The initial study is outdated, with its dataset created for a specific purpose that is now rather limited. Our new study, on the other hand, utilizes a more comprehensive and current dataset specifically designed for lung cancer detection, a crucial medical application. As a retrospective study covering the years 1993 to 2007, there may be biases from inaccurate or incomplete historical medical records. Additionally, the study does not consider several potential confounding variables that could affect lung cancer incidence and prognosis, such as genetic predispositions, environmental exposures, or socioeconomic factors. The outdated diagnostic equipment may not adequately capture the complexities of lung cancer progression and treatment response, making some findings less applicable to modern clinical practices. These limitations should be considered when interpreting the study's results and recommendations.

Another valuable resource is the RECIST PFS/OS lung cancer dataset, available on Mendeley Data. This dataset includes annotated CT scan images of lung cancer cases. The Salah Azaiez Institute in Tunisia provided data for creating a dataset that includes, for each patient, age, sex, treatment, presence of mass and nodules, censoring information, objective response, and survival time in days, using CT scans and reports from radiologists at the institute [36]. The dataset primarily uses the RECIST criteria to evaluate tumor response to treatment, which, while standardized, may not fully account for all the subtleties of tumor biology and patient outcomes. Additionally, as a retrospective and observational dataset, it may suffer from biases such as selection bias and information bias. Lastly, although it includes key variables such as sex, age, type of therapy, and survival times, it may lack other significant factors like genetic data, detailed treatment plans, and environmental exposures.

These datasets are limited by their lack of diversity and clinical settings that may not fully represent the unique characteristics of lung cancer in Tunisia.

Our study addresses this gap by creating the first Tunisian lung cancer dataset, which includes DICOM CT scans from 123 Tunisian individuals, annotated by experienced radiologists to cover various types of lung cancer at different stages. This comprehensive dataset ensures a more accurate representation of the Tunisian demographic, making it better suited for developing localized diagnostic tools. The aim of our dataset is to provide the necessary data to detect lung cancer accurately.

VI. Tunisian Lung Cancer Dataset

In order to meet the urgent demand for localized medical datasets in Tunisia, we sought the advice of experts at the esteemed ”Military Hospital of Instruction of Tunis (HMPIT)” [31], an institution renowned for its competence in medical care and research. It is one of Africa’s biggest and most prominent university hospitals. The Tunisian Ministry of National Defense is in charge of this medical center. The partnership with Military Hospital of Instruction of Tunis (HMPIT) played a pivotal role in procuring the superior CT scans required for our project.

We obtained DICOM-formatted CT scans from 123 individuals, where 80% or 98 persons have lung cancer and are treated at this hospital. For the purpose of compiling an extensive and representative dataset of lung cancer cases unique to the Tunisian population, these scans were essential. Because of the medical experts, the dataset was made more robust and applicable by included a variety of patients that represented different stages and forms of lung cancer.

Along with the radiologists and oncologists involved, the annotation process was carried out to guarantee the dataset’s quality and dependability. Their knowledge was extremely helpful in precisely identifying and dividing up the lung nodules and other pertinent elements in the CT scans. This cooperative method helped the concerned teams create capacity and transmit expertise, in addition to improving the quality of the annotations.

The DICOM format CT scans of 98 lung cancer patients, encompassing adenocarcinoma, squamous cell carcinoma, and small cell lung cancer in all stages, are included in the collection from the Military Hospital of Instruction of Tunis (HMPIT) along with the CT scans of the other 25 healthy indivduals representing 20% of the dataset. Nodule counts, sizes, types, features, follow- up status, tumor volume, density, growth rates, involvement of lymph nodes, and documentation of metastases are all included in the annotations. The scans provide high-resolution images with an average of 350 slices per scan, and they are obtained utilizing advanced imaging modalities including Siemens SOMATOM Perspective and GE Healthcare Lightspeed VCT. Included are demographics, clinical data on symptoms, past medical histories, and results.

A. Scanners Used

Modern CT scanners commonly found in hospitals through- out Tunisia—the Siemens SOMATOM Perspective and the GE Healthcare Lightspeed VCT—were used to carefully generate the lung cancer dataset images. Our dataset contains high-quality and consistent data because these scanners were selected due to their extensive use in clinical settings, advanced imaging capabilities,and dependability.

1) Siemens SOMATOM perspective: The Siemens SO-MATOM Perspective is well known for its remarkable image quality and low radiation dosage, which makes it perfect for the in-depth imaging needed to diagnose lung cancer. With the use of cutting- edge technology like iterative reconstruction, this scanner greatly improves image clarity while lowering the patient's radiation dose. By reducing distortions brought on by metal implants, the metal artifact reduction feature helps to improve diagnostic precision. Moreover, the scanner offers adaptability in identifying a variety of illnesses and supports a broad range of clinical applications.

However, like presented in Table I, the scanner does, have certain drawbacks, including high operating costs because of maintenance and operating costs, the requirement for thorough training for best use, potential problems with image quality because of patient movement (motion artifacts), and the lack of advanced features in older models.

TABLE I. SIEMENS SOMATOM PERSPECTIVE STRENGTHS AND WEAKNESSES

Siemens SOMATOM Perspective	
Strengths	**Weaknesses**
High image quality	High operational costs
Low radiation dose	Complex operation
Iterative reconstruction	Susceptibility to movement artifacts
Metal artifact reduction	Limited advanced features in older models
Versatile clinical applications	

2) GE Healthcare Lightspeed VCT: Another high-performance scanner with a reputation for quick and high-resolution imaging is the GE Healthcare Lightspeed VCT. It has cutting-edge technology like low-dose imaging protocols and the Volume Imaging Protocol (VIP), which guarantee thorough lung scans with little radiation exposure. Because of its quick picture acquisition capabilities, this scanner is perfect for use in high-throughput clinical settings and emergency situations where time is of the essence. Its advantages include quick image acquisition, improved workflow efficiency, detailed images appropriate for in-depth analysis, low-dose protocols that minimize radiation exposure while preserving image quality, and quick and easy image acquisition in hectic clinical settings.

Its shortcomings include the necessity for frequent calibration to preserve picture accuracy, the high cost of maintenance and consumables, the vulnerability to artifacts caused by patient movement, and the limited availability of specialized imaging modes in certain configurations. Table II summarizes the GE Healthcare Lightspeed VCT Strengths and Weaknesses.

TABLE II. GE HEALTHCARE LIGHTSPEED VCT STRENGTHS AND WEAKNESSES

GE Healthcare Light speed VCT	
Strengths	**Weaknesses**
Rapid image acquisition	High operational costs
High-resolution imaging	Susceptibility to movement artifacts
Low-dose protocols	Requires frequent calibration
Efficient workflow	Limited specialized imaging modes

To guarantee data integrity, quality and patient confidentiality, the generated images were safely stored in DICOM format on encrypted external drives. The external drives were kept in a safe, climate-controlled environment, and frequent backups were made to guard against data loss. Extensive metadata was recorded to make retrieval and analysis simple.

B. DICOM Format CT Scans

The images in the collection are kept in the DICOM (Digital Imaging and Communications in Medicine) format, which is a commonly utilized format for organizing, transferring, and storing data related to medical imaging. DICOM is made to make sure that systems that create, show, transmit, store, query, process, retrieve, print, and manage medical pictures can communicate with one another. The DICOM format was selected primarily because it can maintain excellent picture quality without adding compression artifacts, which is essential for preserving the images' diagnostic integrity.

In addition to the image data, DICOM files include an abundance of metadata, such as patient demographics, scan parameters, imaging modality specifics, and facts on the hospital and its equipment. This metadata is immediately included into the DICOM file, offering a thorough record that is necessary for precise diagnosis, study repeatability, and other purposes. For instance, for comparison research and to ensure uniformity between scans, scan characteristics including slice thickness, resolution, and radiation dose are essential.

Furthermore, DICOM is a flexible option for multi-modality imaging investigations since it supports a broad variety of imaging modalities, such as CT, MRI, ultrasound, and X-ray. Sensitive information is safeguarded since the format complies with global standards for patient privacy and medical data security.

By using the DICOM format, the dataset can be used in a variety of clinical and research settings because it is compatible with a wide range of medical imaging applications and systems. In order to provide easy access and analysis by medical professionals, this compatibility is especially crucial for integration with Picture Archiving and Communication Systems (PACS), which are utilized in clinics and hospitals. Furthermore, DICOM's ability to handle sophisticated imaging capabilities including 3D reconstructions and multi-frame functionality increases its usefulness for in-depth research of lung cancer.

CT scans are especially useful in the detection of lung cancer because they provide high-resolution images that can detect tumors and small nodules that might not be visible with other imaging modalities. Additionally, CT imaging offers excellent contrast between different types of tissue, which is crucial for precisely identifying and characterizing lung nodules, as well as determining their size, composition, and size.

CT scans provide 3D reconstruction of the lung structure, offering a thorough perspective that facilitates accurate tumor location and evaluation in relation to adjacent tissues. Planning surgical procedures, directing biopsies, and tracking the efficacy of treatments over time are all made possible by this capacity.

By choosing CT scans in DICOM format, we ensure that the dataset meets the highest standards of image quality, data integrity, and interoperability, making it a robust and valuable resource for ongoing and future research in lung cancer diagnosis and treatment. Detailed information about the dataset is provided in the Table III.

TABLE III. DATASET DETAILS FROM MILITARY HOSPITAL OF INSTRUCTION OF TUNIS (HMPIT)

Attribute	Details
Number of Patients	123 (including both healthy and sick patients)
Health Status	• Healthy Patients: 25 • Sick Patients: 98
Format	DICOM
Types of Lung Cancer	• Adenocarcinoma: 45 patients • Squamous Cell Carcinoma: 33 patients • Small Cell Lung Cancer: 20 patients
Stages	• Stage I: 34 patients • Stage II: 26 patients • Stage III: 28 patients • Stage IV: 10 patients
Annotations	• Number of nodules: Detailed count per patient • Size of nodules: Measurements in millimeters • Nodule type: Solid, part-solid, or ground-glass • Nodule characteristics: Margin, shape, and calcification status • Follow-up status: Monitoring of nodule changes over time • Tumor volume and density • Tumor growth rate (if multiple scans available) • Identification and annotation of affected lymph nodes • Documentation of any metastasis to other parts of the body visible in scans
Imaging Modalities and Scanners	• **GE Healthcare LightSpeed VCT:** High-speed imaging capabilities and good spatial resolution • **Siemens SOMATOM Perspective CT Scanner:** Precise imaging and dose efficiency
Technical Details	• Resolution: Typically 512 x 512 pixels • Slice Thickness: 1-5 mm, ensuring consistency and quality • Number of Slices per Scan: Average of 300 slices per CT scan • Scan Duration: Approximately 5-15 minutes per scan • Imaging Dates: January 2020 - April 2024 • Scanner Settings: Voltage (120 kVp), Current (200-400 mA), Exposure Time (0.5-1 seconds perslice)
Demographics	• Age: Range from 20 to 80 years, with an average age of 60 • Gender: 73 males, 50 females • Relevant Medical History: Includes smoking history (80% of patients), family history of lungcancer (30% of patients)
Clinical Data	• Symptoms: ○ Cough: 84 patients ○ Chest pain: 53 patients ○ Shortness of breath: 76 patients • Treatment History: ○ Surgery: 42 patients ○ Chemotherapy: 69 patients ○ Radiation therapy: 50 patients • Outcomes: ○ Survival rate ○ Recurrence ○ Cancer-free • Additional Annotations: ○ Histopathological findings ○ Genetic mutations (e.g., EGFR, ALK) ○ Biomarker levels (e.g., PD-L1 expression)

C. Data Quality

The lung cancer dataset was created with the highest priority on ensuring high data quality. Advanced imaging technologies such as Siemens SOMATOM Perspective and GE Healthcare LightSpeed VCT CT Scanners were used to obtain all CT scans. This ensured that all images were high-resolution, with a typical resolution of 512 x 512 pixels and consistent slice thicknesses ranging from 1 to 5 mm. In order to protect the quality and integrity of the images and prevent compression artifacts, they were stored in DICOM format.

Qualified radiologists painstakingly analyzed the images, recording in-depth information regarding every nodule, such as numbers, millimeter diameters, kinds (solid, part-solid, or ground- glass), and features including margin, shape, and calcification status. The volume, density, and growth rates of the tumor were annotated, as well as the lymph nodes that were afflicted and any obvious metastases. These thorough annotations were saved as structured CSV files, which offer a common format for simple analysis and integration with different data processing applications.

A thorough validation procedure was put in place to guarantee the highest level of accuracy. Peer evaluations of the annotations, several cross-checks, and consistency checks against accepted medical norms were all part of this process. To make sure that data management procedures were being followed, the dataset also went through routine audits and quality reviews. To stop data deterioration, the external disks holding the data were encrypted, often backed up, and kept in a safe, climate-controlled location.

The dataset is an important and dependable resource for research and development in lung cancer diagnosis and therapy because of the exact, well-documented annotations and high-quality photos. Table III contains comprehensive details about the dataset.

D. Data Preparation

Making ensuring the raw data is appropriately structured, cleaned, and arranged is the goal of data preparation so that it may be used for additional processing and analysis. There were several important steps in this phase. To enable uniform analysis, all CT scans were first standardized to a uniform resolution and slice thickness, usually between 1 and 5 mm. The maintenance of uniformity across images acquired from various scanners, such as the Siemens SOMATOM Perspective and the GE Healthcare Lightspeed VCT, required this standardization. The quality of the scans was then improved by applying image noise reduction techniques, which included algorithms to filter out aberrations and improve the visibility of minute features.

After that, radiologists performed a preliminary examination of the scans to find and fix any irregularities, like motion artifacts or partial images. This quality check made sure that the dataset contained only the best images. Critical data, including patient demographics, scan parameters, and gear characteristics, were included in the metadata and carefully checked for accuracy.

1) Data cleaning: Data cleaning in the data preparation stage of our Tunisian lung cancer dataset entailed finding and fixing mistakes or inconsistencies in the DICOM images. Before processing the dataset further, this involved correcting missing values, standardizing data formats, and eliminating duplicate records in order to guarantee its integrity and quality.

2) CT imaging parameters: There are 123 subjects' worth of CT images in DICOM format available. Since this is a ret-respectively gathered dataset, various subjects were scanned with different scanners, protocols, and parameters: slice thickness of 1-4 mm (median: 3 mm) and an X-ray tube current of 200-400 mA (mean 250 mA) at 100-140 kVp (mean 120 kVp). Specific scanning parameters, such as the make and model of the scanner, are specified in the DICOM headers. The subjects were scanned while supine, and the scans were obtained from the apex of the lung to the adrenal gland in a single breath-hold.

3) Image segmentation: Further, a segmentation procedure was applied to each scan, defining the lung regions in order to isolate the key areas of the image and concentrate on the area of interest. For it to enable accurate annotations and lessen computing load during analysis, this step was crucial. As part of the preparation stage, imaging protocols were standardized to reduce variability brought about by various scanning configurations and methods.

E. Image Annotations

The process of locating and labeling pulmonary nodules in CT scans and other medical imaging studies is known as ”nodule annotation.” Medical professionals must conduct a thorough examination of 3D volumetric data in order to identify, quantify, and categorize nodules that might be signs of lung cancer. The purpose of nodule annotation is to produce an accurate and thorough dataset that can be utilized to train machine learning models for dependable and accurate lung nodule detection.

The first step in annotating our our Tunisian lung cancer dataset CT scans, is selecting the right annotation software. We employed software such as 3D Slicer and ITK-SNAP, which are well acclaimed in the medical imaging field for their feature-rich and intuitive interfaces. For the purpose of designating pulmonary nodules, these technologies are perfect because they enable the thorough inspection and annotation of 3D volumetric data.

- 3D Slicer is an open-source software platform that can handle a wide range of imaging formats and is highly adaptable for medical image informatics, image processing, and three-dimensional visualization. Users can load DICOM images, and it offers strong visualization tools for precisely locating and labeling nodules [20].
- Another well-liked software with a focus on 3D medical image segmentation is ITK-SNAP. Experts can more easily annotate nodules with precision thanks to its

semi-automated segmentation capabilities and user-friendly manual segmentation features [21].

Second step, the CT scans for our Tunisian dataset were imported into the selected tools which were set up to show the pictures in a way that makes it simple to identify nodules. This setup comprised:

- Changing the Window and Level Settings: To bring the nodules out against the background lung tissue, adjust the brightness and contrast.
- Multi-Planar Reconstructions (MPR) are made possible: permitting views in the axial, sagittal, and coronal planes to give a thorough understanding of the nodule's structure.
- Effective Navigation: Guaranteeing that images are easily panned, zoomed in on, and navigated so that specialists can examine them in-depth.

After that, each scan was examined by radiologists and oncologists from hospitals in Tunisia to look for lung nodules. Being able to differentiate nodules from other anatomical features and possible artifacts needed a high level of knowledge. In order to obtain a thorough grasp of the nodule's properties, we collaborated with the specialists and made use of the tools' features to zoom in on areas of interest, change the contrast of the image, and switch between different views.

The following was a part of the annotation process:

- Exact Position: The nodule's x, y, and z coordinates were noted. Mapping the nodule's location in the lung's three-dimensional space requires these coordinates.
- The size measurement: A measurement of the nodule's diameter was made. This measurement aids in the classification of the nodule and determines whether it is potentially cancerous.
- Classification: Based on its features, each nodule was categorized. Nodules were often categorized as malignant or benign (0).
- Existence of Nodules: In order to clearly distinguish between scans with and without nodules, this was additionally noted if there were none.
- Disease Stage: Each patient's disease stage was recorded, which added further context for the severity and course of the sickness.

More annotations are found in the dataset descriptive Table I.

For convenience of access and integration with machine learning techniques, the annotated data was stored as a CSV file. The CSV file contained multiple distinct columns, each of which represented a single nodule. Table IV lists and describes some annotations in our CSV file.

Several experts examined the annotations to guarantee their uniformity and accuracy. After disagreements between reviewers were reviewed and settled, the final annotations underwent validation and quality control to make sure they adhered to the required accuracy requirements. In order to confirm the validity and suitability of the Tunisian lung cancer dataset for machine learning model training, this step was essential.

TABLE IV. ANNOTATION CSV FILE COLUMNS

Column	Description
patient id	A distinct identitfier for each patient.
series id	A unique and distinct identifier for the collection of images ofeach patient.
coordX, coordY, coordZ	The nodule coordinates within the lungs.
diameter mm	The nodule diameter in millimeters.
class	The nodule classification (0 for benign, 1 for malignant).
nodule present	A boolean representing whether nodules are present (1) or absent (0).
stage	The cancer stage (Stage I, Stage II, Stage III, Stage IV).

F. *Data Compliance and Standards*

One of the main tenets for establishing the lung cancer dataset was adhering to legal and ethical guidelines. The relevant institutional review board granted ethical approval to the project prior to data collection, guaranteeing that the study complied with all relevant ethical standards. Every patient gave their informed consent, ensuring that they understood exactly how their information would be used, maintained, and safeguarded.

In accordance with the Tunisian National Instance for the Protection of Personal Data (INPDP) [18], the dataset was painstakingly de-identified to remove any personal identifiers. The integrity and usability of the data were preserved while patient privacy was protected thanks to this de-identification procedure.

1) De-Identification of imaging DICOM data: Before being analyzed at the Military Hospital of Instruction of Tunis (HMPIT), all imaging data were de-identified. Using XNAT (eXtensible Neuroimaging Archive Toolkit), we were able to de-identify the imaging data. With the help of XNAT, medical imaging data can be securely managed and made anonymous, guaranteeing that DICOM objects no longer contain protected health information (PHI).

Every personal identification was eliminated from the dataset in order to preserve patient confidentiality. By de-identifying the data, privacy laws were satisfied with by the dataset. To further improve the dataset's resilience, several versions of the preexisting photos were produced using data augmentation techniques. To give context and make it easier for other researchers to use the dataset, thorough documentation about its creation, properties, and annotations was produced.

We used again XNAT to execute a second round of de-identification before releasing the data for research, ensuring that all identifying information had been completely removed. With options like Clean Pixel Data, Clean Descriptors, Retain Longitudinal with Modified Dates, Retain Patient Characteristics, Retain Device Identity, and Retain Safe

Private Options, this de- identification procedure conforms to international requirements for medical data privacy.

2) Data encryption: The DICOM standard, which offers a framework for the interchange and storage of medical images and related data, is one of the worldwide standards for medical imaging that the dataset was created to comply with. The broad use and integration of medical imaging devices and software is facilitated by compliance with DICOM standards, which guarantees interoperability.

The dataset was also stored using encryption and frequent backups, which followed the best practices for data security and integrity. We made sure that the dataset respects patient rights and privacy in addition to meeting high-quality benchmarks by closely adhering to these ethical and regulatory norms. This makes it a dependable and morally sound resource for lung cancer research.

To preserve data quality, the external disks were kept in a safe, climate-controlled environment. Extensive metadata documentation made it simple to retrieve and analyze the dataset, which made it a strong and useful tool for studying lung cancer.

VII. Tunisian Lung Cancer Dataset Model Selection

To make certain our lung cancer dataset is high-quality and useful for training cutting-edge machine learning models, it must be tested. Extensive tests enable us to assess the dataset's robustness and detect any potential biases or restrictions that can impair model performance. We can learn a great deal about the dataset's suitability for lung nodule identification and diagnosis by carefully evaluating it. Our dataset's value in practical applications is demonstrated by benchmarking it against well-established models, which also reveals its potential to increase diagnostic accuracy. The results of these studies will serve as a strong basis for upcoming investigations, propelling the creation of more accurate and effectivemedical imaging instruments.

