data holder selects an attribute set, utilizes the information to construct a framework for threshold access control, and then uses this structure to encrypt cloud storage resource files. Each authorized user is assigned an attribute set according to the holder. After the authorization center generates the authorized user's private key, the authorized user's public key is used to encrypt the private key, and the encryption result is sent to the ECS. In the decryption operation, authorized users use their private keys to obtain cloud storage resources through the decryption algorithm.

Algorithm for each step:

1) Parameter initialization: The data holder chooses the prime number that P, cyclic groups G_1, G_2, $e\colon G_1 \times G_1 \to G_2$ denotes the bilinear mapping, the H represents a hash function. Map the ID of an authorized user asG_1elements, the data holder determines the array of attributes ψ as a secondary consideration, for every attribute $i \in \psi$, the data proprietor produces a pair of arbitrary values $\alpha_i, \beta_i \in Z_p$, then the user's private and public keys are:

$$Sk_u = S_{CASTLE,1}\{\alpha_i, \beta_i, i \in \psi\} \tag{2}$$

$$Pk_u = S_{CASTLE,1}\{e(g_1, g_1)^{\alpha_i}, g^{\beta}, i \in \psi\} \tag{3}$$

2) Encrypted links: In encrypted messages M, the data holder selects the attribute $i \in \psi$, based on a collection of attributes ψ to define the access structure P. Choosing polynomials that Q_x and P_x, and $Q_x(0) = s$, $P_x(0) = 0$. accessing each leaf node of the access control structure x corresponding to a random number r_x, then calculate:

$$\begin{gathered} D_{x,1} = e(g_1, g_1)^{Q_x(0)} \cdot e(g_1, g_1)^{\alpha_x r_x} \\ D_{x,2} = g_1^{\gamma x} \\ D_{x,3} = g_1^{\beta_x \gamma_x} \cdot g_1^{p_x(0)} \end{gathered} \tag{4}$$

The ciphertext is encrypted as follows:

$$M_e = Enc^{sym}_{e(g,g)^x}(M) \tag{5}$$

Finally, upload the encrypted cloud storage resource to F Cloud Servers:

$$D = \{\forall x, D_{x,1}, D_{x,2}, D_{x,3}, P, M_e\} \tag{6}$$

3) Key generation: The data holder receives the authorized user ID_u from the cloud server and selects the attribute collection I_u to allocate the authorized user, the data holder calculates the authorized user key as follows:

$$Sk_D = \{g_1^{\alpha_i} H(ID_u)^{\beta_i}, i \in I_u\} \tag{7}$$

The encrypted with the authorized public key of the user $Sk_D$is produced to the authorized user through the server of the cloud, and the authorized users are the ones who possess the private key and can decrypt Sk_D.

4) Decryption session: The Authorized users download encrypted cloud storage resources F, $H(ID_u)$, of which $D = \{\forall x, D_{x,1}, D_{x,2}, D_{x,3}, P, M_e\}$, calculate after the authorized user selects the attributes meeting the access structure P:

$$\prod_x \left(\frac{D_{x,1} \cdot e\big(H(ID), D_{x,3}\big)}{e\big(Sk_D, D_{x,2}\big)} \right)^{\Delta x} \tag{8}$$

$$\prod_x \left(\frac{D_{x,1} \cdot e\big(H(ID), D_{x,3}\big)}{e\big(Sk_D, D_{x,2}\big)} \right)^{\Delta x} = e(g_1, g_1)^s \tag{9}$$

Finally, the user restores the encrypted cloud storage resource to M:

$$M = Dec^{sym}_{e(g,g)^s}(M_e) \tag{10}$$

So far, the efficient and secure access authorization of cloud storage resources that integrates Pail lier-based asymmetric fuzzy searchable encryption and CP-ABE-based access control methods has been completed.

III. Experimental Analysis

To validate the method of this paper, a laboratory computer was chosen to conduct experiments. The parameters of the laboratory computer and the cloud server are shown in Tables I and II, respectively.

Under the above experimental configuration, set up the experimental environment as shown in Fig. 4. The database size is set to 1000 pieces of data, the false alarm rate of the Bloom filter is 0.01, the capacity is 10000 elements, and the average file size is 100KB.

TABLE I. COMPUTER PARAMETERS

Attribute	Parameter
CPU	i5-12400
Internal memory	32GB
Hard disk	1TB
Graphics card	RTX3070
System	windows10
Network bandwidth	10Gbps

TABLE II. CLOUD SERVER PARAMETERS

Attribute	Parameter
Number of CPU cores	32
Memory capacity	10TB
Memory capacity	256GB
Network bandwidth	10Gbps
Storage protocol	NFS, FTP, CIFS Etc.
Data backup	Remote backup to another data center

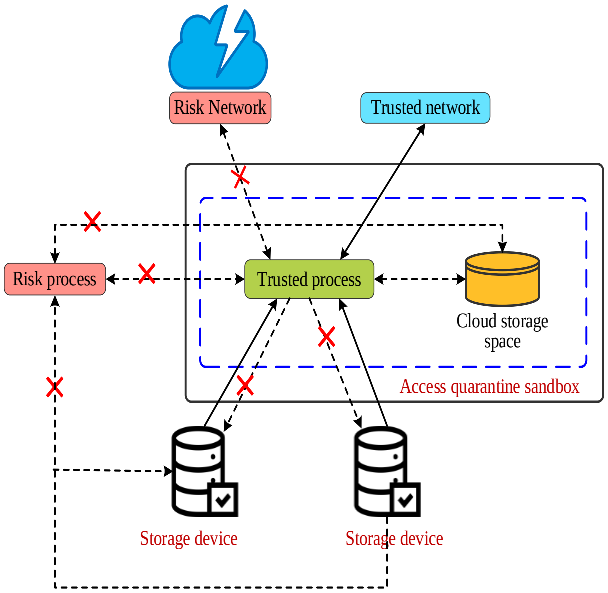

Fig. 4. Experimental environment.

The size of the fuzzy sets constructed based on the wildcard method in the fuzzy search process using the method of this paper at different edit distances is shown in Fig. 5.

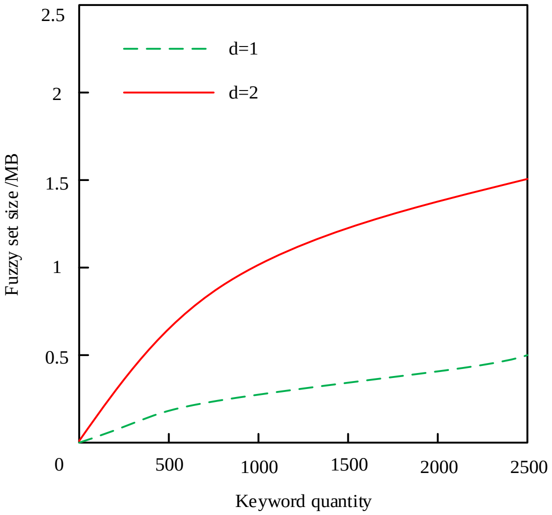

Fig. 5. Fuzzy set size.

By observing Fig. 5, when using this method to build a fuzzy set, the size of the fuzzy set will increase with the increase in editing distance. However, even if the editing distance is 2, the fuzzy set size of 2500 keywords is only 1.5 MB. This shows that the fuzzy set constructed by the method in this paper has the advantages of small data volume, high efficiency, and small space occupation. Compared with the traditional methods, this method has significant advantages in the construction of fuzzy sets. Traditional methods usually need more time and space resources to complete the same task, but this method can generate smaller fuzzy sets in a shorter time, which improves the processing efficiency. This method is efficient and practical in the construction of fuzzy sets and can provide more convenient and fast support for fuzzy search.

The proposed method used in this paper to build the index as well as the time to build the keywords is shown in Fig. 6.

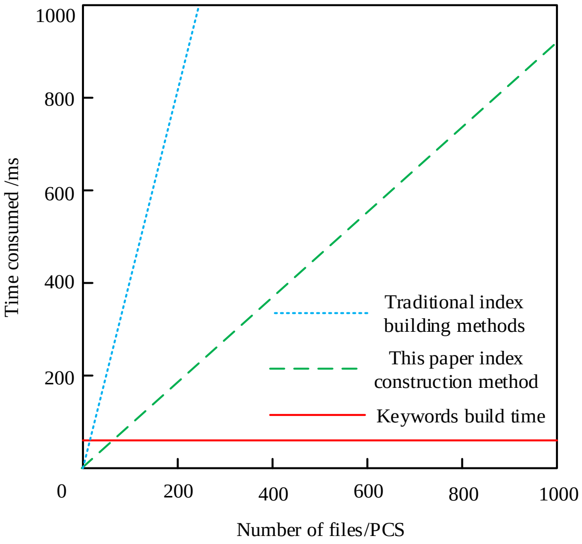

Fig. 6. Index and keyword build time.

By observing Fig. 6, the time overhead increases linearly with the increase in the number of files. This is because the traditional index generation method is less efficient when dealing with a large number of files, and it takes more time to complete the index generation task. In contrast, the index generation method proposed in this paper adopts more efficient algorithms and data structures, which greatly improves index generation speed. In addition, the construction of the keyword verification set and the verification of search integrity operations are executed on the private cloud server. Since these operations need to be performed only once, the time spent is very small. This further proves the efficiency and practicality of the method in this paper. In conclusion, the index generation method proposed in this paper has an obvious time advantage when dealing with a large number of files and can accomplish the index generation task more quickly. This provides strong support for the efficient index generation of private cloud storage systems and helps to improve the overall performance and user experience of private cloud storage systems.

For the fuzzy searchable encryption technique used in this paper, the search time at different numbers of trapdoors is shown in Fig. 7.

By observing Fig. 7, the fuzzy search time will increase as the number of trapdoors increases. This is because the increase in the number of trapdoors will lead to an increase in the amount of data to be searched, thus increasing the search time. However, compared with traditional methods, the search method in this paper has significant advantages in terms of time efficiency. Even if the number of trapdoors reaches 8, with 1000 keywords, the method in this paper can still complete the search in about 35 ms. This advantage in time efficiency benefits from the efficient algorithm and data structure used in this method. By optimizing the search process and reducing redundant operations, this method can locate the target results faster, thus reducing the search time. The search method in this paper has high time efficiency when dealing with large-scale data and can meet the needs of practical applications. Compared with the traditional methods, the advantages of this method in terms of time efficiency make it more suitable for large-scale data fuzzy search scenarios.

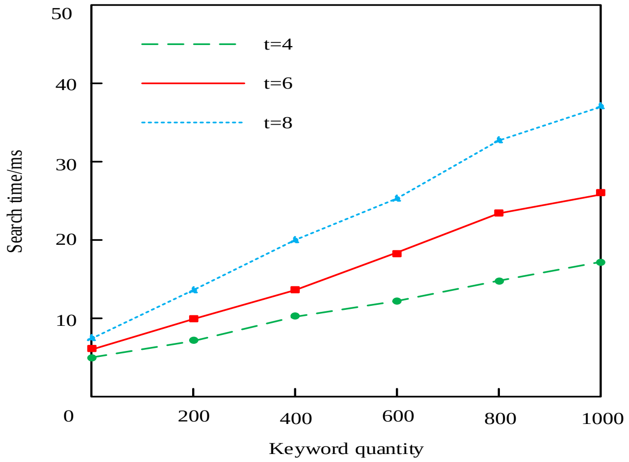

Fig. 7. Fuzzy searchable encryption search time.

In access control, the main reason that affects the access control time is the generation time of the authorization credentials and the generation time of the key, the method of this paper, and the two consumption times as shown in Fig. 8.

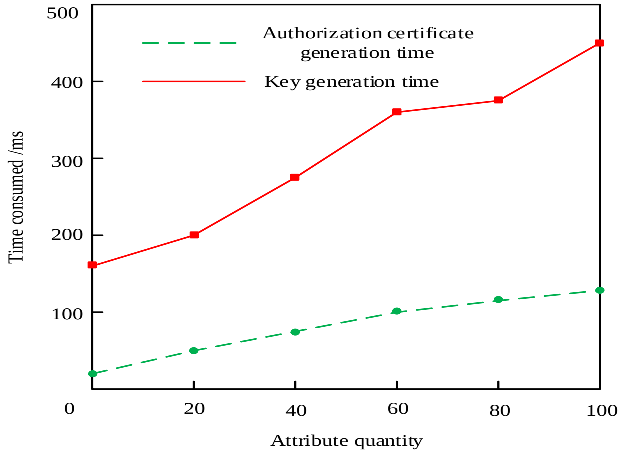

Fig. 8. Influencing factors of access control time.

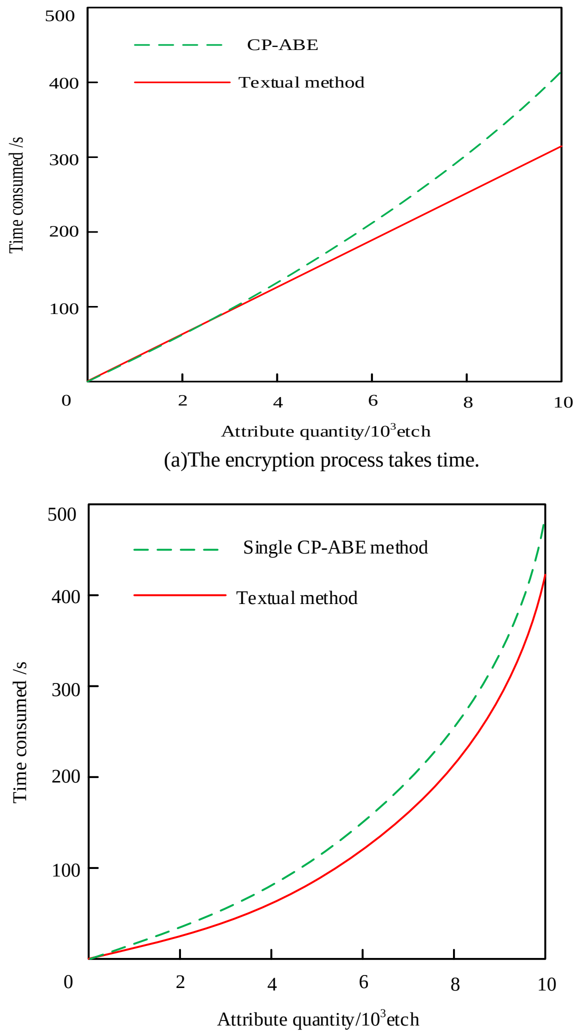
By observing Fig. 8, among the main factors that affect the access control time, the generation time of authorization credentials accounts for a considerable proportion. This is mainly because the generation of authorization credentials needs to consider the user's attributes, permission levels, and other related factors and verify and calculate them according to the preset access control policies. This process requires a series of computationally intensive operations, such as encryption algorithms and hash functions, which all take a certain amount of time. In addition, with the increase in user attributes, the generation time of authorization credentials will increase accordingly. This is because more attributes mean more calculation and verification steps are required, thus increasing the generation time. When the attribute is 100, it takes 450 ms to generate the authorization certificate.

The file encryption and decryption times of the single CP-ABE access control method and the method in this paper for data encryption security access authorization are shown in Fig. 9.



(a)The encryption process takes time.

(b)Time consuming decryption process.

Fig. 9. The encryption/decryption process takes time.

By observing Fig. 9, the method presented in this article demonstrates significant advantages over a single CP-ABE method in terms of encryption/decryption time for cloud storage resources. By combining fuzzy searchable encryption technology, this method can quickly and accurately complete encryption and decryption operations when dealing with slight changes in keywords, thereby greatly improving the efficiency of the encryption/decryption process. This efficiency improvement not only reduces the waiting time of users but also provides the possibility for large-scale data processing, especially in high concurrency and large data volume cloud storage environments, where our method can maintain stable performance. In addition, the innovation of this method lies in its implementation of fine-grained access control and integration of fuzzy search functions, which is difficult to achieve in traditional CP-ABE methods. By adopting a dual encryption mechanism of CP-ABE encryption and fuzzy searchable encryption, this method has reached new heights in data security and privacy protection. This dual protection mechanism provides a solid protection barrier for data, ensuring that even in complex network environments, data can be protected from unauthorized access and malicious attacks.

Using study [8] method, study [9] method, and study [10] method as comparison methods for our method, we conducted comparative analysis with access delay and throughput as indicators. Among them, access delay is the average time from the user initiating the query to receiving the result, and throughput is the number of queries processed by the server per unit time. The experimental results are shown in Table III.

TABLE III. EXPERIMENTAL RESULTS OF ACCESS LATENCY AND THROUGHPUT

Method	Number of users	Dataset size	Access latency (ms)	Throughput (queries/sec)
Reference [8]	100	1000	150	20
	200	2000	180	18
	300	3000	210	16
	400	4000	240	14
	500	5000	270	12
Reference [9]	100	1000	120	25
	200	2000	140	23
	300	3000	160	21
	400	4000	180	19
	500	5000	200	17
Reference [10]	100	1000	100	30
	200	2000	120	28
	300	3000	140	26
	400	4000	160	24
	500	5000	180	22
Method of this paper	100	1000	80	35
	200	2000	90	33
	300	3000	100	31
	400	4000	110	29
	500	5000	120	27

As shown in Table III, the access latency of our method is lower than that of other methods in all combinations of user numbers and dataset sizes. As the number of users and dataset size increase, the growth rate of access latency is also relatively small, indicating that CP-ABE can still maintain low latency when processing large-scale data. The throughput of this method is higher than other methods in all cases. As the number of users and dataset size increase, the decrease in throughput is also relatively small, indicating that CP-ABE can still maintain high throughput when handling high loads. Overall, it can be seen that the method proposed in this article outperforms other comparison methods in terms of access latency and throughput, especially when dealing with large-scale user and high load datasets. This indicates that CP-ABE has higher efficiency and better performance in fuzzy searchable encrypted access authorization for cloud storage resources. Through fine-grained access control and efficient encryption technology, CP-ABE can better meet the security and query convenience requirements of cloud storage resources.

In order to further verify the universality and applicability of the proposed method, comparative experiments were conducted on different datasets with safety as the indicator. The experimental dataset consists of three different sizes: small (1000 files), medium (5000 files), and large (10000 files), each with a size of 1MB. The experimental results of the methods in this article, study [8], study [9], and study [10] are shown in Table IV.

TABLE IV. EXTENSIVE EXPERIMENTAL RESULTS

Method	Dataset size	Data leakage risk (%)	Access Control Effectiveness (%)
Reference [8]	small-scale	5	95
	medium-sized	7	93
	large	10	90
Reference [9]	small-scale	4	96
	medium-sized	6	94
	large	9	91
Reference [10]	small-scale	3	97
	medium-sized	5	95
	large	8	92
Method of this paper	small-scale	2	98
	medium-sized	4	96
	large	7	93

From Table IV, it can be seen that in small datasets, the data leakage risk of all methods is relatively low. However, the data leakage risk of our method is the lowest, only 2%, and the access control effectiveness is the highest, reaching 98%. This indicates that CP-ABE can provide higher security and more effective access control in small datasets. In medium-sized datasets, as the size of the dataset increases, the data leakage risk of each method increases. However, the growth rate of data leakage risk in our method is relatively small, at 4%, while the effectiveness of access control remains at a high level, at 96%. This indicates that CP-ABE can still provide good security and access control on medium-sized datasets. Under large datasets, the risk of data leakage in various methods further increases. The data leakage risk of this method is 7%, while the effectiveness of access control is 93%, which is still better than other methods. This indicates that even in large datasets, CP-ABE can maintain a lower risk of data leakage and higher effectiveness of access control. Overall, it can be seen that the method proposed in this article exhibits superior security on datasets of different sizes, especially when dealing with large datasets. Through fine-grained access control and efficient encryption technology, CP-ABE can better protect cloud storage resources from the threat of data leakage and ensure the effectiveness of access control. This makes CP-ABE an ideal choice for secure access authorization of cloud storage resources.

In summary, the method in this paper further improves the security and privacy protection of data through double encryption and fuzzy search functions on the basis of realizing access control and providing a more convenient cloud storage service for users. This design idea and method can provide a more secure and efficient solution for the cloud storage system in practical applications.

IV. Results and Discussion

This study proposes a method that combines fuzzy searchable encryption and attribute based encryption based on ciphertext strategy (CP-ABE) to improve the security and search efficiency of data in cloud storage environments. Through a series of experiments and analysis, the following main results and discussions have been obtained.

Firstly, in terms of constructing fuzzy sets, it is observed that as the editing distance increases, the size of the fuzzy set also increases accordingly. However, even with an editing distance of 2, the fuzzy set size of 2500 keywords is only 1.5MB, indicating that the method can effectively support fuzzy search of keywords while maintaining small storage overhead. This result is attributed to the efficient algorithms and data structures used, which greatly improve the speed and efficiency of index generation.

Secondly, in terms of fuzzy search performance, although the search time increases with the number of trapdoors, the search method proposed in this paper has significant advantages in time efficiency compared to traditional methods. Even when the number of trapdoors reaches 8 and the number of keywords reaches 1000, our method can still complete the search in about 35ms. This efficiency is mainly attributed to the optimization algorithms and data structures used, which can quickly locate matching data items.

In terms of access control, it is noted that the generation time of authorization credentials accounts for the main part of the access control time. This is mainly because the generation of authorization credentials involves complex encryption algorithms and computationally intensive operations such as hash functions. However, by optimizing algorithms and reducing unnecessary computational steps, the generation time of authorization credentials can be further reduced. In addition, as user attributes increase, the generation time of authorization credentials will also increase accordingly, but the method can still be completed within a reasonable time.

In terms of encryption/decryption performance, the method proposed in this paper demonstrates significant advantages compared to a single CP-ABE method. By combining fuzzy searchable encryption technology, the method can quickly and accurately complete encryption and decryption operations when dealing with slight changes in keywords, greatly improving the efficiency of the encryption/decryption process. This advantage is particularly important in cloud storage environments as it ensures the security of data during transmission and storage.

In terms of access latency and throughput, our method performs excellently in all combinations of user numbers and dataset sizes. As the number of users and dataset size increase, the increase in access latency is relatively small, while the decrease in throughput is also relatively small. This indicates that CP-ABE can still maintain low latency and high throughput when processing large-scale data, thereby ensuring the availability and performance of cloud storage services.

Finally, in terms of data leakage risk and access control effectiveness, our method exhibits lower data leakage risk and higher access control effectiveness across all dataset sizes. Even on large datasets, the data leakage risk of our method is only 7%, while the effectiveness of access control reaches 93%, which is still better than other methods. This result fully demonstrates the advantages of CP-ABE in providing high security and effective access control.

In summary, the method proposed in this article that combines fuzzy searchable encryption and CP-ABE has demonstrated excellent security and performance in cloud storage environments. By optimizing algorithms and data structures, the speed of index generation and search efficiency can be improved, while reducing the generation time of authorization credentials and the risk of data leakage. In addition, CP-ABE can still maintain low latency and high throughput when processing large-scale data, ensuring the availability and performance of cloud storage services.

V. Conclusion

This paper proposes an efficient and secure access authorization strategy for cloud storage resources based on fuzzy searchable encryption technology. Combining fuzzy searchable encryption and CP-ABE access control, it ensures that data is not accessed illegally and provides flexible and efficient search functions. Fuzzy searchable encryption technology can realize efficient data encryption and retrieval on edge devices, providing a safe and efficient data protection scheme for the development of the Internet of Things and edge computing. In addition, with the wide application of artificial intelligence and machine learning technology, higher requirements are put forward for data privacy protection and secure retrieval. Fuzzy searchable encryption technology can provide a safe and efficient data protection scheme for the training and use of machine learning models and promote the healthy development of artificial intelligence and machine learning. In conclusion, the prospect of an efficient and secure access authorization strategy for cloud storage resources based on fuzzy searchable encryption technology is broad. It will play an important role in big data, the Internet of Things, edge computing, artificial intelligence, and other fields, providing a more secure, efficient, and flexible solution for data security and privacy protection. At the same time, with the continuous development and improvement of technology, this strategy will continue to be optimized and improved to adapt to the changing application needs and market environment.

Although fuzzy searchable encryption technology allows keywords to have a certain range of variation, balancing search flexibility and user privacy protection remains a challenge in practical applications. Therefore, in the future, privacy protection technologies such as differential privacy will be introduced in the process of fuzzy searchable encryption. By adding a certain amount of random noise to the query results, the privacy of users will be protected. Even if attackers obtain the query results, it is difficult to infer specific sensitive information.

***Abstract*—This study focuses on enhancing the accuracy of traffic sign detection systems for self-driving. With the increasing proliferation of autonomous vehicles, reliable detection and interpretation of traffic signs is crucial for road safety and efficiency. The primary goal of this research was to improve the performance of traffic sign detection, particularly in identifying unfamiliar signs and dealing with adverse weather conditions. We obtained a dataset of 3,480 images from Roboflow and utilized deep learning techniques, including Convolutional Neural Networks (CNNs) and algorithms such as YOLO and the Vision Engineering (VGG) toolkit. Unlike previous studies that focused on a single version of YOLO, this study conducted a comparative analysis of different deep-learning models, including YOLOv5, YOLOv8, and VGG-16. The study results show promising outcomes, with YOLOv5 achieving an accuracy of up to 94.2%, YOLOv8 reaching 95.3% accuracy, and VGG-16 outperforming the other techniques with an impressive 98.68% accuracy. These findings highlight the significant potential for future advancements in traffic sign detection systems, contributing to the ongoing efforts to enhance the safety and efficiency of autonomous driving technologies.**

***Keywords*—Traffic signs; detection; classification; YOLO; VGG16**

I. Introduction

Traffic sign detection plays a crucial role in the development of autonomous driving systems. The ability of these systems to accurately identify and understand road traffic signs is essential for ensuring road safety and efficiency. In recent years, there has been an increasing reliance on autonomous vehicles [1], which makes accurate detection and interpretation of traffic signs even more important. This research aimed to enhance the accuracy of traffic sign detection systems, with a particular focus on detecting unusual traffic signs that may not be widely recognized. Deep learning techniques and algorithms were important in the field of self-driving cars, as they were increasingly being used to detect traffic signs [2]. This led to increased efficiency and safety in self-driving cars. In particular, deep learning algorithms such as YOLOv8, YOLOv5, and VGG-16 were useful in achieving accurate traffic sign detection. These algorithms enabled traffic signs to be recognized and interpreted, thus enhancing the capabilities of autonomous driving systems. By training YOLO models on labeled datasets, algorithms could learn to identify the different shapes, colors, and symbols associated with road signs. The use of these algorithms to detect road signs ensured that vehicles were able to proactively respond to traffic signals, thus improving road safety and efficiency. By leveraging these algorithms, self-driving cars could effectively recognize different types of road signs, including speed limits, stop signs, yield signs, and more. This information was then used to make informed decisions and adapt the vehicle's behavior accordingly.