A. Comparative Analysis of Model Architectures

In this section, we compare and contrast a number of renowned model architectures from the field of medical imaging, including CNN, U-Net, VGG, and ResNet. These models were selected for comparison because they are widely used and have a track record of success in a variety of image processing applications, including medical imaging. It is crucial to comprehend these models' performance and applicability for lung nodule identification in order to choose the best architecture for our dataset. We hope to determine the advantages and disadvantages of each model through this comparison, giving a convincing explanation for our selection. This comparison analysis aids in our decision-making process for choosing the most suitable model for our application by offering a thorough grasp of how various architectures function in the contextof lung nodule identification.

Table V shows the different architecture and various use cases of each model mentioned.

Table VI lists the multiple advantages and also disadvantagesof each model.

TABLE V. MODELS ARCHITECTURE AND USE CASES

Model	Architecture	Use Case
CNN [25]	sequence of convolutional layers, pooling layers, and fully connected layers in order of succession	General image classification
U-Net [26]	symmetric layer encoder-decoder design with skip connections	Biomedical image segmentation
VGG [27]	16 or 19-layer deep architecture with tiny (3x3) convolution filters	Large-scale image classification
ResNet [19]	Identity mapping can be achieved with a deep architecture featuring residual blocks.	Complex image classification and detection

TABLE VI. MODELS ADVANTAGES AND DISADVANTAGES

Model	Advantages	Disadvantages
CNN [24]	Simple and efficient for extracting features, well-established and straightforward to develop	Vanishing gradient causes Problems with highly deep networks, which may necessitate extensive tweaking for complicatedtasks.
U-Net [28]	Great for segmenting images, very accurate for localization tasks	Computationally demanding, could not adapt well to tasks requiring classification without adjustments
VGG [29]	Robust large-scale image classification performance with a straightforward and deep architecture	High memory consumption, high computational expense, and less useful for very deepnetworks
ResNet [30]	Residual learning reduces the vanishing gradient issue and enables the formation of extremely deep networks with exceptional performance on challenging tasks.	Can have a more complicated architecture and be computationally demanding than conventional CNNs.

The comparison study draws attention to the unique traits and functionalities of the CNN, U-Net, VGG, and ResNet models. Every architecture has advantages and disadvantages that affect which medical imaging tasks they are best suited for.

Based on the unique needs of lung nodule detection—which necessitates a deep architecture capable of capturing delicate and detailed features—ResNet models were chosen over CNN, U-Net, and VGG. We have collected high-resolution CT scans from 123 individuals 80% from them have lung cancer in Tunisia and 20% are healthy. This large and heterogeneous dataset demands a model that can efficiently identify and learn from intricate patterns and minute differences in the data. A model that can successfully capture and learn from intricate patterns and minor variations in the data is required because of this large and diverse dataset.

The vanishing gradient issue is successfully addressed by ResNet's residual learning framework, which makes it especially suitable for this purpose and makes it possible to train very deep networks—which are necessary for high-accuracy detection tasks. ResNet is perfect for managing the complex characteristics in our dataset because of its ability to retain performance in deep networks by alleviating the vanishing gradient issue [19], making it possible to extract detailed features from complicated data. Even with deeper network architecture, steady training and enhanced performance are guaranteed by the incorporation of residual blocks and skip connections. CNNs lack the depth required for more sophisticated tasks, even if they are simple and efficient for basic picture categorization [24]. U-Net performs quite well in segmentation, but its large processing overhead increases when applied to classification tasks [28]. Though powerful, VGG’s high memory needs make it computationally costly and less useful for very deep networks [29].

The most balanced method for creating a lung nodule identification model that can effectively utilize the rich and extensive data in our Tunisian dataset is ResNet, thanks to its depth, resilience, and performance. Accurate and dependable lung nodule detection in a variety of clinical scenarios can be efficiently supported by its ability to handle complicated data structures and retain high accuracy [30].

B. Resnet Models

In their 2015 publication”Deep Residual Learning for Image Recognition”, Kaiming He et al. [19] introduced ResNet, short for Residual Network, a kind of deep neural network. ResNet’s main breakthrough is residual learning architecture, which makes it possible for the network to train considerably deeper models than it could have before. With this invention, the vanishing gradient problem—a prevalent difficulty in deep learning—is addressed. As network depth increases, gradients become increasingly small, making learning ineffective. ResNet models were initially created to classify 2D images; however, they have since been expanded to 3D versions to handle volumetric data, including CT scans. To be more specific, ResNet models have been expanded to 3D versions [23] in the context of medical imaging, particularly for 3D data such as CT and MRI scans. These models make use of 3D convolutional layers, which perform three-dimensional convolution operations to capture spatial data in the dimensions of depth, height, and width. This is crucial for activities that depend on the geographical context in three dimensions, such as lung nodule detection.

Multiple residual blocks, each having a set of convolutional layers, make up ResNet models. The input is added back to the original input after passing through convolutional layers in a residual block, creating a skip or shortcut link. This facilitates the learning of identity mappings by the model and aids in maintaining the gradient flow, which facilitates the training of deeper networks.

Bypassing one or more layers, the skip connections add the input straight to the stacked layers’ output. This lessens the degradation issue, which occurs when a sufficiently deep model gains more layers, increasing training error.

The multiple layers that make up the architecture of 3D ResNet models are intended to capture varying degrees of abstraction from the input data. The essential elements consist of [19]:

- 3D Convolutional Layers: These layers use three-dimensional convolution processes to capture spatial data related to the input volumes’ depth, height, and width.
- Layers for batch normalization: These layers speed up training and increase the stability of the model by normalizing the output of convolutional layers.
- Layers of ReLU Activation: The Rectified Linear Unit (ReLU) activation adds non-linearity to the model so that it may pick up intricate patterns.
- Residual Blocks: By allowing the model to learn residual functions in relation to the layer inputs, these blocks make it possible to build extremely deep networks without experiencing any degradation.
- Pooling layers: These layers help to downsample the data and lower computational complexity by reducing the spatial dimensions of the input.
- Fully Connected Layers: These layers create final predictions at the conclusion of the network by combining features that were extracted by earlier levels.

ResNet models come in a number of depths: ResNet10, ResNet18, ResNet34 and ResNet50. The number denotes the total number of layers in each model. To depict varied levels of complexity and detail, these models feature different arrangements of leftover blocks [19].

- ResNet10:

Architecture: Ten-layer ResNet’s most basic model. It is effective at capturing important information during training even with constrained computational resources.

Use: Fits well with activities that need faster inference times and less complexity.

- ReNet18:

Architecture: An eighteen-layered, relatively deeper model. Its ability to strike a balance between performance and complexity qualifies it for a variety of uses.

Use: Frequently applied to tasks involving generic medical picture classification.

- ResNet34:

Architecture: A 34-layer, deeper model that enables more precise feature extraction.

Use: Perfect for jobs like segmentation and tiny anomaly identification that call for in-depth analysis and excellent accuracy.

- ResNet50:

Architecture: A complex model with 50 layers, offering the highest capacity for capturing intricate patterns in the data.

Use: Best suited for highly detailed tasks that require extensive computation, such as multi-class segmentation and advanced diagnostic analysis.

VIII. Dataset Robustness Testing

We ran thorough tests using multiple 3D ResNet models to assess the resilience of our lung cancer dataset. CT scan pictures with annotations for lung nodules were used to train the models. Several ResNet designs (ResNet10, ResNet18, ResNet34, and ResNet50) were used in the training process, and the outcomes were contrasted with those attained using the Tencent MedicalNet models.

A. Tencent MedicalNet Models

A set of pre-trained models created especially for medical imaging tasks are available through Tencent's MedicalNet initiative [22]. The models are optimized for certain tasks, such lung nodule identification, after having undergone extensive and varied pre-training on a vast collection of medical images.

We painstakingly duplicated Tencent MedicalNet's experimental setting to verify the reliability of our lung cancer dataset. To guarantee a direct and impartial comparison between the MedicalNet models' and our dataset's performance, this required sticking to the same 3D ResNet models and training parameters.

A wide range of modalities, target organs, and diseases were covered by the 23 datasets that were combined for the MedicalNet project. The models can acquire universal feature representations through this thorough pre-training, which they may then apply to a variety of medical imaging tasks. The models were tested for adaptability and high performance on a variety of tasks, such as lung segmentation and pulmonary nodule classification. The research ensured a thorough and diversified dataset for pre-training by compiling data from multiple sources, such as MRI and CT scans. The study made use of a variety of 3D ResNet designs (ResNet10, ResNet18, ResNet34, and ResNet50) to capture varying degrees of intricacy and detail in the data. MedicalNet used spatial and intensity normalizing approaches to address the diversity in spatial resolution and intensity distributions. This improved the training process by guaranteeing that the data given into the modelswas consistent.

We selected Tencent's MedicalNet to showcase the resilience of our lung cancer dataset, thanks to its pre-trained 3D ResNet models. Pre-trained on an extensive and varied collection of medical images, MedicalNet's models improve their generalization and performance on a range of tasks. We are able to assess our dataset's quality and its potential to help construct high-performance diagnostic tools by using these pre-trained models. This thorough assessment highlights the contribution of our dataset to the advancement of medical image processing in general and lung nodule detection specifically.

B. Transfer Learning

Transfer learning is a potent deep learning technique in which a pre-trained model is refined on a smaller, task-specific dataset after it was first trained on a larger dataset. By utilizing the knowledge gained from the lengthy pre-training phase, this method improves generalization and increases the model's efficiency in learning from the smaller dataset. In medical imaging, where it might be difficult to gather big annotated datasets, transfer learning is very helpful [32]. We may greatly improve our models' performance by utilizing pre-trained models, like Tencent's MedicalNet, since they gain from the wide range of feature representations that are acquired during the pre-training stage. This methodology enhances the models' accuracy and robustness when used for particular tasks, such lung nodule identification in our dataset, while also lowering the computational resources needed for training.

We used pre-trained 3D ResNet models from Tencent's MedicalNet to implement transfer learning in our study. Since a big and varied collection of medical images served as the initial training set, the models were able to pick up a wealth of attributes pertinent to medical imaging. With the help of our lung cancer dataset, we adjusted these pre-trained models so they could be specifically used for lung nodule detection.

The procedure entailed starting with the MedicalNet models' pre-trained weights and completing the training on our dataset. By using this method, the models were better able to identify and categorize lung nodules because they could make use of the generic traits that they had acquired during the first training phase. Our goal in fine-tuning these models was to bring together the unique characteristics of our dataset with the advantages of thorough pre-training.

C. Pre-processing and Training

We were able to use the same architectures—ResNet10, ResNet18, ResNet34, and ResNet50—and apply comparable pre-processing methods, optimization tactics, and evaluation criteria by coordinating our experiments with those carried out by MedicalNet. We were able to provide a thorough and consistent review thanks to this strategy, which also made sure that any discrepancies in performance could be traced back to the datasets themselves insteadof deviations in methodology.

To guarantee consistency and enhance the learning process, the CT scan images had been processed before being used for the training and assessment of the 3D ResNet models. Among the preprocessing actions were:

- Format Conversion: DICOM CT scans were programmatically transformed to NEFTII format. This modification made handling and processing of both our and Tencent Medicalnet volumetric data more efficient.
- Normalization: To make sure that the intensity values were scaled correctly for the neural network, each CT scan was normalized to a range of [-1, 1].
- Resizing: To standardize the input size and lower processing needs, the scans were downsized to a uniform shape of 64x64x64 voxels.
- Data Augmentation: During training, data augmentation techniques like random rotations and flips were used to improve the models' capacity for generalization.
- Data Division: The dataset was divided into training, validation, and testing subsets in order to guarantee the efficient training and assessment of machine learning models. This tactical separation is essential to creating reliable and accurate models. The full range of variations seen in the entire dataset was carefully reflected in these divides, which were made to maintain diversity and balance. Training is for 70% of the split, validation for 15%, and testing for 15%.

The preliminary actions made to collect, arrange, and structure the raw data in order to make it suitable for analysis or modeling are referred to as data preparation. A more detailed step called “data pre-processing” entails getting the cleaned and sorted data ready for the real machine learning or data analysis work. The goal of this step is to change the data in order to improve the models’ accuracy and performance. Therefore after making sure that our data is ready for the models we proceed to the training.

There were multiple steps in the training:

1) Data loading: After being loaded, CT scan images underwent preprocessing to standardize and resize them into a form that would work with the models. Tencent MedicalNet’s pre-trained ResNet models, including ResNet10, ResNet18, ResNet34, and ResNet50, are loaded. These models have a good pattern recognition capacity because they have already been trained on big datasets. The final layers are adjusted to meet our classification requirements in order to customize these models for our particular task of lung nodule identification. By utilizing the power of transfer learning, this phase enables the pre-trained models to efficiently apply the features they have learnt to our dataset.

2) Hyperparameter configuration: One important stage in the training process is configuring the hyperparameters. The learning rate, which regulates the step size during gradient descent, the number of epochs, or full runs through the training dataset, the batch size, which establishes the quantity of samples processed before the updating of the model’s internal parameters, and the loss criteria, which direct the optimization procedure, are important hyperparameters. Appropriate hyperparameter selection is essential to maximize model performance and guarantee effective training.

3) Training of the models: Using the training set, the models’ weights are modified during the training phase. The validation set is used to assess the model’s performance at each epoch in order to keep an eye out for overfitting. When a model performs well on training data but poorly on unknown data, this is known as overfitting. We can reduce overfitting by using early stopping or other regularization strategies by evaluating the validation set. Every ResNet model underwent ten epochs of training, during which the accuracy and loss were noted.

4) Evaluation: Accuracy served as the main performance indicator for each model. Ten epochs were required to record the final accuracy. The test set is used to assess the final models’ performance after training, giving an objective appraisal of the model’s capabilities. The model’s accuracy is assessed to assess how well it detects lung nodules. To verify the reliability and efficacy of our dataset and model modifications, these outcomes are then contrasted with the performance metrics of the previously trained models on comparable datasets

D. Results and Analysis

The resilience and good quality of the dataset were demonstrated by the models trained on it, which repeatedly displayed excellent performance.

The accuracy trends of each model trained on our dataset, are clearly represented visually in the Fig. 6.

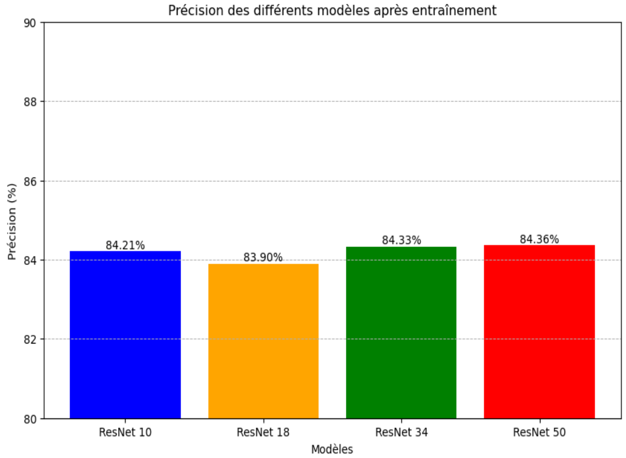

Fig. 6. Comparison of the accuracy achieved by different 3D ResNet models over the training epochs

Following training, each model’s final accuracy is listed in Table VII below which shows a comparison between the accuracy of each model trained on our dataset and the models trained on Tencent MedicalNet datasets.

TABLE VII. COMPARISON OF ACCURACY BETWEEN OUR DATASET AND TENCENT MEDICALNET MODELS

Model	Your Dataset Accuracy	MedicalNet Accuracy
ResNet10	84.21%	96.56%
ResNet18	83.90%	94.68%
ResNet34	84.33%	94.14%
ResNet50	84.36%	89.25%

All of the models that were trained on our dataset performed admirably, with an accuracy rate of above 84%. ResNet50 demonstrated the best accuracy of 84.36%, demonstrating the resilience of our dataset in the identification of lung nodules. Nevertheless our models’ accuracy was slightly lower than Tencent’s MedicalNet models’, which were pre-trained on a larger and more varied collection of medical images. For example, the MedicalNet ResNet10 model attained an astounding 96.56% accuracy, while our dataset only managed 84.21%. There are various reasons for this disparity.

- First off, MedicalNet has a big edge because to its thorough pre-training on a variety of medical images. By learning a wide range of characteristics that are applicable to many tasks, the models benefit from this pre-training, which improves their performance on new datasets. Even though our dataset is strong, it is smaller and less varied than MedicalNet’s, which restricts the models’ capacity to generalize to previously undiscovered data.

- Second, the improved performance of the MedicalNet models can be attributed to the variety in the dataset, which encompasses numerous modalities and target organs. This variety enhances the models' accuracy and resilience across a range of tasks by enabling them to gain a more thorough grasp of medical imagery.

- Thirdly, more thorough training and fine-tuning are made possible by MedicalNet's large computational resources and longer training periods, which can have a big impact on the final performance. We could get better outcomes if we extend the training period and increase our computational resources.

- Fourthly, the discrepancies in accuracy seen might have been caused by the scanners we utilized to obtain our dataset, including the Siemens SOMATOM Perspective and GE Healthcare Lightspeed VCT. Variations in imaging techniques and scanner features may result in inconsistent image quality and resolution, which could have an impact on the performance of the model.

E. An Overview of the Tunisian Lung Cancer Dataset Creation Workflow

To ascertain the quality, reliability, and usability of the Tunisian lung cancer dataset for the development of sophisticated machine learning models, a number of crucial procedures have to be taken during the creation process, like shown in Fig. 7.

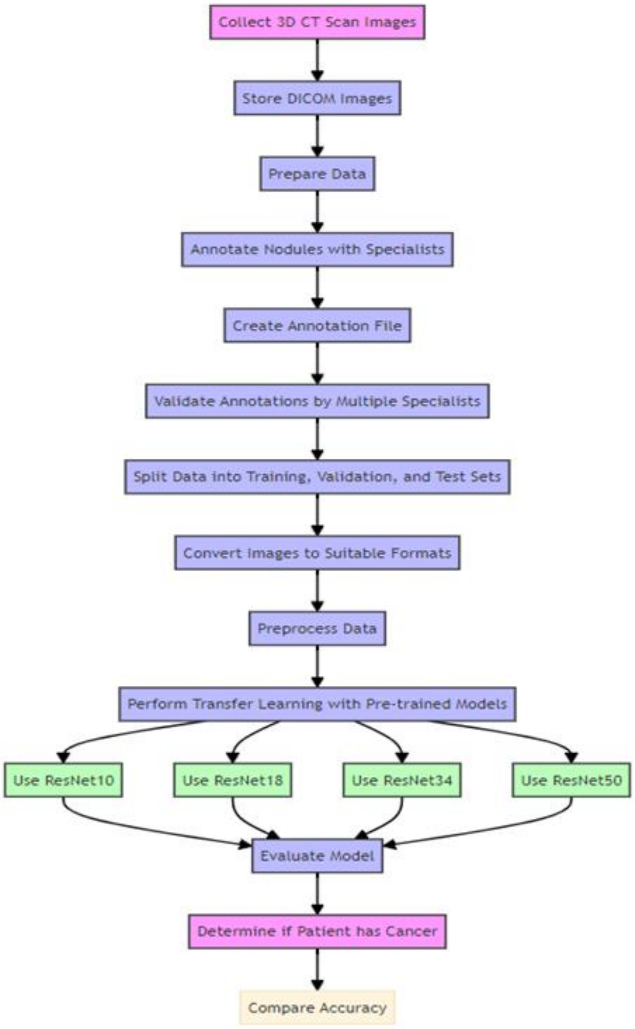
1) Data collection: We started by gathering DICOM images from the Military Hospital of Instruction in Tunisia (HMPIT). Siemens SOMATOM Perspective and GE Healthcare Lightspeed VCT were the two scanners used to capture the images.

2) DICOM image storage: The integrity and confidentiality of patient data were then preserved by importing these images onto a safe external device.

3) Data preparation: The data preparation stage began along with gathering and safely storing the DICOM images from the Military Hospital of Instruction of Tunis (HMPIT). Setting up parameters, fixing mistakes, getting rid of duplication, and standardizing formats are all part of this phase. Furthermore, segmentation is done to divide the data into areas that make sense, allowing for more focused and effective analysis. By doing this, we guarantee that the dataset is reliable, consistent, and prepared for the thorough annotation and pre-processing stages necessary for training a machine learning model.

4) Nodule annotation: We worked together with specialized software like 3D Slicer and ITK-SNAP to annotate the CT images. Strong capabilities and intuitive user interfaces were offered by these tools for in-depth examination and annotation.

5) Nodule annotation validation: Several experts examined the annotations to guarantee uniformity and accuracy. Consensus meetings were used to settle disagreements.



Collect 3D CT Scan Images
Store DICOM Images
Prepare Data
Annotate Nodules with Specialists
Create Annotation File
Validate Annotations by Multiple Specialists
Split Data into Training, Validation, and Test Sets
Convert Images to Suitable Formats
Preprocess Data
Perform Transfer Learning with Pre-trained Models
Use ResNet10
Use ResNet18
Use ResNet34
Use ResNet50
Evaluate Model
Determine if Patient has Cancer
Compare Accuracy

Fig. 7. The workflow of the creation and validation of the lung cancer Tunisian dataset.

6) Dataset splitting: To make sure that each set accurately reflected the diversity of the full dataset, it was divided into training, validation, and testing sets. Typically, training would account for 70% of the split, validation for 15%, and testing for 15%.

7) Data pre-processing: To ensure compatibility with Tencent MedicalNet models, data pre-processing for our Tunisian lung cancer dataset project entailed converting DICOM pictures to NEFTII format. Standardized image resolutions and normalized intensity values were achieved. Rotation and flipping are examples of data augmentation techniques that produced additional training samples. To ensure accurate model evaluation and peak performance, the dataset was finally divided into 70% training, 15% validation, and 15 % testing.

8) Transfer learning with ResNet models from tencent MedicalNet: We used Tencent MedicalNet's pre-trained ResNet models (e.g. ResNet10, ResNet18, ResNet34, and ResNet50). We adjusted these models with our Tunisian lung cancer dataset. Using the knowledge from pre-trained models, transfer learning was used to improve performance on our particular dataset.

9) Experiments and validation: We ran experiments to assess how well the refined ResNet models performed using our dataset defining how well the models can detect lung cancer patients thus the accuracy was measured.

10)Compare accuracy: The robustness of our dataset was evaluated by contrasting its results with those obtained from the MedicalNet models. To make sure the models translate effectively to fresh, untested data, they were verified using the testing set. Upon contrasting our accuracy outcomes with those obtained from MedicalNet, we discovered that although our dataset had strong performance, the models trained on MedicalNet data demonstrated slightly greater accuracy. This demonstrates that in order to match the performance of existing datasets, additional improvements in data quality and diversity are required.

Every stage of the dataset creation procedure, including data preparation, annotation, pre-processing, training of models, and collection, was thoroughly documented. This documentation guarantees reproducibility and offers precise instructions for further study and advancements. In order to provide transparency and promote cooperation with other researchers, it also includes metadata regarding the dataset, annotation processes, and pre-processing techniques utilized. Following ethical and privacy rules, the dataset and model results were shared and archived securely.

IX. Conclusion

To enhance lung nodule detection and develop diagnostic techniques tailored to the local population, it is crucial to address the lack of a lung cancer dataset in Tunisia. We assembled a comprehensive dataset of 123 well-annotated DICOM-format CT images from various locations within Tunisia. By utilizing pre-trained 3D ResNet models from Tencent's MedicalNet and applying transfer learning, we validated the robustness of our dataset. After refinement, these models exhibited outstanding performance, demonstrating the effectiveness of our approach.

The significance of broad and varied pre-training on a variety of datasets is shown by the superior performance of MedicalNet models. Future work will focus on several key areas to enhance the dataset and its applicability. First, improving pre-processing and augmentation techniques will be crucial to improve the quality and robustness of the dataset. Additionally, we aim to expand the dataset by including more diverse and comprehensive data sourced from additional medical institutions across Tunisia. Incorporating multi-modality imaging, such as MRI and PET scans, will provide a more holistic view of lung cancer characteristics, enhancing the depth and scope of the dataset. Finally, we will seek collaboration with international research bodies to standardize annotation protocols and integrate the Tunisian dataset with global datasets, facilitating broader applicability and creating new research opportunities.

Ensemble Feature Selection for Student Performance and Activity-Based Behaviour Analysis

Varsha Ganesh[1], S Umarani[2]*
Research Scholar, Department of Computer Science, SRMIST, Ramapuram, Chennai, India[1]
Professor, Department of Computer Science and Application (BCA), SRMIST, Ramapuram, Chennai, India[2]

Abstract—**Analyzing students' behaviour during online classes is vital for teachers to identify the strengths and weaknesses of online classes. This analysis, based on observing academic performance and student activity data, helps teachers to understand the teaching outcomes. Most Educational Data Mining (EDM) processes analyze students' academic or behavioural data; in this case, the accurate prediction of student behaviours could not be achieved. This study addresses these issues by considering student's activity and academic performance datasets to evaluate teaching and learner outcomes efficiently. It is necessary to utilize a suitable method to handle the high dimensional data while analyzing Educational Data (ED), because academic data is growing daily and exponentially. This study uses two kinds of data for student behaviour analysis. It is essential to use feature reduction and selection methods to extract only important features to improve the student's behaviour analysis performance. By utilizing a hybrid ensemble method to get the most relevant features to predict students' performance and activity levels, this approach helps to reduce the complexity of the feature-learning model and improve the prediction performance of the classification model. This study uses Improved Principal Component Analysis (IPCA) to select the most relevant feature. The resultant features of the IPCA are given as input to an ensemble method to select the most relevant feature sets to improve the prediction accuracy. The prediction is done with the help of Residual Network-50 (ResNet50) is combined with a Support Vector Machine (SVM) to classify students' performance and activity during online classes. This performance analysis evaluates the students' behaviour analysis model. The proposed approach could predict the performance and activity of students with a maximum of 98.03% accuracy for online classes, and 98.06% accuracy for exams.**

Keywords—Behaviour analysis; deep learning; educational data mining; student performance prediction; students activity monitoring; machine learning

I. Introduction

Educational Data Mining (EDM) [1] techniques help in understanding students' learning situations and improve the teaching support for better decision-making in the educational system. The modern education system, which is evaluated from offline learning to online teaching [2] and learning mode, assesses the outcomes [3] and teaching effects [4]. Online learning, which has been increasing significantly during the last decade, enables students to learn in a comfortable environment. Students are the core resources of any educational institution. The academic sectors must deal with many changing factors to offer quality education using offline and online systems. Management must implement innovative [5] and effective teaching and learner outcome evaluation methods [6] to improve the quality of their graduates. This also helps teachers to evaluate the learners' effects to understand their condition easily by analyzing students' online data such as activity and behaviours [7], concentration levels, and academic performance [8]. These behavioural changes also affect learners' academic performance. Hence it is necessary to keep track of students' learning patterns by monitoring their activities and analyzing academic performance [9]. EDM techniques [10], which help in performing this monitoring and analyzing task, use Machine Learning (ML) [11], Deep Learning [12], Statistics, and other data mining techniques to analyze student behaviours and predict their performance. In addition, the COVID-19 pandemic forced the education system [13] to continue regular learning and teaching actions online. These changes made EDM an emerging research field to make the teaching and learning process more effective for online learning environments.

A. Research Objective

Researchers have utilized both quantitative and qualitative methodologies, revealing that students frequently exhibit unforeseen behaviours throughout online class sessions. So, the management implements some preventive actions by using many online data analytics tools to control the students. These online teaching platform-based devices produce many student activity and academic performance-related data. Proper utilization of analytics techniques in these ED gives better analysis results to predict student behaviours. Analyzing students' behaviours during the online platform is a vital part of teachers identifying their strengths and weaknesses.

- This analysis of observed academic performance and student activity data helps teachers to understand the teaching outcomes.
- Many Educational Data Mining (EDM) studies focus on either academic or behavioural data, yet in this instance, accurate prediction of student behaviours remained elusive. This study addresses these issues by considering both datasets to evaluate teaching and learner outcomes efficiently.
- Employing an appropriate technique to manage the expanding high-dimensional educational data is essential due to its daily growth.
- A prediction model is designed to investigate the same data types simultaneously. But it does not correlate students' behaviours with academic performance. So, this study uses two different kinds of datasets for

*Corresponding Author.

performance analysis. Alternative methods of analyzing student behaviour and performance necessitate the implementation of an efficient model.

The Hybrid DL model is developed by combining the Convolutional neural network with ResNet50 to perform this analysis for the prediction task.

B. Paper Organization

The remainder of the article is organized as: Section II discusses the various author's research opinion on the student's performance prediction-based methods. Section III explains the student's activity and performance prediction methods adopted in this research. Section IV gives details about the hybrid ensemble feature selection model. Results and analysis and discussion are given in Section V and Section VI respectively. Finally, Section VII concludes the paper.

II. Literature Review

Erick Odhiambo Omuvan [14] et al. (2021) described irrelevant and redundant information negatively influencing and creating complexity during selection operations in the classification algorithm. Principal Component Analysis (PCA) is utilized to support the ML-based classification models to improve the performance by avoiding irrelevant and redundant features. It selects the best feature combinations from the original data to support the ML classifiers.

A. Jenul et al., 2021[15] presented a feature selection approach using the Repeated Elastic Net Technique (RENT) which uses an ensemble model with elastic net regularization. Each model is trained with different feature sets of data. It follows three strategies to evaluate the weightage distribution of features among all the elementary models, which leads to relevant feature selection with higher stability that improves the robustness of the final model. It also provides valuable data for the model analysis concerning identifying objects in the data that are difficult to predict during the training. The performance of the RENT, analyzed with different healthcare data, shows that RENT achieves better performance than other methods.

Wen Xiao et al. (2021) [16] developed a hybrid feature selection method for student performance prediction. It uses score-based feature ranking and a heuristic approach to build the RnkHUE algorithm. The heuristic search strategy and forward ranking from the Genetic Algorithm (GA) help to select the significant features from the students' dataset. Initially, it identifies the evaluation criteria based on considering student performance factors such as distance, information metrics, dependency, and consistency. The heuristic method finds the best subsets among all the features using the search strategy. Further, the selected candidate feature sets are used for feature selection to improve the prediction performance of the proposed approach.

Ali AI Zawqari et al. (2022) [17] developed a flexible feature selection model for student performance prediction in four categories of student performance data. This prediction framework uses two concepts: improving the prediction performance with feature selection, and skipping feature engineering. Initially, features are embedded continuously and applied directly on an Artificial Neural Network (ANN) to perform prediction. The second approach uses all the embedded features to perform feature reduction with the help of Random Forest (RF) before performing the prediction. The evaluation results show that the feature selection-based model helps the prediction model to obtain a better accuracy of 93% for dropout prediction. This model also obtained 86% accuracy prediction for students' pass grade and 88% prediction for distinction grade data.

Sing R et al., (2021) [18] prepared a comprehensive study on the performance of various feature selection methods on students' academic data. It discusses the different contemporary approaches broadly used to foresee the educational outcome of the under study. It brings forth the fact that the academic performance of the enrolled students in any course has some patterns. Moreover, the feature choice predicts student performance to obtain significant results.

R. Singh et al., 2020 [19], developed a Machine Learning (ML) based ensemble model to predict students' performance. This model utilizes the ensemble of Decision Tree (DT), K-Nearest Neighbour (K-NN), extra tree, and Naive Bayesian (NB) methods. It uses bagging-based boosting methods for performance prediction. The ensemble model accuracy is improved to 86.83% for the students' performance dataset. The results show that the NB performs well compared to other models. However, the complex structure of ensemble models failed to obtain a reliable accuracy level with NB.

Hussain et al., 2021 [20] prepared an automatic students' marks and grade forecasting framework using ML models. A Genetic Algorithm (GA) selects features from the students' dataset. The GA-selected parts are classified by Regression and DT classifier. The regression model achieved a dependable accuracy rate of 96.64%. However, with the escalating volume of data, scalability becomes a significant concern. The ML-based model requires further refinement to enhance its performance. So a deep learning-based regression model needs to be integrated.

Tarik A et al., 2021 [21], designed an ML model to predict Moroccan students' performance in the region of Guelumim Qued Noun through a recommendation system using artificial intelligence. The prediction model presented in their study indicates the baccalaureate mean as a function of many exploratory variables, such as grades and core subjects. The performance of linear regression, regression-based DT, and regression-based Random Forest (RF) models is evaluated. Among these three, DT with RF method obtained a maximum of 61.08% accuracy. However, poor model fitting led this combination to perform poorly for students' datasets.

Abellan-Abenza J et al., 2017 [22] introduced a surveillance system based on the human behaviour analysis technique. The current behaviour of a person is identified while crossing a surveillance camera. Various human behaviour expression image datasets are utilized for training the classifier. The behaviour identification is performed by combining the Convolutional Neural Network (CNN) with the Recurrent Neural Network (RNN).

Rastrollo Guerrero JL et al., 2020 [23] prepared a deep preview for predicting students' performance. This review focuses on identifying the students' classroom behaviour-based dropout prediction model. This study utilizes the image datasets for the analysis. Its review describes the various stages of the prediction processes to perform the dropout prediction.

Chowanda et al., 2021 [24], the performance of multiple machine learning models was evaluated on sentiment-related text datasets derived from students. Emotions of students were detected using Naive Bayes (NB), Generalized Linear Model (GLM), Support Vector Machine (SVM), Decision Tree (DT), Fast Large Margin (FLM), and Artificial Neural Network (ANN). Among these models, GLM achieved the highest accuracy rate of 0.902. While the emotions anger and joy were consistently identified with high accuracy, the classification of the emotions fear and sadness posed challenges for the classifier in emotion recognition tasks.

J Zhao et al., 2020 [25] used educational data analytics containing text enhancement phase, Synonyms Replacement (SR), Random Insertion (RI) of words, Random Swap (RS), and Random Delete methods were performed while extracting the text emotion reorganization. This reorganization has been achieved with the help of a Directed Acyclic Graph (DAG) with an SVM model to train the various textual sentiment data.

D Selvapandian et al., 2020 [26] introduced an Efficient Fusion based Neural Network (EF-NN) model for sentiment analysis from feedback documents of students. This hybrid model integrates the SVM classifier with CNN. Students' feedback data set is extracted based on attribute features like the interaction between the student, examination, and notes given.

BHKT H.M. Perera et al., 2021 [27], an innovative e-learning surveillance system was introduced to assist instructors in online exam monitoring. This system is capable of identifying low engagement levels, detecting suspicious activities, and flagging instances of multiple logins at the onset of online exam sessions. What sets this approach apart is its ability to not only predict academic performance but also forecast learning behaviours. Consequently, it enhances the accuracy of performance prediction among students, thereby contributing to improved assessment quality.

Saba T [13] et al., 2021 [28] developed an automatic exam monitoring system to assist instructors in monitoring students without being present in the exam centres. It builds a deep model to form a 46-layered CNN model. The extracted features are used for selecting significant features using Atom Search Optimization (ASO) to improve the prediction performance of variants of SVM and KNN models; among these, KNN model obtained the best accuracy rate (93.88%).

A. Problems Identified

This review identifies that ML models suffer from fitting issues while handling different kinds of educational data. This has been overcome by adopting suitable feature selection, and reduction approaches to manage high or low volumes of student data.

- Moreover, educational data is of different types based on the kind of analysis. However, most ML models can perform well on similar types of educational data.
- It is necessary to develop a hybrid model to analyze multiple types of educational data. This study has developed a mixed method to lessen the fitting issues.
- Generally, hybrid methods take longer for data processing. Because it combines the features of two methods, this study utilizes the ResNet-50 method to improve the time complexity during the prediction process.
- The linear SVM method generally performs well for educational data in low dimensions. Nevertheless, achieving a better balance in the model is necessary as it is currently influenced by irrelevant features within the dataset.
- So it is necessary to develop an effective feature selection method to avoid fitting issues which would also help to reduce the loss rate and improve the prediction performance by using two levels of the feature selection approach.

B. Research Contribution

- The first stage performs the feature reduction using the IPCA method to remove the irrelevance of the students' behaviour-related academic performance and online activity data.
- The second stage uses the reduced features for the most relevant feature, which supports improving the students' performance and activity prediction performance using the ML-based ensemble feature selection method.
- The ML models used in the ensemble methods are chosen based on their performance analysis on student datasets in recent studies.
- The ensemble method strengthens the weak ML methods used in this approach in more potent ways by using ensemble stacking. The ensemble stacking method identifies the most relevant feature combination for behaviour analysis.

The functionality of the proposed students' performance and online activity-based behaviour prediction approach is described in a subsequent section.

III. Student Performance and Activity Based Behaviour Analysis Approach

This section discusses the functionalities of various methods used in behaviour analysis approaches. This Student data contains four phases: data collection, preprocessing, feature selection, and prediction analysis. Initially, the students' performance and online activity datasets utilized in this section are taken from two publicly available datasets. The preprocessing stage utilizes the one-hot encoding method to normalize categorical data. The third phase develops a feature selection method using a hybrid ensemble method; it combines IPCA with the Ensemble feature method. Finally, the prediction phase uses ResNet-50 to train the model, the SVM classifier to test the data and classify the students' behavioural data. The general flow of the four phases is depicted in Fig. 1.

A. Data Sources

This analysis uses two different datasets for students' behaviour and performance prediction. The student activity and academic data are collected from publicly available open databases. The academic dataset is collected from the Kaggle [29] database, which covers 480 instances and 16 attributes. These features are categorized into three groups: (1) Demographic features such as gender and nationality; (2) Academic background features such as educational stage, grade level and section; (3) Behavioural features such as raised hands-on class, opening resources, answering survey by parents and school satisfaction.

Student activity datasets are taken from the UCI repository [30], which is publicly available for educational research and contains log information for each student. Generally, these data, captured using various LMS tools, is given on a per session basis, per student basis, and exercise basis. It is comprised of six sessions of data. Each exercise file contains the session's start, end, and learning activity. The dataset consists of 230318 records and 13 attributes, recorded and taken for analysis from 115 subjects.

The analysis divides both datasets for training and testing the model. The ResNet50 network's training and SVM model's testing phases use 70% and 30% of students' activity data respectively. The student's academic performance data is divided into 75% for training and 25% for testing.

B. Preprocessing

These datasets contain both numerical and categorical data. So, it is necessary to use proper preprocessing steps to normalize the datasets. This study uses one hot encoding method to normalize the raw datasets. It represents the categorical data as numerical data to train the ML models and improve the model performance by providing more information about the unlimited data.

Every categorical data in the datasets is part of a given categorical feature written in vectors, consisting only of 0 and 1. It converts into a vector whose elements are only 0's or 1's. Each word is encoded uniquely in this method. It allows the term can be identified uniquely by its one-hot vector. Table I shows the uniquely converted code for student genders for the labels. The male, female, and transgender data are converted as 100, 010, and 001, respectively.

However, this one hot encoding method increases the dimensionality of the dataset and may lead to overfitting and sparse data issues. So it is essential to use proper feature reduction approaches to reduce the dataset's dimensionality and identify the most significant students' academic and activity-related feature information.

2	0	1	0
3	0	0	1

IV. HYBRID ENSEMBLE FEATURE SELECTION METHOD

Normalization of students' records avoids the overfitting by adopting a suitable feature reduction technique. Since ML-based classification models must be more balanced due to irrelevant dataset features, it is necessary to develop an effective feature selection method to avoid fitting problems. This also helps reduce the loss rate and improve the prediction performance. Two levels of the feature selection approach can achieve it. The first stage is performing the feature reduction using the IPCA method to remove the irrelevant behaviour-related academic performance and online activity data. The second stage uses the reduced features for the most relevant feature, which supports improving the students' performance and activity prediction performance using the ML-based ensemble feature selection method. The ML models used in the ensemble methods are chosen based on their performance analysis on student datasets in recent studies.

The ensemble method strengthens the weak ML methods used in this approach in more potent ways by using ensemble stacking, which identifies the most relevant feature combination for behaviour analysis. This study uses the hybrid ensemble method to perform the feature selection, which combines the Improved Principal Component Analysis (IPCA) with the ensemble feature selection method to reduce the dimensionality of the students' record at the initial level. The ensemble method is designed to select the most relevant features to predict academic performance and activity datasets.

Fig. 2 illustrates the hybrid feature selection method using IPCA and ensemble method. The IPCA is utilized to identify the reduced set. Then the resultant sets are used in the ensemble method to select the relevant feature set, which influences the classification model to improve the prediction accuracy.

A. Principal Component Analysis

Any high-dimensional dataset can use this PCA to reduce the dimensionality. It rotates the cordiality system to convert a large dataset of possible interrelated indicators into a smaller set of linear correlated indicators. Each feature's interrelationship is ensured using the PCA to examine the correlation between indicators. The standardization process in traditional PCA leads to loss of dispersion degree information of the original dataset. These issues can be avoided by utilizing the IPCA approach for feature reduction, which performs the following six steps for measuring students' academic and activity features: standardizing the input matrix, computing correlation coefficient, computing eigenvalues and eigenvector, defining principal component, identifying the indicators belonging to the determined PCs, and calculating the component score.

1) Standardization of the input matrix: The number of input data samples is n and m indicators are considered for the feature reduction. The input feature vector is represented as X_{nxm}. The standardization assures perfect comparability between indicators. The original feature matrix $X_{nXm}$is transformed as $Y_{nxm}$with zero mean and unit variance.

$$y_{ij} = (x_{ij} - \bar{x}_j)/S_{x_j} \tag{1}$$

The value of i and j in eq(1) is initiated as i=1,2,..n and j=1,2,..m. The representation $x_{ij}$is the jth indicator value of the ith sample in the feature matrix of student records X_{nxm},*and* x_j is the jth indicator of X_{nxm}. Then, the mean and standard deviation of x_j is represented as $\bar{x}_j$ and S_{x_j} respectively. The standardized value of $x_{ij}$is y_{ij}.

2) Computing the correlation coefficient: Correlation information between the indicators is computed using the correlation coefficient (ϕ).

$$\phi = (\rho_{y_j,y_k})_{mXm} = \frac{1}{n-1} Y^T Y \tag{2}$$

In eq(2), y_j *and* y_k are the jth and kth column vectors of Y_{nxm} , respectively. The expression ρ_{y_j,y_k} denotes the correlation coefficient between (y_j *and* y_k), which are the jth and kth indicators.

3) Computation of eigenvalues and eigenvector:

$$|\phi - \lambda E| = 0 \tag{3}$$

The eigenvalues and eigenvectors of ϕ are obtained using eq(3).

All the eigenvalues are arranged in descending order as $\lambda_1, \lambda_2, \lambda_3, \dots., \lambda_j, \dots., \lambda_m$.Each eigenvalue has its corresponding eigenvector.

$$\phi b_j = \lambda_j b_j \tag{4}$$

According to eq(4), the unit vector(b_j) corresponds to λ_j and assigned $\sum_{i=1}^{m} {b_{ij}}^2 = 1$. Therefore, $B = (b_1, b_2, \dots, b_m)$ is a unit orthogonal matrix consisting of all the units of the eigenvector.