II. Literature Review

Qian et al. [3] found that the recognition of traffic signs has gained significant importance in applications such as self-driving cars, traffic mapping, and traffic surveillance in recent years. The dataset used is the German Traffic Sign Recognition Benchmark (GTSRB). It is a benchmark dataset specifically designed for traffic sign recognition. The dataset consists of images of traffic signs captured under various conditions, such as different lighting and weather conditions. Each image is labeled with the corresponding traffic sign category. The algorithm used in the paper is a Convolutional Neural Network (CNN). The proposed CNN architecture consists of multiple convolutional layers, activation layers, max pooling layers, fully connected layers, and a softmax layer for classification. The CNN Committee achieved high accuracy, which is 99.46%. The advantages of the proposed approach are that it achieves outstanding performance on the GTSRB dataset, indicating its effectiveness in traffic sign recognition tasks, and The deep learning model (CNN) used in the system has powerful representational learning capabilities, allowing it to extract discriminative features from traffic sign images.

Arcos- García et al. [4] improved traffic sign classification using deep learning in diverse real-world scenarios. They compared different optimization algorithms, including Stochastic Gradient Descent (SGD), SGD with Nesterov momentum (SGD-Nesterov), RMSprop, and Adam, and analyzed the impact of integrating Spatial Transformer Networks (STNs) into CNN. The authors utilized publicly available traffic sign datasets from Germany and Belgium, specifically the German Traffic Sign Recognition Benchmark (GTSRB). Their proposed CNN achieved an impressive recognition rate accuracy of 99.71% in the GTSRB, surpassing previous methods and demonstrating improved memory efficiency.

Morillo et al. [5] provided a comprehensive analysis of state-of-the-art object detection systems, along with several feature extraction tools, for traffic sign detection. The study utilizes the GTSDB dataset, which contains 900 images of traffic lights with various orientations and lighting conditions. The authors fine-tuned object detection models, namely Faster R-CNN, R-FCN, SSD, and YOLO V2, all of which employ the CNN algorithm. The results indicate that Faster R-CNN Inception Resnet V2 achieves the highest accuracy (95.77%), followed by R-FCN Resnet 101 with an accuracy of 95.15%. Additionally, the YOLO V2 and SSD Mobilenet models are highlighted for their competitive performance and lightweight design. Overall, the researchers provide valuable insights for practitioners and researchers working in the field of traffic signal detection.

Rajendran et al. [6] addressed the challenges that traffic sign detection systems using Yolo methods are facing, such as poor accuracy and small object detection issues, unlike the CNN-based methods that provide high accuracy and real-time performance. The authors proposed an approach for traffic sign recognition using YOLOv3 for detection and a CNN-based classifier for classification. The methodology is evaluated using the German Traffic Sign Detection Benchmark (GTSDB) dataset, which contains 600 training images and 300 test images. They also utilized the German Traffic Sign Recognition Benchmark (GTSRB) dataset, which consists of more than 50000 traffic sign images divided into 39209 training images and 12630 test images. The YOLOv3 detector and the CNN-based classifier are implemented using Keras with a TensorFlow backend. The detector performance results were compared with another detector called the faster R-CNN-based method. According to the results, the proposed YOLOv3 outperformed the other detector in terms of accuracy, with an mAP of 92.2% on the GTSDB test set and a frame rate of 10 fps. The CNN-based classifier was evaluated using the GTSRB test set, and it achieved a high accuracy of 99.6%. The future work involves exploring simulation detection and classification using single-stage detectors without the need for an additional traffic sign classification network.

Tabernik et al. [7] addressed the problem of automating traffic signal detection and recognition. They propose a deep learning-based approach using the Mask R-CNN algorithm and present a new dataset called DFG, consisting of 200 classes of traffic lights. The dataset contains a total of 13,000 traffic light instances and 7,000 high-resolution images. The results of their study demonstrate the effectiveness of their approach, as they achieved error rates of less than 3%. This makes it suitable for practical applications in traffic signal inventory management. The researchers present a comprehensive deep learning analysis for dealing with traffic signals with different appearances. Additionally, it provides a challenging dataset that serves as a benchmark. However, one limitation of the paper is that the dataset is limited to the categories chosen by the researchers, and its generalizability to a wider range of traffic signals remains uncertain.

Sichkar et al. [8] presented a holistic model for real-time traffic sign detection and classification, which was important for car vision systems and future autonomous vehicles. The model utilized YOLO version 3 for traffic sign localization and CNN for classification. The detection model was trained on the German Traffic Sign Detection Benchmark (GTSDB) dataset, consisting of 630 training RGB images and 111 validation images. Meanwhile, the classification model was trained on the German Traffic Sign Recognition Benchmark (GTSRB) dataset, which included 66,000 RGB images. The YOLO-based detection model achieved a 97.22% mAP accuracy on four traffic sign categories, while the CNN-based classification model achieved an accuracy of 0.868% on the test dataset.

Zhu et al. [9] explored the application of deep learning techniques, specifically the latest version of YOLOv5, for accurate and efficient traffic sign detection and recognition. The dataset used in the paper is referred to as "our dataset" and was specifically created for Traffic Sign Recognition (TSR) experiments. It contains 2,182 images with eight classes of traffic signs. The algorithm used for TSR in the paper is YOLOv5, which stands for "You Only Look Once" Version 5. It compares the performance of YOLOv5 with another algorithm called SSD (Single Shot MultiBox Detector). YOLOv5 achieved a mean Average Precision (mAP) of 97.70% at a threshold of 0.5 for all classes in terms of TSR. On the other hand, SSD obtained a mAP of 90.14% under the same conditions. It is also mentioned that YOLOv5 outperformed SSD in terms of recognition speed. The advantages of using YOLOv5 for TSR are its improved accuracy compared to previous models like YOLOv3, faster detection speed, and the ability to simultaneously predict bounding box coordinates, target confidence, and class probabilities. As for the disadvantages, the paper does not provide a comprehensive analysis of the limitations or potential drawbacks of YOLOv5 compared to SSD or other TSR algorithms.

Song et al. [10] proposed a deep learning-based algorithm that aims to improve the performance of intelligent vehicles in accurately detecting and recognizing traffic signs. The study utilized the CCTSDB 2021 dataset, which includes 16,356 images with 13,876 prohibitive signs, 4598 warning signs, and 8363 mandatory signs. They improved the algorithm; TSR-YOLO is built upon YOLO (You Only Look Once) and achieved a high detection accuracy of 96.62%. Furthermore, this paper specifically focuses on Chinese traffic signs, making it difficult to assess the generalizability of the algorithm for all types of traffic signs.

Qu et al. [11] proposed an algorithm for traffic sign detection in complex weather conditions based on an improved version of the YOLOv5s model. The study utilized the CCTSDB 2021 dataset, which includes 5268 new traffic scene images. The algorithm employed is PSG-Yolov540, an enhanced version of YOLOv5s, which incorporates improvements such as coordinate attention (CA), an additional prediction head, and the utilization of Alpha-IoU to enhance the original positioning loss CIoU. The algorithm achieves a precision increase of 12.5% and an improved recall rate of 23.9% compared to the original YOLOv5s model, resulting in a precision of 88.1% and a recall rate of 79.8%. However, the paper lacks a thorough discussion of the algorithm's limitations and does not explore potential challenges or failure cases that may arise in real-world scenarios.

Liu et al. [12] introduced an enhanced methodology called ETSR-YOLO, a modified version of the YOLOv5 object detection algorithm. The study introduced two improved C3 modules that aim to suppress background noise interference and enhance the feature extraction capabilities of the network. This paper introduced several enhancements to YOLOv5, including the upgrade of the path aggregation network to capture more contextual information, which improves the detection of traffic signs of varied sizes. Second, we incorporated a coordinated attention method into the backbone network to adaptively improve key features while suppressing noise. Third, the ConvNeXt block increases the network's receptive field and minimizes information loss during feature fusion. Finally, during post-processing, they utilized the WIoU function to improve the predictability and robustness of the model. They utilized the TT100K (Tsinghua-Tencent 100K) dataset, which contains 6634 training images and 1659 test images, and also the CCTSDB2021 (CSUST Chinese Traffic Sign Detection Benchmark 2021) dataset, which contains 14258 training images and 3571 test images. According to the experimental results, ETSR-YOLO increases MAP at 0.5 by 6.6% on the TT100K dataset and 1.9% on the CSUST Chinese Traffic Sign Detection Benchmark 2021 (CCTSDB2021) dataset. Future research aims to enhance the model's performance in complicated road situations and improve computing efficiency for more accurate traffic sign recognition on embedded platforms in vehicles.

One limitation in many studies that train models on traffic signs is that they focus on traffic signs in clear weather and not traffic signs with difficult weather conditions such as rain and fog. This gap in training data can lead to reduced performance and accuracy when the models encounter these difficult weather signs in real-world scenarios. Secondly, many studies do not provide a comprehensive analysis of the limitations or potential drawbacks of YOLOv5 compared to other algorithms. Thirdly, most of the previous studies didn’t make a comparison between the different models and their results.

III. Data Collection and Methodology

A. Dataset

It was necessary to have a dataset of images to train deep-learning models. In the context of traffic sign detection and classification, the dataset needed to include various types of traffic signs, including clear and unclear signs, covering most of the possible factors that affect the visibility of traffic signs. After conducting a comprehensive search, an existing dataset was found to meet these specific requirements. Additionally, the available dataset of traffic signs varied in size, encompassing different weather conditions. Also, these types of traffic signs varied in shape, size, and popularity in terms of usage. Images were collected from the Roboflow dataset named "Road Sign Detector Image Dataset Computer Vision Project".

Finding a sufficient number of traffic signs was difficult, as they weren't abundantly available in most dataset sources, and it was challenging to find images in challenging weather conditions due to their limited availability. Extensive searching was conducted on multiple sources to assist in finding a wide range of traffic signs in challenging weather conditions. As a result, 3480 images (3,006 for training, 186 for testing, and 288 for validation) of traffic signs encompassing different and numerous classes were collected from Roboflow, with the aim of ensuring diversity and clarity to assist autonomous vehicles under challenging weather conditions. We did not find these data from any other free or open-source datasets, and had to use the data available on Roboflow. We searched other sources like Kaggle and GitHub, but could not find a ready-to-use dataset that met our requirements, so we could not train our models on different datasets.

B. Methodology

1) Yolo algorithms: The YOLO (You Only Look Once) algorithm is a highly popular and efficient object detection algorithm known for its innovation and speed [15]. YOLO works uniquely by analyzing the entire image in a single pass. Instead of using a proposal-based detection approach, YOLO divides the image into a grid of cells and predicts the bounding boxes and confidence scores for each cell in a single pass. This holistic approach gives YOLO the ability to leverage the overall context of the image to improve the accuracy of its predictions. Additionally, YOLO is characterized by its high response speed, making it suitable for applications that require fast object detection, such as autonomous driving and surveillance.

a) YOLOv8: YOLOv8 is an advanced object detection algorithm in computer vision. It has revolutionized the field by achieving superior detection accuracy and real-time performance using a single end-to-end neural network. YOLOv8 is widely utilized in various applications, such as autonomous driving, surveillance systems, and robotics, where rapid and accurate object detection is crucial. Its impressive performance and versatility have made it a popular choice among researchers and practitioners in the computer vision community.

b) YOLOv5: YOLOv5 is an enhanced version of the YOLO (You Only Look Once) architecture, renowned for its improved efficiency, accuracy, and speed in object detection tasks. It features a streamlined design and incorporates advanced techniques like a novel backbone network and multi-scale prediction strategy. YOLOv5 has gained significant popularity in domains such as autonomous driving, surveillance systems, and robotics, thanks to its balanced trade-off between detection accuracy and computational efficiency. It offers faster inference times while maintaining competitive performance, making it a preferred choice for real-time object detection applications.

2) VGG-16: VGG-16, or Visual Geometry Group 16, is a renowned deep convolutional neural network architecture known for its simplicity and effectiveness in image classification tasks. With 16 layers, including 13 convolutional layers and 3 fully connected layers, VGG-16 captures complex features from input images. Despite newer models surpassing its performance, VGG-16 remains a popular choice for transfer learning due to its strong feature extraction capabilities and publicly available pre-trained weights.

3) Training methodology: The primary objective of this study was to compare the performance of YOLO with previous studies in detecting traffic signs. Additionally, we employed the VGG-16 model to perform the same task, but with the classification of traffic signs. This comparison allowed us to assess and evaluate the effectiveness of both YOLO and VGG-16 in the context of traffic sign detection and classification. The models were trained using a dataset consisting of 3480 images and a set of hyperparameters that included epochs varying from 20 to 45 and batch sizes of 16 for Yolov5s, 16 for Yolov8n, and 16 for VGG-16. Below are the Table I, and II that show the hyperparameter settings.

TABLE I. THE HYPERPARAMETERS SET FOR YOLOV5 AND YOLOV8

Hyperparameters	YOLOv5	YOLOv8
Input image size	640	640
Epochs	45	32
Batch size	16	16
Optimizer	AdamW	AdamW
Initial learning rate	0.01	0.01
Final learning rate	0.01	0.01
Momentum	0.937	0.937
Weight decay	0.0005	0.0005

TABLE II. THE HYPERPARAMETERS SET FOR VGG-16

Hyperparameters	VGG-16
Target size	224
Epochs	20
Batch size	16
learning rate	0.01

4) Training environment: To meet our training requirements for both YOLO and VGG-16, we utilized Google Colab. This platform provided us with the necessary infrastructure to execute the Python code and leverage advanced computational power, including GPUs. By leveraging the capabilities of Google Colab, we were able to efficiently train the models and take advantage of the accelerated processing provided by GPUs. This expedited the training process and enabled us to achieve optimal performance for both YOLO and VGG-16.

IV. RESULTS AND DISCUSSION

In this section, we present the results obtained from training three different models: YOLOv5, YOLOv8, and VGG16. We discuss the performance of each model and provide an analysis of their strengths and areas for improvement.

A. YOLO Object Detection and Classification

YOLO versions 5, and 8 were used for object detection and classification of traffic signs under weather conditions.

YOLOv5, as shown in Table III, achieved mAP50s of 79.3%, 89.6%, 91.3%, 94.1%, and 94.2% over epochs 5, 10, 20, 40, and 45, respectively. The results show the high performance of the model. Furthermore, Fig. 1 displays the results for YOLOv5 at epoch 45. Additionally, Fig. 2 presents performance metrics for YOLOv5, including the precision of 92.37%, the recall rate of 90.85%, the mean average precision at an IoU threshold of 0.5 (mAP50) of 94.23%, and the mean average precision at IoU thresholds ranging from 0.5 to 0.95 (mAP50-95) of 70.28%. Fig. 3 shows the recall confidence curve for all classes 0.97 at 0.000, the precision confidence curve for all classes 1.00 at 0.964, the precision-recall curve for all classes 0.947 mAP 0.5, and the F1-confidence curve for all classes 0.92 at 0.689. Fig. 4 shows the training batch. Fig. 5 shows a sample of the validating batch prediction. Fig. 6 shows a sample of the validating batch label. The total estimated VRAM usage during training for YOLOv5 on a Tesla T4 GPU is approximately 8-12 GB. This includes memory for model parameters, activation maps, gradients, and batch data. The total estimated VRAM usage during inference is around 4-8 GB, primarily due to model parameters and activation maps, with lower requirements as no gradients are stored. YOLOv5 computation time is 61.68 minutes.

YOLOv8, as shown in Table IV, achieved mAP50s of 75.6%, 89.3%, 94%, 94.2%, and 95.3% over epochs 5, 10, 20, 25, and 32, respectively. The results show the high performance of the model. Additionally, Fig. 7 displays the results for YOLOv8 at epoch 32. Next, Fig. 8 presents performance metrics for YOLOv8, including the precision of 92.58%, the recall rate of 92.73%, the mean average precision at an IoU threshold of 0.5 (mAP50) of 95.31%, and the mean average precision at IoU thresholds ranging from 0.5 to 0.95 (mAP50-95) of 71.23%. Fig. 9 shows the recall confidence curve for all classes 0.97 at 0.000, the precision confidence curve for all classes 1.00 at 0.979, the precision-recall curve for all classes 0.958 mAP 0.5, and the F1-confidence curve for all classes 0.93 at 0.535. Fig. 10 shows the training batch. Fig. 11 shows a sample of the validating batch prediction. Fig. 12 shows a sample of the validating batch label. The total estimated VRAM usage during training for YOLOv8m on a Tesla T4 GPU is approximately 10-12 GB. This includes the memory for model parameters, activation maps, gradients, and batch data. The total estimated VRAM usage during inference is around 5-8 GB, primarily due to model parameters and activation maps, with lower requirements as no gradients are stored. YOLOv8 computation time is 59.64 minutes.

B. VGG16

Lastly, the VGG-16 model [13], [14] that we trained exhibited excellent performance, as demonstrated in Table V. It had achieved accuracies of 68%, 96.4%, 99.5%, and 100% for epochs 5, 10, 15, and 20, respectively. These results showcased the model's remarkable ability to classify images with a very high degree of accuracy. Fig. 13 shows the accuracy of the VGG16 model for the training epochs. Fig. 14 shows the loss of the VGG16 model for the training epochs. The accuracy curve steadily increased, reaching 98.68% by the 20th epoch, while the loss curve correspondingly decreased, indicating the model's effective learning and optimization during the training process. The VGG16 model has strong performance metrics, as shown in Fig. 15. It achieves a recall of 98.59%, precision of 100%, and F1 score of 99.29%. As you see in Figure 16, the confusion matrix shows the VGG16 model made 178 false positive predictions, where it incorrectly classified a sample as belonging to a certain class when the true class was different. However, it only made 8 false negative predictions, where it failed to correctly identify a sample's true class.

- False positives: the cases where something is incorrectly identified as positive or present when in reality it is negative or absent.
- False negatives: the cases where the diagnosis fails to identify something as positive or present when in reality it is positive or present.

Fig. 15. Confusion matrix for the VGG16 model.

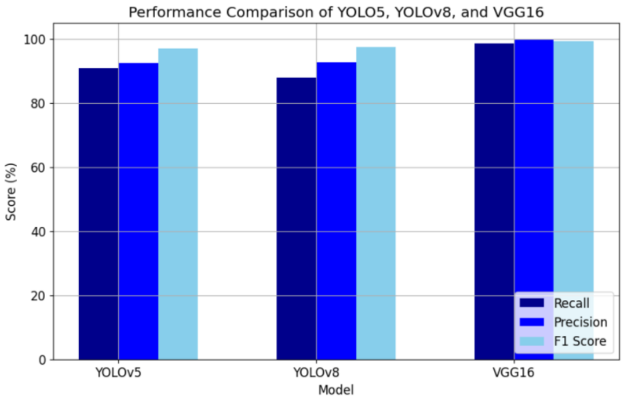

Fig. 16. Performance comparison of YOLO5, YOLOv8, and VGG16.

V. Overall Comparison and Insights

After reviewing the results of the three models, we found that the YOLOv5 model confirmed its fast inference speed, making it suitable for real-time applications such as autonomous driving. Although the accuracy is good, it is slightly lower than the other two models we evaluated. Also, there is a risk of overfitting, as this model may sometimes struggle to generalize to new, unseen data, and the model's performance may degrade in adverse weather conditions or with occluded or partially visible traffic signs. As for YOLOv8, it is one of the latest versions of the YOLO algorithm, and this model is generally characterized by its lightweight and efficiency. However, one of its drawbacks is that maintaining a balance between accuracy and inference speed may be a challenge, as the increasing model complexity can impact real-time performance. And the VGG16 model gave us remarkable results, as the model's ability to achieve an accuracy of 98.68% indicates its high capability to handle the challenges posed by adverse weather conditions and detect unfamiliar traffic signs. However, despite this, VGG16 is a relatively larger and more complex model compared to the YOLOv5 and YOLOv8 models, and the training and fine-tuning of the VGG16 model may be more time-consuming and resource-intensive compared to the YOLO models.

TABLE VI. YOLO and VGG-16 Results

Model	Epoch	Performance measure	for each class (Training)	The performance measure for all
YOLOv5	5	mAP50	79.3%	94.2%
	10		89.6%	
	20		91.3%	
	40		94.1%	
	45		94.2%	
YOLOv8	5	mAP50	75.6%	95.3%
	10		89.3%	
	20		94%	
	25		94.2%	
	32		95.3%	
VGG16	5	Accuracy	61.73%	98.68%
	10		96.65%	
	15		97.79%	
	20		98.68%	

In terms of results, in our evaluation of the YOLOv5, YOLOv8, and VGG16 models, we gained valuable insights. Regarding the model trained using YOLOv8, it achieved largely satisfactory results. It demonstrated a precision of 92.58%, a recall of 88%, a mAP50 of 95.31%, a mAP50-95 of 71.23%, and an F1 score of 97.5%. These metrics indicate its effectiveness in accurately detecting traffic signs under weather conditions. In the case of the model trained using YOLOv5, it achieved a precision of 92.37%, a recall rate of 90.85%, a mAP50 of 94.23%, a mAP50-95 of 70.28%, and an F1 score of 97%. These results indicate its ability to detect and classify objects with a reasonable level of precision and consistency across varying IoU thresholds. On the other hand, the model trained using VGG-16 exhibited a highly satisfactory result, achieving an accuracy of 98.68%, a recall of 98.59%, a precision of 100%, and an F1 score of 99.29%. This showcases its capability to classify images with a high level of accuracy. Table VI presents all the model's results for a clear comparison between them. . In terms of the overall evaluation, the performance comparison as shown in Figure 17, including their recall, precision, and F1 scores, indicates that the VGG-16 model outperforms the YOLOv5 and YOLOv8 models in terms of precision, recall, and F1 score. However, the YOLO models offer faster inference speed, which can be crucial for real-time applications like autonomous driving. The choice of the most suitable model ultimately depends on the specific requirements and trade-offs between accuracy, inference speed, and computational resources for the given application.

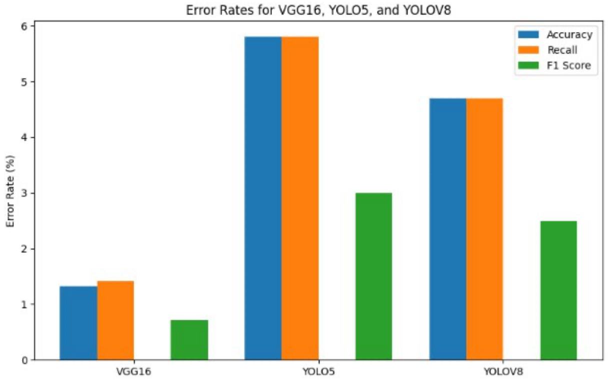

Fig. 17. The performance of different models using error rate.

VI. Analyze the Performance of Different Models Using Error Rate

The error rate is a measure that determines the accuracy of a machine learning model in making predictions. It is calculated by finding the percentage of incorrect predictions out of the total predictions. This metric is important for evaluating model performance and identifying which one performs better. In this analysis, we calculated the error rates for three different models: VGG16, YOLO5, and YOLOV8. These error rates were calculated with respect to three key performance metrics: Accuracy, Recall, and F1 Score.

1) Error Rate from Accuracy

Accuracy = 100 - model_accuracy

2) Error Rate from Recall

Recall = 100 - model_recall

3) Error Rate from the F1 Score

F1 Score = 100 - model_f1_score

- Performance metrics for VGG16:

  Accuracy: 98.68

  Recall: 98.59

  F1score: 99.29

  - VGG16 Error Rate from Accuracy: 1.32%
  - VGG16 Error Rate from Recall: 1.41%
  - VGG16 Error Rate from F1 Score: 0.71%

- Performance metrics for YOLOv5:

  Accuracy: 94.2

  Recall: 94.2

  F1score: 97.0

  - YOLOv5 Error Rate from Accuracy: 5.80%
  - YOLOv5 Error Rate from Recall: 5.80%
  - YOLOv5 Error Rate from F1 Score: 3.00%

- Performance metrics for YOLOv8:

  Accuracy: 95.3

  Recall: 95.3

  F1score: 97.5

  - YOLOv8 Error Rate from Accuracy: 4.70%
  - YOLOv8 Error Rate from Recall: 4.70%
  - YOLOv8 Error Rate from F1 Score: 2.50%

By comparing these results, we can observe that VGG16 outperforms YOLOv5 and YOLOv8 in terms of all the mentioned performance metrics. It also exhibits the lowest average error rate. Therefore, VGG16 is the best performing model among the three studied.

The main claims of our paper revolve around the comprehensive evaluation of multiple deep learning models for traffic sign detection and classification, with a particular focus on improving accuracy, especially in difficult weather conditions and with unfamiliar signs. Our findings highlight the great potential for further progress in this area, which is critical to enhancing the safety and efficiency of autonomous driving technologies.

VII. Conclusion

The field of traffic sign detection plays a crucial role in advancing autonomous driving systems and ensuring road safety. Many studies on traffic sign detection focus on detecting signs in normal weather conditions rather than challenging weather. This research aims to enhance the accuracy of traffic sign detection systems, particularly in challenging weather conditions such as rain and fog. Deep learning techniques and algorithms, including various versions of YOLO such as YOLOv5, YOLOv8, and VGG16, were employed to achieve precise recognition and interpretation of traffic signs.