4) Defining principal component: The number of principal components is generally determined according to the criterion of eigenvalues > 1, which is along with the screen plot, or cumulative percentage variance < 80%, which is constructed using the values of a_j and β_p in Eq. (5) and Eq. (6).

$$a_j = \frac{\lambda_j}{\sum_{j=1}^{m} \lambda_j} \tag{5}$$

The a_j in Eq. (5) is the percentage variance of ith Principal Component (PC).

$$\beta_p = \sum_{k=1}^{m} \lambda_k \,/\, \sum_{j=1}^{m} \lambda_j \tag{6}$$

Eq. (6) is used to calculate the cumulative percentage variance (β_p) of p PC and the $p \le m$. Whenever $\beta_p \ge 80\%$ first appears, the PC (p) is selected.

5) Identifying the indicators belonging to the determined PCS: The factor loading of each indicator on each persistent PC is

$$\theta_{jk} = b_{jk} \sqrt{\lambda_k} \tag{7}$$

The correlation coefficient θ_{jk} between the jth indicator and kth PC is calculated by Eq. (7). λ_k indicates the eigenvalue corresponding to kth PC, and b_{jk} is the jth value of b_k. It considers the indicator with $\left|\theta_{jk}\right| \geq 0.5$, indicating that the jth indicator belongs to kth PC.

6) Calculating component score: Every PC is a weighted linear combination of all indicators, and the PC scores $\left(f_1, f_2, f_3, \ldots., f_p\right)$ are obtained using $F = YB$.

$$w_k = \frac{\lambda_k}{\sum_{j=1}^{m} \lambda_j} \tag{8}$$

Besides, the percentage of variation explained by each PC is used as a weight CF, calculated using Eq. (8).

$$CF = \sum_{k=1}^{p} w_k f_k \tag{9}$$

The total component score CF is obtained based on Eq. (9).

$$z_{ij} = \left(x_{ij} - \bar{x}_j\right)/\varepsilon_{x_i} \tag{10}$$

Eq. (10) in the traditional PCA set the variance of each indicator to 1. This reduces the influence of dispersion degree difference on PCs. So, improved standardization is used in this study. Eq. (10) is used to compute the enhanced standardization, where $\varepsilon_{x_i} = \max\left(x_j\right) - \min(x_j)$ and the $\varepsilon_{x_i} > 0$, z_{ij} is the standardized value of x_i.

$$\bar{z}_j = \sum_{i=1}^{n} \frac{x_{ij} - \bar{x}_j}{\varepsilon_{x_i}} /n = \frac{\sum_{i=1}^{n}(x_{ij} - \bar{x}_j)}{n\varepsilon x_i} \tag{11}$$

$$S_{z_j} = \sqrt{\frac{1}{n-1}\sum_{i=1}^{n}(z_{ij} - \bar{z}_j)^2} = \sqrt{\frac{1}{n-1}\sum_{i=1}^{n}\left(\frac{x_{ij} - \bar{x}_j}{\varepsilon_{x_i}}\right)^2} = \frac{S_{x_i}}{\varepsilon_{x_i}} \tag{12}$$

The mean and the standard deviations of *the* jth indicator (z_j) in Z_{nxm} are obtained using Eq. (11) and Eq. (12) respectively.

$$\rho_{z_j,z_k} \left.\begin{aligned} &= \frac{C_{z_j,z_k}}{S_{z_j},S_{z_k}} = \frac{1}{n-1}\sum_{i=1}^{n}(z_{ij},\bar{z}_j)(z_{ik},\bar{z}_k)/S_{z_j},S_{z_k} \\ &= \frac{\frac{1}{n-1}\sum_{i=1}^{n}\frac{(x_{ij},\bar{x}_j)}{\varepsilon_{x_j}}\frac{(x_{ik},\bar{x}_k)}{\varepsilon_{x_k}}}{\left(\frac{S_{x_j}S_{x_k}}{\varepsilon_{x_j}\varepsilon_{x_k}}\right)} \\ &= \frac{1}{n-1}\sum_{i=1}^{n}(x_{ij},\bar{x}_j)\frac{(x_{ik},\bar{x}_k)}{\left(S_{x_j},S_{x_k}\right)} = \rho_{x_j,x_k} \end{aligned}\right\} \tag{13}$$

According to Eq. (13), the $Z_{nxm}$and X_{nxm} are the same correlation coefficient matrix. It indicates that the improved standardization methods retain correlation information of all indicators. Notably, the dispersion degree difference of all hands is partly retained according to the standard deviation in Eq. (12).

B. *Ensemble Features Selection*

1) Elastic net: Elastic net is a combination of Ridge and Lesso regression methods which are popular for regularizing variants of linear regression. Lesso used the penalty L1, and Ridge used the penalty L2 method. The specialty of the elastic net is that it uses both L1 and L2 for penalty regularization.

$$ElasticNet = MSE\left(y, y_{pred}\right) + \ a_1\sum_{i=1}^{m}|\theta_i| + \ a_2\sum_{i=1}^{m}|\theta_i| \tag{14}$$

The elastic net function is expressed as in Eq. (14) to compute the loss value between actual (y) and predicted output class with the loss value of ridge regression $(a_1\sum_{i=1}^{m}|\theta_i|)$ and loss value of Lesso regression ($a_2\sum_{i=1}^{m}|\theta_i|$). The control parameters are a_1 and a_2 to control the L1 and L2 penalty respectively. The number of optimal parameters is represented as.

2) Recursive Feature Eliminator (RFE): RFE is a wrapper-type feature selection method. In contrast with filter-based feature selection that scores each feature and selects those features with the most significant score, RFE searches for a subset of features by starting with all features in the training dataset and successfully removing features until the desired number remains. It has been used to fit the ML algorithm. Rank features by importance. It gives an external estimator that assigns weights to features. The estimator is trained on the initial set of features, and the features' importance is obtained through any specific attribute. Discard the less critical features and re-fit the model. These steps are repeated until the preferred number of features is eventually reached.

3) Hybrid method: The hybrid method combines the (i) Decision Tree (DT) and (ii) Random Forest (RF) methods. The single DT method is unsuitable for high dimensional data, so the RF method is combined with the DT to improve the performance of the feature selection model.

a) Decision tree (DT): DT is a graphical representation for all possible solutions to a problem based on given conditions. DT is a tree-structured method where internal nodes indicate the dataset's features, branches show the decision rules, and the leaf node indicates the prediction outcome. The decision nodes contain multiple units and make any decisions. It does not have any additional nodes. It asks questions to split the tree into subtrees based on the answers. The main issue in the DT algorithm is the best attribute selection for root and sub-nodes. It uses two popular methods to perform the best attribute.

$$IG = \ Entropy(S) - (Weighted\ average\ * \ Entropy(each\ features)) \tag{15}$$

The DT algorithm improves an attribute's Information Gain (IG) using Eq. (15). The attribute or node having the highest IG is split first. The total number of student records is represented as S.

$$Entropy(S) = -P(yes)log2\ P(no)log2\ P(no) \tag{16}$$

The impurity of an attribute is specified randomly in data by estimating the entropy (Entropy(S)) in eq(16). Probability of yes and no is represented as P(yes) and P(no).

DT Algorithm

Step 1: Begin the tree with the root node; it contains the complete dataset.

Step 2: Select the best attributes in the dataset using the attribute selection method.

Step 3: Spilt the S into subsets which contain possible values for the best attributes.

Step 4: Create a DT node which contains the best attributes.

Step 5: Repeatedly make new decision trees using the subsets of the dataset created.

The DT algorithm is applied to the dataset to select the best feature sets. However, the DT's performance falls with greater number of samples.

b) Random Forest: RF is simply a collection of DTs whose results are aggregated into one final result. RF is a strong modelling technique and much more potent than a single DT. It aggregates many DTs to limit overfitting and errors due to bias. It can restrict overfitting without significantly increasing error due to bias. It reduces variance by training on different samples of the data. Another method is by using a random subset of features. Each tree can utilize a specified number of random features. More trees in the RF include many or all features. The presence of many features helps in limiting the errors due to bias and due to variance. If features are not selected randomly, base trees in the forest correlate highly. Since some features are partially predictive, many base trees can choose the same features. Many of these trees contain the same features; it cannot be combined error due to variance. The proposed hybrid ensemble method uses academic performance and online activity datasets to evaluate the performance of the hybrid ensemble method.

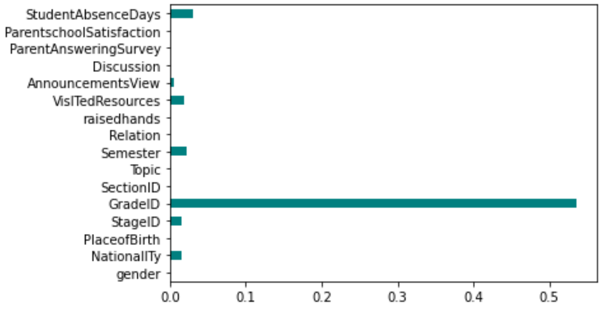

Fig. 3. Feature importance graph for students' academic dataset using the hybrid ensemble method.

The students' Academic dataset shown in Fig. 3 contains 16 features; the ensemble method selects seven features to predict students' academic performance with a higher accuracy level.

The feature importance graph in Fig. 4 depicts the feature selection results of the hybrid ensemble method. The activity dataset contains a total of 12 features. The hybrid ensemble method selects seven features to predict the students' activity-based behaviours during the online sessions.

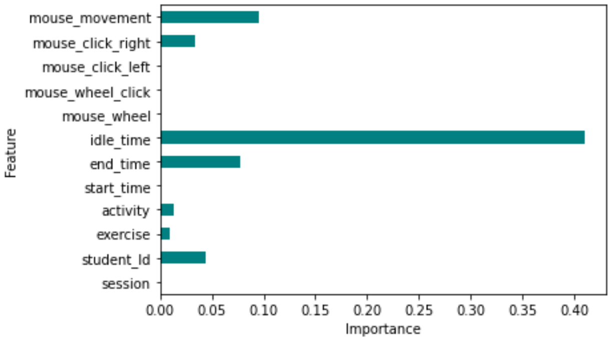

Fig. 4. Feature importance graph for students' online activity dataset using the ensemble method.

C. RESNET50 Trained SVM Model for Prediction

The students' academic performance-based behaviour prediction and online activity-based behaviour prediction are performed using the CNN-trained SVM model. Residual Network-50 (ResNet 50) is a kind of CNN. The 50-layer network model contains 48 Convolutional Layers (CL), 1 max pooling, and one average pooling layer to perform the prediction. The architecture of the ResNet 50-trained SVM model is depicted in Fig. 5. It follows two main rules to process the data. Such amount of filters in each layer is the same contingent on the size of the output feature map; if the feature map's size is split, it has twice the number of filters to preserve the time complexity of each layer. The 50 layers' network utilizing the 1x1 CL helps to reduce the number of parameters and matrix multiplication operation. This feature enables the model to train faster at each layer. A stack of three layers is used in this model. It has one 7x7 kernel convolutional alongside 64 other kernels with 2-sized strides and one 2-sized stride in the max pooling layer. More 9 layers are 3 3x3, 64 kernel convolution and 3 1x1, 256 kernels, and 1x1, 256 kernels. These three kernels are repeated thrice consequently. They are succeeded by 12 layers with 1x1, 128 kernels, 3x3, 128 kernels, and 1x1, 512 kernels. These three kernels are consequently repeated four times. Then 18 more layers with 1x1, 256 cores, 3x3, 256 cores, and 1x1, 1024 cores repeated 6 times. Final 9 more layers with 1x1, 512 cores, 3x3, 512 cores, and 1x1,2048 cores iterated thrice. Followed by this, 50 layers of average pooling and fully connected layers with 1000 nodes using SoftMax activation are incorporated.

The deep model performs better with larger training sample sizes, but the amount of data utilized in this study could be more extensive in dimension and size. So the ResNet-50 model-trained results are used by a machine learning model to improve the performance by utilizing the transfer learning concept to improve the analysis model of students' behaviour. It uses the ResNet 50 network to train the students' behavioural features, and the SVM classifier is utilized to predict students' behaviours. This concept also helps to achieve higher performance even if the model is trained with a small sample of student data.

Support Vector Machine, a popular ML model for classification and regression problems, assigns the newly entered samples to one of the trained categories. So, it is called a non-probabilistic binary linear classifier. It efficiently performs the classification task by applying the proper kernel tricks. SVM classifier separates data points with different class labels using a hyperplane with the maximum amount of margin. The hyperplane acts as a decision boundary. Sample data points are called Support Vectors (SV). This data defines the hyperplane by estimating the margin. Separation gap between the two lines on the closest data points is estimated as a perpendicular distance from the line to data points or SV. The SVM tries to improve the separation gap to get the maximum margin. Sometimes, the sample data points are so discrete that it is not conceivable to distinguish using the hyperplane. In such a situation, kernel tricks transform the input space to a higher dimension space by using a mapping function to transform the input space. The linear separation method is applied to the data points to separate them. This student behaviour analysis model uses the linear kernel to map the students' data to higher dimensional data.

$$K(\bar{x}) = \begin{cases} 1\ if\ \|\bar{x}\| \le 1 \\ 0\ otherwise \end{cases} \qquad (17)$$

Eq. (17) is the linear kernel $(K(\bar{x}))$, which is used to map the students' behavioural data $(\bar{x})$. The mapping range used by the linear kernel is [0, 1]. Data points which are $\leqslant 1$ are mapped as 1; others are considered as 0. This linear kernel is used whenever the input data are need to be separated linearly. It is mainly used for text data classification problems and whenever many data features are in a dataset. The students' behavioural dataset contains categorical data points. So, this study uses linear kernel tricks to map the students' behavioural features.

Moreover, it is also utilized to speed up the classification, since it is required to optimize the regularization parameter. The performance of the selected features by hybrid ensemble method based on the students' performance and online activity are predicted to identify the students' behaviour using the CNN-trained SVM model. The performance analysis is discussed in the consequent section.

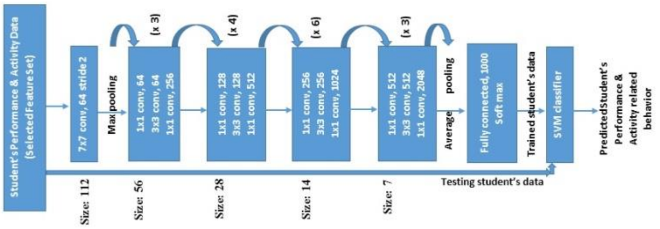

Fig. 5. The general structure of the RESNET50 trained SVM model.

V. Result Analysis

This section analyzes the performance analysis of the proposed hybrid ensemble method's Feature Selection (FS) accuracy for student behaviour analysis using a CNN-trained SVM model. The competence of the hybrid ensemble methodis evaluated by comparing the various ML methods and hybrid feature selection methods such as PCA [14], Elastic Net [15], Genetic PSO-ACO based RNKHEU [16], and ANN with RF[17], RF[19], and DT[21]. These comparison methods are considered for analysis based on their superior performance on student datasets in recent times. Different evaluation metrics such as accuracy, precision, recall, f-score, specificity, and sensitivity are utilized to analyze the influence of the FS method on improving the performance of the prediction model.

Table II compares the FS outcomes of the hybrid ensemble method with other FS methods. It contains information on the number of features used by all the FS methods for the analysis and the number of selected features. It shows that the Hybrid Ensemble Feature selection method chose 7 as the most relevant informative feature to predict the students' performance with a higher accuracy rate.

Table III shows the FS results for students' activity data using the hybrid ensemble method compared with other FS methods. It comprises the evidence of the number of features selected by all the FS methods considered. Totally seven relevant features give a higher accuracy rate, thus significantly improving the prediction performance of students' online activity. Thus, the reduction of figures by the IPCA algorithm help the Ensemble FS method to identify the most relevant features to improve the performance.

Table IV displays the prediction outcome of students' academic and online activity datasets before and after applying the ensemble method. The IPCA method reduces the number of required features from the students' datasets. The reduced feature information helps the ensemble FS method to improve the prediction performance by selecting the most relevant features from the reduced feature sets.

Students' activity dataset	96.34	96.34	96.45	96.35

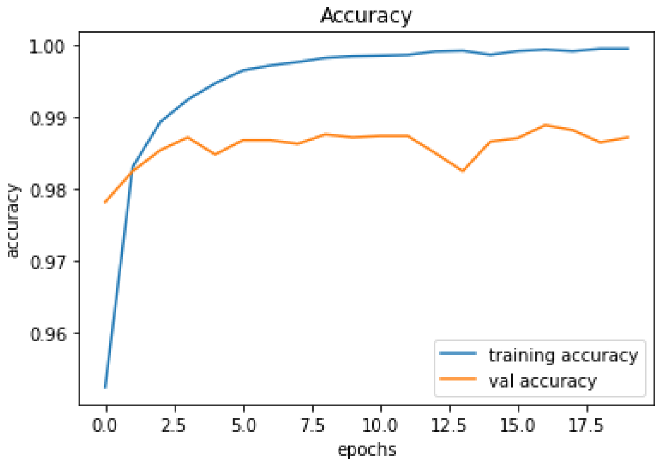

Fig. 6. Training and testing Accuracy rate obtained by the ResNet-50 trained SVM classifier.

Fig. 6 depicts the students' performance accuracy achieved by the ResNet-50 during the training process and the SVM model's testing or prediction accuracy rate. This study uses ResNet-50 network to train the students' behavioural features, and the SVM classifier is utilized to predict the students' behaviours. It reposts another related task for faster prediction. This concept helps achieve higher performance even if the model is trained with a small sample of student data.

Fig. 7 illustrates the students' performance loss rate attained by the ResNet-50 during the training and testing process using the SVM model, which reposts another related task for faster prediction. This concept helps to reduce the loss rate even if the model is trained with a small amount of sample students' data. Moreover, the prediction outcome proves that the IPCA method reduced features supports the ensemble FS method to select more relevant features and hence minimize the prediction loss.

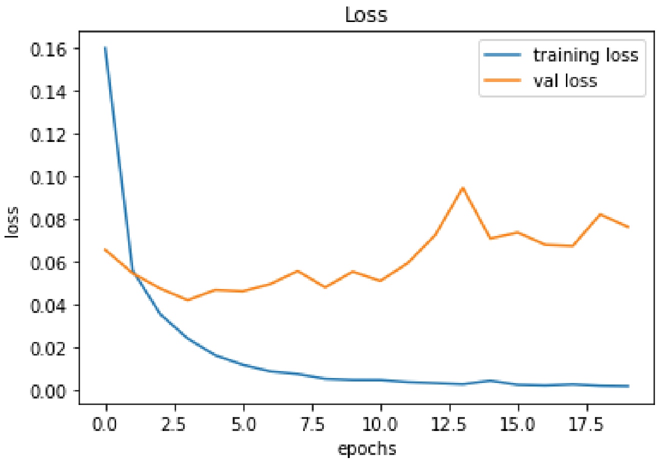

Fig. 7. Training and testing loss rate of RESNET-50 trained SVM classifier.

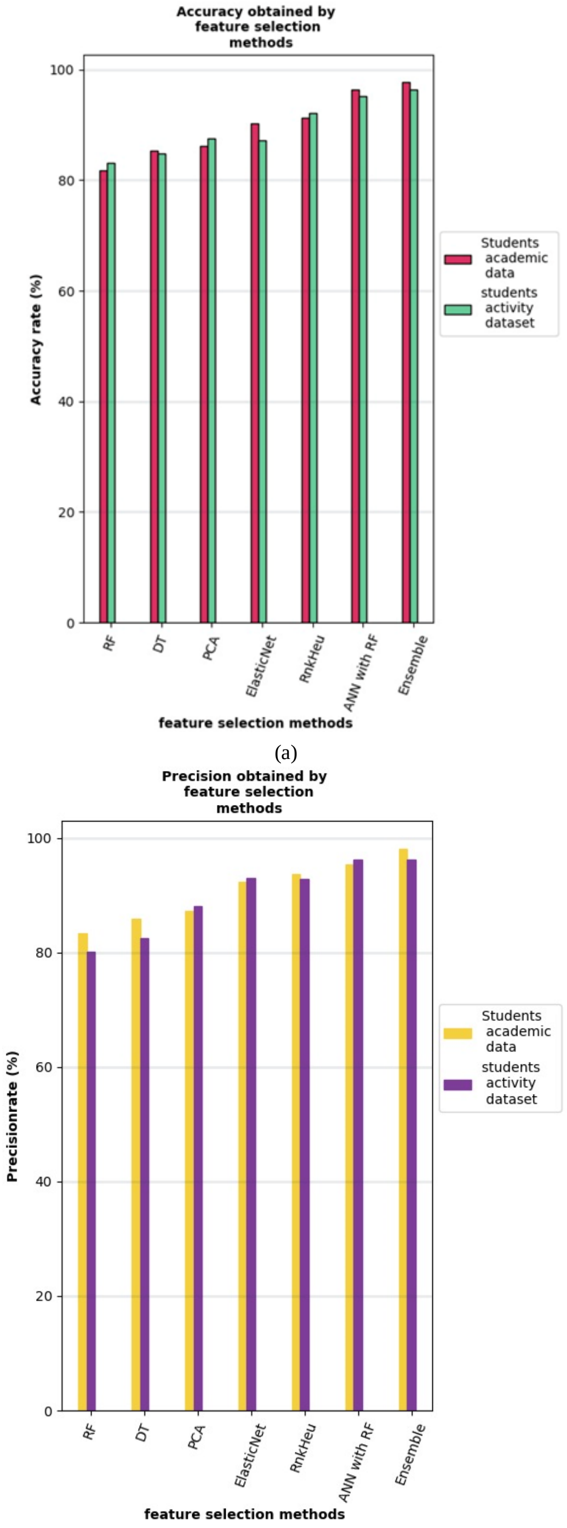
Fig. 8(a) illustrates the accuracy rate obtained by six FS methods along with the ensemble FS method. The comparison results depict that by introducing the Hybrid ensemble FS methods, the ensemble model achieves a higher level of accuracy on measuring both student performance and online activity datasets. This has been achieved by introducing the Hybrid ensemble FS methods. The ensemble method achieveda maximum accuracy rate of 97.78% for students' academic data and 96.34% for students' activity data. Moreover, the comparison results depict that the ensemble model achieves a level of performance higher than the comparison methods.

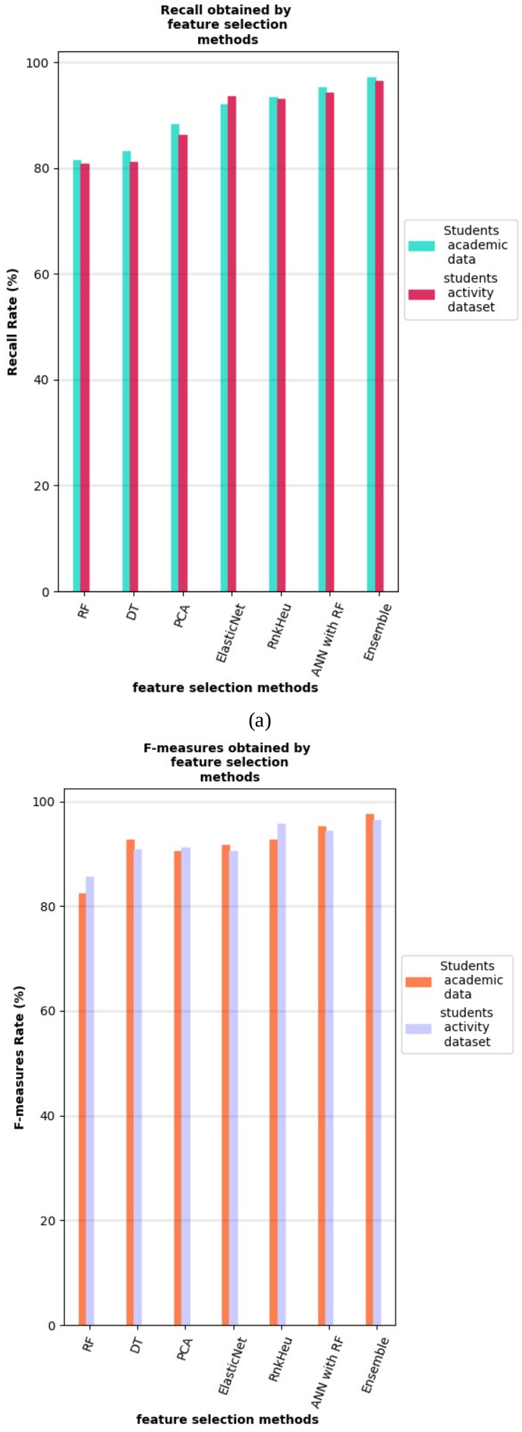


(a)

(b)

Fig. 8. (a) Illustrates the accuracy rate comparison, (b) Demonstrates the precision rate comparison.

Fig. 8 (b) demonstrates the precision rate gained by six FS methods and the hybrid ensemble FS method. The ensemble method achieved a maximum of 98.13% precision rate for students' academic data and 96.34% for students' activity. The comparison results depict that the ensemble model reaches a level of performance higher than the comparison methods. This has been achieved by applying the Hybrid ensemble FS method to select relevant features for analysis.



(a)

(b)

Fig. 9. (a) Recall rate comparison, (b) F-Measure rate comparison.

Fig. 9 (a) illustrates the Recall rate obtained by six FS methods along with the ensemble FS method. The comparison results reveal that the ensemble model achieves a higher level of performance both on student performance and online activity datasets. The ensemble method achieved a maximum recall rate of 97.23% for students' academic data and 96.45% for students' activity data. Moreover, the recall rate comparison results reveal that the ensemble model achieves a level of performance higher than the comparison methods.

Fig. 9 (b) demonstrates the F-score rate of six FS methods and the hybrid ensemble FS method for the two students' behavioural-related datasets. The ensemble method achieves a maximum of 98.13% f-measure rate for students' academic data and 96.34% for students' activities. The F-score measure comparison outcomes depict that the ensemble model performs better than the comparison methods.

The comprehensive competence analysis presented in this section reveals that the ensemble method significantly enhances the performance of the behaviour prediction model compared to conventional methods across various educational datasets. This validates that the proposed approach for analyzing students' behaviour effectively fulfills its research objective by enhancing overall performance and managing behavioural data adeptly.

VI. Discussion

This section shows that the overall performance of the prediction model is improved compared to other behaviour and academic performance prediction models. The improved accuracy prediction is observed for academic performance and student activity data. The results can be used by teachers to understand their teaching outcomes. This study used both quantitative and qualitative methodologies, revealing that students frequently exhibit unforeseen behaviours throughout online class sessions. These methodologies support the management in implementing students' performance monitoring actions and taking preventive actions. This approach can integrate with online data analytics tools to control the student's behaviour during online sessions. This prediction model uses online teaching platform-based monitoring devices produced data (student activity and academic performance-related data). Analyzing students' behaviours is one of the vital parts of teachers to identify their strengths and weaknesses.

This improved accuracy, precision, recall and f-score rate for both datasets reveals that the ensemble of different feature learning models efficiently uses the benefits of different models' accuracy to strengthen the weak model feature learning performance. The novel method outcome is reflected in the increased recall rate compared with existing methods. It effectively addresses these issues in predicting teaching and learner outcomes. Employing a suitable dimensionality technique to manage the expanding high-dimensional educational data is essential due to the daily growth of educational data. The previous prediction model (considered from the literature review) is mostly designed to handle single educational data (like behaviour data or academic performance data). However, it does not correlate students' behaviours with academic performance. So, this study uses two different kinds of datasets for performance analysis. Alternative methods of analyzing student behaviour and performance necessitate the implementation of the ensemble feature learning integrated prediction model.

The overall result and discussion section show that the ensemble feature learning integrated DL model is performing effectively on these students' data by combining multiple model features to strengthen the overall outcome.

VII. Conclusion

The study's main objective is to improve the overall performance of the student's behavioural data analysis. This analysis supports the educational sectors to incorporate innovative methods to enhance students' learning outcomes. This study contributes a feature selection method to measure the students' behaviour-related performance and online activity data. The performance evaluation conducted in this study demonstrates that the hybrid ensemble method outperforms the comparison benchmarks. The IPCA truncated features support the different weak ML methods to strengthen the feature selection performance using feature stacking methods. The selected features help the ResNet-50 trained SVM model to achieve higher prediction outcomes for students' academic performance and online activity. The analysis results show that the ensemble method obtained a maximum of 97.78%, 98.13%, 97.23%, and 97.57% as the accuracy rate, precision rate, recall rate, and f-measure rate, respectively, for behaviour-related students' academic performance data. The ensemble method achieves a maximum accuracy rate (96.34%), precision rate (96.34%), f-score rate (96.35%), and recall rate (96.45%) for students' online activity data. The efficiency analysis shows that the ensemble method helps the behaviour prediction model achieve results more accurately than comparison methods for both students' educational datasets. This proves that the proposed students' behaviour analysis approach achieves its research objective of improving the overall performance of the student's behavioural data analysis.

This study suggests the usage of this proposed ensemble FS-based approach for better measurement and prediction of students' behavioural analysis performance as it improves the prediction performance of different behaviour-related educational data. Students' behavioural analysis outcomes of this study do not utilize personalized learning. So, the study is extended to incorporate a customized study material recommendation model based on the prediction outcome of this student's analysis.

***Abstract*—Using the Arduino platform under the Internet of Things (IoT) platform to diagnose individuals at risk of heart diseases. An enormous volume of data focus has been placed on delivering high-quality healthcare in response to the increasing prevalence of life-threatening health conditions among patients. Several factors contribute to the health conditions of individuals, and certain diseases can be severe and even fatal. Both in industrialised and developing nations, cardiovascular illnesses have surpassed all others as the leading causes in the last few decades. Significant decreases in mortality may be achieved by detecting cardiac problems early and keeping medical experts closely monitored. Unfortunately, it is not currently possible to accurately detect heart diseases in all cases and provide round-the-clock consultation with medical experts. This is due to the need for additional knowledge, time, and expertise. Aiming to identify possible heart illness using Deep Learning (DL) methods, this research proposes a concept for an IoT-based system that could foresee the occurrence of heart disease. This paper introduces a pre-processing technique, Transfer by Subspace Similarity (TBSS), aimed at enhancing the accuracy of electrocardiogram (ECG) signal classification. This proposed IoT implementation includes using the Arduino IoT operating system to store and evaluate data gathered by the Pulse Sensor. The raw data collected includes interference that decreases the precision of the classification. A novel pre-processing technique is used to remove distorted ECG signals. To find out how well the classifier worked, this study used the Hybrid Model (CNN-LSTM) classifier algorithms. These algorithms detect normal and abnormal heartbeat rates based on temporal and spatial features. A Deep Learning (DL) model that uses Talos for hyper-parameter optimisation has been recommended. This approach dramatically improves the accuracy of heart disease predictions. The experimental findings clearly show that Machine Learning (ML) methods for classification perform much better after pre-processing. Using the widely recognised MIT-BIH-AR database, we assess the planned outline in comparison to MCH ResNet. This system leverages a CNN-LSTM model, which was optimized using hyper-parameter tuning with Talos, achieving outstanding metrics. Specifically, it recorded an accuracy of 99.1%, a precision of 98.8%, a recall of 99.5%, an F1-score of 99.1%, and an AUC-ROC of 0.99.**

I. Introduction

The healthcare industry has seen significant changes worldwide in the last decade due to digitization and digital transformation [1-2]. The progress of human evolution has been closely intertwined as a result of technological and scientific progress. The Internet of Things (IoT) is a significant driver of Information and Communications Technology (ICT) technological advancement, propelling numerous sectors towards automation and decentralised intelligence [3]. The IoT is constantly evolving and profoundly impacts every aspect of our lives, almost like a living being. Scientific and technical advancements have been driven by healthcare-related activities since the emergence of technology services that enabled the remote collection, analysis, and control of patients' conditions. IoT is playing a significant role in driving innovations in healthcare and ultimately transforming the industry. It does this by collecting the physiological data of patients using wireless sensor networks and wearable devices [4].

Although Machine Learning (ML) algorithms have been used in stratified healthcare research, there is an increasing recognition of the importance of incorporating ML algorithms into healthcare diagnosis systems [5–7]. There is a plethora of medical data available for analysis using ML methods since the health sector has collected it over the last decade. This analysis can help identify patterns, create Smart Diagnosis Systems (SDS), and uncover valuable insights to address numerous challenges [8]. Amongst the numerous illnesses, cardiovascular diseases (CVD) stand out as the primary cause of death globally. However, in today's fast-paced society, many individuals tend to neglect regular medical check-ups unless they experience significant health problems. Similarly, many individuals neglect routine heart check-ups due to the time-consuming and inconvenient nature of traditional methods for obtaining these checkups. Not being aware of their current heart condition can lead to serious health issues and, in the most extreme cases, unexpected fatalities.

An SDS is essential to conveniently and efficiently monitor one's heart condition. In today's world, the IoT has become an essential asset to the healthcare sector. Its key features, including connectivity, sensing, reliability, linearity, and intelligence, have proven invaluable [9]. It is a method of revolutionising modern healthcare by offering personalised and proactive care, using devices that can sense and monitor important health indicators like pulse rate, blood pressure, and electrocardiogram (ECG) [10–12]. A collection of wearable sensor devices can collect physiological evidence as it happens. Once this data is processed, it can be transformed into health records that are valuable for diagnosing, treating, and recovering from CVD. Once more, ML is an application of Artificial Intelligence (AI) that can use past knowledge to make predictions about future events using labelled examples [13-16].

*Corresponding Author.

This study adds a cardiac patient monitoring device that uses the IoT idea with many physiological data sensors and an Arduino microcontroller. Sensor networks employ the IoT to collect, process, and communicate data from one node to another. The IoT is a young and quickly evolving technology that enables many sensors and data collectors to sense, exchange, and interact over Internet Protocol (IP) networks, whether public, private, or otherwise. The sensors collect data at regular intervals, analyse it, and then use it to initiate the necessary action. An intelligent cloud-based network for investigation, arranging, and decision-making is also available to them.

The first step in developing a CVD model integrated with IoT sensors is to obtain data from patients who are wearing the IoT sensor. The data has to be collected for extended periods for better comprehension and recognition of respiration rate, heart rate, and other critical indicators. Thus, the data can reveal all the irregularities that are noticed in a patient's heartbeat, which can be the reason for some diseases. Now, the Deep Learning (DL) algorithm can be applied to simulate the model that will identify the difference between normal and abnormal rhythms in both waves and correctly detect disorders from the data. Again, the developed model can be applied in real situations, and in this case, it can be updated in case errors appear. When the model is refined to a satisfactory level of accuracy, it may be sent out to the IoT sensors to monitor the heart rate of the individual and notify the healthcare team in the event that any heart condition is identified.

The primary objectives of this work:

1) This study aims to create a wearable hardware device that can effectively extract vital heart condition measurement signs from the user's body in real time, including ECG data.

2) Data pre-processing methods apply to the data collected from IoT sensors related to heart disease risk prediction—transfer by Subspace Similarity (TBSS) aimed to improve the categorization accuracy of ECG signals.

3) The strategy that has been recommended is that it is possible to estimate the probability that a patient has CVD using a Hybrid Model (CNN-LSTM) classifier, which incorporates an attention mechanism.

4) A DL model has been proposed that utilises Talos for hyperparameter optimisation. This approach dramatically improves the accuracy of Heart Disease Predictions (HDP).

The rest of the article is structured into four major sections. Section I is an introduction, Section II is a literature review, Section III is a technique section, Section IV is an analysis of the findings, and Section V is a conclusion with future scope.

II. Literature Survey

Several studies have been tested on HDP using IoT and ML techniques. As an illustration, research by [17-20] examined four heart disease datasets from UCI to predict CVD using ML algorithms. Their findings indicated that Logistic Regression had the highest accuracy rate at 86.5%.

In a study by [21-23], they implemented hybrid ML techniques to HDP. A different study presented a UCI dataset and found that Random Forest (RF) had the most accuracy, 89%, for HDP. Meanwhile, [24-26] demonstrated that a Multilayer Perceptron Neural Network (MPNN) with backpropagation achieved an accuracy of approximately 100% in HDP using 40% of the UCI Cleaveland dataset as training data. [27-29] conducted a meta-analysis to assess and explain the overall predictive ability of ML algorithms in CVD.

Further, [30-35] proposed ontology-based recommendations to provide patients with personalized suggestions containing their past clinical records and real-time data. Once again, remarkable research has portrayed the potential HDP from ECG-based data only.

For example, [36-40] presented an HDP system that capitalizes on big data and the AD8232 ECG sensor for collecting the data. This system effectively eliminates noise from raw ECG signals and crucial Feature Extraction (FE) to aid in diagnosis, providing valuable support to patients and medical experts.

In a similar study, [41-45] demonstrated the detection of CVD using a Support Vector Machine (SVM) and Neural Network. They analysed FE from processed ECG signals. In addition, [46-49] proposed DL methods in conjunction with the Internet of Medical Things (IoMT) to create a screening system for CVD. Human skin temperature and blood circulation are the two variables that this method uses. Nonetheless, a licenced examiner or competent doctor had to review the results of the medical tests as part of the process.

In their study, [50-55] discussed various ML techniques that focused on real-time and remote health monitoring on IoT setup, specifically concerning cloud computing. Input was obtained from the public data set HC, which was stored on the cloud. The system provided recommendations based on the available data stored in the cloud, including historical and empirical data. In their study, [56-60] introduced a multi-sensory system that used an intelligent IoT to collect data from Wireless Body Area Sensors (WBAS). This method was designed to alert users to the possibility of cardiac arrest in its early stages. Prior research attempted to develop an undetectable, intelligent IoT system that could take readings of vital signs from a user's phone without drawing attention to itself.

In their study, [61-65] proposed a method that used ML techniques to identify essential features. This meant that there was better precision in the HDP. The RF and Linear methods have been combined [66-70] to form a hybrid RF with a linear model. In the research work of [71-73], the authors proposed a multi-sensory system based on IoT technology that collects readings of heart rates and body temperatures. Data from ECG and the body temperature were acquired on a smartphone in real-life conditions with an intelligent skin attached using a Bluetooth chip for low-power connectivity. Sophisticated signal processing and a collection of sensor data have been processed using ML methods to make an accurate HDP of the probability of an imminent heart attack.

In the paper, [74-78] developed a brilliant Health Care Kit based on IoT technology. They proposed collecting multiple data parameters from the patient and forwarding timely notifications regarding patient health to the doctor for their knowledge and awareness. However, their system is not capable of determining any diabetic condition of the patients; thus, it cannot detect any heart attack problem of the patient caused by diabetes or obesity.

In this paper, [79-80] proposed a system where Arduino Uno and an Infrared (IR)-based sensor have been used to monitor the heart rate. The device shall track all the physical parameters, such as heartbeats, and provide a physician with the collected data through the Short Message Service (SMS). However, IR sensors are not capable of providing precise heart rate measurements. In their study, [81-85] introduced a heart rate counter based on a Microcontroller that was designed to be affordable. Microcontrollers have been used for heart rate measurement with the help of an IR sensor. However, it should be noted that IR sensors may not provide precise heart rate values and lack versatility [86-90].

III. Methods and Materials

As CVDs account for a significant percentage of deaths across the globe, it is essential that they should be detected and monitored at an early stage. Most of the existing HDP systems lack accuracy, and they require continuous medical regulation. This project devised the solution for the above-stated problems by developing an IoT-based HDP system on a platform called Arduino. In the proposed system [91-95], a novel preprocessing method called TBSS-Transfer by Subspace Similarity is used to classify the ECG signal accurately [96-100].

A. *Problem Definition*

With a collection of raw ECG signals $X = \{x_1, x_2, \ldots, x_n\}$ obtained using a Pulse Sensor on the Arduino platform, the objective is to precisely categorise these signals as either normal or abnormal heartbeat rhythms. There is the noise and interference problem, to start with, with the raw ECG signals. To a great extent, it may badly affect the accuracy of the classification performed. This is the problem formulation as follows:

Each instance is represented by an ECG signal, (x_i) , which consists of a series of time points, $x_i = \{x_{i1}, x_{i2}, \ldots, x_{iT}\}$. Utilise the TBSS technique to effectively eliminate any noise and interference present in the raw ECG signals, resulting in a set of cleaned signals denoted as $X_{clean} = \{x'_1, x'_2, \ldots, x'_n\}$. Mathematically, this preprocessing step can be represented as a function f_{TBSS}, EQU (1).

$$X_{clean} = f_{TBSS}(X) \tag{1}$$

Identify essential characteristics by extracting features $F_i = \{f_{i1}, f_{i2}, \ldots, f_{im}\}$ from each processed ECG signal x'_i, where m is the total number of features. Then, utilize a hybrid CNN-LSTM classifier C to classify the FE into normal or abnormal heartbeat rhythms.

The function C assigns labels y_i to the feature set F_i, EQU (2).

$$y_i = C(F_i) \tag{2}$$

The labels for y_i are binary.

B. *Proposed Methodology*

The proposed methodology in this section for constructing IoT-based CVD prediction using the Arduino platform involves data collection, preprocessing done through Transfer by Subspace Similarity (TBSS), feature extraction, classification using the hybrid CNN-LSTM model with hyper-parameter optimization using Talos, and performance evaluation.

1) IoT model design: The IoT device for cardiac illness forecasting is built to function using a microcontroller and several sensors. The primary components used in this setup include the LM35 Temperature Sensor, AD8232 ECG Sensor, and Pulse Sensor, Arduino Uno. The multi-sensor, along with the portable IoT-based microcontroller suggested system of CVD prediction, gathers and processes the physiological data in this paper. The body temperature reading is given using the LM35 Temperature Sensor. It gives an analogue output proportional to temperature that ranges with ±0.5 $°C$ accuracy. The Pulse Sensor measures the user's heart rate by blood flow through the finger in order to deliver analogue signals through its output, which represents the heartbeat. AD8232 ECG Sensor ensures that the electrical activity of the heartbeat is taken so that an output ECG signal can be delivered. Since it provides high-quality signals, the operational amplifiers and filters are built for signal conditioning. With a USB connection, six analogue inputs, fourteen digital input/output pins, and an ATmega328P core, this microcontroller board is known as Arduino Uno. It communicates with sensors to collect data and then uploads it to the cloud. Such meticulous planning allows for comprehensive and precise surveillance of the HDP of cardiac illness. Fig. 1 shows the IoT Model design for HDP.