The YOLOv5 model achieved a mAP50 of 94.2% after 45 iterations, while the YOLOv8 model demonstrated satisfactory results, with a mAP50 of 95.3% after 32 iterations and 95.2% after 45 iterations. The VGG16 model, which focuses on object classification, displayed high accuracy in training, reaching 98.68% after 15 iterations. Overall, the utilization of deep learning models, such as YOLOv5, YOLOv8, and VGG16, has shown significant potential in improving the accuracy and efficiency of traffic sign detection systems under challenging weather conditions. These models can be trained on labeled datasets to learn and recognize various shapes, colors, and symbols associated with road signs.

The research presented promising results in traffic sign detection under challenging weather conditions, contributing to the advancement of autonomous driving systems and promoting safer and more efficient roadways. Further optimization and refinement of the models can lead to even better performance.

The novelty of this study lies in its holistic evaluation of multiple YOLO versions and the VGG-16 model, which provides a more nuanced understanding of the performance and applicability of these deep learning techniques for traffic sign detection under diverse environmental conditions. This comparative approach represents a significant contribution to the field, as it goes beyond the limitations of previous studies that focused on a single YOLO version, and offers valuable insights for the development of advanced autonomous driving systems.

Ensemble IDO Method for Outlier Detection and N_2O Emission Prediction in Agriculture

Ahmad Rofiqul Muslikh, Pulung Nurtantio Andono, Aris Marjuni, Heru Agus Santoso
Faculty of Computer Science, Dian Nuswantoro University, Semarang, Indonesia

***Abstract*—Nitrous oxide (N_2O) emissions from agricultural activities significantly contribute to climate change, necessitating accurate predictive models to inform mitigation strategies. This study proposes an ensemble framework combining Isolation Forest, DBSCAN, and One-Class SVM to enhance outlier detection in N_2O emission datasets. The dataset, consisting of 2,246 rows and 21 columns, was preprocessed to address missing values and normalize data. Outlier detection was performed using each method individually, followed by integration through hard and soft voting techniques. The results revealed that Isolation Forest identified 113 outliers, DBSCAN detected 1,801, and One-Class SVM found 118. Hard voting identified 165 outliers, while soft voting detected 734, ensuring a refined dataset for subsequent modeling. The ensemble approach improved the accuracy of the XGBoost model for N_2O emission prediction. The best results were obtained using the Random Search Cross Validation hyperparameter tuning, with a test size is 20%, achieving a CV MSE of 0.0215, MSE of 0.0144, RMSE of 0.1200, MAE of 0.0723, and an R^2 of 0.6750. This study demonstrates the effectiveness of combining multiple outlier detection methods to enhance data quality and model performance, supporting more reliable predictions of N^2O emissions.**

Keywords*—Ensemble framework; outlier; detection; N2O emission; isolation forest; DBSCAN; one-class SVM

I. Introduction

Nitrous oxide (N2O) emissions from agricultural activities significantly threaten climate stability due to their high global warming potential [1], approximately 298 times greater than carbon dioxide [2]. Accurate prediction of N2O emissions is essential for effective environmental management and climate change mitigation. However, existing predictive models often struggle with outliers, which can skew results and reduce model accuracy [3]. Recent studies have highlighted the complexity of predicting N2O emissions due to various influencing factors, such as soil type, climatic conditions, and agricultural practices [4], [5]. Traditional predictive models, ranging from empirical observational models to more complex process-based models, face significant challenges in handling outliers, resulting from measurement errors, extreme weather events, or anomalies [6]. Effectively identifying and handlinghese outliers are crucial for improving model accuracy and reliability [7].

Outlier detection plays a critical role in enhancing the accuracy of predictive models. Various methods, such as Isolation Forest, DBSCAN, and One-Class SVM, have been effective in identifying outliers in environmental data [6], [3], [8]. These methods are essential for ensuring data quality and improving the reliability of predictive models used for N_2O emission analysis [9]. However, using these methods individually has limitations regarding parameter sensitivity and scalability. The proposed IDO ensemble framework combines these methods to provide a more robust and accurate outlier detection mechanism.

The comparative results differ across datasets due to varying data characteristics such as density, distribution, and noise levels. Isolation Forest an ensemble method isolates observations by randomly selecting a feature and then choosing a split value between the maximum and minimum values of the selected feature [10]. Isolation Forest efficiently handles high-dimensional data but may struggle with clustered anomalies. This technique has proven to be robust for detecting various types of outliers in well-log datasets, achieving an accuracy of 90.2% in distinguishing between inliers and outliers [11], [12].

Its efficiency in handling high-dimensional data makes it suitable for large and complex datasets. DBSCAN, a density-based clustering algorithm, identifies core, borderand noise points based on a specified radius and minimum number of points [13]. DBSCAN excels at identifying clusters in noisy data but requires precise parameter tuning. This method effectively detects noise and manages noisy datamaking it valuable for environmental data analysis where noise is common [11].

One-Class SVM, a machine learning algorithm for anomaly detection, constructs a boundary around normal data points to identify outliers [11]. One-Class SVM effectively defines decision boundaries in complex feature spaces but is sensitive to kernel choices. This technique is outstanding in detecting anomalies with high correctness, distinctiveness, and robustness, proving to be particularly useful in identifying rare but significant anomalies in agricultural datasets [9].

Although Isolation Forest, DBSCAN, and One-Class SVM each have unique strengths, using them individually has parameter sensitivity and scalability limitations. Combining these methods into an ensemble can provide more robust and accurate outlier detection [6] [14]. This ensemble framework leverages the strengths of each algorithm while mitigating their inherent weaknesses. Isolation Forest excels at managing high-dimensional data but can struggle with detecting clustered anomalies. DBSCAN is proficient at identifying clusters and noise but demands meticulous parameter tuning. One-Class SVM effectively defines decision boundaries but is sensitive to kernel choices.

By integrating these methods, this ensemble framework provides a comprehensive outlier detection mechanism, improving data quality and model performance.

The ensemble approach reduces reliance on precise parameter settings for any single method, thereby enhancing overall robustness. The ensemble method efficiently handles high-dimensional data by utilizing the strengths of Isolation Forest and One-Class SVM, while DBSCAN manages dense clusters and noise. The hard and soft voting mechanisms ensure that outliers identified by multiple methods are more likely to be genuine anomalies [15] [18], thereby reducing the likelihood of false positives and false negatives. By effectively identifying and removing outliers, the ensemble framework ensures higher quality data, leading to improved predictive model performance.

By integrating these methods, the IDO framework ensures comprehensive outlier detection, adapting to different data characteristics and improving overall model eprformance. For instance, Isolation Forest's random partitioning effectively isolates anomalies in datasets with high-dimensional features. In contrast, DBSCAN performs better in datasets with dense clusters and noise, identifying core points and noise points. One-Class SVM excels in scenarios with complex decision boundaries, distinguishing normal data from anomalies. The ensemble approach leverages these strengths, ensuring robust outlier detection across various datasets, thereby enhancing the quality and reliability of predictive models.

In addition to outlier detection, this study focuses on predictive modeling of N_2O emissions using the XGBoost algorithm. Known for its high performance and efficiency in handling large datasets, XGBoost has shown superior predictive capabilities compared to traditional models [16], [14]. Hyperparameter tuning is crucial for maximizing model performance, and this study compares the untuned XGBoost model with models optimized through Grid Search and Random Search techniques [17], [18], [19].

The models are evaluated using cross-validation techniques to assess their robustness and generalizability. Cross-validation helps mitigate the risk of overfitting by validating the model on different subsets of the data, ensuring comprehensive and robust performance evaluation [20]. Validation measures play a critical role in ensuring the robustness of predictive models.

Cross-validation techniques, including KFold and standard cross-validation, help mitigate overfitting by validating the model on different data subsets, ensuring comprehensive performance evaluation. Conducting thorough comparisons with existing related work is essential to highlight the advancements and improvements brought by the proposed model. Comparing performance metrics such as Mean Squared Error (MSE), Root Mean Squared Error (RMSE), Mean Absolute Error (MAE), and R^2 scores across different models provides valuable insights into the effectiveness of the proposed approach. This study also explores the impact of different test sizes on model performance, ensuring that the findings are applicable across various scenarios in agricultural data analysis.

Despite advancements in predictive modelling and outlier detection, integrating these methods effectively remains challenging. This research addresses this gap by developing and evaluating new outlier detection methods suitable for high-dimensional agricultural data and implementing ensemble methods to enhance robustness [21]. The study aims to improve the predictive accuracy of N_2O emissions models, providing valuable insights for environmental management and contributing to effective climate change mitigation strategies.

II. Method

To address the challenges in predicting N2O emissions and to enhance the accuracy of outlier detection, this study employs a comprehensive methodology combining advanced statistical techniques and ensemble learning.

A. Dataset

In this study, we utilized a comprehensive public dataset on nitrous oxide (N2O) emissions from agricultural activities provided by Saha et al. (2021) [21]. The dataset spans from 2002 to 2014, encompassing 2,246 entries and 21 distinct variables. This dataset is instrumental in exploring the effects of agricultural practices and environmental conditions on N2O emissions. It facilitates robust outlier detection and supports reproducibility, enabling comparative analyses across different studies [22][23].

Key variables in the dataset include temporal information such as the date, month, and year of the measurements, experimental details like the type of experiment, the purpose of the data usage, and replication identifiers. Environmental conditions are captured through variables like vegetation type and N_2O concentration, as well as the nitrogen application rate. Additionally, the dataset includes meteorological and soil data, including precipitation levels, air temperature, and days after treatment and seeding. Detailed soil properties such as water-filled pore space at a 25 cm depth, ammonium content, nitrate content, and the proportions of clay, sand, and soil organic matter are also recorded. These variables are crucial for understanding how seasonal conditions and soil characteristics impact N_2O emissions, providing essential insights for developing accurate predictive models and understanding the underlying influencing factors [24][25][26].

B. Data Preprocessing

This study us comprehensive preprocessing techniques, including normalization, data cleaning, and handling missing values, to prepare the N_2O emissions dataset for accurate analysis and effective outlier detection [24]. These steps are crucial for maintaining data quality, ensuring the dataset's suitability for model training, and achieving reliable results in classification and anomaly detection tasks [27]. The inherent null values and outliers in the dataset necessitated thorough preprocessing.

Outlier analysis revealed several types, such as point outliers from potential measurement errors or unusual local conditions, and contextual outliers, which seem normal independently but are abnormal in specific contexts, like unusually low emissions during periods of high microbial activity in winter [28][29]. Moreover, collective outliers can arise when data groups deviaterom the norm due to changes in agricultural practices [30]. Global outliers, representing extreme values beyond the typical data range, indicate rare events not accounted for by existing conditions or strategies [31]. These variations highlight the need for robust detection techniques to manage agricultural data's complexities.

Understanding dataset characteristics is essential before applying methods such as data augmentation or outlier detection. This is exemplified in the classification of rice leaf diseases, where model effectiveness is closely linked to the dataset's attributes [32]. Given the dataset's characteristics and the various types of outliers, we explored the application of ensemble methods for outlier detection. Ensemble methods, which combine predictions from multiple models, are recognized for producing more stable and accurate results. Techniques such as Isolation Forest, DBSCAN, and One-Class SVM have proven effective in identifying outliers [9] [11]. These methods complement each other by handling different aspects of outlier detection, such as identifying isolated points or anomalies within dense clusters. By integrating the results from multiple models, ensemble methods enhance the stability and accuracy of predictions, making them particularly suitable for the nuanced analysis required for N_2O emissions in agriculture [33]. This approach ensures a more robust analysis and improves the dataset's quality, facilitating more accurate and reliable N_2O emission predictions.

C. Outlier Detection

Outlier detection is essential for maintaining the accuracy of predictive models in N_2O emissions studies [34]. Outliers, which can result from measurement errors, data entry mistakes, or rare occurrences, significantly affect data analysis if not properly managed. Traditional detection methods, such as statistical tests, visualization, and distance measures, vary in their ability to identify global or local anomalies [35]. This study applies advanced techniques—Isolation Forest (IF), DBSCAN, and One-Class SVM—independently to robustly identify outliers in the N2O emission dataset. The IDO framework integrates these methods, leveraging their strengths to comprehensively address global and local outliers. This multi-method approach enhances the dataset's integrity and significantly improves the performance and reliability of predictive models, highlighting the importance of meticulous data handling in high-quality research.

D. Proposed Ensemble Method

This study introduces an advanced framework called IDO (Isolation Forest, DBSCAN, and One-Class SVM) to improve the detection of outliers in N_2O emission datasets from agricultural activities. The IDO framework combines three established outlier detection techniques into an ensemble approach, enhancing the accuracy and effectiveness of anomaly identification.

Isolation Forest (IF) effectively detect outliers, particularly in high-dimensional datasets. It works by isolating data points using random partitioning, identifying anomalies based on how quickly they can be isolated from the rest of the data [35]. Point x's isolation is measured by the path length h(x), which represents the number of splits required to isolate the point. For a dataset X, the Isolation Forest algorithm can be mathematically described by the following steps:

The first step is Feature Selection, and Random Split process described in (1) outlines the method of randomly selecting a feature $(\mathrm{f_j})$ from the set of all features $(\{\mathrm{f_1, f_2, \dots, f_d}\})$ and choose a random split value (s) within the range of this feature. After choosing the feature, a random split value (s) is selected within the range of the chosen feature. This random selection is fundamental to the Isolation Forest algorithm's ability to partition data and isolate anomalies effectively.

$$f_j \in \{f_1, f_2, \dots, f_d\} \text{ and } s \in \left[\min(f_j), \max(f_j)\right] \quad (1)$$

here f_j is a random chosen feature, and s is the split value within the range of f_j.

The second step, Recursive Partitioning process noted on (2), describes a critical step in the Isolation Forest algorithm.

$$\text{Left Child: } \{\mathrm{x} \in \mathrm{X} \mid \mathrm{x_{f_j}} \leq \mathrm{s}\}$$

$$\text{Right Child: } \{\mathrm{x} \in \mathrm{X} \mid \mathrm{x_{f_j}} > \mathrm{s}\} \quad (2)$$

This involves recursively applying the partitioning to the dataset, which creates a tree structure. The data is split into two subsets based on the selected feature (f_j) and split value (s). This recursive partitioning continues until each data point is isolated in a unique partition, or a predefined maximum tree depth is reached. This iterative splitting is crucial for the algorithm's ability to effectively isolate anomalies within the dataset.

The next step is Tree Construction. This involves recursively continuing the partition until each data point is isolated in its unique partition or the tree reaches a predefined maximum depth.

$$h(x) = \text{number of splits to isolate } x \quad (3)$$

Eq. (3) defines the Path Length $h(x)$ for each data point (x). This path length represents the number of splits or edges traversed from the root of the tree to the point's leaf node. The shorter the path length, the quicker the data point is isolated, indicating it is likely an anomaly. Calculating $h(x)$ is essential for determining how well each data point is isolated within the tree structure.

Eq. (4) describes the Anomaly Scoring process used in the Isolation Forest algorithm. This step utilizes the average path length $h(x)$ to compute the anomaly score for each data point (x). Points with shorter path lengths are more likely to be outliers because random partitions isolate them more quickly. The anomaly score for a data point (x) is given by:

$$\text{Score}(x) = 2^{-\frac{h(x)}{c(n)}} \quad (4)$$

where: $h(x)$ is the average path length of the data point(x), $c(n)$ is a normalization factor approximated by Eq. (5)

$$c(n) = 2H(n-1) - \frac{2(n-1)}{n} \quad (5)$$

and $H(i)$ is the i-th harmonic number defined as (6)

$$H(i) = \sum_{k=1}^{i} \frac{1}{k} \quad (6)$$

The final step in the Isolation Forest algorithm is Outlier Identification, where data points are classified based on their anomaly scores. A threshold is set to distinguish between normal points and outliers: points with scores above the threshold are considered normal, while those below are deemed outliers.

Following this, DBSCAN (Density-Based Spatial Clustering of Applications with Noise), Unlike Isolation Forest, which relies on random partitioning, DBSCAN is a density-based algorithm that clusters data points and identifies outliers as those that do not fit into any cluster [13]. Its effectiveness in identifying clusters and noise in spatial data makes it an apt choice for this ensemble [36]. Since there is no single mathematical equation that defines it, but rather a set of rules describing the clustering process, the general steps of the DBSCAN algorithm are as follows [37] [36].

Eq. (7) define the selecttion a point *P* from the dataset *D* that has not been visited.

$$P \in D \setminus V \tag{7}$$

where *V* is the set of visited points.

Eq. (8) define ϵ-neighborhood $N_\epsilon(P)$ of point P, which includes all points within distance ϵ from *P*

$$N_\epsilon(P) = \{Q \in D \mid \mathrm{dist}(P, Q) \leq \epsilon\} \tag{8}$$

where dist (P,Q) is the distance between points P and Q.

Eq. (9) define core point, if the ϵ -neighborhood $N_\epsilon(P)$ contains at least MinPts points, then P is a core point.

$$|N_\epsilon(P)| \geq \mathrm{MinPts} \tag{9}$$

where $|N_\epsilon(P)|$ denotes the cardinality of the ϵ -neighborhood of *P*.

Eq. (10) define cluster formation, if *P* is a core point, then all points Q in its ϵ-neighborhood $N_\epsilon(P)$ are added to the same cluster *C*.

$$Q \in N_\epsilon(P) \Rightarrow Q \in C \tag{10}$$

If P is associated with multiple clusters, those clusters are merged.

Eq. (11) and Eq. (12) define border point and noise identification. Points Q that are within the ϵ-neighborhood of a core point but do not satisfy the *MinPts* condition are classified as border points. Points that are not in the ϵ-neighborhood of any core point are considered noise or outliers.

$$Q \in N_\epsilon(P) \text{ and } |N_\epsilon(Q)| < \text{MinPts} \rightarrow \text{Q is border point} \tag{11}$$

$$Q \notin N_\epsilon(P) \text{ for any core point } P \rightarrow \text{Q is noise} \tag{12}$$

Eq. (13) define process iteration that repeat the steps until all points in the dataset *D* have been visited.

$$\forall P \in D,\ P \in V \tag{13}$$

Having outlined the DBSCAN algorithm, which excels in identifying clusters and outliers based on density, we now shift our focus to One-Class SVM. This method adopts a different approach, leveraging machine learning techniques to distinguish between normal and anomalous data points. One-Class SVM is particularly useful in scenarios where the dataset contains complex feature spaces, making it a robust choice for detecting outliers in agricultural N2O emission data.

One-Class SVM (Support Vector Machine) is a machine learning technique that models decision boundaries to separate normal data from outliers. It is adept at handling agricultural data, defining the regions in the feature space that correspond to typical data points, thus identifying anomalies outside these regions [38][39]. The following steps outline the One-Class SVM algorithm.

The algorithm starts by defining the One-Class SVM model using a training dataset ($\{x_1, x_2, \ldots, x_N\}$) where each data point x_i belongs to a d-dimensional feature space ($\in \mathrm{R}^{\mathrm{d}}$). Then the kernel selection, as defined by Eq. (14), involves choosing an appropriate kernel function to transform the input data into a higher-dimensional feature space, if needed. This step is crucial for capturing the complex relationships in the data. A commonly used kernel is the Radial Basis Function (RBF) kernel, which is expressed as follows:

$$\mathrm{K}(\mathrm{x_i}, \mathrm{x_j}) = \exp(-\gamma|\mathrm{x_i} - \mathrm{x_j}|^2) \tag{14}$$

where ($\gamma > 0$) is a parameter that defines the width of the kernel.

Eq. (15), Eq. (16) defines the optimization problem that aims to determine the decision boundary separating the majority of the data points from the outliers. This optimization process identifies the boundary that encloses the normal data within a specified region of the feature space while isolating the anomalies outside this region.

$$\min_{w,\xi,\rho} \frac{1}{2}|w|^2 + \frac{1}{\nu N}\sum_{i=1}^{N} \xi_i - \rho \text{ subject to:} \tag{15}$$

$$(w \cdot \phi(x_i)) \geq \rho - \xi_i, \quad \xi_i \geq 0, \quad i = 1, \ldots, N \tag{16}$$

where (w)is the normal vector to the decision boundary, ($\phi(\mathrm{x_i})$) is the feature mapping, (ξ_i) are slack variables allowing for some margin violations, (ρ) is the offset, and ($\nu \in (0,1]$) controls the fraction of outliers and support vectors.

Eq. (17) define decision function for determining whether a new data point x is an outlier is given by:

$$f(x) = (w \cdot \phi(x)) - \rho \tag{17}$$

where, A data point x is classified as normal if ($f(x) \geq 0$) and as an outlier if ($f(x) < 0$)

After defining the optimization problem in Eq. (18), the next step is to identify the support vectors, which are the data points closest to the decision boundary. These vectors are crucial as they shape the boundary and define the margin. The decision function is then applied to classify new data points as normal or outliers based on their position relative to this boundary, effectively separating typical data from anomalies.

Integrating these methods into the IDO ensemble framework leverages the strengths of Isolation Forest, DBSCAN, and One-Class SVM while compensating for their limitations. This combination provides a robust and comprehensive approach to outlier detection, which is essential for analyzing N2O emissions in agriculture, where data precision is critical for developing effective mitigation strategies.

The proposed method in Fig. 1 outlines an innovative ensemble approach to detect outliers in N_2O emission data. This approach combines Isolation Forest, DBSCAN, and One-Class SVM (the IDO model) into an ensemble framework to enhance accuracy and reliability in identifying outliers in agricultural N_2O emission datasets. The primary objective is to improve the quality of N_2O emission data [11], which will enhance the accuracy of emission prediction models and support efforts to mitigate climate change and promote sustainable agricultural practices.

As shown in Fig. 1, the IDO model framework integrates Isolation Forest, DBSCAN, and One-Class SVM to comprehensively detect outliers using an ensemble method. The process begins with raw data and includes preprocessing steps for outlier detection and result integration. Isolation Forest uses decision trees to isolate outliers, DBSCAN identifies clusters and outliers based on data density, and One-Class SVM uses a hyperplane for differentiation. These methods' results are combined to produce normalized scores, followed by a voting mechanism to identify outliers and set decision boundaries, refining the training dataset. This integrated approach enhances data analysis reliability and accuracy, making it particularly useful for complex environmental and agricultural datasets.

Once outliers are identified and handled, the dataset is split into test data for model evaluation and train data for model training. Feature engineering follows, selecting, transforming, and creating new features from the cleaned training data to optimize the dataset for training. The model is trained on this engineered data, including tuning to enhance performance. After training, cross-validation and performance evaluation validate the model's effectiveness. A validated model confirms its ability to generalize well to new data. The validated model then predicts N2O emissions using test data. This phase evaluates the model against real-world data. Hyperparameter tuning further refines the model parameters, improving accuracy and efficiency. This iterative process creates a feedback loop between feature engineering and parameter optimization.

Hyperparameter optimization is crucial for maximizing model performance [40]. It involves adjusting parameters significantly affecting the model's accuracy and generalization ability [41]. Each algorithm in the ensemble has specific parameters to tune: Isolation Forest adjusts the number of trees and sample size [42], DBSCAN optimizes epsilon and minPts [43], and One-Class SVM tunes nu and gamma for decision margin and complexity [44]. Techniques like Bayesian optimization can efficiently determine the best configurations by modeling performance and selecting the next parameters to test [41].

Proper hyperparameter optimization enhances model accuracy by balancing bias and variance, preventing overfitting and underfitting [40]. Optimized models fully utilize the dataset, providing precise insights for predicting N_2O emissions in agriculture. Integrating these methods within an ensemble framework creates a robust system for outlier detection in high-dimensional environmental data [41]. This approach improves data accuracy, enhancing analysis quality and prediction reliability. Implementing this method increases N_2O emission prediction accuracy, supporting climate change mitigation and sustainable agriculture. This framework combines outlier detection, model tuning, and evaluation into a robust process, ensuring accurate anomaly detection crucial for N_2O emission prediction.

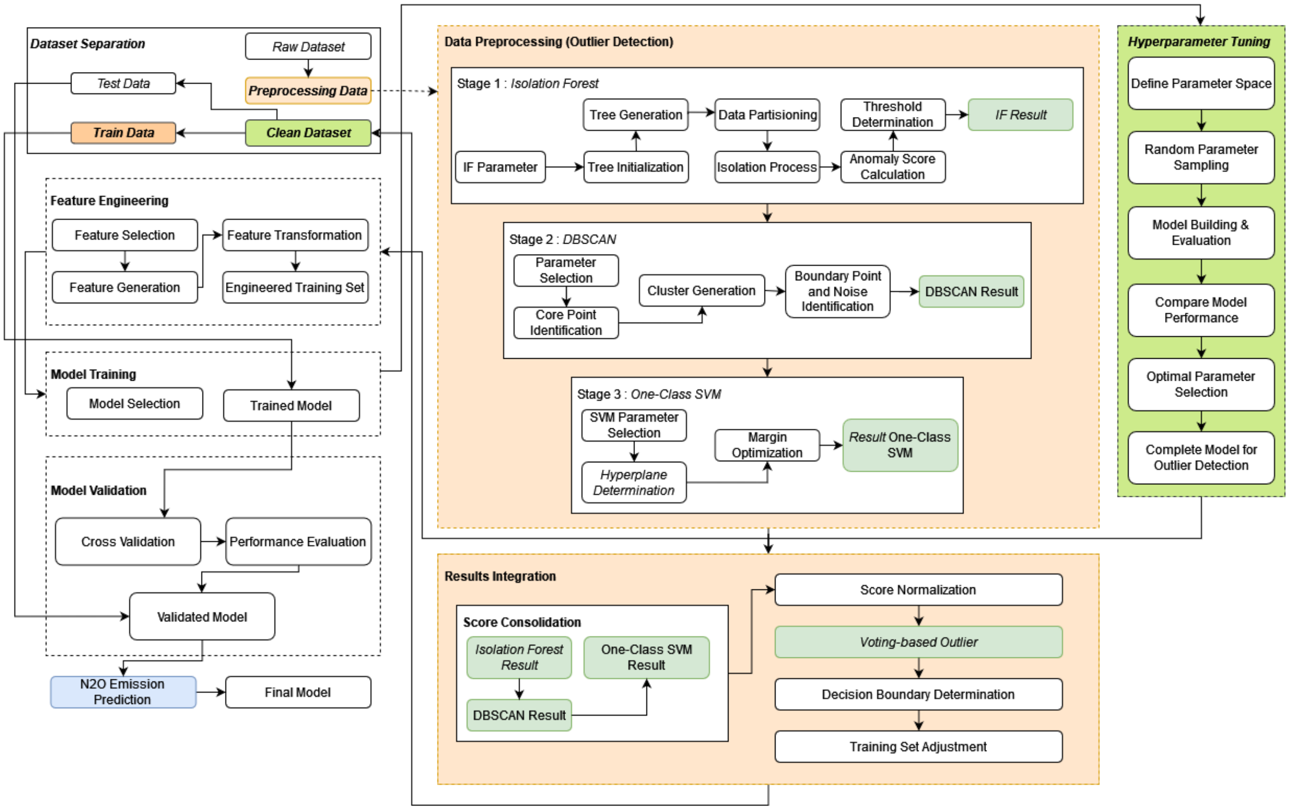

Fig. 1. Proposed model outlier detection with IDO (Isolation Forest – DBSCAN – One-Class SVM) ensemble algorithm.