2) AD8232 ECG sensor: This sensor acquires the heart's electrical activities. With an output connection to an analogue input pin, which is A2 in Arduino Uno, this sensor gives the ECG signal, which forms the basis for diagnosing heart conditions. This sensor is critical since it provides details of the electrical activities that are going on in the heart and can, therefore, detect any abnormal heart activities. The processing unit of this system is the Arduino Uno microcontroller. Here, programming does all the data readings from all connected sensors; some initial preprocessing is done for noisy data. These processed bits of data are sent into a cloud-based IoT Platform. All the sensors inter-interface with the Arduino Uno through the analogue input pins of the board. For wireless communication, a Wi-Fi (or) Bluetooth module is used. The system uses a Wi-Fi module like ESP8266, for instance, or Bluetooth, like the HC-05. Using the Wi-Fi module, Arduino could send the data directly to a cloud server using the Message Queuing Telemetry Transport (MQTT) protocol. The protocol is. Light messaging protocol is super ideal for IoT applications. On the other hand, the Bluetooth module sends it to nearby devices, such as a Smartphone, that would forward this data to the cloud server.

The transmitted data is stored in a cloud-hosted database, commonly of the NoSQL type, such as MongoDB, in order to handle the unstructured nature of the sensor data. The cloud storage solution provides scalability and security to store large volumes of data that can be accessed anytime. The raw ECG data is cloud-prepped and cleaned for noise by using the technique of Transfer by Subspace Similarity or, basically, TBSS. From the cleaned-up data, FE accommodates the temporal and spatial features of the ECG signals.

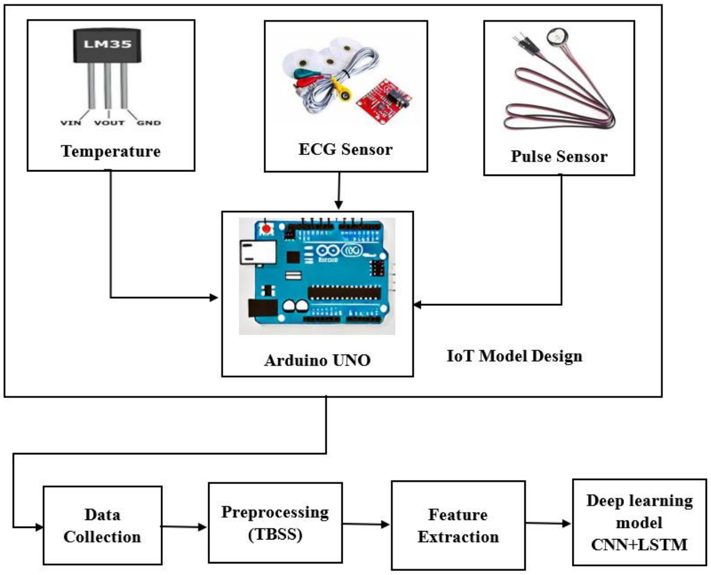

Fig. 1. The IoT model for CVD prediction.

C. Data Collection

The dataset of heart disease was developed from the UCI Machine Learning Repository. Out of the 75 sets of attributes in this data set, only 14 have been considered for prediction purposes. The dataset includes the records of 303 patients, encompassing various factors. There are different types of chest pain, including typical angina, non-anginal pain, atypical angina, or asymptomatic. Resting ECG results may include regular patterns, ST-T wave abnormalities, and indications of left ventricular hypertrophy according to Estes' criteria. Meanwhile, thalassemia is categorised into three types: usual, fixed defect, and reversible defect. This extensive dataset allows for a thorough analysis, enabling the system to accurately predict heart disease using a wide range of patient profiles.

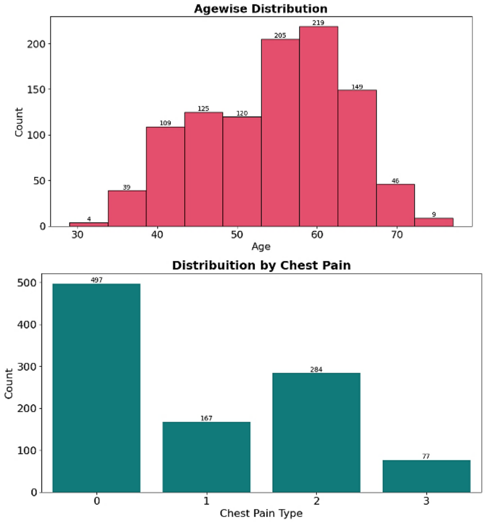

Fig. 2. (a) Data distribution per age (b) data distribution per chest pain type.

Fig. 2(b) illustrates the distribution of chest pain types among patients in the dataset. A total of 497 patients experience typical angina, which is characterised by its predictability and association with physical exertion or stress. There are an additional 284 patients who are experiencing non-anginal pain, which is not related to any heart problems. There are 167 patients who have been diagnosed with atypical angina, a condition that is characterised by its unpredictable nature and lack of association with physical exertion. Finally, there are 77 patients who do not experience chest pain despite potentially having underlying heart issues. This distribution is beneficial for accurately diagnosing heart conditions, training ML models, and efficiently planning healthcare resources.

1) *Preprocessing of TBSS:* For the HDP technology to be reliable and accurate, the data must be adequately extracted. In order to ensure that the ECG signals collected by the sensors we use are noise-free, researchers use an advanced technique called TBSS in the present study. This approach is essential for filtering unprocessed sensor data, which is overflowing with noise and distortion and may significantly affect our prediction algorithms' accuracy. By transforming the uncompressed signals into a refined subspace and minimising errors, the TBSS approach improves the level of accuracy of ECG signal classification.

The initial stage of the recommended method is collecting unprocessed ECG signals employing the AD8232 ECG Sensor that is connected to the Arduino Uno programming board. Interference from electricity and patient motion are two of the numerous forms of noise that can be detected in these signals. The application of digital filters makes it possible to deal with the starting point noise. The vital elements of the ECG signals can be separated from noise in the background and baseline variation through the use of these filters. Principal Component

Analysis (PCA) is an approach that represents the filtered signals in a lower-dimensional subspace. By filtering to eliminate extra noise, these methods reliably capture the vital features of the ECG signals. Researchers test the predicted signals to a set of ideal ECG signals within the domain in order to analyse data. Here, we compare the corrupted signals to the clean signals of reference in the simulated space to determine how comparable they are. Using this comparable metric system, researchers can determine precisely how comparable the good-quality signals are to the noisy ones. This can be represented formally as EQU (3).

$$S\left(X_{clean}, X_{noisy}\right) = \sum_{i=1}^{n} \left(\frac{X_{clean,i} \cdot X_{noisy,i}}{\|X_{clean,i}\| \|X_{noisy,i}\|} \right) \quad (3)$$

where X_{clean} are the reference clean signals, X_{noisy} are the noisy signals, and S is the similarity measure. In order to create unreliable signals that appear increasingly similar to the free signals from the signal's source, researchers use the calculated similarity to modify signals. This method improves the ECG signals by eliminating unwanted FP and noise in the background.

The result of the TBSS process is a set of cleaned ECG signals $X_{clean} == \{x'_1, x'_2, \ldots, x'_n\}$ which are then ready for further FE and classification. The TBSS technique gives us the ability to enhance the ECG quality of the signal significantly. A precise human HDP algorithm requires precise FE and classification, which have been significantly improved by higher quality. By ensuring more clean data, the TBSS preliminary processing phase is essential to enhancing the overall accuracy and reliability of the HDP system.

Algorithm 1. Algorithm for TBSS

```
Input: Raw ECG signals X, Reference clean signals $X_{clean}$
Output: Cleaned ECG signals $X'_{clean}$
Step 1.   1: $X_{filtered} \leftarrow$ ApplyNoiseFiltering(X)
Step 2.   2: $X_{projected} \leftarrow$ ApplySubspaceProjection($X_{filtered}$)
Step 3.   3: $X_{reconstructed} \leftarrow$ []
Step 4.   4: for each $x_{pi}$ in $X_{projected}$ do
Step 5.   5:     S ← CalculateSimilarity($X_{clean}$, $x_{pi}$)
Step 6.   6:     $x_{ri} \leftarrow$ AdjustSignal($x_{pi}$, S, $X_{clean}$)
Step 7.   7:     Append $x_{ri}$ to $X_{reconstructed}$
Step 8.   8: end for
Step 9.   9: $X'_{clean} \leftarrow X_{reconstructed}$
Step 10.  10: return $X'_{clean}$
Function ApplyNoiseFiltering(X)

  For Each $X_{clean_j}$ in $X_{clean}$ Do
    S += (DotProduct($X_{clean_j}$, $x_{pi}$) / (Norm($X_{clean_j}$) * Norm($x_{pi}$)))
  End For
  Return S
Function AdjustSignal($x_{pi}$, S, $X_{clean}$)
  $x_{ri} \leftarrow x_{pi}$ * S
  For Each $X_{clean_j}$ in $X_{clean}$ do
    $x_{ri}$ += $X_{clean_j}$ * (S / length($X_{clean}$))
  End For
  Return $x_{ri}$
```

D. FE Using Convolutional Neural Network (CNN)

The key component of the preliminary processing queue, FE transforms filtered ECG signals into beneficial attributes for an algorithm that HDP`. To perform automated FE from the initially processed ECG signals, researchers use CNNs in the present investigation. CNNs are particularly effective in capturing local patterns in data, making them ideal for processing time-series signals like ECGs.

The cleaned ECG signals $X_{clean} == \{x'_1, x'_2, \ldots, x'_n\}$ are segmented into fixed-length windows to standardize the input size for the CNN. A CNN model is constructed with multiple layers, each designed to extract different levels of features from the ECG signals. Fig. 3 shows the Planned CNN for FE.

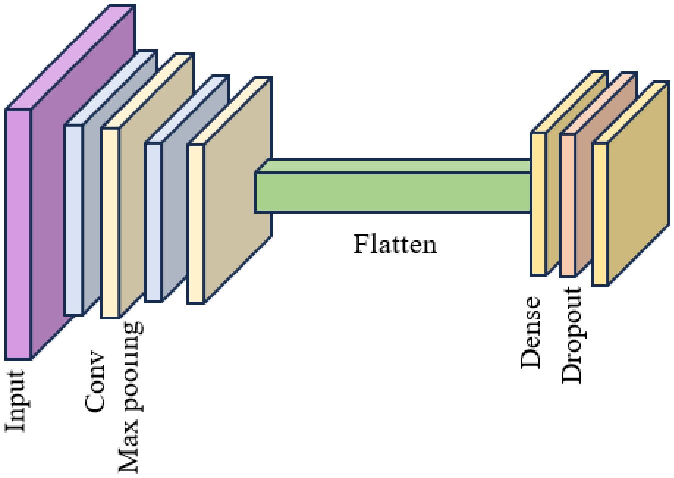

Fig. 3. The proposed CNN model for FE.

The input layer receives the segmented ECG signals. Each segment is represented as a matrix $S \in \mathbb{R}^{T \times C}$, where T is the length of the segment, and C is the number of channels or features.

The convolutional layers utilise multiple filters to analyse the input data and identify local patterns, such as peaks and valleys in the ECG signals. Filters $'w'$ slide over the input data and perform a convolution operation to generate a feature map. The first convolutional layer applies $'F_1'$ filters of size $k_1 \times C$ to the input segments. It produces feature maps M_1 by convolving the filters with the input EQU (4).

$$M_{\{1,j\}} = \sigma(W_{\{1,j\}} * S + b_{\{1,j\}}) \tag{4}$$

where $W_{\{1,j\}}$ and $b_{\{1,j\}}$ are the weights and biases of the j-th filter, $' * '$ denotes the convolution operation, and $'\sigma'$ is the activation function (ReLU). Subsequent convolutional layers apply $'F_l'$ filters of size $k_l \times 1$ to the feature maps from the previous layer, EQU (5).

$$M_{\{l,j\}} = \sigma(W_{\{l,j\}} * M_{\{l-1\}} + b_{\{l,j\}}) \tag{5}$$

In order to make the feature maps more concise while keeping all the relevant data, pooling layers are implemented, typically using max pooling or average pooling. Max pooling reduces each feature map by taking the maximum value within non-overlapping regions of size *-np*, represented as EQU (6)

$$P_{\{l,j\}} = Maxpool(M_{\{l,j\}}, p) \tag{6}$$

The resulting feature maps are flattened into a single vector. This vector represents the extracted features from the input ECG segment. Let $'f'$ denote the flattened feature vector. The flattened vector is fed into fully connected layers to combine the extracted features and enable further learning, EQU (7).

$$h_i = \sigma(W_i f + b_i) \tag{7}$$

where W_i and b_i are the weights and biases of the i-th fully connected layer. When it comes to classification, the output layer usually employs a sigmoid or SoftMax activation process. In this test case, the features are classified into normal or abnormal heartbeat rates. This is represented as EQU (8).

$$y = SoftMax\left(W_{\{out\}} h + b_{\{out\}}\right) \tag{8}$$

where $'y'$ is the output probability distribution over classes. The first Conv1D layer applies 32 filters of size 5 to the input data using a one-dimensional convolution operation with a Rectified Linear Unit (ReLU) activation function. To further reduce the data's density while keeping the most relevant features, the MaxPooling1D layer uses max pooling with a pool size of 2. A second Conv1D layer then applies 64 filters of size 3 and ReLU activation to the output of the previous layer. Following this, another MaxPooling1D layer with a pool size of 2 further down-samples the data. In order to make it suitable for entry to the thick layers, the Flatten layer converts the output through a one-dimensional array, a fully connected Dense layer with 128 units and a ReLU activation function is then applied to the flattened data.

To prevent overfitting, a dropout layer is used, applying dropout regularization with a rate of 0.5 and randomly setting 50% of the input units to zero during training. Lastly, the two classes' categorization probabilities are produced by the 2-unit Dense output layer using a SoftMax activation function.

E. Proposed Model of Hybrid CNN-LSTM with Talos Hyper-Parameter Optimization

The CNN+LSTM hybrid model brings together the rewards of CNN+LSTM. While LSTMs are suitable for learning dependencies over time, CNNs, on the other hand, tend to be utilized more effectively in spatial FE from the ECG signals. Additional improvement in performance is achieved by using Talos for hyper-parameter optimization. Fig. 4 shows the Architecture of the Hybrid CNN+LSTM with Talos Hyper-Parameter Optimization.

Spatial FE from the pre-processed ECG signals by passing them through convolutional layers. These patterns in the ECG data include QRS complexes, P and T-waves. The sequence of spatial features that are assumed by CNN is then fed into LSTM layers to capture temporal dependencies. By doing so, the temporal patterns and trends in the ECG signals are learnt by the model for accurate HDP, which is very important. The output from the LSTM layers is fed into fully connected layers to combine the features and produce the final heart rate prediction.

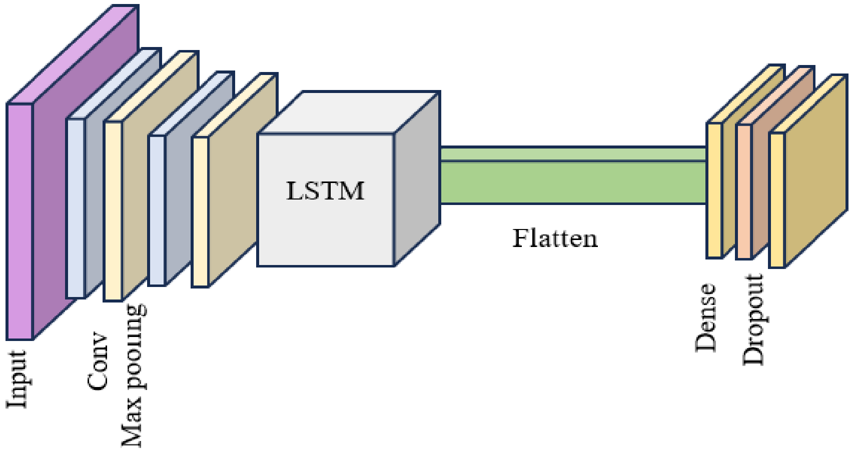

Fig. 4. Architecture of hybrid CNN+LSTM model with talos hyper-parameter optimization.

For a sequence of CNN feature vectors $\{x_t\}$ where t is the time step, EQU (9) to EQI (14).

LSTM Cell Computations,

$$fg_t = \sigma(W_{fg} \cdot [h_{t-1}, x_t] + b_{fg}) \tag{9}$$

$$it_t = \sigma(W_{it} \cdot [h_{t-1}, x_t] + b_{it}) \tag{10}$$

$$\widetilde{Cg}_t = \sigma(W_{cg} \cdot [h_{t-1}, x_t] + b_{cg}) \tag{11}$$

$$Cg_t = fg_t \odot Cg_{t-1} + \widetilde{Cg}_t \tag{12}$$

$$ot_t = \sigma(W_{ot} \cdot [h_{t-1}, x_t] + b_{ot}) \tag{13}$$

$$h_t = ot_t \odot tanh(Cg_t) \tag{14}$$

where 'σ' is the sigmoid function, $tanh$ is the hyperbolic tangent function, W and b are weights and biases, and $\odot$ denotes element-wise multiplication.

For the LSTM output h_t at the final time step T, EQU (15).

$$y \;=\; W_y \cdot \; h_T \;+\; b_y \tag{15}$$

where W_y and b_y are the weights and biases of the fully connected layer. The hybrid CNN+LSTM starts with an input layer that determines the form of the information. To start with, there is the first Conv1D layer, which uses 1-D convolution operation with ReLU activation function by applying 32 filters of size 5 to the input data then followed by a MaxPooling1D layer having pool size two, thus reducing data dimensionality and maintaining significant features. The next step is another Conv1D layer holding 64 filters of size 3 together with the activation function of ReLu for extracting more spatial features. Additionally, this includes another MaxPooling1D layer using pool size 2 to down-sample further the data. Secondly, the model also comes with a 100-unit-layered LSTM, which then processes the sequence of features derived from CNN layers by capturing the temporal dependencies in the data.

The resulting output from this layer is then 1-D-arrayed into a flattened array using a flattened layer before being fed to dense layers. After that, there is a dense layer with 128 neurons and a ReLU activation function, which continues processing the extracted features. A dropout rate of 0.5 has been used in this model in order to avoid overfitting; it means that during training, half of all input units will be randomly set to '0' every time. Finally, the model finishes with a SoftMax activation function in its output Dense Layer, which contains two units representing classification probabilities for normal or abnormal class options. Through the Talos software package, various hyperparameters such as filter number, learning rates, kernel sizes, and number of LSTM units, dropouts' rates, batch_size are optimized, increasing the performance and robustness of this model.

Algorithm 2. Algorithm for Hyper Parameter Optimization using Talos

```
Input: Pre-processed ECG data $X$, labels $y$, parameter grid $P$
Output: Optimized CNN-LSTM with best hyper-parameter configuration
Step 1: Data Preparation
1.1 Split data into training and testing sets
$(X_{train}, X_{test}, y_{train}, y_{test})$ = train_test_split (X, y, $test_{size}$ =0.2, $random_{state}$=42)
1.2 Standardize the data using StandardScaler
$X_{train}$ = scaler.fit_transform ($X_{train}$.reshape(-1, $X_{train}$.shape[-1])). reshape($X_{train}$.shape)
$X_{test}$ = scaler. Transform ( $X_{test}$ .reshape(-1, $X_{test}$ .shape[-1])). reshape($X_{test}$.shape)
1.3 Convert labels to categorical format
    $y_{train}$ = to_categorical ($y_{train}$, num_classes=2)
    $y_{test}$ = to_categorical ($y_{test}$, num_classes=2)
Step 2: Model Creation Function
2.1 Define create_model function to build and compile the CNN-LSTM using  hyper-parameters from P
Step 3: Define Parameter Grid
3.1 Specify the range of hyper-parameters in P
Step 4: Perform Hyper-Parameter Optimization
4.1 Use the Talos Scan function to train models with different hyper-parameter combinations
t=talos.Scan(x=$X_{train}$,y=$y_{train}$, params=P, model=create_model, experiment_name='hybrid_cnn_lstm', $x_{val}$ =$X_{test}$, $y_{val}$=$y_{test}$)
Step 5: Analyze Results
5.1 Analyze results using the Talos Analyze function to identify the best hyper-parameter
Configuration
a = Talos.Analyze(t)
5.2 Print or store analyzed data print(a.data)
Step 6: Deploy Best Model
6.1 Retrieve and save the best model configuration using the Talos Deploy function
$best_{model}$ = Talos.Deploy(t, 'best_model')
End Algorithm
```

IV. Result Analysis

A. About Simulation Data and Tool

This section analyses the performance of the optimized CNN+LSTM after hyper-parameter optimization using Talos. This study evaluates the model using numerous metrics, compares its performance with baseline models, and gains insights from the hyperparameter tuning process. These measures are used to measure how well the model works. The term "accuracy" refers to the number of correctly anticipated events in a fraction of all cases, EQU (16).

$$Accuracy \;=\; \frac{TP + TN}{TP + TN + FP + FN} \tag{16}$$

where TP is true positive, TN is true negative, FP is false positive, and FN is false negative. Precision, EQU (17), is the proportion of accurate analyses to the total number of accurate predictions.

$$\text{Precision (Pre)} \;=\; \frac{TrPt}{TrPt + FaPt} \tag{17}$$

The sensitivity or recall of a model of prediction is expressed as the percentage of accurate predictions compared with the overall number of positive cases, represented as EQU (18).

$$\text{Recall(Rec)} = \frac{TrPt}{TrPt + FaNt} \tag{18}$$

EQU (19) demonstrates that the F1-score, an unbiased measurement, provides the harmonic mean of recall and accuracy.

$$\text{F1} - \text{score} = 2 \times \frac{\text{Pre}\cdot\text{Rec}}{\text{Pre}+\text{Rec}} \tag{19}$$

Considering the test set, the improved CNN+LSTM's metrics for performance are displayed in Table I. These parameters entirely assess the ability of the model to differentiate between normal and abnormal ECG signals.

TABLE I. PERFORMANCE ASSESSMENT OF THE CNN+LSTM HDP

Metric	Value
Accuracy	99.1%
Precision	98.8%
Recall	99.5%
F1-Score	99.1%
AUC-ROC	0.99

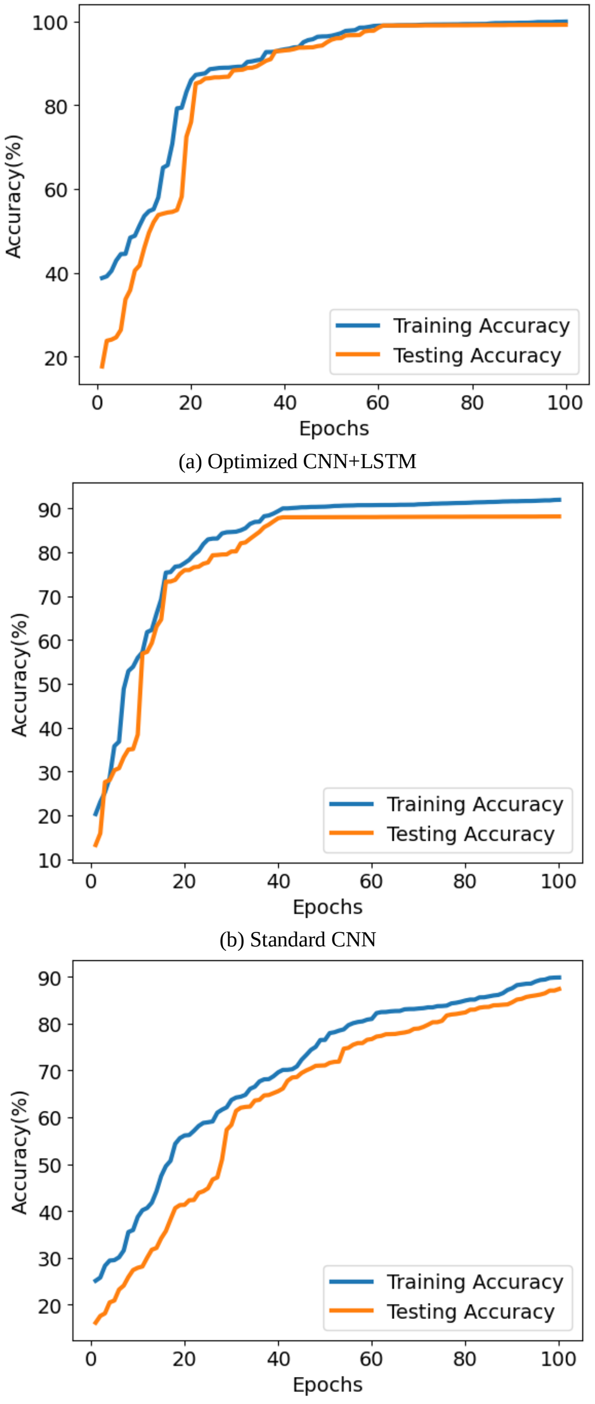
The optimised CNN+LSTM improves the standard model in ECG signal classification based on its success measures. The algorithm is highly successful, with statistics like an F1-score of 99.1%, a recall of 99.5%, a precision of 98.8%, and an area under the curve (AUC-ROC) of 0.99. The accuracy of the method for HDP is demonstrated by the above findings. In Table II, the developers observe how the improved CNN+LSTM fares in comparison to two baseline models, one of which uses CNN and the other LSTM. The comparison below indicates that the CNN+LSTM's hybrid model and hyper-parameter optimisation significantly boosted performance.

TABLE II. PERFORMANCE COMPARISON OF THE PROPOSED OPTIMISED CNN+LSTM WITH THE BASELINE MODEL

Metric	Optimized CNN+LSTM	Baseline CNN	Baseline LSTM
Accuracy	99.1%	88.1%	87.4%
Precision	98.8%	86.5%	85.8%
Recall	99.5%	89.0%	88.5%
F1-Score	99.1%	87.7%	87.1%
AUC-ROC	0.99	0.91	0.90

Metrics for accuracy indicate that the CNN+LSTM with optimisations functions exceptionally well regarding ECG signal detection. The model exhibits high performance with 99.1% accuracy, 98.8% precision, 99.5% recall, 99.1% F1-score, and 0.99 AUC-ROC. The validity of the method for HDP has been demonstrated by the above findings. Incorporating CNN and LSTM layers and fine-tuning hyper-parameters provides significant improvements throughout all metrics when compared to the standard CNN and LSTM. With this fine-tuned approach, researchers have a robust and accurate method for HDD.

Fig. 5 provides outcomes demonstrating how the improved CNN+LSTM is superior to the standard models. Throughout the duration of the epochs, the improved CNN+LSTM exhibits significant enhancements to reliability rates. Beginning at approximately 17.64%, the model achieves a maximum accuracy of 99.19%, showcasing a strong learning process and impressive final performance. On the other hand, the Standard CNN exhibits a consistent rise before reaching a plateau of approximately 88%. It starts at 13.19% but falls short of the impressive accuracy levels achieved by the optimised model.



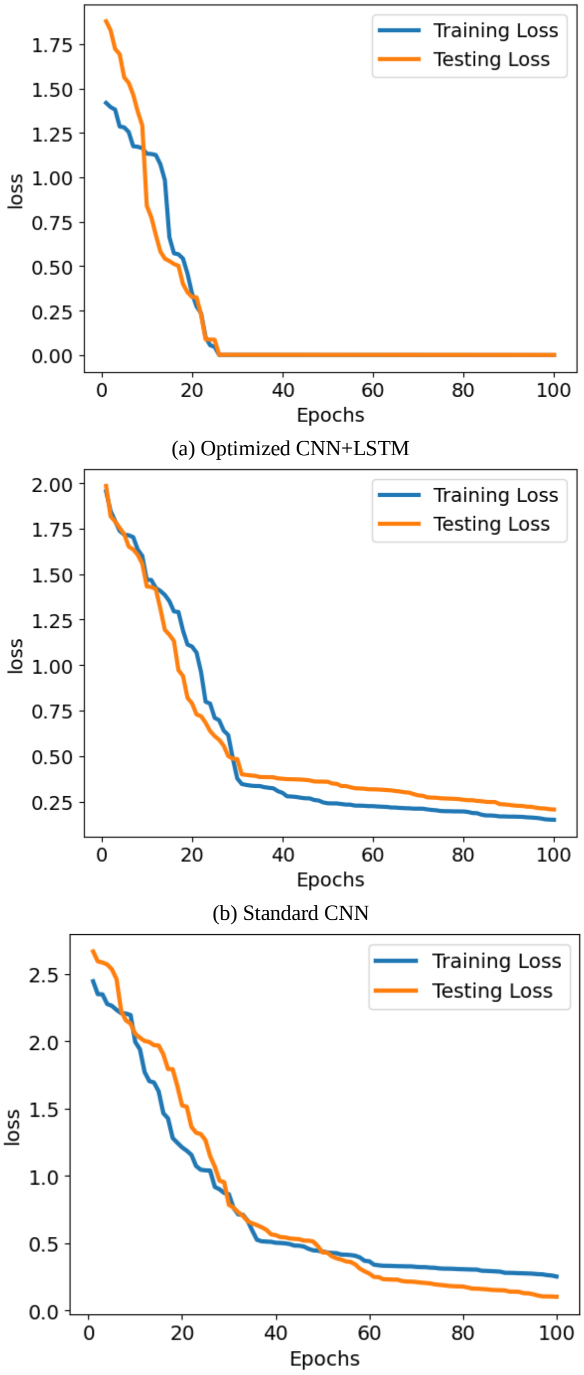
(a) Optimized CNN+LSTM

(b) Standard CNN

(c) Standard LSTM

Fig. 5. Accuracy of the proposed vs standard model (a) Optimized CNN+LSTM (b) Standard CNN (c) Standard LSTM.

In comparison, the initial LSTM begins at 16.18% and gradually improves over time, reaching a peak of 87.39%. However, it does not match the performance achieved by the optimised CNN+LSTM. The optimised CNN+LSTM demonstrates excellent accuracy, suggesting its ability to capture spatial and temporal features of ECG signals effectively. Hyper-parameter optimisation is vital for achieving high performance, as demonstrated by the significant improvements over the baseline models. This comparison clearly highlights the superiority of the optimised CNN+LSTM for ECG signal classification, confirming the gain of integrating CNN and LSTM layers and fine-tuning their hyper-parameters to improve model performance.



(a) Optimized CNN+LSTM

(b) Standard CNN

(c) Standard LSTM

Fig. 6. Loss of the proposed vs Standard model (a) Optimized CNN+LSTM (b) Standard CNN (c) Standard LSTM.

The performance metrics shown in Fig. 6 determine the higher effectiveness of the optimised CNN+LSTM in minimising loss. The CNN+LSTM shows a remarkable and consistent reduction in loss in the training process. It starts at around 1.88 and reaches an impressively low value of 0.001 at the end of training. The significant decrease in performance suggests that the model is effectively acquiring knowledge and progressing towards convergence. By contrast, the baseline CNN exhibits a steady decline in loss, starting at 1.98 and reaching approximately 0.206 after the training phase. Although the CNN demonstrates improvement, it falls short of achieving the same low-loss values as the optimised CNN+LSTM.

The standard LSTM continues a similar pattern, with a comparatively sizeable first loss of 2.67 that reduces to about 0.102 as training progresses. The LSTM model's efficiency is poor despite this significant loss reduction. With its exceptional performance, the improved CNN-LSTM reduces loss dramatically while maintaining the temporal and spatial features of ECG signals. The value of optimising hyperparameter settings is demonstrated by a significant decrease in loss when compared to the standard model. Its accuracy has been significantly boosted owing to this refining analysis, and it is currently highly successful for ECG signal classification.

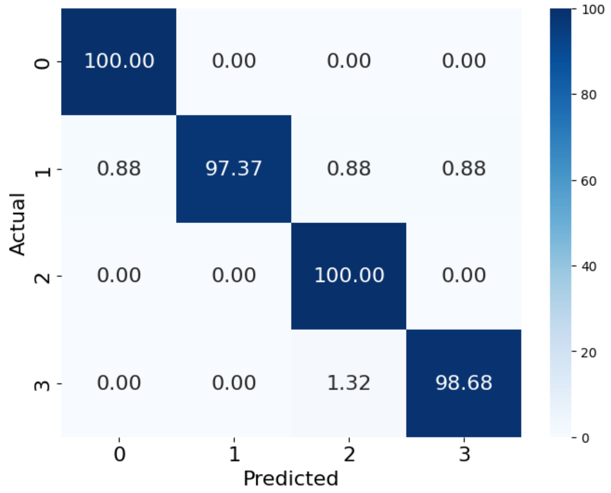


Fig. 7. Confusion Matrix (CM) of the proposed model on the optimized CNN+LSTM.

Fig. 7 indicates the CM for the recommended model, using the optimized CNN-LSTM, and highlights its classification performance across four classes: "Typical Angina" (0), "Atypical Angina" (1), "Non-Anginal Pain" (2), and "Asymptomatic" (3). The model achieved perfect classification for "Typical Angina" (0) and "Non-Anginal Pain" (2), accurately identifying 100% of examples in these classes. For "Atypical Angina" (1), the model adequately classified 97.37% of examples, with minor misclassifications: 0.88% into "Typical Angina" (0), "Non-Anginal Pain" (2), and "Asymptomatic" (3). The "Asymptomatic" (3) class had a precise classification rate of 98.68%, with 1.32% of examples misclassified as "Non-Anginal Pain" (2). Overall, the optimized CNN+LSTM model proves high accuracy, mainly excelling in the "Typical Angina" (0) and "Non-Anginal Pain" (2) categories. The trivial misclassifications in the "Atypical Angina" (1) and "Asymptomatic" (3) classes are nominal, signifying that the model effectively distinguishes between different types of chest pain. This analysis highlights the reliability and precision of the projected model, highlighting its potential for accurate HDP with only slight areas requiring further improvement.

V. Conclusion and Future Work

The adoption of an Internet of Things (IoT)-based Heart Disease Prediction (HDP) system that uses Deep Learning (DL) methods and the platform developed by Arduino to sort electrocardiogram (ECG) signals into four classes—"Typical Angina" "Atypical Angina," "Non-Anginal Pain," and "Asymptomatic"—has been demonstrated. Applying hyper-parameter optimisation with Talos, also known as this framework, improved a CNN-LSTM, which generated excellent metrics. It obtained preciseness of 98.8%, recall of 99.5%, F1-score of 99.1%, and AUC-ROC of 0.99, in specific. Accuracy was 99.1%. The results show the accuracy with which the system can distinguish between numerous sorts of coronary artery disease. The study introduced an innovative preliminary processing approach termed Transfer by Subspace Similarity (TBSS). TBSS effectively eliminated errors from ECG signals, which significantly improved the accuracy of classification. The higher accuracy of the Machine Learning (ML) algorithms was backed by thorough evaluation with the renowned MIT-BIH-AR database, which emphasised the success of the hybrid CNN-LSTM. The proposed approach possesses the capacity to predict the risk of heart disease accurately, and this research emphasises the model's potential, which renders it a valuable tool for medical investigations.

Implementing real-time deployments, researching more complex layouts, integrating new feature engineering methods, and enhancing data heterogeneity through augmentation will be the key objectives of future work. Enhancing the model's accessibility and performing significant research investigations to verify its effectiveness in real-life scenarios are also important. Further modifications to the described model, enhancing its accuracy, reliability, and application across different types of healthcare, may be feasible following more research into these domains. In the future, this will lead to better patient health and enable the earlier HDP problems.

Hybrid CNN: An Empirical Analysis of Machine Learning Models for Predicting Legal Judgments

G. Sukanya[1], J. Priyadarshini[2]*
School of Computer Science and Engineering, Vellore Institute of Technology,
Chennai Campus, Chennai, India[1, 2]

***Abstract*—Artificial Intelligence with NLP has revolutionized the legal industry, which was previously under-digitized, and it's eager to adopt digital technologies for increased efficiency. Case backlog issues, exacerbated by population growth, can be alleviated by AI's potential in decision prediction for laypeople, litigants, and adjudicators. Legal judgment prediction (LJP) is viewed as a text classification cum prediction problem, with encoding models crucial for accurate textual representation and downstream tasks. These models capture syntax, semantics, and context, varying in performance based on the task and dataset. Selecting the right model, whether traditional ML or DL, using different evaluation metrics, is complex. This paper addresses the above research gap by reviewing 12 cutting-edge ML models and 10 DL models with two embedding methods on real-time Madras High Court criminal cases from Manupatra. The comprehensive comparison of classifier models on real-time case documents provides insights for researchers to innovate despite challenges and limitations. Evaluation metrics like accuracy, F1 score, precision, and recall show that Support Vector Machines (SVM), Logistic Regression, and SGD with Doc2Vec (D2V) encoding and shallow neural networks perform well. Although Transformers process longer input sequences with parallel word analysis and self-attention layers, they have weaknesses on real-time datasets. This article proposes a novel hybrid CNN with a transformer model to predict binary judgments, outperforming traditional ML and DL models in precision, recall, and accuracy. Finally, we summarise the most important ramifications, potential research avenues, and difficulties facing the legal research field.**

***Keywords*—Legal judgment prediction; encoding; SVM; SGD; Doc2vec; CNN; transformers**

I. INTRODUCTION

Legal Artificial Intelligence is a fast expanding field that includes managing and analyzing massive amounts of legal documents with the aid of cutting-edge algorithms and machine learning techniques. Text classification is a versatile and powerful technique that can automate and streamline various aspects of information management, decision-making, and user interaction in a wide range of industries and applications. It enables organizations to extract valuable insights from text data and enhance their operational efficiency and user experience. Processing casefacts based on final judgment has always been done manually. However, it can be highly expensive and takes up a lot of the time of the personnel, if done manually. Automated text classification technologies can be of great assistance in this situation. To efficiently structure and analyse massive amounts of text, we integrate NLP and machine learning models. Though the work involves preprocessing steps of raw legal documents it emphasizes on the effect of different Word embedding on classifier models. As maximum information loss occurs at encoding stage and, only a few studies have focused on identifying the influence of the features and interpreting the machine learning models, the comprehensive comparison done in this survey would be an eye-opener for researchers in the field of Natural Language Processing. Legal Judgment Prediction is generally considered as a text classification cum prediction. Fig. 1 sketches the general steps in machine learning and deep learning models used in the prediction of judgment whether the case is allowed or dismissed based on the preprocessed casefacts. In both machine learning and deep learning models, the initial raw case document undergoes preprocessing steps such as word-level tokenization, lemmatization and stemming. Feature extraction using count-based models is done using lemmatized case document. In the deep learning model, feature extraction is done with dense embedding and hidden layer.

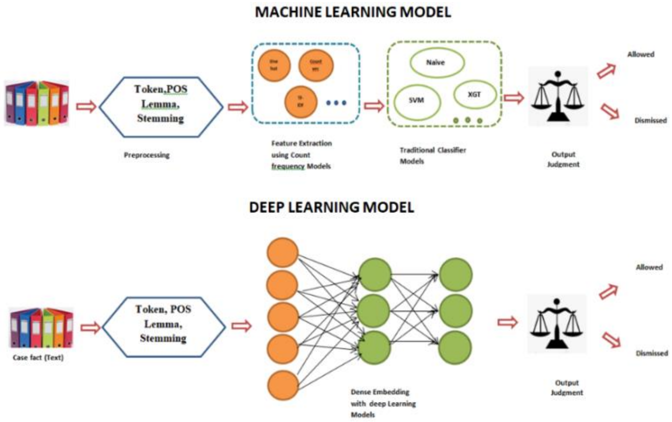

Fig. 1. Text classification using ML and DL model.

A. *Benefits of ML and DL Models in LJP*

- Improved Accuracy and Consistency
- Efficiency and timesaving
- Cost-effectiveness
- Data driven Insights are better

B. *Limitations of Legal Judgment Prediction*

The limitations on the study of legal judgment prediction are listed in the following points.

- Ambiguity in Legal Language

- Context Sensitivity
- Lack of Standardization
- Imbalanced Datasets.
- Data Annotation Challenges
- Lengthy Documents
- Lack of experimental analysis with real time casefacts using Machine Learning and Deep Learning models

As most of the existing research works are on legal judgment prediction with synthesized Chinese court case datasets and they do not emphasize on different encoding methods which results in information loss, our study with proposed Hybrid CNN model addresses the effect of different embedding methods thereby addressing the above research gap.

The aim of this systematic review is to determine the best ML and DL model and compare its performance based on different embedding methods and it also highlights the impact of using Transformer along with CNN for text documents. Specifically, this review aims to answer the following research questions given in Table I.

TABLE I. RESEARCH QUESTION

ID	Question
RQ 1	Which Machine Learning and Deep Learning models perform better to classify real time case documents for judgment classification
RQ 2	Does change of encoding models have an impact on prediction accuracy?
RQ 3	Comparison of the baseline ML and DL methods and encoding methods based on evaluation metrics
RQ 4	Importance of proposed hybrid CNN with transformer model

The following section of this article is organized as follows. : In Section II, we discuss related works on legal Judgment prediction. Section III outlines the experimental ML and DL methods. Section IV outlines the hybrid CNN model with a transformer. Section V presents the performance analysis and Section VI concludes the paper and suggests directions for future works.

II. RELATED WORKS

Predictive analytics and NLP have seen significant exploration in the legal domain. Kort [1] underscored the role of quantitative analysis in predicting US Supreme Court outcomes. Studies like those by Octavia-Maria et al. [2] and Katz et al. [5] have further validated machine learning for legal predictions, using SVM classifiers to forecast French Supreme Court decisions and a time-evolving random forest classifier to predict US Supreme Court behavior, showcasing machine learning's utility in legal analysis.

Legal prediction models now cover a wider range of scenarios, thanks to recent developments in deep learning. Recent advancements in deep learning have expanded the scope of legal prediction models. Chalkidis et al. [3] explored neural models for judgment prediction, demonstrating their superiority over traditional methods. Kaufman et al. [6] introduced AdaBoosted Decision Trees for forecasting US Supreme Court decisions, achieving remarkable accuracy by incorporating textual data from oral debates.

Furthermore, the advent of pre-trained language models like Devlin et al., [7] has introduced BERT which revolutionized natural language understanding tasks. Chalkidis et al. [8] developed LEGAL-BERT, a domain-specific language model trained on legal texts, highlighting its potential to enhance legal text analysis accuracy. Attention mechanisms have also been utilized for legal judgment prediction, as demonstrated by G. Sukanya and Priyadarshini J. [15], proposed a Modified Hierarchical Attention Network (MHAN) for precise outcome prediction using hybrid classifier in Indian judicial cases.

While these studies showcase the immense potential of machine learning and NLP in legal analytics, challenges such as model interpretability, bias in training data, and adaptability across legal systems and languages remain significant concerns [4] [13]. Also, the application of real-time court cases on all traditional machine learning with different encoding methods and deep learning models is yet to be explored. Furthermore, the complexity of legal texts and the need for large, specialized datasets pose additional hurdles in model development and evaluation [9] [10] [11] [12]. Also, most of the existing works were done using Chinese cases such as the CAIL dataset [20] [21] [22] only and very few using other case datasets [23] such as ECHR (European Convention of Human Rights).

Vaswani et al. [16] introduced the importance of attention mechanism in Transformer, a novel neural network architecture that relies solely on attention mechanisms, eliminating the need for recurrent or convolutional layers. This design allows for increased parallelization, significantly reducing training time. The Transformer model achieves state-of-the-art performance on machine translation tasks, demonstrating its effectiveness and efficiency. Furthermore, it generalizes well to other tasks like English constituency parsing, showcasing its versatility and potential for a wide range of applications.