III. Results

Predicting nitrous oxide (N_2O) emissions in agriculture is challenging due to complex factors. This section examines how advanced machine learning techniques, like outlier detection and ensemble methods, improve the accuracy of N_2O predictions using the XGBoost model.

A. *Outlier Detection using Ensemble IDO (IF-DBSCAN-OneClassSVM)*

Outlier detection improves model performance by identifying and removing anomalies. Combining Isolation Forest (IF), DBSCAN, and One-Class SVM, the IDO ensemble approach enhanced N_2O emission prediction accuracy. Fig. 2 shows a box plot of N_2O levels, focusing on the 2,072 inliers identified by the IDO method. This cleaned dataset provides a clearer view of the central distribution. The median N_2O level is 1.81, while the mean is 3.22, indicating a slight right skew due to higher inlier values.

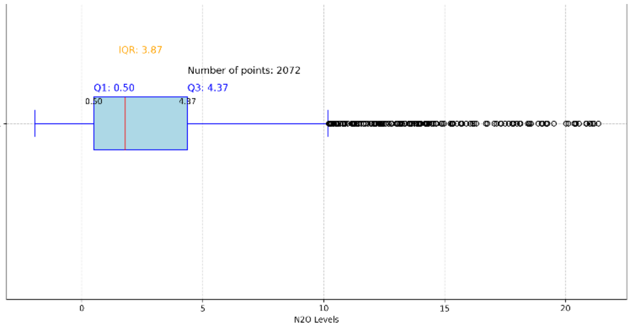

Fig. 2. The inliers identified after applying IDO.

The interquartile range (IQR) for N_2O levels is 3.87, spanning from the 25th percentile (0.50) to the 75th percentile (4.37), showing variability within the central 50% of the data. The range of inliers stretches from -1.94 to 21.36. This indicates that most N_2O levels are concentrated at the lower end but vary significantly within the inliers. Detecting outliers is crucial as it helps exclude extreme values that could distort the dataset. Using the IDO ensemble method effectively removes these outliers, providing a cleaner, more accurate dataset for analyzing and predicting N_2O levels.

Table I summarizes the outlier detection results using Isolation Forest, DBSCAN, and One-Class SVM, highlighting the value of employing multiple techniques. Each method identified distinct sets of outliers, reflecting their unique strengths. Isolation Forest, which isolates points requiring fewer partitions, identified 113 outliers and 2133 inliers. DBSCAN detected 1801 outliers out of 2246 data points, leaving 445 inliers. One-Class SVM, found 118 outliers and 2128 inliers.

TABLE I. N_2O Outlier Detection Result

Method	Outliers	Inliers
Isolation Forest	113	2133
DBSCAN	1801	445
One-Class SVM	118	2128

Applying hard and soft voting methods refined these results, removing the most consistently identified outliers. This process enhanced the dataset's quality and representativeness, crucial for effective predictive modeling.

B. *Voting-based Outlier Detection*

Integration of outlier detection results from Isolation Forest, DBSCAN, and One-Class SVM was done using Hard and Soft Voting techniques as shown in Table II. The analysis of voting-based outlier detection methods reveals distinct differences in their ability to identify outliers and inliers within the dataset.

TABLE II. Voting-based Outlier Detection Result

Voting Method	Outliers	Inliers
Hard Voting	165	2081
Soft Voting	734	1512

Hard voting identified 165 outliers, leaving 2081 data points as inliers. In contrast, soft voting detected a significantly higher number of outliers, amounting to 734, with the remaining 1512 data points classified as inliers. These results illustrate the varying sensitivity and specificity of the two voting methods, with soft voting being more inclusive in its outlier detection compared to the more stringent hard voting approach.

Post-voting, the XGBoost model's performance was evaluated without cross-validation to set a baseline. Evaluations across test sizes of 20%, 25%, 30%, and 35% aimed to assess the model's robustness and accuracy. Key metrics such as Mean Squared Error (MSE), Root Mean Squared Error (RMSE), Mean Absolute Error (MAE), and R^2 score were used to gauge initial effectiveness.

C. *XGBoost Model Evaluation with Cross-Validation*

In evaluating the XGBoost model's performance, two cross-validation methods were compared: KFold XGBoost (xgb.cv) and Standard Cross Validation (cross_val_score). The results in Tables III and IV, demonstrate the effectiveness of both approaches in enhancing model robustness.

TABLE III. Prediction Evaluation with KFold XGBoost

Test Size	CV MSE	MSE	RMSE	MAE	R2
20%	0.1892	0.0361	0.1900	0.1135	0.1847
25%	0.1917	0.0346	0.1860	0.1139	0.1815
30%	0.1981	0.0330	0.1816	0.1138	0.1848
35%	0.1985	0.0297	0.1724	0.1102	0.1943

KFold XGBoost produced Mean Squared Error (MSE) values ranging from 0.0297 to 0.0361, Root Mean Squared Error (RMSE) values from 0.1724 to 0.1900, Mean Absolute Error (MAE) values from 0.1102 to 0.1139, and R^2 scores between 0.1815 and 0.1943.

TABLE IV. Prediction Evaluation with Standard Cross Validation

Test Size	CV MSE	MSE	RMSE	MAE	R^2
20%	0.0259	0.0143	0.1195	0.0738	0.6776
25%	0.0266	0.0165	0.1286	0.0829	0.6091
30%	0.0269	0.0155	0.1245	0.0791	0.6174
35%	0.0289	0.0152	0.1234	0.0789	0.5876

The results are summarized in Table IV, highlighting various performance metrics. For a test size of 20%, the model exhibited the best performance, achieving the lowest CV MSE of 0.0259 and MSE of 0.0143. Additionally, this configuration resulted in the lowest RMSE of 0.1195 and MAE of 0.0738, along with the highest R² score of 0.6776, indicating that the model could explain a substantial portion of the variance in the data.

These results collectively demonstrate that the model performs optimally at a test size of 20%, balancing error metrics and explanatory power. This optimal performance highlights the model's robustness in predicting N_2O emissions under this specific configuration.

D. Hyperparameter Tuning using GridSearchCV and RandomizedSearchCV

XGBoost model using two hyperparameter tuning methods: GridSearchCV and RandomizedSearchCV. The results, detailed in Tables V and VI, demonstrate that GridSearchCV slightly outperforms RandomizedSearchCV in terms of key performance metrics but at a higher computational cost.

TABLE V. XGBOOST GRIDSEARCHCV HYPERPARAMETER TUNING EVALUATION

Test Size	CV MSE	MSE	RMSE	MAE	R²
20%	0.0223	0.0150	0.1223	0.0750	0.6621
25%	0.0230	0.0157	0.1252	0.0807	0.6293
30%	0.0238	0.0151	0.1229	0.0791	0.6268
35%	0.0265	0.0138	0.1175	0.0755	0.6256

GridSearchCV showed Mean Squared Error (MSE) improvements ranging from 2.8% to 6.5%, Root Mean Squared Error (RMSE) improvements from 3.8% to 6.1%, and Mean Absolute Error (MAE) reductions from 4.9% to 10.8% over the untuned model.

TABLE VI. XGBOOST RANDOMIZEDSEARCHCV HYPERPARAMETER TUNING EVALUATION

Test Size	CV MSE	MSE	RMSE	MAE	R²
20%	0.0215	0.0144	0.1200	0.0723	0.6750
25%	0.0222	0.0152	0.1234	0.0789	0.6397
30%	0.0228	0.0150	0.1224	0.0775	0.6299
35%	0.0255	0.0138	0.1173	0.0756	0.6271

RandomizedSearchCV also improved performance with MSE enhancements from 2.8% to 4.9%, RMSE improvements from 3.9% to 5.7%, and MAE reductions from 4.9% to 8.4%. Although GridSearchCV provided slightly better results, it required significantly more computational resources and time, whereas RandomizedSearchCV was 20-30% faster and more efficient.

Fig. 3 and Fig. 4 visually compare these tuning methods across different test sizes (20%, 25%, 30%, and 35%), focusing on metrics such as Cross-Validation MSE, MSE, RMSE, and MAE. Fig. 3 illustrates the comparison of MSE across different tuning methods. GridSearchCV and RandomizedSearchCV exhibit lower and more stable MSE values than KFoldXGBoost, with StandardCrossVal consistently showing the lowest and most stable MSE values across all test sizes.

In comparison, in Table IV Standard Cross Validation showed significantly better performance with lower MSE values (0.0143 to 0.0165), RMSE values (0.1195 to 0.1286), MAE values (0.0738 to 0.0829), and much higher R² scores (0.5876 to 0.6776). as R² scores that explain a substantially higher percentage of variance in the data. This suggests that Standard cross-validation provides more reliable and accurate assessments for model evaluation.

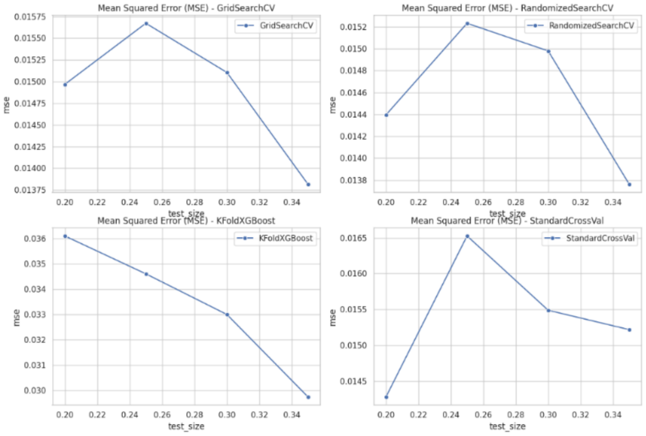

Fig. 3. Comparison of MSE evaluation performance.

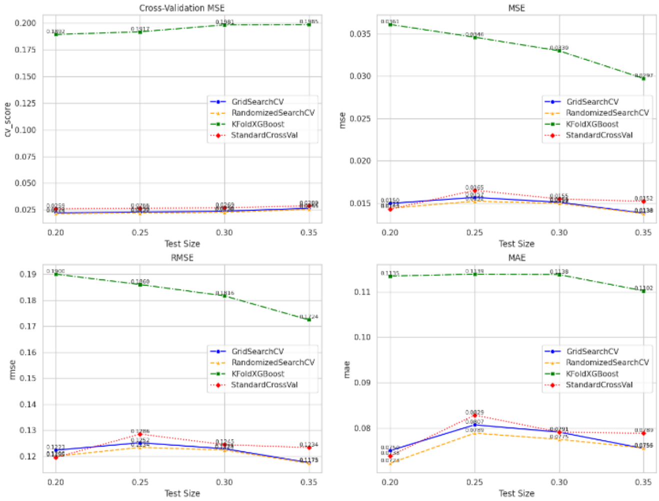

Fig. 4. Comparison of MSE evaluation with different test size.

Fig. 4 expands on these findings by comparing Cross-Validation MSE, RMSE, and MAE across the tuning methods. KFoldXGBoost has the highest Cross-Validation MSE values, indicating higher variance. In contrast, StandardCrossVal and Randomized-SearchCV consistently achieve lower MSE and RMSE values, with StandardCrossVal performing best overall. For example, at a test size of 20%, StandardCrossVal achieves an MSE of 0.0143 compared to KFoldXGBoost's 0.0361, indicating a significant performance advantage.

Similarly, StandardCrossVal shows the lowest RMSE and MAE values, signifying the smallest average prediction errors. At the same test size of 20%, StandardCrossVal achieves an RMSE of 0.1195 and an MAE of 0.0738, compared to KFoldXGBoost's RMSE of 0.1900 and MAE of 0.1135, showcasing a notable reduction in error rates. Overall, the comparative analysis highlights a trade-off between computational efficiency and model performance.

While GridSearchCV offers marginally better performance, RandomizedSearchCV provides a more practical balance of speed and efficiency, making it suitable for scenarios demanding quicker turnaround times. StandardCrossVal emerges as the most consistent method across all performance metrics, suggesting its robustness and reliability for hyperparameter tuning in XGBoost models.

This analysis emphasizes that the choice of hyperparameter tuning method should consider both the performance improvements and computational resources available. RandomizedSearchCV is an efficient choice for most practical applications, especially in the context of agricultural N_2O emission predictions.

IV. Discussion

In this study presents an advanced ensemble framework that enhances outlier detection in agricultural datasets by combining Isolation Forest, DBSCAN, and One-Class SVM. This integrated approach overcomes issues like parameter sensitivity and scalability associated with individual methods. The researchers processed a dataset containing 2,246 entries and 21 variables, was carefully preprocessed to handle missing values and normalize data.

The ensemble framework's hard and soft voting mechanisms refined outlier detection, identifying 165 outliers with hard voting and 734 with soft voting. Optimized using Random Search Cross Validation, the XGBoost model showed improved predictive performance, with a Mean Squared Error (MSE) of 0.0144 and an R^2 of 0.6750, highlighting the approach's effectiveness in enhancing data quality and supporting accurate N_2O emission predictions critical for climate change mitigation.

Given these findings, it is crucial to delve deeper into the methodologies and their implications on model performance. The study further explores the hyperparameter tuning methods, specifically GridSearchCV and RandomizedSearchCV, and analyzes their impact on the XGBoost model's performance.

A. Comparative Analysis

Outlier detection in N2O emission datasets is challenging due to agricultural data's complexity and high dimensionality. The proposed IDO (Isolation Forest – DBSCAN – One-Class SVM) ensemble framework addresses this by combining three powerful algorithms: Isolation Forest, DBSCAN, and One-Class SVM. Isolation Forest effectively identifies anomalies in high-dimensional data, DBSCAN excels at detecting clusters and differentiating noise based on density, and One-Class SVM distinguishes between normal data and anomalies.

By leveraging these methods through a voting mechanism, the IDO framework ensures accurate outlier detection and enhances data quality, making it highly suitable for analyzing agricultural N2O emissions.

In contrast, previous research has explored different approaches to enhancing outlier detection and clustering validity. For instance, [42] focused on improving cluster validity indices using an ensemble of K-means, K-means++, and Fuzzy C-means clustering algorithms. While this method effectively improved cluster separation, it struggled with robustness in high-dimensional and variable datasets. Similarly, [43] aimed to balance diversity and accuracy in unsupervised outlier ensembles primarily targeting clustering methods. However, this approach often overlooked anomalies that did not form distinct clusters.

Other studies, such as [44], combined multiple detection algorithms to achieve high accuracy in high-dimensional data, but this came at the cost of increased computational complexity. For instance, [45] utilized Isolation Forest with satellite data to detect crop anomalies, achieving high true positive rates but with limited applicability to other types of data. The EBOD method in study [46] effectively handled noisy datasets but lacked the adaptability needed to address the specific challenges of agricultural N2O emissions. While effective in certain contexts, these methods often failed to provide a comprehensive solution for diverse and high-dimensional datasets typical in environmental studies. Table VII shows the comparative analysis of outlier detection methods.

TABLE VII. Comparative Analysis of Outlier Detection Methods

Study	Dataset	Method	Evaluation Metrics	Key Findings
[42]	General clustering datasets	Ensemble of K-means, K-means++, and Fuzzy C-means	Cluster Validity Indices	Improved cluster validity indices post outlier removal. Enhances data quality in various datasets.
[43]	Various real-world datasets	Diversity-Accuracy Balanced Ensemble	True Positive Rate, Diversity-Accuracy Balance	Achieved high true positive rates and balanced detection diversity and accuracy.
[44]	High-dimensional datasets	Ensemble of LOF, KNN, HBOS, iForest, COPOD, PCA	Accuracy, ROC	High accuracy and ROC in detecting outliers in high-dimensional data.
[45]	Sentinel-1 & Sentinel-2 crop data	Isolation Forest with Sentinel-1 and Sentinel-2 data	True Positive Rate	Detected crop anomalies with 94.1% true positive rate for rapeseed and 95.5% for wheat.
[46]	Noisy datasets	EBOD (Ensemble-Based Outlier Detection)	Outlier Detection Accuracy, Noise Robustness	Effective in noisy environments, providing robust outlier detection across various noisy datasets.

Integrating Isolation Forest, DBSCAN, and One-Class SVM, the IDO framework demonstrated superior performance in detecting outliers within N_2O emission datasets. This method identified 113 outliers with Isolation Forest, 1801 with DBSCAN, and 118 with One-Class SVM. Through hard voting, 165 outliers were confirmed, and soft voting identified 734 outliers. This comprehensive detection approach significantly enhanced the dataset's quality and improved the predictive accuracy of the XGBoost model, achieving an R^2 of 0.6750, MSE of 0.0144, RMSE of 0.1200, and MAE of 0.0723. Compared to other methods, the IDO framework provided a more robust, adaptable, and accurate approach for high-dimensional anomaly detection, demonstrating its effectiveness in enhancing N_2O emission predictions.

V. Conclusion

This study highlights the effectiveness of advanced machine learning techniques, particularly cross-validation and hyperparameter tuning, in enhancing the predictive accuracy of the XGBoost model for N2O emissions. Standard Cross Validation outperforms other methods, achieving the lowest errors and highest stability, with significant reductions in RMSE, MAE, and MSE values as low as 0.0143. GridSearchCV delivers slightly better performance metrics but at a higher computational cost, while RandomizedSearchCV provides an efficient alternative with comparable performance improvements. These findings are crucial for improving N2O emission predictions, which are vital for environmental management and climate change mitigation.

Future research should explore sophisticated models and methods, such as deep learning, diverse ensemble learning models, and advanced hyperparameter optimization techniques like Bayesian optimization, to further enhance predictive accuracy and efficiency. Additionally, developing hybrid models and leveraging transfer learning from related datasets could more effectively capture the complex relationships in N2O emissions data. In summary, the choice between GridSearchCV and RandomizedSearchCV depends on balancing computational efficiency and model performance, with RandomizedSearchCV offering a practical solution under computational constraints.

***Abstract*—The lack of a scientific and reasonable optimal evacuation path planning scheme is one of the main causes of casualties in fire accidents. In addition to the high temperature and harmful smoke in the fire environment, the crowding problem caused by the change of the position of the crowd in the evacuation process will also affect the evacuation effect. Therefore, by improving the multi-agent depth deterministic strategy gradient algorithm, an AMADDPG (Adjacency Multi-agent Deep Deterministic Policy Gradient) model suitable for fire evacuation is proposed. First, the dangerous grid area is defined, and the influence of congestion degree and nearest exit is considered at the same time. The learning framework of "distributed execution and centralized local learning" is adopted to realize experience sharing among neighboring agents. Improve the learning efficiency and evacuation effect of the model. The experimental results show that the model can basically adapt to the complex and dynamic fire environment well, achieve the optimal path planning within 30, and ensure that the degree of congestion on the evacuation path is maintained within 0.5, which can achieve the safe evacuation goal. Meanwhile, compared with the MADDPG algorithm, the model has obvious advantages in terms of training efficiency and stability. It has good application value.**

Keywords*—Fire evacuation path; congestion degree; dangerous grid; multi-agent; Multi-Agent Deep Deterministic Policy Gradient

I. Introduction

In recent years, fire accidents occur frequently and become one of the major disasters threatening public safety, which not only brings huge property losses, but also often causes serious casualties. According to statistics, 825,000 fires were reported in China in 2022, with 4,175 casualties and direct property losses of 7.16 billion. The main causes of casualties are the sudden occurrence of fire, the blindness of crowd evacuation and the lack of scientific measures to guide crowd evacuation [1]. It is an urgent problem to provide reasonable and feasible optimal evacuation path planning scheme for trapped personnel, improve the safety evacuation efficiency of the crowd, and maximize the reduction of casualties in the fire accident.

At present, many scholars have carried out a lot of research on fire evacuation path planning. Zhong and Yu [1] proposed the idea of building a real-time fire evacuation system for smart cities based on the Internet of Things, using Floyd algorithm and building topology to plan the optimal evacuation path for personnel; Ye and Pan [2] proposed a path planning intelligent model based on BIM (Building Information Modeling) and cellular automata, and added dynamic obstacle model and random catastrophic fire model to the fire field, which can scientifically and efficiently avoid static and dynamic obstacles; Choi and Chi [3] used the smoke propagation prediction data provided by the fire dynamics simulator to improve the A* algorithm [4-5] on the basis of considering the safety status of subsequent nodes in the path, so as to find the optimal evacuation path and improve the algorithm; Liang and Wang [6] targeted the comprehensive building fire, considering the effects of fire products and crowd density on personnel escape speed, a personnel evacuation path planning model based on improved ant colony algorithm [5,7-8] was constructed; Dong et al. [9] applied the combination empowerment method to assign reasonable evacuation priorities to different crowd gathering points in view of indoor fires in commercial buildings, and optimized Dijkstra algorithm [10-12] to solve the congestion problem on the evacuation path.

The traditional path planning algorithms above are mostly based on static scenes and require complete evacuation environment information, which is not consistent with the actual evacuation situation. DRL (Deep Reinforcement Learning) algorithm [13] is one of the hotspots in the field of artificial intelligence research and is suitable for solving complex decision problems in unknown environments [14]. It has been applied to many fields such as robot control [15], military deduction, path planning [16-17], etc. Ni et al. [18] proposed a collaborative double-depth Q network algorithm to obtain good path planning results through the interactive learning experience between agents and dynamic environments in multi-exit fire scenarios. Zhang et al. [19] combined Deep Reinforcement Learning with multiple agents to improve the global guidance strategy and neural network structure, so as to be suitable for personnel evacuation in complex dynamic and multi-exit environments. Although the above crowd evacuation planning method has effectively solved the evacuation path optimization problem of the dynamic change of the fire danger area over time in the multi-exit fire scenario in practical application, there are still some problems, such as not considering the congestion caused by the change of the crowd position status in the evacuation process, and the punishment for deviating from the nearest exit in the multi-exit fire scenario. Therefore, this paper proposes an AMADDPG (Adjacency Multi-agent Deep Deterministic Policy Gradient) model suitable for fire evacuation. Through mathematical modeling of fire path planning, The MADDPG (Multi-agent Deep Deterministic Policy Gradient) algorithm is improved to realize evacuation under complex dynamic fire environment.

This study makes two primary contributions. First, the danger grid, congestion degree, and distance from the agent to the exit in fire evacuation path planning are mathematically defined, and the fire evacuation is modeled as a reinforcement learning problem in multi-agent environment. Through the definition of multi-agent state space and action space as well as reward function, the optimal fire evacuation path planning is realized to maximize the reduction of personnel crowding, avoidance of dangerous areas, and multi-exit fire scenarios. Second, the learning framework of "distributed execution and centralized local learning" is adopted to reduce the complexity of network training and show obvious advantages in training speed and system stability.

The rest of this article is organized as follows. Section I is given to model the fire environment and establish the mathematical model of fire path planning. Section II introduces the basic principle of MADDPG algorithm and the specific implementation of its improved algorithm AMADDPG. Section III introduces the construction of the fire environment of the fire evacuation experiment. In Section IV, the results of the fire evacuation experiment are analyzed. Discussion is given in Section V. Finally, in Section VI, the main research results of this study and the next research plan are summarized.

II. Material and Research Method

A. *Problem Description and Modeling*

In a multi-exit fire environment, personnel in each room of the building must avoid dangerous roads such as high temperature and heavy smoke, and quickly arrive at the nearest exit under the guidance of reasonable evacuation path planning to minimize casualties and property losses. To facilitate the research, the following assumptions are made:

1) The building is simplified into a two-dimensional finite plane space where the location of obstacles and safety exits is known.

2) Fire site information can be obtained in real time through sensor devices, such as temperature, smoke and toxic gas detection.

3) All evacuees in each room are regarded as one agent, and each agent is numbered as $\{Agent_i,\ i=1,2,3\ldots,n\}$, and the initial location of each agent is known, ignoring the impact of individual differences of evacuees on the speed of personnel movement.

a) Environmental modeling: In this paper, the grid method [20] is adopted to model the building plan, which is divided into several grids of equal size and non-overlapping. Each grid represents a feasible area or obstacle area with a length of 1m. In the feasible area, personnel can move freely, which is represented by white grid. While in the obstacle area, personnel cannot pass through, which is represented by black grid, usually a wall, column of a building. Grid coordinates increase from left to right, from bottom to top, and are represented by their center point coordinates. Fig. 1 shows the building plan created using the grid method. The grid coordinates in the lower left corner are (0, 0), and, the grid coordinates in the upper right corner are (m-1, n-1), and m, n are the number of grids in the horizontal and vertical directions, respectively. When a fire occurs, if the temperature, smoke visibility and toxic gas volume concentration in the feasible area grid exceed the preset critical value, it becomes an impassable dangerous grid.

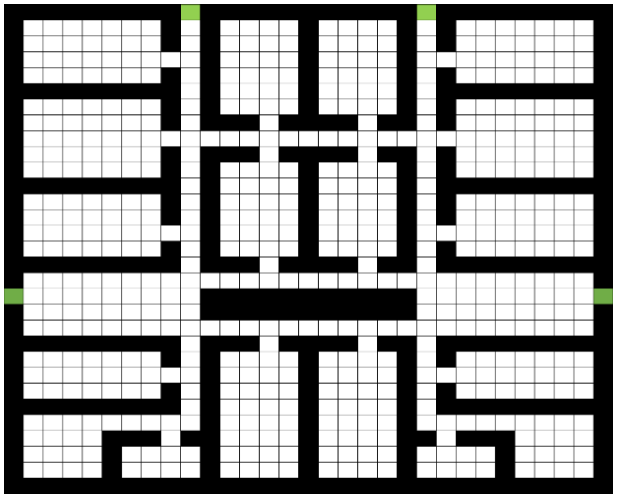

Fig. 1. Building modeling with grid method.

b) Mathematical model of fire path planning: (1) Definition of dangerous grid: In a fire environment, fire products such as the volume fraction of toxic gas (CO), smoke visibility, and temperature will affect the life safety of evacuees. If the evacuation path planning guides personnel to enter dangerous areas, casualties may be caused. Therefore, according to the effect of CO volume fraction, smoke visibility and temperature on human body in fire [21-22], the dangerous grid is defined,

$$G_{xy}=\{(x,y)\,|\,0<VIS<3\cup\varphi\ \ (CO)\geq 0.5\cup T_s\geq 70\} \tag{1}$$

where, G_{xy} is the actual state of the grid at coordinates (x, y), *VIS*, $\varphi(CO)$ and T_s are smoke visibility, CO volume fraction and ambient temperature in the grid respectively.

1) Congestion degree

The congestion degree of evacuation directly affects the speed of movement and evacuation time of personnel, and will greatly reduce the efficiency of evacuation in serious cases. In order to represent the congestion degree of evacuees in a certain area during evacuation, the concept of congestion degree [23] is introduced to reflect the congestion of evacuation channels with time and space dimensions.

$N(t)$ is defined as the number of evacuees in the evacuation channel at evacuation time *t*, $C(t)$ is the passage capacity of the channel,

$$C(t) = \frac{SA_q}{\pi r^2} \tag{2}$$

where SA_q is the area of the evacuation channel, and the evacuees are regarded as circular particles, r is 1/2 of the normal shoulder width of people, usually takes a value of 0.25 m. $c = N(t)/C(t)$ represents the congestion degree of the evacuation channel at time *t*. The greater the value, the more serious the congestion degree in the corresponding channel. When *c*≤0.5, the interference between evacuees is small and has no impact on the evacuation process and efficiency. But when *c*>0.5, the evacuation pedestrians began to be crowded, and the degree of congestion increased exponentially with the increase of saturation.

Calculate the congestion degree c_t^i of the $Agent_i$ located at coordinate (x^i, y^i) at time *t* in evacuation channel *P*. For the convenience of the research, assume that the evacuees in each agent are evacuated in a one-line formation, $(x^i, y^i) \in P$. The area of evacuation channel is denoted as SA_{real}, and N^i is the number of evacuees of the $Agent_i$. Consider it in the following two cases:

i) When there is no other agent in the evacuation channel, $N(t) = N^i$, $SA_q = SA_{real}$.

ii) Otherwise, $N(t) = N^i + \sum_{j=1}^{k} N^j$, $SA_q = SA_{real}$, where N^j is the number of evacuees of the $Agent_j$ located at coordinates (x^j, y^j), $(x^j, y^j) \in P$.

2) The distance between the agent and the exit

For the need of fire safety, the Code for Fire Protection in Building Design expressly stipulates the number of safety exits for public buildings: each fire protection zone or each floor of a fire protection zone in a public building shall have no less than 2 safety exits. In the multi-exit fire environment, when the number of evacuees and the initial location are determined, the choice of the nearest exit must be considered to achieve the optimal path planning. In this paper, Manhattan distance is used to define the distance between evacuees and each exit. Assuming that the $Agent_i$ is located at the evacuation grid at coordinates (x^i, y^i), and define the distance between the j exit at coordinates (x^j, y^j) is defined, $d_j^i = \left|x^i - x^j\right| + \left|y^i - y^j\right|$. And for the exit set $\{e_j, j = 1,2,3,...,m\}$, the exit number closest to the evacuee $Agent_i$ is $q = \arg\min_j \{d_j^i, j = 1,2,3,...,m\}$, the coordinate is (x^q, y^q).

B. Principle of Algorithm

1) *MADDPG algorithm*: Multi – agent Deep Deterministic Policy Gradient algorithm (MADDPG) applicable to traditional reinforcement learning method to handle the multi-agent cooperation task [24], by empirical playback mechanism and "centralized training, distributed execution" framework to learn. As shown in Fig. 2, each agent has an Actor network and a Critic network. During the training process, each agent interacts with the environment through its own Actor network according to the local information of its own state, to obtain action strategies, and evaluates the action of the Actor network according to the global information of the action state of all agents through the Critic network. This network structure effectively improves the policy stability and robustness of multi-agent systems.

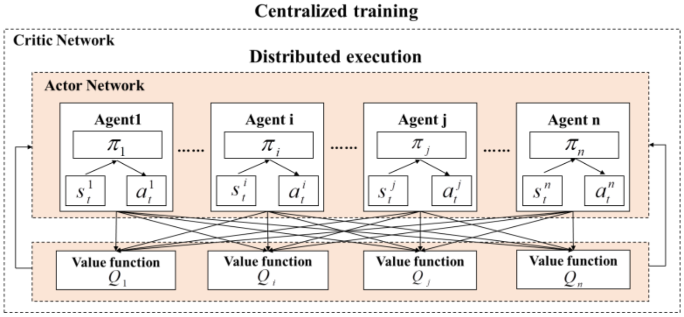

Fig. 2. Multi-agent depth deterministic strategy gradient algorithm MADDPG.

a) State space: In the process of fire evacuation, the location of evacuees and the congestion degree of adjacent areas have an impact on the choice of evacuation path, therefore, the state s_t^j of *Agent*$_i$, *i=1,2,3…,n* at time t as $(x_t^i, y_t^i, c_t^{i1}, c_t^{i2}, c_t^{i3}, ..., c_t^{i8}, d_t^{i1}, d_t^{i2}, d_t^{i3}, ..., d_t^{im})$, where x_t^i, y_t^i represent the horizontal and vertical coordinates of the $Agent_i$ position; $c_t^{i1}, c_t^{i2}, c_t^{i3}, ..., c_t^{i8}$ represents the congestion degree of the 8 areas closest to the $Agent_i$. If one area is an obstacle, the congestion degree of the corresponding area is set to infinity. $d_t^{i1}, d_t^{i2}, d_t^{i3}, ..., d_t^{im}$ represents the distance between the $Agent_i$ and m exits.

b) Action space: During fire evacuation, on the basis of environmental rasterization, the agent can select actions according to the observed environmental state information in 8 directions around it. Therefore, this paper defines that the $Agent_i$ can select actions in eight directions (up, down, left, right, upper left, upper right, lower left and lower right) in any state at time t, denoted as a_t^j.

c) Reward function: The reward function is an important reference for the agent to judge its own strategy, and it affects the learning effect and convergence speed of the algorithm to some extent. According to the goal of path planning, which is to find the shortest distance between all agents and the nearest exit on the basis of minimizing overcrowding and avoiding dangerous areas. In this paper, for each action performed by the $Agent_i$, if the agent is in a non-free active grid, a negative reward $R_a^i = -20$ is given; otherwise, whether the agent reaches the exit is judged. If yes, a larger positive reward $R_a^i = 100$ is given; otherwise, a negative reward $R_a^i = -1$ is given. In order to ensure the maximum reduction of personnel congestion during the evacuation process, the congestion degree C^i of the evacuation area of the $Agent_i$ is specified. When $C^i > 0.5$, negative reward $R_c^i = -\exp\left(c^i\right)$ is given; At the same time, in order to make the agent move towards the direction of the nearest exit and avoid entering the dangerous grid G_{xy}, suppose that the angle between the vector of $Agent_i$ from the position $\left(x_t^i, y_t^i\right)$ at time t to the position $\left(x_{t+1}^i, y_{t+1}^i\right)$ at time $t+1$ and the vector from its position $\left(x_t^i, y_t^i\right)$ at time t to the nearest exit $\left(x^q, y^q\right)$ is denoted as α, and the reward value R_e^i is divided into the following four cases, as shown in Table I. In conclusion, this paper defines the reward function as: $R^i = R_a^i + R_c^i + R_e^i$.

TABLE I. REWARD FUNCTION OF FIRE EVACUATION PATH PLANNING

	$(x_{t+1}^i, y_{t+1}^i) \notin G_{xy}$	$(x_{t+1}^i, y_{t+1}^i) \in G_{xy}$
$\alpha < 90^\circ$	$R_e^i = 0.5$	$R_e^i = -10$
$\alpha \geq 90^\circ$	$R_e^i = -1$	$R_e^i = -20$

2) Improved MADDPG algorithm: Lowe et al. [25] pointed out that the "distributed execution, centralized training" learning framework of MADDPG is suitable for multi-agent interaction scenarios. However, with the increase in the number of agents, the input dimension and training parameter scale of the centrally trained Critic network increase rapidly, which will greatly increase the training difficulty of the network. This makes it impossible to deal with large-scale multi-agent learning problems. In fact, in the process of fire evacuation, the action strategy of the agent is only affected by its surrounding environment and the agent close to it. Therefore, this paper proposes AMADDPG to improve it and adopts the learning framework of "distributed execution and centralized local learning", that is, only the status and action data of top-k other Agent Actors closest to the current Agent are considered as the input of the current Agent Critic network. The block diagram of AMADDPG algorithm is shown in the Fig. 3.

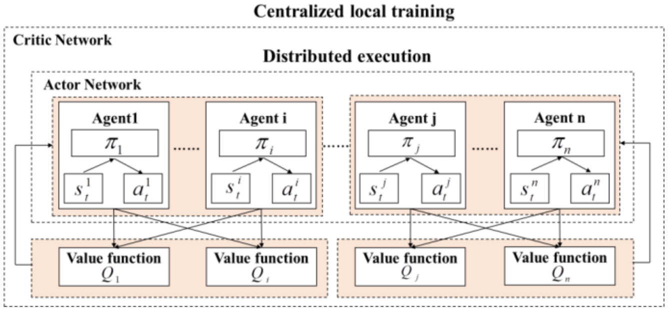

Fig. 3. Block diagram of improved AMADDPG algorithm.

The Actor of each $Agent_i$ independently uses local information to complete the interaction with the surrounding environment. During model training, it maximizes the cumulative expected return $J\left(\theta_i\right) = Q\left(s_t^i, s_t^{kNN(i)}, a_t^i, a_t^{kNN(i)}\right)\Big|_{a_t^j=\mu^j\left(s_t^j\right)}$ and minimizes the loss function of the locally centralized action value function in their respective Critic networks as follows:

$$L\left(\theta_i\right) = E\left[\left(Q_i^\mu\left(s_t^i, s_t^{kNN(i)}, a_t^i, a_t^{kNN(i)}\right) - y\right)^2\right] \tag{3}$$

$$y = Ri + \gamma Q_i^\mu\left(s_{t+1}^i, s_{t+1}^{kNN(i)}, a_{t+1}^{i'}, a_{t+1}^{kNN(i)'}\right)\Bigg|_{a_{t+1}^{j'}=\mu^{j'}\left(s_t^j\right)} \tag{4}$$

where $s_t^{kNN(i)}$、$a_t^{kNN(i)}$ indicate the status and actions of the top-k agents closest to the $Agent_i$.

The pseudo-code of the AMADDPG algorithm is as follows:

```
Initialize environment parameters, parameter variables;
for episode=1 to M do
    Initialize random noise N;
    Initialize the initial state of fire evacuation S0;
    for t=1 to max- episode-length do
        for agent i = 1 to n do
```

```
            According to the state $s_t^i$, the random policy is used to perform an action $a_t^i$, get the immediate reward $R_t^i$, and reach the new state $s_{t+1}^i$;
            Find the top-k other Agent sets $kNN(i)$ that are closest to.
            Store $< s_t^i, s_t^{kNN(i)}, a_t^i, a_t^{kNN(i)}, R_t^i, a_{t+1}^i, a_{t+1}^{kNN(i)} >$ in the experience pool
        end for
        $S_t \leftarrow S_{t+1}, S_t = \{s_t^i, i = 1,2,3..,n\}, S_{t+1} = \{s_{t+1}^i, i = 1,2,3..,n\}$
        for agent j = 1 to n do
            Random sampling $< s_t^i, s_t^{kNN(i)}, a_t^i, a_t^{kNN(i)}, R_t^i, a_{t+1}^i, a_{t+1}^{kNN(i)} >$ from empirical pool.
            Set the target Critic network function value
              $y = R^i + \gamma Q_i^{\mu'}(s_{t+1}^i, s_{t+1}^{kNN(i)}, a_{t+1}^{i'}, a_{t+1}^{kNN(i)'})|_{a_{i+1}^{j'} = \mu^{j'}(s_t^j)}$
            Minimize the loss function $L(\theta_i)$ update Critic.
            Policy gradient $\nabla J(\theta_i)$ update Actor for calculating expected return.
        end for.
        Update target network parameters:
        $\theta_t' \leftarrow \alpha\theta_t + (1-\alpha)\theta_t'$
    end for
end for
```

III. Fire Environment Construction for Fire Evacuation Experiment

In order to verify the effectiveness of the AMADDPG algorithm on fire evacuation path planning, python 3.7 was used to simulate the algorithm. The hardware configuration of the experiment environment is as follows: the CPU is Intel Xeon (R) Bronze 3104, the operating system is Windows Sever2012 R2, and the deep learning framework is Pytorch 1.4.

In this experiment, the evacuation situation of a large building fire scene is simulated. As shown in Fig. 4(a). The building has an area of approximately 900 m^2 and constructs grid maps with dimensions of 30 × 30, each grid side length of 1m. There are four safety exits in the building, as shown by the green grid in the figure. The blue grid in the figure is the initial position of the agents, which are numbered in turn. The number of evacuees represented by each agent is randomly generated at the beginning of each training round, and the total number of evacuees is about 200. When all agents reach the safety exit in the shortest time, it is considered as a successful evacuation.

The main materials of combustibles in buildings are wooden furniture and fabrics, and the fire area is an indoor environment in the building, as shown by the red grid in the Fig. 4(b). In order to make the simulation test more close to the real fire, the heat release rate changes according to the fast t square fire, and the maximum heat release rate is set to 4 MW/m2. It is assumed that the fire continues to maintain the burning state after reaching the maximum heat release rate. The continuous change of fire environment information, such as smoke visibility, CO volume fraction and ambient temperature, is obtained through the numerical simulation results of FDS fire simulator. According to the definition of danger grid, the danger area in the process of fire spread is represented in yellow as shown in Fig. 4(b).

(b) The spread of a large building fire at *t*=30s

Fig. 4. Fire scene of a large building.

IV. Experimental Results and Analysis

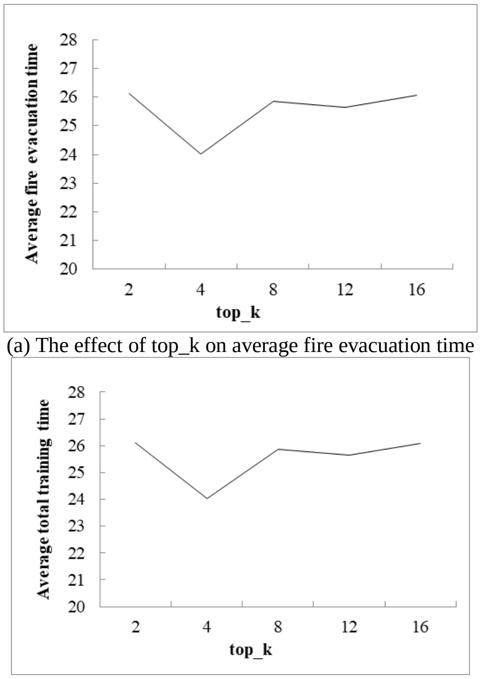
In order to evaluate the evacuation path planning ability of AMADDPG algorithm, the total number of training rounds was set to 1000 in the experiment, and the maximum evacuation simulation steps in each training round was set to 500. The evacuation time $T_e = D_e/v$ is defined, where D_e is the evacuation distance and v is the evacuation speed. Since the evacuation speed will be affected by the congestion degree, the greater the congestion degree, the more serious the degree of congestion, and the slower the moving speed of the evacuees. Therefore, according to literature, an exponential function is used to describe the evacuation speed, and $V_{\max}$ is the walking speed of normal people, which takes a value of 1.5m/s.

$$v = \begin{cases} V_{max}, c < 0.5 \\ V_{max} * e^{-0.5c}, other \end{cases} \tag{5}$$

A. Sensitivity Analysis

In AMADDPG algorithm, the value of top_k will affect the evacuation ability and training time complexity of the model to some extent. Specifically, the smaller the value of top-k, the less surrounding information the agent obtains, which affects the value evaluation of the action of the Actor network. Otherwise, the model parameters will increase rapidly, which increases the difficulty of training and makes it difficult to converge. Therefore, it is necessary to discuss top_k. By using the average of the fire evacuation time and the total model training time of the three experiments, this study compared and analyzed the influence of top-k of 2, 4, 8, 12 and 16 on the evacuation ability and model training. As shown in Fig. 5.

As shown in Fig. 5, when top_k is 2, 4, 8, 12, 16, the fire evacuation time and model training time reach the lowest value when top-k is 4. After analysis and research, it is believed that when top_k is small, although the model parameters are small, the ability of the agent to perceive the environment becomes weak, the stability is poor, and it is not conducive to convergence during training. Therefore, it is more appropriate to set top_k to 4, and take this value as the fixed parameter value for subsequent experiments.



(a) The effect of top_k on average fire evacuation time

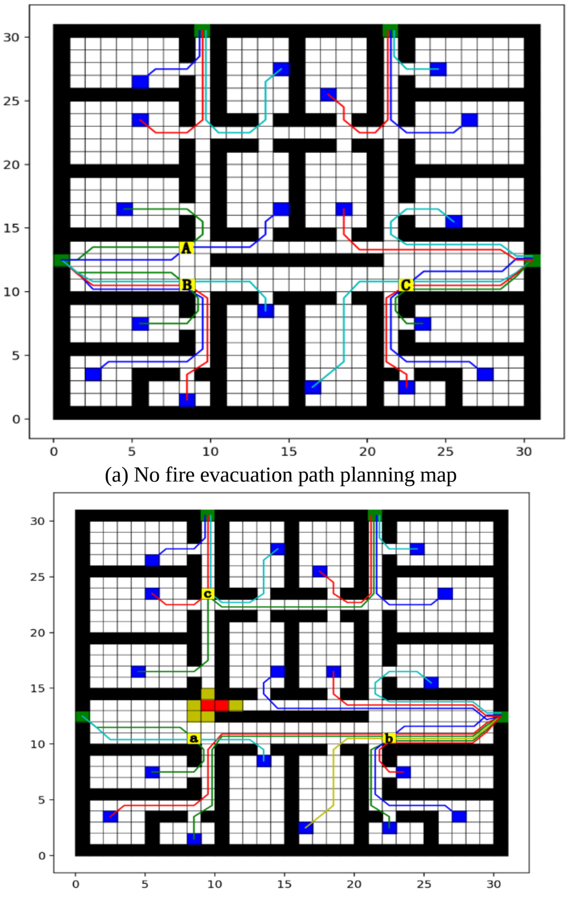
(b) The effect of top_k on average total training time

Fig. 5. Influence of top_k on the model.

B. Evacuation Effect Analysis

According to the discussion of top_k in 4.2.1, on this basis, the personnel evacuation situation before and during fire is analyzed and compared, and the experimental results are shown in Fig. 5 and Table II.

From the comparison of Fig. 6 (a) and Fig. 6 (b), it can be seen that all agents can complete the total evacuation of personnel within 35 steps regardless of whether the fire occurs or not. According to the definition of evacuation time, the evacuation time can be controlled within 30s. In addition, when a fire occurs, due to the spread of the fire and the generation of combustion products, the evacuation path of some people is changed, so that they can bypass the dangerous area to reach the appropriate safety exit, as shown in the figure of agents 1, 2, 9 and 10. It shows that AMADDPG algorithm can adapt to the influence of dynamic environment change on path planning, and can plan the optimal path for multi-agent system.



(a) No fire evacuation path planning map

(b) Fire evacuation path planning maps are available

Fig. 6. Evacuation path planning diagram of a large building.

In the process of evacuation, the congestion phenomenon caused by the dynamic change of crowd location will have a certain impact on the evacuation effect. Combined with Fig. 6, the congestion degree of agent paths in A, B, C and a, b respectively without fire and when fire occurs is shown in the Table II.

TABLE II. CROWDING DEGREE OF AGENT EVACUATION TRAJECTORY

No-fire condition		Fire condition	
Tracking point	Congestion degree	Tracking point	Congestion degree
A	0.613	a	0.617
B	0.662	b	0.668
C	0.539	c	0.643

It can be seen from Fig. 6 and Table II that in the absence of fire, the algorithm adjusts the evacuation paths of agents 10, 3 and 7 when the congestion exceeds the threshold value 0.5 at points A, B and C respectively. Similarly, in the case of fire, the evacuation paths of agents 3, 7 and 9 are dynamically planned according to the congestion degree at points a, b and c respectively, which indicates that AMADDPG algorithm can effectively solve the congestion problem caused by the dynamic change of crowd location in the evacuation process, so as to ensure that all agents can quickly complete the evacuation within the safe evacuation time.

C. *Comparative Analysis of AMADDPG Algorithm and MADDPG Algorithm*

In order to reduce the training difficulty of the network and improve the computational efficiency of the algorithm, AMADDPG algorithm is an improvement of the MADDPG algorithm's centralized global learning, which only considers the state and action of the agent near the current agent. Through three experiments, this study analyzed and compared the training and evacuation conditions of AMADDPG algorithm and MADDPG algorithm in fire scenarios, and evaluated the efficiency of AMADDPG algorithm.

1) Comparison of evacuation time: Evacuation time refers to the time between the start of evacuation movement and the evacuation of all personnel to indoor or outdoor safe areas, and its definition is the same as 4.2.1. In order to ensure the safe evacuation of personnel in the building, the evacuation time of the fire site should be controlled within 90 seconds according to the requirements of the Code for Fire Protection in Building Design. The evacuation time in a fire scenario is shown in Table III.

TABLE III. COMPARISON OF EVACUATION RESULTS BETWEEN AMADDPG ALGORITHM AND MADDPG ALGORITHM IN FIRE SCENARIO

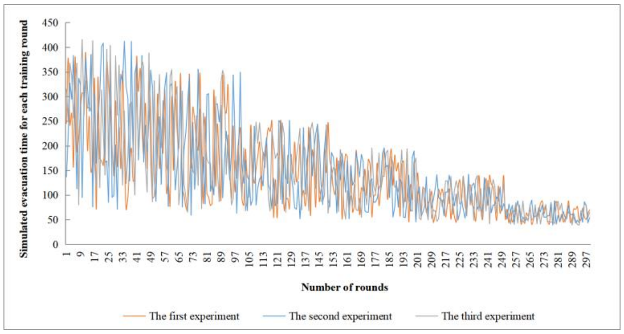
Algorithm evacuation result	AMADDPG algorithm	MADDPG algorithm
The first experiment	23.49	26.14
The second experiment	23.46	25.85
The third experiment	23.50	28.37
Mean evacuation time	23.48	26.79

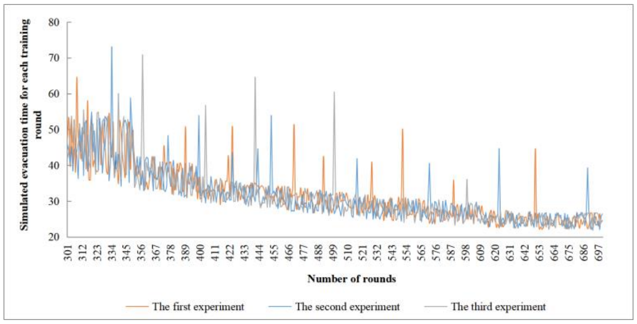
As can be seen from Table III, in a fire environment, the average evacuation time of the AMADDPG algorithm and the MADDPG algorithm three times is less than 30 s, and there is no significant change in the results of the three repeated experiments of the AMADDPG algorithm, while the evacuation time of the MADDPG algorithm is different. This shows that the two algorithms are acceptable in terms of path planning ability in fire scenes, and the evacuation effect is good, and the AMADDPG algorithm is better than the MADDPG algorithm in terms of algorithm stability. To analyze the reasons, the MADDPG algorithm needs to evaluate the status and actions of all agents in a complex and changeable fire environment. As a result, the input dimension of Critic network is too large, the complexity is too high, the convergence is difficult, and the stability of the algorithm is also affected. Therefore, compared with MADDPG algorithm, AMADDPG algorithm can obtain more stable optimal path planning results under complex dynamic environment and achieve the goal of safe evacuation.

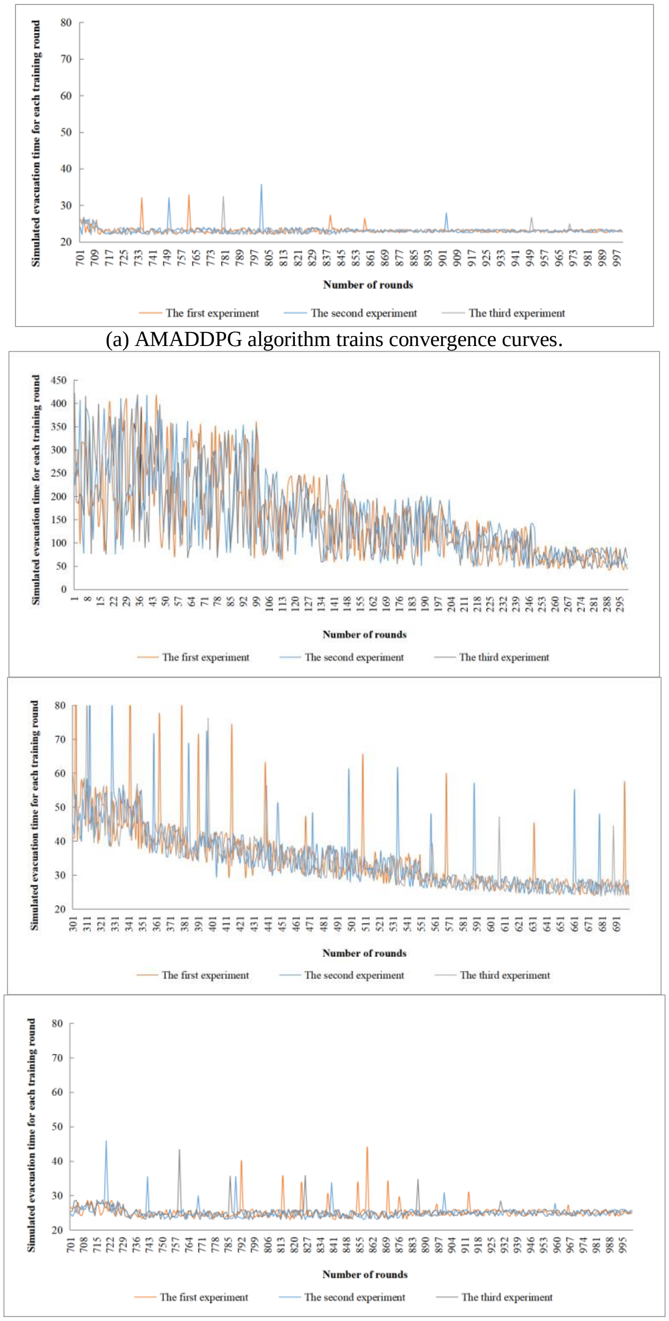
2) Convergent rounds: The training running time and convergence of AMADDPG algorithm and MADDPG algorithm are shown in Table IV and Fig. 7.

TABLE IV. TRAINING OF AMADDPG ALGORITHM AND MADDPG ALGORITHM IN FIRE SCENARIO

Algorithm	1000 rounds total training time			Average training time per round	Average convergent iteration rounds
	The first experiment	The second experiment	The third experiment		
AMADDPG algorithm	62467	64003	63861	63.44	708
MADDPG algorithm	68242	67508	67022	67.59	734







(a) AMADDPG algorithm trains convergence curves.

(b) MADDPG algorithm trains convergence curve.

Fig. 7. Convergence curves of AMADDPG and MADDPG algorithms in a fire scenario.

As can be seen from Table IV, the average running time of each training round of the AMADDPG algorithm is 4.15s shorter than that of the MADDPG algorithm, the average number of convergent iteration rounds is also reduced by 26 rounds, and the training efficiency is improved by 6.14% compared with the MADDPG algorithm. It shows that AMADDPG algorithm has higher training and learning effect, can effectively improve the convergence speed of the algorithm, and obtain the optimal evacuation path with less training time.

As can be seen from Fig. 7, in the first 400 rounds of the two algorithms, the evacuation time of each training round is generally above 30s, which is basically exploration oriented. With the accumulation and utilization of learning experience, the evacuation time of each training round converges to 23s until the 700 rounds, and the curve fluctuation of the AMADDPG algorithm is significantly less than that of the MADDPG algorithm, and is relatively stable. Therefore, AMADDPG algorithm can make the whole fire evacuation model convergence better and more stable.

V. Discussion

In order to verify the effectiveness of the algorithm, the evacuation process was simulated with or without fire, and the AMADDPG algorithm proposed in this study was compared with the MADDPG algorithm, as follows:

1) Through the simulation experiment with or without fire, it is verified that AMADDPG algorithm can basically adapt to the influence of dynamic environment changes on path planning, and can plan the optimal path for multi-agent system within 30s regardless of whether a fire occurs. Moreover, it can effectively solve the crowding caused by the dynamic change of the crowd position during the evacuation process, and the congestion degree on the multi-agent evacuation path is basically maintained within 0.5, so that the trapped people can move orderly at normal walking speed in the evacuation channel, and ensure a better evacuation effect.

2) By comparing the evacuation effect of AMADDPG algorithm and MADDPG algorithm in fire scenarios through three experiments, it can be concluded that AMADDPG algorithm can get the optimal path solution after 700 iterations. Compared with MADDPG algorithm, the average convergence iteration rounds of AMADDPG algorithm are reduced by 26 rounds, and the curve fluctuation is significantly less than MADDPG algorithm. Therefore, AMADDPG algorithm can achieve more stable and efficient optimal path planning in complex dynamic environment, and achieve safe evacuation goal.

VI. Conclusion

In this paper, an AMADDPG model suitable for fire evacuation is proposed by improving MADDPG algorithm. The experimental results show that the AMADDPG model can adapt to complex and dynamic fire environment, maximize the reduction of personnel congestion and avoid dangerous areas, and efficiently realize the optimal path planning for multi-exit fire scenarios.

From the technical point of view, the model has certain application potential and can be used in fire evacuation path planning. However, since the current research is still based on simulation, the subsequent research needs to be applied to the actual fire environment, and the algorithm should be deployed on multiple large public building [26] fire evacuation systems to further optimize the model and improve the generalization ability and robustness of the model [27] under different complex evacuation scenarios.

***Abstract*—The importance of the Learning Management System (LMS) has been discussed over recent years as it is crucial for students to manage this tool for their learning. The study's objective was to ascertain whether learners believe the LMS satisfies their learning goals and to bridge the gap between the growing body of research on learner-centered instructional design and LMS design. A survey was carried out with 528 students to get the data. The results revealed that most of the learners agreed that LMS is a useful tool to enhance their learning. This proves that LMS can be used as a device to make their learning better and more effective. The study's conclusions could be used as a guide for the university's administration as it adopted pertinent digital technologies, with the goal of creating an efficient implementation strategy that would enhance service delivery. Universities and colleges would benefit from this established approach in selecting the best learning management system (LMS) to meet their diverse needs. It will also act as a guide for developers who want to create an assessment system.**

Keywords*—*Learning management system; perceptions; usefulness; ease of use

I. INTRODUCTION

A Learning Management System (LMS) is used by many institutions to manage their students' education. An LMS is a dashboard or web-based platform that gives instructors the ability to organize, assess, automate administration, record training sessions, and carry out the learning process [1] According to Alharbi [2] and Turnbull [3], the LMS is a digital technology used to develop, distribute, track, and manage a variety of training and educational content. In higher education, a dynamic and reliable LMS is seen as essential to the administration and execution of the teaching, learning, and assessment processes. Students must stay in touch with the learning environment outside of scheduled class times since group projects, peer learning, and group activities all contribute to their learning in addition to in-class involvement. Distributing educational resources, managing student learning activities, assigning assignments, displaying grade transcripts, holding quizzes, and holding discussions with students can all be facilitated by an LSM. Students can perform a variety of things to make learning more flexible and efficient rather of relying solely on one approach. This platform facilitates an interactive learning environment with audio, video broadcasting, forums, and discussions. An LMS may be a very useful tool for tracking student participation and reporting on their academic achievement. Students with an Internet connection can access this LMS from any location.

Higher education institutions use a variety of learning management systems, including Sakai, Moodle, Blackboard, and Canvas [4, 5]. LMSs are used as sustainability platforms by cutting-edge digital networks like Edmodo, Google Classroom, Forum, EdX, MOOC, and Coursera, as well as by specialized education. Interactive and computer-managed learning are two types of LMS. A key component of an institutional LMS is the sharing of learning resources, which are always available to students and accessible from anywhere. Moreover, LMS facilitates learning assessment by organizing tests, generating quizzes, and importing grades. The instructor can tie the learning experiences and assessments with the established outcomes for each course and the matching Blooms level through the institutional LMS. Tools for gathering stakeholder input on the curriculum and the teaching and learning process are also included in LMSs. Thus, this study is to elicit students' perceptions of its usefulness and ease of use on a Learning Management System. The purpose of the study was to close the knowledge gap between the increasing amount of research on learner-centered instructional design and LMS design and to find out if learners perceive that the LMS meets their learning goals.

II. LITERATURE REVIEW

Universities must take into account the needs of a variety of stakeholders when selecting an LMS, including administration, faculty, support staff, and all of their students. Numerous students, including undergraduates, graduates, professionals, and other trainees, are frequently enrolled at colleges and universities. They might also choose to offer their staff compliance-based training using the learning management system, or they might want to provide opportunities for faculty development. When choosing their various LMSs, higher education institutions frequently take into account two main features: the capacity to interact with students and alternatives for instructors to arrange content [6-7].

Previous studies have been carried out where a small sample of students may be directly involved in the search process [7] or many universities may take student satisfaction into account [8]. In these situations, students participate in the technology selection committee and offer their comments on specific features or how easy they think the technology is to use. Students should be given the chance to express and select the learning resources they use. Generally speaking, while creating products like an LMS, sound design principles demand that all end users be taken into account [9]. There is not much study that assesses students' choice in the design of their learning management system (LMS), despite earlier studies looking at how satisfied students are with their LMS. The study contributed to the corpus of research that views college students as co-designers of the learning resources they utilize.

An open-source learning management system called Moodle encourages instructors to build their own webpages for their classes [10]. This strategy makes sense because administrators typically buy these systems and support their deployment. The other university gives the LMS a different name. Numerous universities worldwide, including those in Malaysia, have made extensive use of the online learning management system. Public and private universities in Malaysia, such as Taylor's University (Times), Universiti Teknologi Mara (iLearn), and International Islamic University Malaysia (iTa'leem), each have their own LMS. For the purpose of facilitating virtual communication between students and instructors, each university creates its own LMS. The official LMS for the institution was designed to handle subjects, courses, tests, and any other pertinent course-related learning materials.

Constructivist learning theory is taken into consideration in contemporary teaching and learning methods. According to this theory, students build their knowledge through experiences, and a combination of application activities, and interwoven recall practice [11-12]. Experts also started endorsing the idea of growth mindsets, which hold that learners can acquire challenging new ideas rather than having a fixed belief in their own intelligence [13]. Thus, teaching has changed from being an instructor-focused activity through lectures to one that is learner-centered, based on data from cognitive science [14].

The mechanisms by which students independently activate and maintain thoughts, feelings, and behaviors methodically geared toward achieving personal goals are referred to as self-regulated learning, whether or not they enlist the assistance of peers, coaches, and instructors [15]. Self-directed learning, in which students select their own learning path at a speed and time that best suits them, is supported by an LMS. This guarantees that the students assume accountability for their education. It is commonly acknowledged that peer interactions contribute to the effectiveness of learning. Through synchronous and asynchronous methods, the LMS offers the chance for these kinds of interactions so that they can consider what they have learned. Although most faculty members are satisfied with the LMS that their university offers, some research indicates that instructors often underuse it, either by not utilizing it for all facets of their teaching or by not taking advantage of all the features that could be useful [16].

Over the past few years, a number of studies have assessed the effect that an LMS has on learning outcomes. According to certain research [17], students who utilized the LMS more frequently had higher grades overall and were more engaged with the course. This finding is not surprising overall. In theory, students should be able to perform well academically if instructors use an LMS to store course content. This is because the more students access the material that is relevant to their courses, the better.

In support of this idea, [18] discovered that specific personality traits predicted the use of LMS, which in turn predicted academic success, especially in online classrooms where students had access to all course materials through the LMS. On the other hand, some, none, or all of the content for in-person classes could be stored on the LMS. Still, there are other ways for students to benefit from the LMS beyond just using it to access their learning outcomes. Kim [19] discovered a positive relationship between learning outcomes and students' proficiency with the LMS and observed that knowledgeable teachers had an impact on students' capacity to master the LMS. Additionally, a study discovered a link between students' motivation for the course and how they used the LMS [20]. These two studies in particular demonstrated that the learner-instructor paradigm went beyond fostering interpersonal relationships and that teachers' role modeling of LMS engagement had a direct and indirect impact on students' performance.

An LMS must offer the essential resources that students often use in order to maximize its effectiveness and aid in the learning process for students. In order to tailor the system's use to the demands of students, its comprehensiveness should be determined by their preferences. According to a study, an LMS can create a favorable correlation between intentional and behavioral usage [21].

The relationship between the instructor and the student should, although it is still hierarchical, represent a two-way partnership rather than a giver-receiver relationship as a result of course design and teaching that puts the learner first. In this collaboration, the learner ought to have a say in the LMS and other resources that help shape and interpret their learning. The study's objective was to ascertain whether learners believe the LMS satisfies their learning goals and to bridge the gap between the growing body of research on learner-centered instructional design and LMS design.

Two studies that researched the LMS design found that it was not adaptable enough to accommodate the needs of all demographics. According to Almaiah [22], many of their instructors and students lacked the baseline technological literacy that the LMS design required. Similar to this, [23] observed that the LMS design functioned best when accessed using a desktop or laptop; yet, a large percentage of the students polled relied on smartphones as they did not have access to personal computers. Several elements influencing students' opinions of their LMS during COVID were also assessed in several research.

Lastly, an American study discovered that elements associated with learning engagement mattered to college and university students. According to Murphy [24], the study discovered that students wanted to participate more actively in synchronous learning activities that used technology, such as audience response systems. This conclusion is especially intriguing because the students said that they would like to modify the teaching strategies to better meet their individual learning needs. However, the study's participants only mentioned external technology to accomplish this; integrated learning management system components were left out. According to Gamage [25], "encouraging quality in online education is not primarily a question of IT support but of academic strategy and educational design" (p. 6), they concur that instructional techniques should alter.

Thus, while using the LMS to assist in constructing and providing meaning to their learning, students' voices matter. In light of this, this study looks into how satisfied students are with the LMS they now use at their university. This study aims to investigate how students perceive the LMS's usefulness and simplicity of use. This study's primary goal is to investigate how undergraduate students see an LMS in terms of its usability and convenience of use. This is a gap that this research aims to fill. The study's objective was to ascertain whether learners believe the LMS satisfies their learning goals and to bridge the gap between the growing body of research on learner-centered instructional design and LMS design.

Specifically, the research objectives are:

1) Assess students' satisfaction with the university's current learning management system; and;

2) Design a user-friendly interface for a learning management system support system for UTeM.

III. Methodology

This study examined undergraduate students' perceptions of an LMS's usefulness and convenience of use. The purpose of the study was to close the knowledge gap between the increasing amount of research on learner-centered instructional design and LMS design and to find out if learners perceive that the LMS meets their learning goals.

An overview and analysis of the Learning Management System (LMS) response data are included in this section. The purpose of this survey was to get feedback from LMS users regarding their opinions and experiences with using LMS. For this study, there were 528 respondents randomly recruited. There were 302 males (57.2%) and 226 females (42.8%) who were aged from 19 to 24 years old; they were undergraduates from all faculties at UTeM. These students use the LMS as part of their academic education.

Quantitative data was used in this research. The study employed a free online survey application called Google Forms. In multiple survey questions, students were asked to indicate alternate ways to navigate their learning management system and to assess the perceived importance of various features on a weighted scale. Prior to completing the questionnaire, students were asked to sign a consent form indicating their willingness to engage in the research, the contents of which would only be used for this study and would remain private. They were made aware of the study's goals. Before beginning to complete the questionnaire, they all signed the consent form. A total of 528 surveys were collected in the study.

This study used the survey approach to gather information on the attitudes, behaviors, opinions, and intentions of a substantial population. In social science, the survey approach is well-established since it helps researchers gather data that can be evaluated to explain certain phenomena [26]. In order to validate the questionnaire, the researchers first reviewed pertinent literature to gain an understanding of the state of multimodal language learning education, as well as the problems and trends that surround it, based on their research goals and objectives. Following the questionnaire's design, they assessed its content validity. They tested the questionnaire's content validity by showing it to professionals in the field of language learning, and they made adjustments in response to their suggestions.

The aim of the research was to ascertain the opinions of undergraduate students regarding the design of their individual learning management systems. The researchers also wanted to know if the students thought the layout of their learning management system helped them learn. Participants specifically discussed how they saw the use of an LMS as a learning tool and how well it facilitated learning activities that adhered to the learner-centered teaching philosophy.

There were 16 multiple choice Likert scale questions where respondents could answer the closed-ended question using a Likert scale or ranking system. The Likert scale identified four levels of agreement: Excellent, Satisfactory, Needs Improvement, and Unsatisfactory. Users of the LMS were sent a link to a Google form, which contained the survey. According to the survey instrument, it would take participants about 20 minutes to finish the questionnaire. The participants are free to respond to every question; they have the choice to skip any question they should not answer for any reason.

There were three primary portions to the questionnaire: the first part asked participants' gender, faculty, and year of study. In the second segment, students answered closed-ended questions on a 4-point Likert scale to elicit their responses about the use of LMS in learning. According to Sharma [27], the Likert scale is a well-accepted psychometric instrument that is mostly utilized in educational and social scientific literature to assess the quantification of attributes. The last segment is students' perceptions of LMS.

IV. Results and Discussion

This section shows the findings of the research. Regarding student attitudes and opinions regarding the design of their learning management systems, or LMSs, the study included three research questions. The researchers gathered information primarily from a survey.

Question 1 is about the gender of the participants. A total of 528 students (42.8%) female and (57.2%) male were given a questionnaire. The study's conclusions are anticipated to serve as a guide for the university's administration as it adopts pertinent digital technologies, with the goal of creating an efficient implementation strategy that would enhance service delivery. LMS users received the survey, which had 20 questions in total, through a link to a Google form. Their responses were tabulated in Fig. 1.

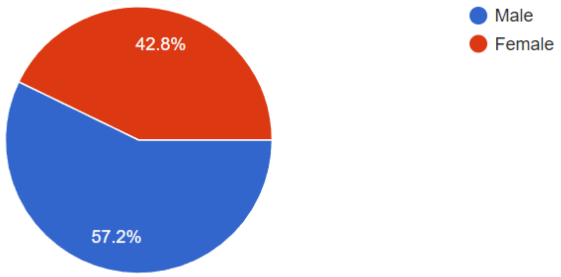

Fig. 1. Gender of the participants.

Question 2 elicits information about the year of study and is presented in Fig. 2. The majority are from the Second year (50.8%), followed by the Third year (50.8%), and the First year (50.8%).

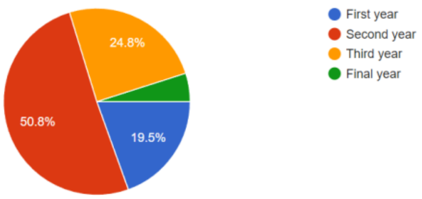

Fig. 2. Year of study.

Fig. 3 presents the results, where the majority of students have Intermediate (48.9%) and Advanced (47.5%) levels of LMS expertise (Q3). The fact that the majority of students are aware of the LMS and possess the skills necessary to use it.

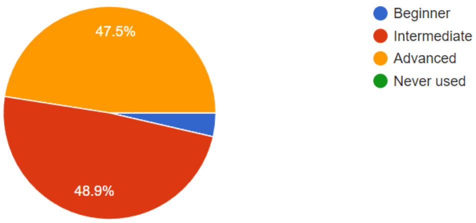

Fig. 3. Level of expertise.

The next question (Q4) is whether students use LMS in their learning. The majority (99.8%) indicated that they use LMS for learning, as shown in Fig. 4.

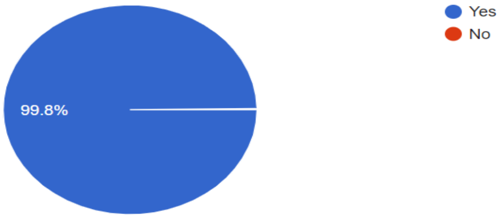

Fig. 4. Do you use LMS in your learning?

Additionally, students reported using the LMS for a variety of reasons (Q5). Fig. 5 shows that the majority of students use LMS for these tasks: submitting assignments (97.9%), taking quizzes (97.7%), downloading documents (97.3%), and recording attendance (93.4%). Subsequently, 86.4% of the respondents watched videos, 70.5% read the announcements, 70.6% provided feedback, 65.2% completed the survey, 60.2% read books or other resources, and 59.1% participated in forums. Viewing their grade or marks (44.5%) was the least useful. This demonstrates how engaged students are in using their LMS. Students are actively using the LMS in their learning.

The next survey question (Q6) asks about users' satisfaction with the LMS's tools. The majority of students are satisfied (48.3%) and very satisfied (41.1%), as illustrated in Fig. 6.

The next question (Q7) concerns how students view the LMS resources. The data in Fig. 7 shows that the majority of students (91.5%) describe the LMS as user-friendly. Students can learn how to utilize the LMS via the instructions and the video. Furthermore, a few students mentioned that the LMS has an intuitive interface. A few students concurred that the LMS is adaptable to combine with other social media platforms or educational tools (51.5%), improves communication and involvement in the classroom (53.2%), and is customizable (50.8%). Only 38.6% of students said they found the LMS fun to use. Tests and quizzes are administered via the LMS, which also serves as a formal venue for teaching and learning. The findings demonstrate that students have a favorable opinion of the features and capabilities of their learning management system.

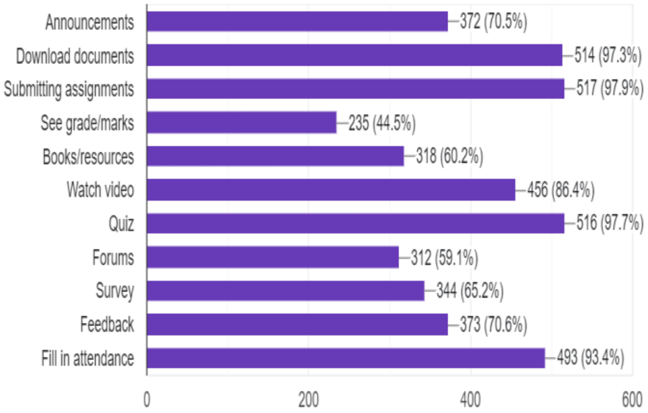

Fig. 5. How do you use LMS?

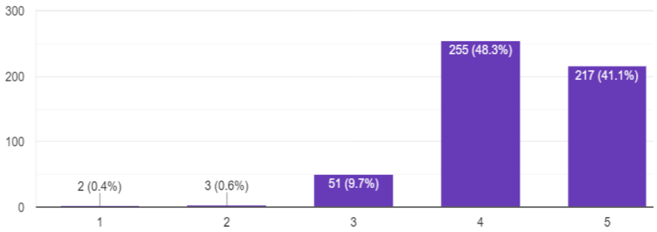

Fig. 6. How satisfied are you with the following LMS tools? (Announcements, feedback, quiz, etc)

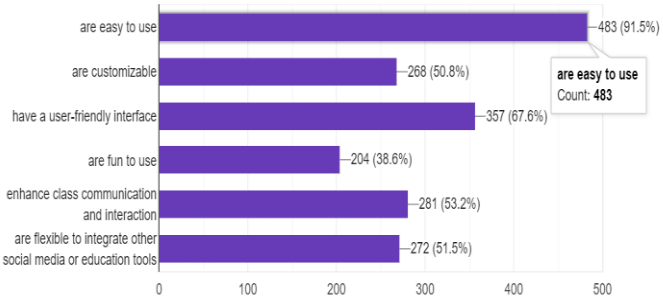

Fig. 7. The perceptions about LMS tools.

The stability of the system is the subject of the following query (Q8). This question asks about the system's dependability and whether it performs as planned. The results in Fig. 8 indicate many students expressed Satisfactory (51.9%), whereas few students selected Excellent (27.7%) and Needs Improvement (20.3%). This data indicates that students are satisfied with the tool.

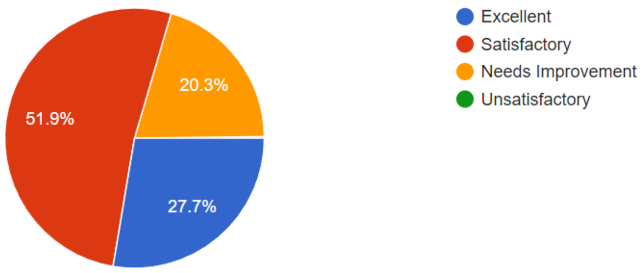

Fig. 8. Students' perception about LMS tools: Stability.

The next question (Q9) is about the reliability of the tool, and the data is shown in Fig. 9. Students have expressed their concern in Fig. 9, where many students expressed satisfaction (56.3%), followed by Excellent (32%), and require improvement (11.6%). This shows students trust the tool to perform their tasks.

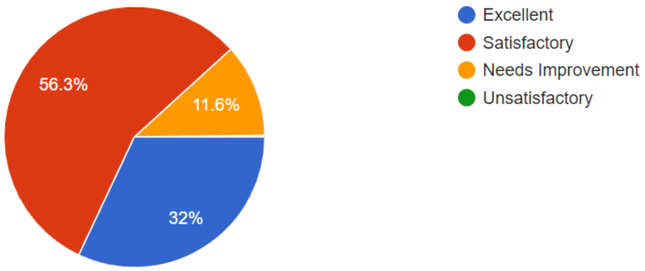

Fig. 9. Students' perception about LMS tools: Reliability.

Question 10 asks students about the speed of the tool. The feedback in Fig. 10 shows the majority students chose Satisfactory (49.4%). However, only some of them selected Excellent (23.3%) and require improvement (26.5%). This signifies that students are quite content with the speed of the tool to perform their tasks.

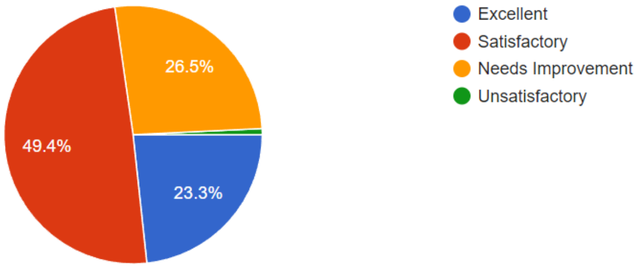

Fig. 10. Students' perception about LMS tools: Speed.

Question 11 seeks information about the usability of the tool. The feedback in Fig. 11 shows the majority of students expressed their satisfaction with Satisfactory (53.4%), and Excellent (39.4%), whereas only a few students chose the option of Needs Improvement (7.2%). This proves that students are very happy with the tool.

Question 12 asks students to rate the user interface in order to provide information on its appearance. Students reported Satisfactory (51.7%), and Excellent (36.7%) whereas, only a small percentage selected the option Needs Improvement (11.4%). The data is illustrated in Fig. 12.

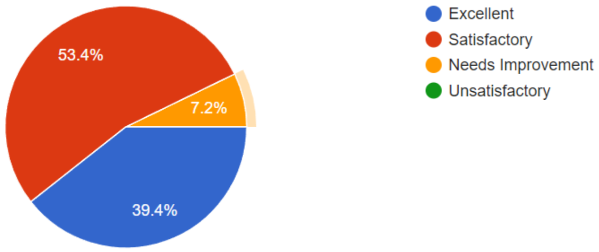

Fig. 11. Students' perception about LMS tools: Usability.

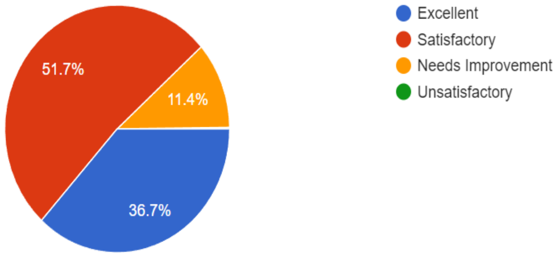

Fig. 12. Students' perception about LMS tool: Appearance.

Question 13 aims to obtain details regarding the navigation of the course. This is about the functionality of navigating through the course, locating, and accessing course material. Students reported Satisfactory (51.9%) and Excellent (36.6%). Only a small percentage selected Needs Improvement (11.6%). This indicates that students do not have difficulty accessing the tool to do their tasks. The data is shown in Fig. 13.

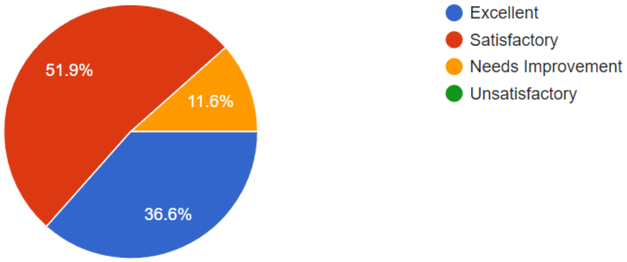

Fig. 13. Course navigation.

The purpose of question 14 is to obtain data regarding the rate of ease of accessing and completing coursework, including tests or quizzes, assignments, and discussion boards. Fig. 14 shows that students agreed that the LMS is accessible and convenient, as proven by their selections of Satisfactory (48.7%) and Excellent (41.3%). Only a few students chose Needs Improvement (10%).

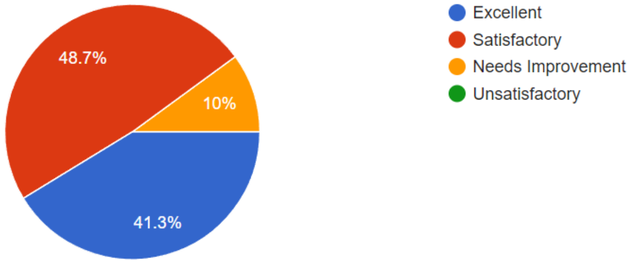

Fig. 14. Students' perception about LMS tool: Completing their coursework.

The next question (Q15) elicits information about Communication Tools: Rating the ease of accessing and using other communication tools, including how simple it is to use the syllabus, announcements, calendar, and personal notifications. Fig. 15 shows that only a small percentage of students selected Excellent (32.6%) and require improvement (12.7%), out of those who expressed Satisfactory (54%). This shows that the majority of students agree that the tools are easy to use and user-friendly.

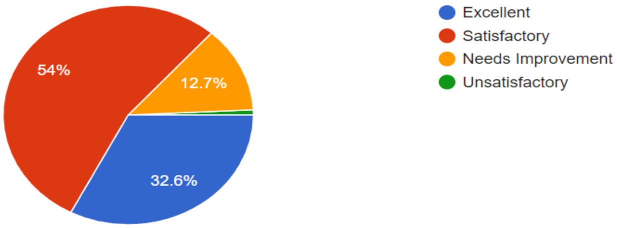

Fig. 15. Students' perception about LMS tools: Communication tools.

Question 16 elicits information about the LMS's functionality. Many students reported being satisfied (57.6%) and Excellent (34.3%), and with only a small percentage, selecting requires improvement (8.1%). This shows that students are happy and satisfied with the tool. The data is presented in Fig. 16.

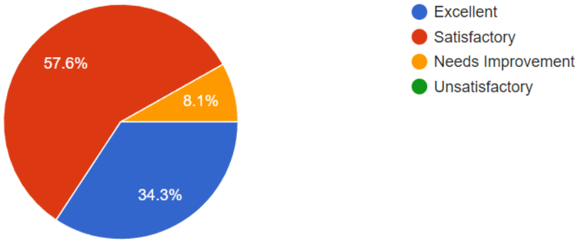

Fig. 16. Students' perception about LMS tools: Functionality.

Overall, the findings of the study showed that the majority of students believed that the LMS's design generally supported their learning needs. In addition, the findings showed that despite having different learning levels and degree programs, and students still had similar needs in terms of features and navigation strategies. According to the study, LMS plays a crucial role in making their learning meaningful as the tool meets the demands of the students. The study's findings can be used to help colleges and universities choose and support LMS. In order to give their students a more efficient learning experience and to fully support learner-centered instructional methods, higher education institutions should think about offering more organized support and development opportunities to front-line instructors.

V. CONCLUSION

In academic contexts, learning management systems, or LMSs, are becoming more and more common. Most Malaysian universities employ several LMSs for their academic activities. LMSs have the power to alter how education is delivered in formal settings. It may significantly optimize the entire process of creating and disseminating knowledge, creating room for creativity and innovation, in addition to making the learning process more focused on the needs of the individual student. When LMSs are used in educational settings properly, classes may become far more inclusive and engaging. Furthermore, it has the potential to enhance the entire learning ecosystem by contributing an engaging and dynamic layer. Creating a shared experience and fostering creative interchange are the goals of implementing LMS-based interactive learning, which will benefit the entire learning community. Therefore, in order to enhance participation in higher education for sustainability, LMS investment optimization is crucial. Funding will be needed in the future for researchers who want to carry out comparable studies so they can publish their results. Stakeholders ought to be more equipped to view remote learning as a practical solution for long-term sustainability in light of the current crisis. This study contains numerous limitations, even though it shows statistical evidence exists.

Future research will need more respondents from a wider range of majors, as well as examinations of other aspects, including educators' opinions regarding LMS and their reasons to utilize them, given that this study's respondents are all from the same university.

ACKNOWLEDGMENT

The authors would like to thank the Pusat Pembelajaran Bahasa, Universiti Teknikal Malaysia Melaka (UTeM), Centre for Research and Innovation Management (CRIM) and Research Group: Centre for Technopreneurship Development (C-TeD – S-iCOMM) for supporting this research.

***Abstract*—Existing multimodal fake news detection methods face three challenges: the lack of extraction for implicit shared features, shallow integration of multimodal features, and insufficient attention to the inconsistency of features across different modalities. To address these challenges, a multi-reading habits fusion adversarial network for multimodal fake news detection is proposed. In this model, to mitigate the influence of feature changes due to events and emotions, a dual discriminator based on domain adversarial training is built to extract invariant common features. Inspired by the diverse reading habits of individuals, three fundamental reading habits are identified, and a multi-reading habits fusion layer is introduced to learn the interdependencies among the multimodal feature representations of the news. To investigate the semantic inconsistencies of different modalities in news, a similarity constraint reasoning layer is proposed, which first explores the semantic consistency between image descriptions and unimodal features, and then delves into the semantic discrepancies between unimodal and multimodal features. Extensive experimentation has been carried out on the multimodal datasets of Weibo and Twitter. The outcomes indicate that the proposed model surpasses the performance of mainstream advanced benchmarks on both platforms.**

Keywords*—Multimodal fake news detection; feature extraction; feature fusion; consistency alignment

I. Introduction

In recent years, the rapid growth of social media has significantly reshaped the traditional way people access information. A growing number of users prefer to consume news via social media platforms, these platforms not only ensures the real-time reporting of events from around the world but also provides rich and engaging content in various media forms, such as videos, images, and audio. Compared to simple text reports, news that incorporates images and video elements can convey stories more vividly and thus attract a wider audience. However, this rich medium has also been exploited by fake news, which spreads rapidly through multimedia means. In particular, fake news containing multiple media is more contagious than fake news containing only text, spreading quickly to a wider area and having a more serious impact [1]. Fake news often contains manipulated or completely fabricated images, which are highly misleading and can spread rapidly to a wide audience in a very short time. The spread of fake news can pose a serious threat to public health safety [2] and may affect or even manipulate key political events [3], thus posing a threat to social stability. Therefore, social media platforms urgently need to solve how to quickly and accurately identify fake news.

Based on the content of the news, existing fake news detection technologies are broadly categorized into two groups: unimodal detection methods and multimodal detection methods.

The early focus of unimodal fake news detection was on using feature engineering for artificial feature construction. This includes statistical features such as the frequency of negative vocabulary occurrence and the number of tag symbol repetitions [4], metadata features such as user information, behavioral information, and news platform information [5], language or semantic features of text content [6][7], emotional features of news publishers and content [8], stance features [9][10], writing style and stylistic features [11], content comment features of news [12], and communication based features [13]; The later stage focuses on using static word vector models Word2Vec, Glove, or dynamic word vector models Bert and Roberta to obtain text features.

With the rapid development of social media, the incidence of fake news manipulated through images and text has surged, underscoring the growing importance of detecting multimodal fake news. While strides have been made in multimodal fake news detection technology, several challenges persist:

1) Feature extraction: Current detection methods typically rely on pre-trained models to extract explicit features. For example, using the BERT model to extract text features [14], or using convolutional neural networks such as VGG to extract image features [15]. However, these methods are sensitive to feature distributions. Fake news tends to focus on certain specific fields [15], and these news items usually have negative and pessimistic emotional tones [16][17].

2) Interactive fusion: Existing methods integrate multimodal features to detect fake news through simple early fusion [18] or late fusion [19] strategies, but these fusion strategies are superficial, such as splicing, adding, or simple neural networks to integrate, making it difficult for them to capture the intrinsic dependencies between features.

3) Consistency alignment: Existing methods mainly emphasize capturing similar semantics between different modalities through alignment mechanisms, such as establishing entity alignment [20], relationship alignment [21], and semantic alignment [22] for detection. However, they neglect the acquisition of widely inconsistent semantics.

To tackle these challenges, the Multi-Reading Habits Fusion Adversarial Network (MHFAN) is proposed. MHFAN

*Corresponding Author

aims to detect fake news by extracting both explicit and implicit common features, employing deep feature fusion, and incorporating similarity constraint reasoning.

During the feature extraction stage, the multimodal pre-trained model CLIP is employed to extract explicit features from news text and images. Inspired by the concept of domain adversarial training, adversarial networks are used to construct an event discriminator and an emotion discriminator. This method enables the model to learn features that are insensitive to changes in events and emotions (implicit common features) through adversarial training. Consequently, this approach mitigates the discrepancies in detection results caused by differing event and emotional distributions.

At the feature fusion stage, three common reading habits are identified when people read:

1) Text is the main focus, with images as a supplement: Read the text carefully, but only browse the images briefly.

2) Images are the main focus, with text as a supplement: Observe the images carefully, but quickly skim the text.

3) Equal emphasis on text and images: Read the text carefully and pay the same attention to image details.

To model these three reading habits, the unimodal content initial embeddings of text and images are used to represent the behavior of brief browsing, while the unimodal information is encoded to represent careful reading behavior. Subsequently, a Multi-Reading Habits Fusion Layer (MHF) is designed to simulate the interaction of each reading habit. This layer learns the dependencies between the multimodal features of the news, thereby deepening the feature fusion process.

At the consistency alignment stage, a Similarity Constraint Reasoning Layer (SCR) is proposed to address the inconsistent semantics across different modalities. Initially, a Consistency Reasoning Block (CRB) is constructed to evaluate the consistency between image text descriptions and unimodal features. Subsequently, an Inconsistent Association Constraint (IAC) is applied to quantify the semantic deviation between unimodal and multimodal features.

The main contributions of this work are summarized as follows:

1) In the feature extraction phase, a pre-trained CLIP model was employed to extract explicit features of text and images. Furthermore, a dual discriminator based on the concept of domain adversarial was designed to eliminate the model's dependency on specific events and emotions by extracting implicit features shared across different events and emotional states.

2) Based on people's reading habits, this paper proposes a multimodal feature fusion method that achieves deep integration of different modal features and explores their inconsistencies for the purpose of fake news detection.

3) Explored the Similarity Constraint Reasoning Layer, which can not only measure the consistency between image-expanded semantics and unimodal features but also obtain the semantic deviation between unimodal and multimodal features.

4) Extensive experiments have been conducted on public Weibo and Twitter datasets. The experimental results demonstrate that the MHFAN excels in fake news detection, outperforming conventional detection models across multiple metrics. Additionally, ablation studies have validated the effectiveness of various components within the model, confirming their contributions to the overall performance improvement.

The structure of the remaining sections of this paper is as follows: Section II reviews prior research in the field of content-based fake news detection. Section III provides a detailed introduction to the proposed model and its key components. Section IV describes the datasets utilized, the experimental setup, the baseline models for comparison, and presents the experimental results along with a thorough analysis. Finally, Section V offers a concise summary of the paper.

II. Related Work

Based on the modality of news content, fake news detection methods are categorized into unimodal and multimodal.

Unimodal fake news detection methods primarily encompass three aspects: text-based, vision-based, and metadata-based.

1) Text-based: Early research primarily utilized manual extraction of statistical features from the context of the content. Guo et al. [23]. counted the proportion of negative words in the text, while Parikh et al. [24]. counted the types and numbers of punctuation symbols. However, manual methods are time-consuming and labor-intensive, making it difficult to meet the demands of large volumes of data. As a result, techniques for automatically detecting fake news using deep learning have emerged. Deep neural networks based on CNN [25], RNN [26], attention mechanisms [27], and GNN [6] are constructed to capture semantic, emotional, stylistic, and stance features for identifying fake news.

2) Vision-based: In addition to textual content, some studies also consider image information in the news [27][28]. These methods typically use VGG, ResNet to capture spatial domain features, or through discrete cosine transform, Fourier transform to capture frequency domain features.

3) Metadata-based: The identification of fake news relies not only on the content but also on social contextual features, i.e., metadata. This includes comments [29] (The comment based approach utilizes an interactive mechanism to obtain valuable features between comments and news), user profiles [30] (The method based on user data is suitable for fake news with a large number of users), platform characteristics [27] (Social platform based methods often appear in cross platform fake news detection tasks), and propagation patterns [13] (The method based on propagation mode has time series characteristics). These metadata features are helpful in fake news detection.

Multimodal fake news detection most research focuses on three aspects: feature extraction, interactive fusion, and consistency alignment.

1) Feature extraction: Multimodal news content detection methods typically employ targeted pre-trained models to extract features from different modalities. For instance, word vector models such as Word2Vec and GloVe are used to extract textual features, while convolutional neural networks like VGG and ResNet extract image features [15]. With the advent of transformer architectures [31], Transformer-based pre-trained models have significantly enhanced the capability of feature extraction by capturing deeper linguistic representations.

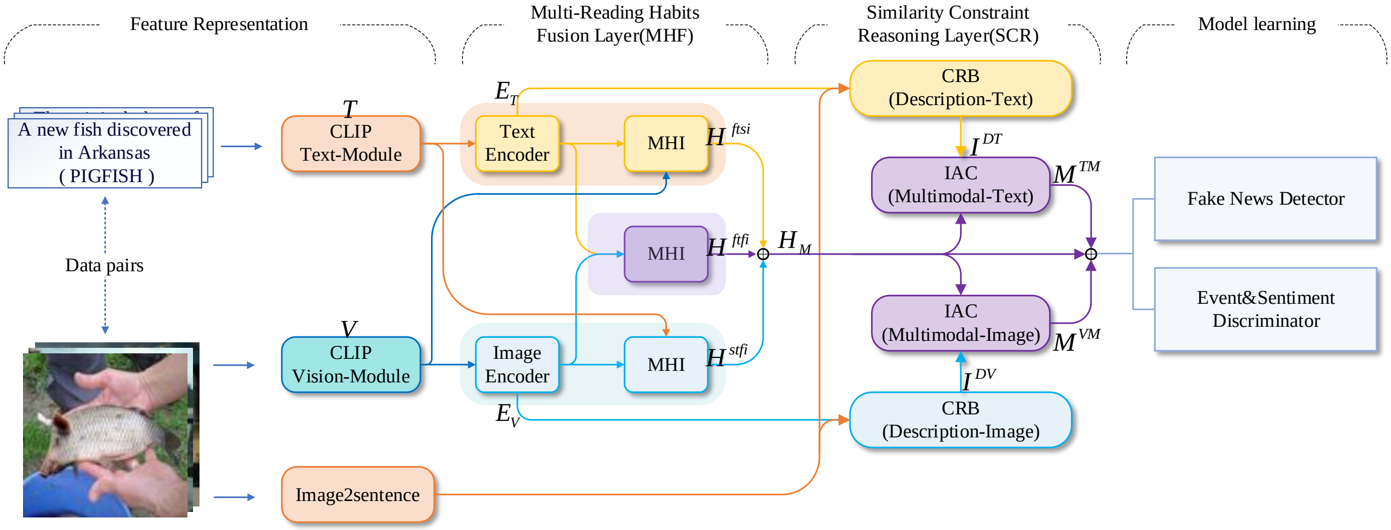

Fig. 1. The model framework MHFAN proposed in this paper consists of four levels: Feature representation, MHF, SCR, and model learning. CLIP and the discriminator are capable of capturing explicit and implicit common features, MHF enhances the deep fusion between features, and SCR can capture the consistency and inconsistency among features.

2) Interactive fusion: The objective of feature interaction fusion is to integrate information from different modality data sources to enhance model performance, and this process is primarily categorized into early fusion and late fusion. Early fusion [32][33][34] also known as feature-level fusion, refers to the combination of different modalities of information through concatenation or addition operations during the feature extraction or feature construction phase of the model. After the fusion, the combined features represent the joint feature space of all modalities, enabling the model to consider information from different data sources simultaneously, with all features being equally output downstream for learning. Late fusion [35][36] also known as decision-level fusion, is where models for each modality are trained independently, learning and extracting features and information from their respective modalities. Each modality's data is first processed and analyzed independently, and the outputs of the same type are fused at the decision stage using operations such as summation, maximum, average, or dot product.

3) Consistency alignment: The mismatch between different information modalities in news is a common source of error, such as discrepancies between images and text. By aligning data from various modalities, we ensure consistency and relevance within a unified representational space. Current research focuses on similarity comparison [20], semantic matching [37], entity alignment [18], and other alignment strategies [38] for detection.

However, the aforementioned methods have the following shortcomings:

- Feature extraction is susceptible to the influence of the distribution of certain news content. For instance, fake news is widely distributed in political and economic spheres and often contains a significant amount of pessimistic emotional content. To mitigate the impact of content bias resulting from data distribution, it is necessary to capture common features that are insensitive to events and emotional changes.
- Methods such as summation, splicing, and averaging for feature fusion are shallow, leading to information loss and redundancy of features;
- Existing alignment methods have not explored the inconsistent information between multimodal features, and there is a lack of correlation and interaction between different types of features.

To address the aforementioned issues, the Multi-Reading Habits Fusion Adversarial Network (MHFAN) has been developed. Initially, during the feature extraction phase, the CLIP pre-trained model is utilized to capture salient features that support the detection task. Concurrently, a dual discriminator is employed to derive common features that are insensitive to event and emotional changes, thereby mitigating bias caused by data distribution. In the feature fusion phase, a Multi-Reading Habits Fusion layer (MHF) is constructed to enhance feature interaction and achieve deep feature integration. Finally, for consistency alignment, a Similarity Constraint Reasoning layer (SCR) is designed to capture both consistencies and inconsistencies between different features, which is then applied to the task of fake news detection.

III. The Proposed Model

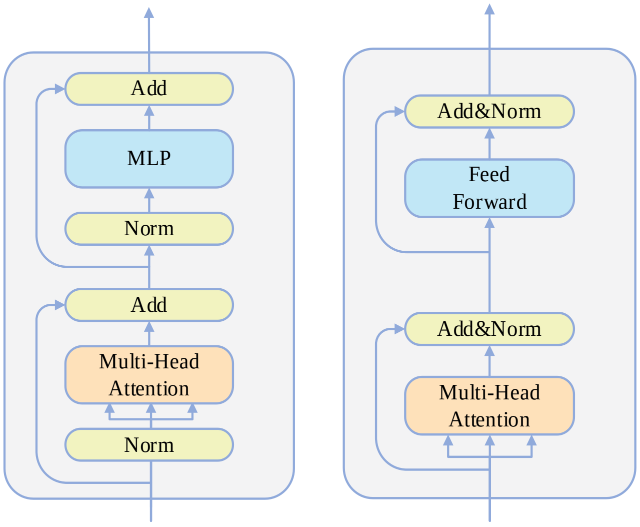
The propose model, MHFAN, has a structure as shown in Fig. 1.

A. *Feature Representation*

The input for MHFAN consists of multimodal news (i.e., image and text content) and image descriptions (expanded from the image content using a pre-trained image2sentence model). For the multimodal news, the text content is represented as a text sequence $T \in \mathbb{R}^{l_T \times d}$, and the sequence T is composed of l_T tokens, where each token $t_i = \mathbb{R}^d$ is a d-dimensional vector learned from the CLIP model. Then, using the CLIP model in the same way to learn the visual features of the image content from the spatial domain, we obtain the image feature vector $V \in \mathbb{R}^{l_V \times d}$ of length l_V in the last hidden layer.

B. *Multi-Reading Habits Fusion Layer(MHF)*

To achieve deep integration of multimodal features, the Multi-Reading Habits Fusion Layer (MHF) has been designed. Based on the differences in how people focus on multimodal information, three reading habits have been identified: "Focus on Image & Scan Text," "Scan Image & Focus on Text," and "Focus on Both Image and Text." In this context, "Focus" indicates thorough reading, while "Scan" indicates cursory reading. Within the MHF, the initial embeddings of the unimodal information are considered as "Scan" behavior, while deeper encoding is regarded as "Focus" behavior. Consequently, MHF first constructs different unimodal encoding blocks and then designs a Multi-Reading Habit Interaction Block (MHI) to model the three types of interactions that occur when people read multimodal information.



(a) Image attention blocks. (b) Text attention blocks.

Fig. 2. The attention block is the basic unit that makes up the encoder.

1) Text and Image encoder: To demonstrate the learning of dependencies between any two text tokens and any two image regions and to extract the intrinsic features of text and images, a Text&Image Encoder based on the self-attention mechanism has been constructed.

The text encoder and the image encoder are attention networks formed by stacking their respective attention blocks, as shown in Fig. 2. The text attention block consists of a multi-head attention mechanism and a feed forward network (FFN), connected through residual connections and layer normalization (Add & Norm). The feed-forward neural network in the image attention block is replaced with a Multilayer Perceptron (MLP). The core of both encoders is the self-attention mechanism, whose computation is illustrated as follows:

$$H = Attention(Q,K,V) = softmax\left(\frac{QK^T}{\sqrt{d_k}}\right)V \tag{1}$$

where, Q, K, and V represent the Query matrix, Key matrix, and Value matrix, respectively. Here, Q=K=V=T, and d_k is equal to $d/2$. To extensively learn richer text contextual information and image upper and lower regional information from different perspectives, the multi-head attention mechanism projects the queries, keys, and values through m different linear projections, and then executes them in parallel. Finally, the processed results are integrated and projected to obtain a new representation, with the computation shown as follows:

$$head = Attention\left(QW_q, KW_k, VW_v\right) \tag{2}$$

$$MultiHead(Q,K,V) = Concat(head_1, \dots\dots, head_m) \tag{3}$$

$$E_T \&\& E_V = MultiHead(Q,K,V) \tag{4}$$

where, $W \in \mathbb{R}^{d \times d}$ are trainable parameters. $E_T \in \mathbb{R}^{l_T \times d}$ is the encoding of the news text content, and $E_V \in \mathbb{R}^{l_V \times d}$ is the encoding of the news image content.

2) Multi-reading habit interaction block (MHI): To model the interactive behaviors within each reading habit, the Multi-Reading Habit Interaction Block (MHI) has been constructed based on the co-attention mechanism to learn the dependencies between multimodal information, as illustrated in Fig. 3. Taking "Focus text&Scan image" as an example, the MHI takes as input the pair $< E_T, V >$, The fusion logic of the MHI is described as follows:

$$\widehat{H_T} = Norm\left(E_T + softmax\left(\frac{E_T(V)^T}{\sqrt{d}}\right)V\right) \tag{5}$$

$$\widehat{H_V} = Norm\left(V + softmax\left(\frac{V(E_T)^T}{\sqrt{d}}\right)E_T\right) \tag{6}$$

$$H_T^{ftsi} = Norm(\widehat{H_T} + FFN(\widehat{H_V})) \tag{7}$$

$$H_V^{ftsi} = Norm(\widehat{H_V} + FFN(\widehat{H_T})) \tag{8}$$

$$H^{ftsi} = concat(H_T^{ftsi}, H_V^{ftsi}) \tag{9}$$

H^{ftsi}represents the integrated semantics of the interaction block specifically for the "Focus text&Scan image" reading habit. The integrated semantics for the "Focus image&Scan text" and "Focus image&Focus text" reading habits are H^{fist} and H^{fift}, respectively.

Finally, the three reading habits are integrated to form a comprehensive fused representation of the multimodal news, denoted as $H_M = concat(H^{ftsi}, H^{ftfi}, H^{fist})$.

C. Similarity Constraint Reasoning Layer (SCR)

To explore the consistency and inconsistency between different modal features, the **S**imilarity **C**onstraint **R**easoning (**SCR**) layer has been designed from two perspectives. First, the **C**onsistency **R**easoning **B**lock (**CRB**) is employed to investigate the consistency between image descriptions and unimodal features. Then, the **I**nconsistent **A**ssociation **C**onstraint (**IAC**) is introduced to capture the semantic deviations between unimodal features and multimodal fused features.

1) Consistency Reasoning Block (CRB): Taking the consistency alignment between the image description S and the textual features E_T as an example, S and E_T are first projected into a shared latent space of the same dimension.

$$F_S = \tanh(W_c S + b_c) \tag{10}$$

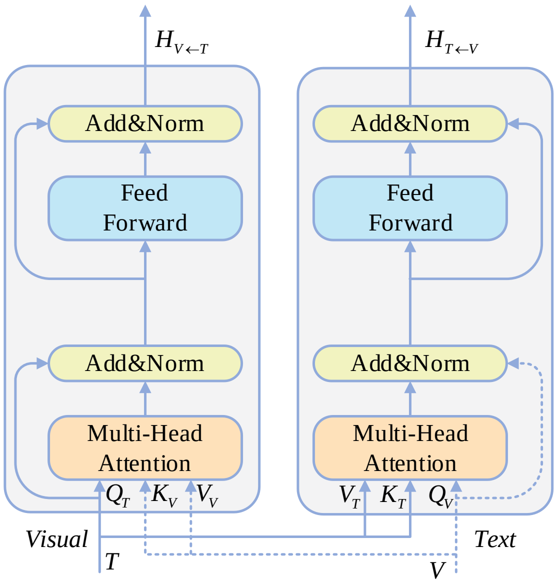
$$F_T = \tanh(W_m E_T + b_m) \tag{11}$$

where, $F_S$and F_T represent the image description and the deep textual semantics in the shared space, respectively. Then, the image description $Q_s = WqF_S$ is used as the query and the deep textual feature $K_T = W_k F_T$ as the keys. Through the attention weight matrix $A_{CM} = softmax(Q_c K_T^T)$, the consistency between these two features is captured. The matrix A_{CM} reflects the degree of attention that the query vector Q_s pays to the key vector K_T.

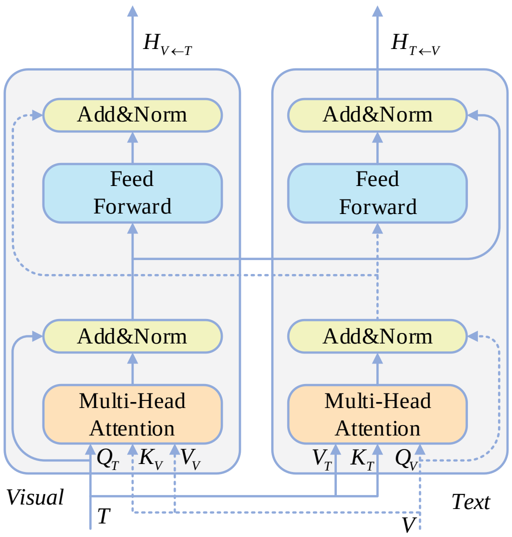
$$A_{CM} = softmax(Q_c K_T^T) \tag{12}$$

$$I^{ST} = F_s + A_{CM} F_T \tag{13}$$

where, I^{ST}represents the consistency aggregation vector between the description and the text, and the consistency aggregation vector between the description and the vision, I^{SV}, follows the aforementioned equation.



(a) Traditional co-attention mechanism.



(b) Multi-Reading Habit Interaction Block (MHI).

Fig. 3. The architecture diagram of co-attention and our MHI.

2) Inconsistent Association Constraint(IAC): The **I**nconsistent **A**ssociation **C**onstraint (**IAC**) is designed to measure the semantic deviation between unimodal and multimodal information in the news. It assesses the deviation between the unimodal aggregated vectors (I^{ST} and I^{SV}) and the multimodal fused semantics. Taking the deviation between I^{ST} and H^M as an example:

$$M_{i,j}^{TM} = \cos(I_i^{ST}, H_j^M) \tag{14}$$

where $M_{i,j}^{TM} \in \mathbb{R}^{l_{ST} \times l_M}$, l_{ST} and l_M are the lengths of the list I^{ST} and H^Mrespectively, and$M^{TM}$is the text multimodal deviation matrix. In this way, M^{VM} represents the image multimodal deviation between I^{SV} and H^M. Subsequently, the two types of deviation matrices are passed to an MLP to obtain the overall semantic deviation M^{all}:

$$M^{all} = MLP(concat(M^{TM}, M^{VM})) \tag{15}$$

Thus, the final multimodal fused features of the news are the comprehensive measure IM of the multimodal features, the consistency aggregated vectors, and the overall semantic deviation:

$$IM = concat(H^M, I^{SV}, I^{ST}, M^{all}) \tag{16}$$

D. Model Learning

The model learning is accomplished by the Fake News Detector and the Event&Sentiment Discriminator. The former consists of a fully connected layer and a softmax layer, with the purpose of correctly classifying the news; the latter is composed of a gradient reversal layer (GRL) and a fully connected layer, with the aim of accurately classifying the news events and sentiments. Both use cross-entropy to calculate the loss. The loss function L_f for the Fake News Detector is defined as follows:

$$L_f = -[y_f \log P_f + (1 - y_f)\log(1 - P_f)] \tag{17}$$

where, P_f represents the predicted label, and y_f is the true label. Similarly, the loss functions for the Event Discriminator and the Sentiment Discriminator are L_e and L_s, respectively.

In fact, due to the presence of the GRL, the Discriminator is inclined to maximize the loss function. A higher loss indicates that the feature distributions are similar, which eliminates the dependency on specific events or specific sentiments. The features learned are common across different events or different sentiments. This sets up a minimax game with the Detector, which tends to minimize the objective function, establishing an adversarial relationship. The final loss function for the model is defined as:

$$L_{final} = L_f - \alpha L_e - \beta L_s \tag{18}$$

where, the loss function parameters α and β are used to balance the losses between fake news detection and event and sentiment classification.

IV. Experiments

A. Datasets and Data Preprocessing

To verify the performance of MHFAN, experiments were conducted on two datasets: Weibo and Twitter. The Weibo dataset, proposed by Jin et al [39]., includes confirmed fake news verified by Sina Weibo's official platform from May 2012 to January 2016, as well as real news verified by Xinhua, an authoritative Chinese news source. The Twitter dataset, proposed by Boididou et al. [40], is used to evaluate multimodal tasks on MediaEval. During the data preprocessing phase, duplicate images were removed, low-quality images were filtered out, and punctuation, numbers, special characters, and short words were eliminated from the text.

It was observed that in both the Weibo and Twitter multimodal datasets, the images and their corresponding text content were not entirely relevant and lacked some semantic information to varying degrees. To address this issue, a pre- trained image2sentence model [41] was employed to generate brief descriptions of the images, thereby providing text information that aligns with the image content. This generated text was used to expand the textual content of the dataset and fill in the missing semantic information. Additionally, the SKEP model [42] was utilized to categorize the datasets into three emotional labels (positive, neutral, negative), and the Single-Pass method [43] was used to detect new events mentioned in the posts.

B. Experimental Settings

To prevent overfitting, the model parameters of CLIP were frozen during training on both the Twitter and Weibo datasets. In the embedding layer, the length of the text sequence was set to 128, and the length of the image representation was 197; the Text&Image Encoder had six attention heads and consisted of 4 attention blocks; furthermore, the model was trained for 100 epochs with a learning rate of 1e-5, and the batch size was set to 128.

C. Evaluation Metrics

The experiments utilized accuracy, precision, recall, and the F1 score to assess the performance of the proposed model.

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \tag{19}$$

$$Precision = \frac{TP}{TP+FP} \tag{20}$$

$$Recall = \frac{TP}{TP+FN} \tag{21}$$

TABLE I. COMPARISON RESULTS OF MHFAN WITH DIFFERENT BASELINE MODELS ON THESE TWO DATASETS

Dataset	Methods	Accuracy	Fake News			True News		
			Precision	Recall	F1	Precision	Recall	F1
Twitter	Visual-Only	0.590	0.580	0.540	0.560	0.600	0.640	0.620
	Text-Only	0.529	0.488	0.497	0.496	0.565	0.556	0.561
	Att-RNN	0.664	0.749	0.615	0.676	0.589	0.728	0.651
	EANN	0.648	0.810	0.498	0.617	0.584	0.759	0.660
	MVAE	0.745	0.801	0.719	0.758	0.689	0.777	0.730
	MCAN	0.809	0.889	0.765	0.822	0.732	0.871	0.795
	MEAN	0.780	0.690	**0.840**	0.760	**0.870**	0.740	0.800
	MHFAN	**0.840**	**0.924**	0.813	**0.865**	0.736	**0.887**	**0.804**
Weibo	Visual-Only	0.640	0.580	0.570	0.610	0.640	0.690	0.660
	Text-Only	0.640	0.741	0.573	0.646	0.651	0.798	0.711
	Att-RNN	0.772	0.854	0.656	0.742	0.720	0.889	0.795
	EANN	0.782	0.827	0.697	0.756	0.752	0.863	0.804
	MVAE	0.824	0.854	0.769	0.809	0.802	0.875	0.837
	MCAN	0.899	**0.913**	0.889	0.901	0.884	**0.909**	0.897
	MEAN	0.894	0.900	0.870	0.890	0.890	0.910	0.900
	MHFAN	**0.905**	0.887	**0.931**	**0.909**	**0.925**	0.877	**0.901**

$$F_1 = \frac{2 \times Precision \times Recall}{Precision + Recall} \qquad (22)$$

where, TP: fake news forecast is fake; TN: real news predicted to be real; FP: real news that is predicted to be fake; FN: fake news predicted to be real.

D. Performance Comparison

MHFAN was compared with several advanced baselines, including both unimodal and multimodal models.

1) Unimodal Models:

a) Visual-Only: This model relies entirely on image information for subsequent classification, using a pre-trained VGG-19 model to extract image features.

b) Text-Only: This model relies entirely on text information for subsequent classification, using Word2Vec combined with Text-CNN to extract text features.

Multimodal Models:

c) Att-RNN [39]: It employs a cross-modality attention mechanism to combine text, visual, and social context features.

d) EANN [15]: While using pre-trained models to extract explicit features from the display, it constructs an event recognizer to obtain implicit common features.

e) MVAE [44]: It uses an encoding-decoding paradigm to capture shared representations that include both visual and textual modalities.

f) MCAN [14]: It integrates features from text, spatial domain, and frequency domain through deeply stacked co-attention layers.

TABLE II. ABLATION ANALYSIS ON TWITTER AND WEIBO DATASETS

Dataset	Methods	Accuracy	Fake News			True News		
			Precision	Recall	F1	Precision	Recall	F1
Twitter	-Text	0.593	0.744	0.539	0.625	0.467	0.685	0.555
	-Image	0.678	0.789	0.666	0.723	0.552	0.699	0.617
	-Description	0.762	0.854	0.750	0.798	0.648	0.783	0.710
	-MHF	0.774	0.842	0.788	0.814	0.676	0.748	0.710
	-SCR	0.807	0.859	0.830	0.844	0.727	0.768	0.747

	MHFAN	**0.840**	**0.924**	**0.813**	**0.865**	**0.736**	**0.887**	**0.804**
Weibo	-Text	0.635	0.640	0.642	0.642	0.630	0.628	0.629
	-Image	0.669	0.673	0.681	0.677	0.666	0.657	0.661
	-Description	0.775	0.782	0.773	0.777	0.768	0.778	0.772
	-MHF	0.773	0.794	0.750	0.771	0.755	0.798	0.776
	-SCR	0.805	0.817	0.793	0.805	0.793	0.816	0.805
	-Adversarial	0.858	0.859	0.865	0.861	0.858	0.852	0.856
	MHFAN	**0.905**	**0.887**	**0.931**	**0.909**	**0.925**	**0.877**	**0.901**

g) MEAN [45]: It utilizes a multimodal generator to enhance the latent discriminative feature representations of text and image modalities.

The results are shown in Table I from which the following observations can be made:

- Compared to the Visual-Only approach that solely relies on visual modality, Text-Only demonstrates a distinct advantage in the task of fake news detection. This suggests that visual information has relatively limited expressiveness and struggles to provide semantic information as rich as text. Therefore, in the task of fake news detection, the textual modality has been proven to be more effective than the visual modality, and better capable of distinguishing between true and fake news information.

- Att-RNN achieves better performance than Visual-Only and Text-Only, indicating that the application of multimodal information is beneficial for detection; EANN constructs an event adversarial neural network and demonstrates strong performance in fake news detection tasks using explicit and implicit common features; MVAE surpasses EANN and Att-RNN in fake news detection with the superior performance of its multimodal variational autoencoder; MEAN improves the model's performance by capturing and learning common features of modalities and events through dual discriminators; MCAN's designed co-attention network shows superior performance compared to MVAE and MEAN, indicating the effectiveness of capturing consistent semantics between multimodal features.

- Compared with the comparative model, the proposed MHFAN fake news detection model shows superiority in various indicators on Weibo and Twitter datasets. In the Twitter dataset, the accuracy of fake news detection increased by 3.5%. On the Weibo dataset, the recall rate of fake news detection increased by 4.2%.

E. Ablation Analysis

1) Effectiveness of each component: To investigate the effectiveness of each component in MHFAN, five model variants were created: -Text, -Image, -Description, -MHF, -SCR, and -Adversarial. These variants denote the removal of the following components: text representation, image representation, image description, the MHF, the SCR, and the adversarial network, respectively.

The results of the ablation study are shown in TABLE II. , from which the following observations can be made:

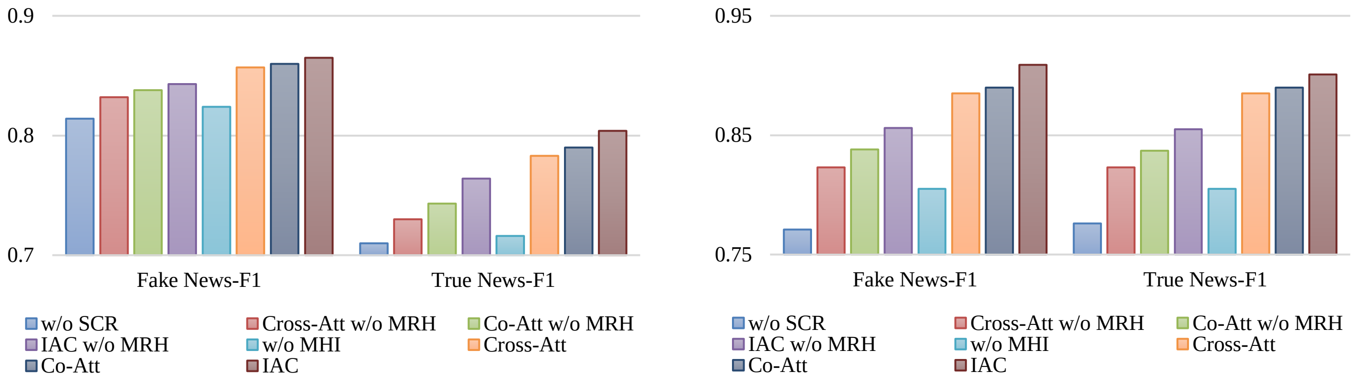
- The removal of different layers led to varying degrees of degradation, demonstrating the effectiveness of each component.
- The -Text and -Image models performed weaker than MHFAN, confirming that relying solely on unimodal information is detrimental to detection. The -Description model also saw a significant performance drop, indicating the importance of image descriptions for semantic expansion.
- The performance of MHFAN without the MHF layer was significantly reduced, reflecting that modeling human reading habits can promote the tight integration of multimodal information; the absence of the SCR layer meant that MHFAN could not obtain the consistency and inconsistency of features between modalities, and its performance also plummeted.
- The -Adversarial model experienced a decrease in precision of 1.9% and 2.8% on the Twitter and Weibo datasets, respectively, illustrating the importance of capturing implicit common features for fake news detection.

2) Comparative analysis of multi-reading habits fusion layer: MHF is the method employed by MHFAN for deep feature fusion and includes two core mechanisms: Multi-Reading Habits (MRH) and the Multi-Reading Habit Interaction Block (MHI). The MRH captures both deep and shallow features of different modalities, while the MHI achieves interactive fusion of features from these modalities. Comparative experiments were conducted under two conditions: one with MRH and one without MRH (w/o MRH). Three alternative methods were also tested to replace MHI: traditional co-attention [46], cross-attention [47], and a version without the MHI module (w/o MHI).

In 0, it is observed that the removal of either MRH or MHI significantly degrades the performance of MHFAN. Under both conditions with MRH and without MRH (w/ MRH and w/o MRH), cross-att, co-att, and IAC all demonstrate superior performance compared to those without SCR (w/o SCR), indicating the necessity for deep interaction between features of different modalities. Moreover, SCR outperforms the other three alternative methods, suggesting that SCR can enhance the interaction of each reading habit, thereby achieving a deeper multimodal feature fusion. Additionally, whether it is the alternative methods or IAC, the scenarios with MRH (w/ MRH) show better results than without MRH (w/o MRH), demonstrating the importance of capturing deep and shallow features from different modalities.

*3) Comparative analysis of inconsistent association constraint*s: Several alternative methods to IAC within MHFAN were evaluated by replacing IAC, which captures feature inconsistency, with the following methods: -IAC (removal of the IAC module), KL-divergence, Euclidean distance, Orthogonality constraints [48], and RA-coherence [49].

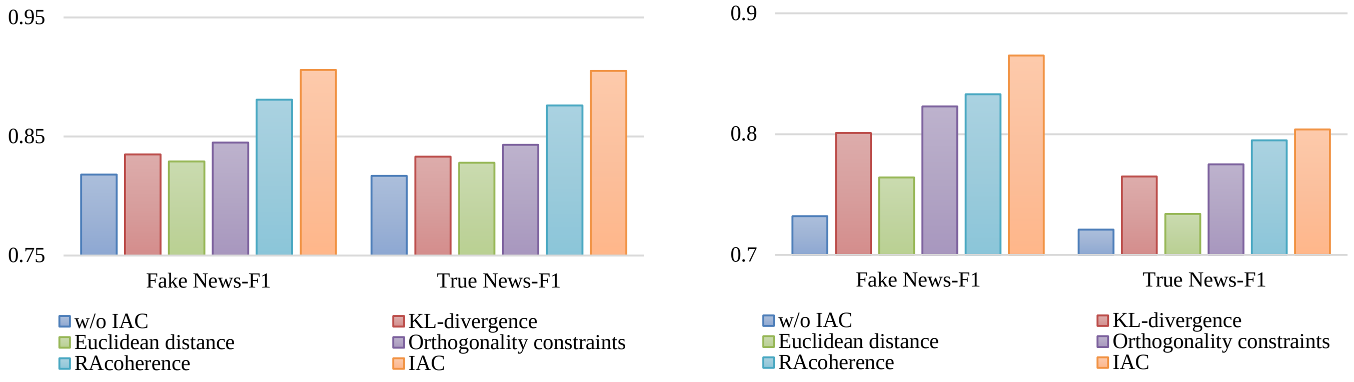
The results, as shown in 0, indicate that compared to w/o IAC, all four variants perform better on both datasets, demonstrating the importance of capturing semantic deviations between different modalities in multimodal fake news detection. Furthermore, IAC outperforms the four alternative methods on both datasets as well. IAC captures the inconsistency between news modalities by calculating the correlation matrices of the two modalities, while the other four methods focus more on the correlation between two types of features and lack an effective measurement of different feature distributions. This proves the superiority of IAC in handling semantic deviations.



(a) On the Twitter dataset

(b) On the Weibo dataset

Fig. 4. Comparison of performance of different ablation blocks in MHF.



(a)On the Twitter dataset

(b) On the Weibo dataset

Fig. 5. Comparison of performance of different ablation blocks in IAC.

V. Case Study

To further illustrate the effectiveness of the proposed method, several cases from the Twitter dataset were selected for visualization.

Image	Visualization	Text	Image description
		A new fish discovered in Arkansas (PIGFISH)	A fish with a head resembling a pig's face.
		Casual shark swimming passed a car	There is a shark swimming in the water next to the car mirror.
		The original photo of Hurricane Sandy over the Statue of Liberty	There is a storm behind the Statue of Liberty that looks like a cat face.

Fig. 6. Visualization case of twitter dataset.

From Fig. 6, it is evident that MHFAN effectively captures features within images and aligns semantically with the corresponding text and image descriptions. In the first example, MHFAN identified the body of the fish and the face of a pig in the image, even though the text did not directly mention pigs, underscoring the importance of image descriptions for semantic expansion. In the second example, MHFAN adeptly focused on the shark and the rearview mirror in the image, achieving semantic alignment with both the text and the image description. The third example similarly demonstrates the model's strengths in feature extraction and consistent semantic alignment.

VI. Conclusion

The dissemination of fake news not only undermines the credibility of news media but also negatively affects the online information environment. The spread of false information severely impedes the healthy development of social media platforms. In response to the existing issues in multimodal fake news detection, the Multi-Reading Habits Fusion Adversarial Network (MHFAN) has been developed, and its effectiveness has been extensively tested and verified on two datasets. Future work aims to refine MHFAN by incorporating factual data from search engines and metadata associated with news articles. This enhancement strategy is expected to bolster the network's resilience and expand its applicability to a wider range of scenarios.

***Abstract*—In 2023, Indonesia experienced an increase Industrial oil palm plantations grew by 116,000 hectares in 2023, an increase of 54% from the previous year. Oil palm is one of the main agricultural commodities in Indonesia, with a significant contribution to the national economy. However, manually mapping and monitoring oil palm land is still a big challenge. This manual process is labor-intensive, time-consuming and costly. In addition, the accuracy of the data generated is often inadequate, especially in identifying the actual crop condition and land area. Remote sensing (RS) provides extensive and comprehensive data on oil palm land and crop conditions through satellite and drone imagery. In this research, a method of mapping oil palm plantations is proposed using medium resolution sentinel satellite imagery data that is widely available and has adequate spatial resolution. In addition, it is proposed to implement the artificial intelligence (AI) method with deep learning (DL) using the UNet classifier which has been proven in previous studies to provide sufficient accuracy. The research will develop a DL model/architecture with ResNet-34 and ResNet-50 backbones that are expected to further improve the accuracy of segmentation results so that it can be used in oil palm land mapping. The research concluded that semantic segmentation using the UNet classifier with ResNet-34 and ResNet-50 backbone produced F1 scores of 0.89 and 0.922, respectively. The accuracy obtained at the inference/deployment model stage for each ResNet-34, and ResNet-50 backbone was 88.8% with an inference duration of 10 minutes and 91.8% with an inference duration of 20 minutes.**

Keywords—Deep learning; UNet; ResNet; oil palm; semantic segmentation

I. Introduction

High-resolution data on oil palm plantations, covering 23.98 million hectares worldwide. This includes 16.66 ± 0.25 million hectares of industrial plantations and 7.59 ± 0.29 million hectares of smallholder plantations [1]. In 2023, Indonesia experienced an increase Industrial oil palm plantations grew by 116,000 hectares in 2023, a 54% increase from the previous year [2]. Oil palm is one of the main agricultural commodities in Indonesia, with a significant contribution to the national economy. However, manually mapping and monitoring oil palm land is still a big challenge. This manual process is labor-intensive, time-consuming and costly. In addition, the accuracy of the data produced is often inadequate, especially in identifying the actual crop condition and land area. To overcome these challenges, RS technology offers a more efficient and accurate solution. Using satellite imagery and drones, RS can provide more comprehensive and real-time data on oil palm land conditions. This technology enables faster and more accurate mapping, identification of land changes, and continuous monitoring of crop health [3]. In addition, RS can also reduce operational and labor costs, and improve overall productivity and land management [4].

One increasingly popular approach to oil palm mapping and monitoring is the use of RS technology combined with AI [5]. RS provides extensive and comprehensive data on oil palm land and crop conditions through satellite and drone imagery. However, the volume and complexity of the data generated often require sophisticated analysis methods. This is where the role of AI becomes crucial. AI, through techniques such as machine learning (ML) and DL, can process and analyze RS data more efficiently and accurately than conventional methods [6]. The implementation of AI in oil palm mapping involves various stages, from plant detection and classification, land area measurement, to plant health monitoring and yield prediction. Using AI algorithms, RS data analysis can be done quickly and provide more accurate results, which in turn supports better and sustainable management decisions [7].

Based on the facts from a recent study, the mapping of oil palm using medium resolution RS data from Planet satellite imagery with SPPNet – UNet (DL Algorithm) and semantic segmentation approaches has only reached a maximum accuracy of 73.63 percent [8] and it is very possible to be developed using different DL algorithms with equivalent resolution RS data. The purpose of the research that has been done is to implement AI, especially with DL algorithms by comparing ResNet-34 and ResNet-50 feature extraction on the UNet classifier. The data used is from medium resolution satellite imagery sentinel-2 which can be obtained for free with the case of industrial oil palm plantation areas in West Kalimantan, Indonesia.

The main structure of this paper consists of an introduction section that discusses the main problems of the research, a previous work section that discusses recent research on mapping oil palm with satellite image data using AI, a methodology section that discusses datasets and DL methods on feature extraction that are compared, a research results section that is discussed with previous research and the last section as a conclusion of the research.