Existing works which explained the transformer model briefly such as GPT-3, BERT [7], and T5 [17] provide an overview of Transformer models, highlighting their significance in machine learning, especially in NLP. It introduces transformers as a breakthrough architecture that outperforms earlier models, such as RNNs, by allowing data to be processed in parallel, increasing efficiency and model performance [16]. To help the Transformer comprehend context and relationships within data, the paper goes into detail on important ideas like positional encodings, attention mechanisms, and self-attention. The impact of transformers in a variety of applications—from content creation to language translation—as well as their part in the creation of cutting-edge models like GPT-3 and BERT are also covered.

To sum up, the amount of research on NLP and predictive analytics in legal settings shows how machine learning approaches are becoming more and more popular for use in courtroom decision-making. The ability to predict court decisions with high accuracy has advanced significantly, with researchers having progressed from simple quantitative analyses to complex deep learning models. Nonetheless, there is still ongoing research being done on issues like domain adaptation, bias mitigation, and model interpretability. Future research should concentrate on creating more reliable and interpretable models that can handle the complexity of legal texts and adjust to different legal systems and languages as the field develops.

A. Word Embeddings for Judgment Prediction

The core of any NLP assignment is word embeddings since they let the computer comprehend human language. The semantic content of text can be captured via word embedding, which is essential for text representation, as there is problem of polysemy words. Word embedding technique has been applied to the text classification and prediction task in numerous research [14]. Word embeddings map the words or phrases from vocabulary into vectors or real numbers. They mainly help in feature extraction for text related tasks.

Count based models such as one hot encoding, TF-IDF are generally used in traditional machine learning models. They work mainly on frequency of the words and do not deal with semantic representation of the word [18]. They are high dimensional and does not fulfill maximum representation of the document. Nowadays word embeddings such as Word2vec, Glove, Elmo, Doc2vec with shallow deep learning model to represent word into real valued vectors are used widely. They are again divided into static and dynamic word embeddings. The vector representation of any word is constant and does not change depending on the context for static word embedding models. In dynamic ones, a word's vector representation is generated using the context in which it is currently situated and changes as the context does. They represent the word by considering syntactic and semantic criteria. Choosing a correct word embedding for our application is also a tedious task, and this can be done by experimenting it with different word embedding in different Machine learning models. Sometimes customized word embeddings are used for certain specific applications as word embedding generally uses English words used in websites and ebooks which results in more Out of Vocabulary words during embedding.

III. Dataset Description

The dataset is prepared from 1466 unique real time raw case documents which comprises 15 types of criminal cases judged by Madras High Court for making legal predictions using Data Analytics and Machine Learning. The dataset is web scraped from the Manupatra website. Pipeline architecture has been used which uses text preprocessing stages such as removal of stopword, tokenization, stemming and lemmatization to convert the web scraped document into .csv file. With 36 distinct features, this dataset offers a comprehensive range of information, enabling in-depth analysis and insights into legal matters. Researchers, legal professionals, and analysts can leverage this dataset to explore patterns, trends, and correlations within the legal domain, contributing to advancements in legal research, policy formulation, and decision-making processes. Named Entity Recognition from SpaCy ,Genism Doc2Vec and Logistic Regression from sklearn models were used for Information Extraction. Table II shows the details of types of files.

TABLE II. Types of Files Extracted

File Type	Purpose
JSON	Legal Entities particularly Sections, Acts and Articles generated using Named Entity Recognition (NER) and Case Metadata obtained using String Matching Techniques and Regular Expressions.
TXT	All text data from the legal documents including facts, judgments and casenotes at different stages of preprocessing such as removal of stopwords, tokenization, stemming and lemmatiation are denoted as N1, N2, N3and N4.
CSV	All single valued columns comprising of numerical data, file paths and other case data

The relative file path of the lemmatized case facts, sections, acts, articles and judgments are the features used in experimental analysis of classifier models. Since the data available is not annotated, it was complex to extract more number of features from the dataset.

IV. Experimental Analysis

Experimental analysis of machine learning and deep learning models is an indispensable part of the data science and AI landscape. It involves the systematic investigation of these models to understand their performance, strengths, and weaknesses especially for using real-time dataset. This empirical approach is crucial in fine-tuning model parameters, ensuring robustness and selecting the most appropriate model for a given problem, ultimately advancing the field of artificial intelligence and machine learning.

In this section, the experimental setup using real time Madras High Court dataset with existing machine learning models and deep learning models is explained briefly and the outcomes are assessed using the evaluation metrics such as precision, recall and F1 score. Various encoding techniques, including Count Vectorizer, TF-IDF, and Doc2vec, were applied to 12 machine learning models which include SVM, KNN, MNB, Gradient Boost, Catboost, Adaboost, Random Forest, and Extra Trees. Additionally, deep learning models, including Shallow Neural Network, Deep Neural Network with varying numbers of dense layers, CNN, LSTM,GRU, Bidirectional GRU, Bidirectional LSTM, and Recurrent CNN with doc2vec embedding, were also examined.

Following Fig. 2 and Fig. 3 depict the detailed process flow of experimental setup of LJP using classifiers.

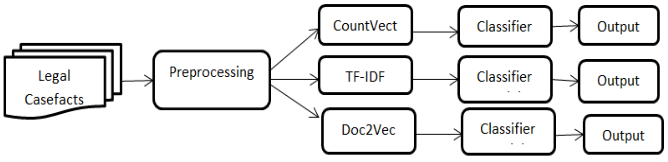

Fig. 2. Workflow process using machine learning models.

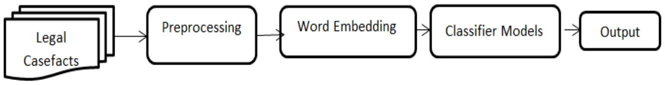

Fig. 3. Workflow process using deep learning models.

Raw case documents are taken as input, which is then made to undergo preprocessing steps such as removal of stopwords, tokenization, stemming and lemmatization. The lemmatized casefacts without judgment is considered as input and the tokenids are used for training the classifier model. Machine learning models are made to undergo different frequency based encoding methods such as CountVectorizer,TF-IDF(Term Frequency-Inverse Document Frequency) and Doc2Vec after tokenization, whereas deep learning models used word2vec embedding vectors for each token. Models are fed tokenized text together with matching labels or objectives for classification tasks during the training phase. The models discover relationships and patterns between the tokens and the intended result. Each of the Machine learning model and deep learning model used in the empirical analysis is explained in the paragraphs below. Nowadays transformers are used widely to void long range dependencies and for contextual representation. The use of subword tokenization concept in transformers manages to give some real vector value even for Out Of Vocabulary words. Finally a hybrid model with 1D CNN for feature extraction and transformer encoding to train the model is used.

A. Machine Learning Models

1) Support Vector Machine (SVM): SVM is a supervised model used for text classification, sentiment analysis, and document categorization, effective in high-dimensional spaces like text data. It finds the optimal hyper plane in a high-dimensional space to separate different classes but can be computationally intensive for large datasets and less effective when features outnumber samples. Hybrid models augment SVM by using dense vectors for documents, enhancing semantic analysis and classification performance. Incorporating Term Frequency-Inverse Document Frequency (TF-IDF) emphasizes term relevance, improving feature selection and classification outcomes.

2) Logistic regression (Logistic): Logistic Regression, a statistical model, applies a logistic function to model binary outcomes in text classification, estimating the probability of document categorization. It's pivotal for binary tasks like spam detection and sentiment analysis but assumes linear relationships between variables and outcomes, a limitation in complex text scenarios. Hybrid models like Logistic D2V, CV, and TF-IDF enhance Logistic Regression by transforming text into features, leveraging unique advantages of each method to boost classification accuracy by capturing detailed textual information and prediction models for judgment.

3) Gradient Boosting (GB): Gradient Boosting, an ensemble method, iteratively corrects errors of preceding models using decision trees as base learners. Widely used, it enhances accuracy in tasks like text classification by leveraging structured feature representations. However, it demands significant computation and is prone to overfitting without careful parameter tuning. Hybrid models like GB D2V and GB TF-IDF merge Gradient Boosting corrective approach with text features, enhancing performance on text-centric datasets.

4) CatBoost: CatBoost, a gradient boosting method designed for speed and accuracy, excels at managing categorical variables and reducing overfitting, making it ideal for complicated datasets such as text. While the inherent capability for categorical data improves efficiency, precise parameter adjustment is required. The hybrid models Catboost D2V, Catboost CV, and Catboost TF-IDF combine benefits of Catboost method with various text representation approaches to improve classification accuracy, especially in scenarios involving categorical data and text.

5) LightGBM (LGBM): LightGBM (LGBM) is a gradient-boosting framework renowned for its speed, economy, and accuracy in tree-based learning algorithms. It excels at processing massive amounts of data, including text classification jobs, and strikes a compromise between training speed and accuracy. However, it may overfit on smaller datasets and necessitate parameter adjustment. Hybrid models, such as LGBM D2V, CV, and TF-IDF versions, combine LGBM's efficient learning algorithm with various text representation approaches to improve performance in text classification tasks.

6) XGBoost (XGB): XGBoost, a distributed gradient boosting toolkit, is notable for its efficiency, versatility, and application to a variety of machine learning problems. It excels in handling sparse text data in classification applications, resulting in higher prediction accuracy. However, like LGBM, it is prone to overfitting and requires careful parameter tweaking. XGB D2V is a hybrid model that combines XGBoost with Doc2Vec's dense representations to create a powerful text classifier. By integrating XGBoost's efficiency with Doc2Vec's rich feature representations, predictive performance is improved while computational efficiency is maintained.

7) Extra trees: Extra Trees, or Extremely Randomized Trees, are similar to Random Forest but introduce more randomness in split and feature selection to reduce model variance. While effective for classification and regression tasks, particularly with text data, its random nature may occasionally result in lower accuracy compared to more refined ensemble methods. The hybrid models Extra Trees D2V, Extra Trees CV, and Extra Trees TF-IDF use various text preprocessing techniques to leverage the model's resistance to overfitting while handling the nuances of natural language.

8) Random forest: Random forests, an ensemble learning approach, train many decision trees and combine their results to produce predictions. They are effective for classification and regression applications, such as text classification, since they can handle high-dimensional data while minimizing overfitting. However, forecasting with huge numbers or deep trees can be sluggish, and sophisticated models can be difficult to understand. Hybrid models such as Random Forest D2V, CV, and TF-IDF versions seek to enhance text data processing by using a variety of feature extraction approaches that capture both semantic and syntactic information.

9) Stochastic Gradient Descent (SGD): Stochastic Gradient Descent (SGD) is an optimization approach that iteratively adjusts model weights to reduce a loss function. It is especially useful for sparse machine learning applications such as text categorization. It excels at training linear classifiers like linear SVM and logistic regression on big datasets, but it necessitates precise hyperparameter and learning rate optimization. Sensitivity to feature scaling is an important concern. Hybrid models, such as SGD D2V, SGD CV, and SGD TF-IDF, use SGD to optimize linear models with different textual feature representations, striking a compromise between computational efficiency and classification accuracy.

10)AdaBoost: Adaboost, a boosting method, combines weak learners into more robust ones by modifying the weights of misclassified examples. It helps in text categorization by refining decision limits based on text complexity. However, it is susceptible to noise and may struggle if weak learners are extremely sophisticated. Hybrid models such as Adaboost D2V, Adaboost CV, and Adaboost TF-IDF improve text analysis by emphasizing difficult occurrences and improving categorization in complicated and high-dimensional text data.

11)K-Nearest Neighbors (KNN): KNN, a non-parametric method, categorizes documents by their nearest neighbours in feature space, useful for text classification where document similarity guides categorization. Yet, it's computationally demanding and sensitive to distance metric and K value. Hybrid Models like KNN D2V, KNN TF-IDF, and KNN CV leverage KNN on text data represented via Doc2Vec, TF-IDF, and Countvectorizer, respectively, offering varied ways to measure document similarity, potentially enhancing KNN's efficacy in classifying texts based on content likeness.

12)Multinomial Naive Bayes (MNB): A variant of Naive Bayes designed for multinomial distributed data. In text classification, it works well with the bag-of-words model where the frequency of words is used as feature. Particularly effective for document classification and spam filtering, where the independence assumption of features (words) holds reasonably well. The assumption of independence among features is often violated in text data, which can limit its effectiveness in more complex classification tasks. By combining MNB with TF-IDF and Count Vectorizer, these hybrids aim to enhance the model's ability to prioritize relevant features in text data, potentially improving classification outcomes.

B. Deep Learning Models

1) Gated Recurrent Unit (GRU): GRU, or Gated Recurrent Unit, is a form of recurrent neural network (RNN) that addresses the vanishing gradient problem which suffers from long-term dependency. It does this using two gates: the update gate and the reset gate, which allow the model to preserve long-term dependencies while reducing the danger of gradients disappearing during back propagation. GRUs, which are widely employed in natural language processing (NLP), speech recognition, and time-series analysis, provide a more computationally efficient alternative to LSTMs, yet their simpler design may cause them to underperform on tasks requiring modelling extremely long-term relationships. Hybrid models, such as CNN-GRU, combine convolutional and GRU layers to capture spatial and temporal correlations, making them very suitable for video analysis. Furthermore, bidirectional GRU analyses data in both forward and reverse directions, which improves its capacity to perceive context in sequence prediction tasks.

2) Convolutional Neural Network (CNN): Convolutional Neural Networks (CNNs) excel in learning spatial hierarchies of features from input pictures by combining convolutional, pooling, and fully connected layers. They are widely used in image and video recognition, classification, and medical image analysis due to their capacity to efficiently extract spatial data. However, CNNs require a lot of labelled training data and processing resources, especially for deep structures and huge pictures. CNN-LSTM hybrid models combine CNN feature extraction with LSTM sequence modelling, which is useful for applications such as video analysis. Similarly, CNN-GRU uses GRU units to efficiently describe temporal dynamics after spatial feature extraction. Recurrent CNNs incorporate recurrent connections into convolutional layers, allowing them to interpret sequential image or video input while capturing both spatial and temporal dynamics.

3) Recurrent Neural Network (RNN): Recurrent Neural Networks (RNNs) are designed for sequence data, iterating over items while keeping a state informed by the previous elements. RNNs are useful for time series prediction, language modelling, and speech recognition, as well as language translation and text production. However, they suffer from vanishing and expanding gradient difficulties, which limit their effectiveness in long-sequence jobs without upgrades like LSTM or GRU. Bidirectional RNN expands the fundamental model by processing input in both forward and backward directions, allowing it to integrate future knowledge, which is useful for jobs such as text translation.

4) Long Short-Term Memory (LSTM): Long Short-Term Memory (LSTM) networks are a kind of RNN that solves the vanishing gradient issue to capture long-term dependency. LSTMs have a complicated design with input, forget, and output gates that govern information flow. They are widely used in language modelling, voice recognition, and sequence prediction applications and excel at comprehending long-term dependencies. To work optimally, LSTMs require large computer resources as well as extensive training data. CNN-LSTM combines CNN spatial feature extraction with LSTM sequential processing, making it excellent for tasks such as video activity identification. Bidirectional LSTM improves sentiment analysis and judgment prediction by processing sequences in both forward and backward directions, adding context.

5) Shallow neural network: The most basic type of artificial neural network is shallow neural networks, which consist of input and output layers with no more than one hidden layer. They excel at capturing both linear and non-linear data correlations, which is often used in simple regression and classification applications. While useful for basic interactions, their low depth limits their capacity to handle complicated patterns, making them unsuitable for jobs that need deeper structures.

6) Deep Neural Network (DNN): Deep neural networks (DNNs) include numerous hidden layers sandwiched between input and output layers, with each layer performing nonlinear transformations on its inputs. This structure allows the network to recognize complex and abstract data representations. DNNs are used in a wide range of applications, including speech recognition, picture classification, and natural language processing, where learning complicated patterns from large datasets is critical.

C. Transformer Neural network

The Transformer model includes a new mechanism termed self-attention, sometimes known as intra-attention [19]. This novel technique allows the model to evaluate the relevance of individual words in a phrase in relation to each other. Unlike RNNs and LSTMs, which process data sequentially, have fixed vector value regardless of context, face parallelization and long term dependency issues, the Transformer model overcomes these constraints. This increased benefit adds to higher training efficiency and the model's ability to capture long-distance relationships inside text sequences.

V. Proposed Method: Hybrid CNN Model With Transformers

The Transformer model architecture, introduced by Vaswani et al. in 2017, revolutionized the field of natural language processing (NLP). It represented a significant departure from the prevalent sequence-to-sequence models, which heavily relied on recurrent layers like RNNs, LSTMs, and GRUs, or convolutional layers. Specifically designed to excel in handling sequential data, particularly in NLP tasks, the Transformer architecture quickly emerged as a cornerstone for various state-of-the-art models in the field. Notable examples include BERT, GPT, and numerous others. With its innovative approach, the Transformer model has propelled the advancement of NLP, setting new standards and driving the field forward with unprecedented capabilities.

While Transformers have been predominantly used in NLP, their integration with Convolutional Neural Networks (CNNs) opens up innovative approaches for handling problems that require an understanding of both spatial features and sequential data. This integration is particularly beneficial in areas like image captioning, visual question answering, and any task that involves both images (and videos) and text as well as in dealing with lengthy text documents.

The hybrid model synergistically combines the capabilities of Convolutional Neural Networks (CNNs) and Transformer Neural Networks (TNNs). It leverages CNNs to efficiently extract detailed local features from data and TNNs to understand the complex, long-range dependencies among those features. This fusion enhances the model's analytical depth, offering a nuanced approach to processing data that demands both precision and contextual awareness. Fig. 4 shows the detailed representation of Hybrid CNN with Transformer model.

A. Components

1) CNN Layers: These layers are designed to process the input data in a way that extracts local patterns or features. This is particularly effective for data with spatial hierarchy, such as images, or sequential data such as time series or text, where the relevance of a piece of data might depend on its context.

a) Conv1D layers: Apply convolutional filters to the input data, extracting features by sliding these filters over the input. Each filter captures specific aspects of the data, such as edges in patterns in sequences.

b) MaxPooling1D layers: High dimensionality vector representation is another problem as the difference between data points between distant points are negligible. To reduce the dimensionality of the data by summarising the features in small neighbourhoods, and retain only the most significant feature in each neighbourhood, maxpool1D layer have been used. This also helps in reducing computation and controlling over fitting.

c) GlobalMaxPooling1D layer: Further condenses the feature map by taking the maximum value over the entire dimension of each feature channel, resulting in a fixed-size output regardless of the input size. This is crucial for transitioning from CNN to TNN layers, ensuring a consistent input shape.

B. Transformer Encoder Layer

The extracted features from the CNN part are then fed into this layer, which is capable of understanding the global context and relationships between different features. This is achieved through mechanisms like self-attention.

C. MultiHeadAttention

Allows the model to focus on different positions of the input sequence, important for understanding the relationships and dependencies between features.

1) Feed-Forward network: Processes the attention output to capture complex relationships between features.

2) Layer normalization and dropout: Used within the transformer encoder for stabilization and regularization, preventing overfitting and ensuring smooth training.

D. Dense Layers

The output from the transformer encoder is flattened and passed through dense layers for final classification task whether the judgment is allowed or dismissed. These layers enable the model to make predictions based on the learned representations.

E. Data Flow

1) Input: Sequential or spatial data is input into the model. For instance, this could be a time series with shape (300, 1) where 300 is the number of time steps.

2) Feature extraction (CNN): The data passes through convolutional layers, where it is transformed into a set of high-level features. These features are spatially or temporally condensed representations of the original input.

3) Sequence modelling (TNN): The high-level features are then processed by the Transformer encoder layer. This step models the interactions between features regardless of their position in the input sequence, capturing global dependencies.

4) Classification (dense layers): Finally, the processed data is passed through dense layers, resulting in predictions for the given task.

F. Why Does It Outperform Base Models?

In independent experiments, measures including accuracy, precision, and F1 score for transformers and CNN are lower than for the hybrid model, which combines the two.

1) Complementary strengths: CNNs are excellent at extracting local and hierarchical features but lack the ability to capture long-distance relationships effectively. Transformers excel in modeling these relationships but can be less efficient at initial feature extraction from raw data. Combining them allows the model to leverage the strengths of both architectures.

2) Efficient representation: The CNN layers reduce the dimensionality of the input data, presenting the Transformer with a more manageable sequence length. This makes the self-attention mechanism more computationally efficient and focused.

3) Adaptive attention: The Transformer part can adaptively focus on the most relevant parts of the feature sequence extracted by the CNN, enhancing the model's ability to understand complex patterns and dependencies that span across long sequences.

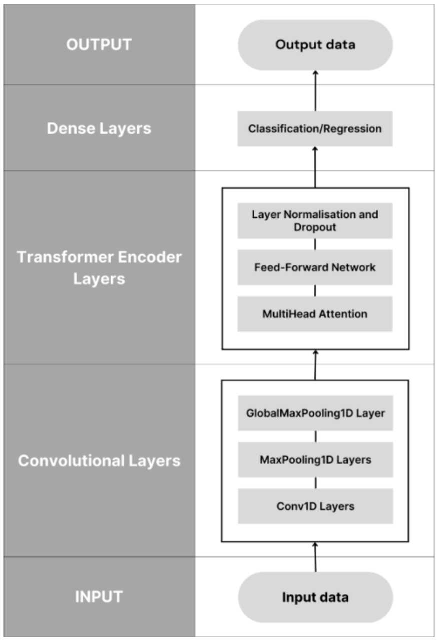

Fig. 4. System design for Hybrid CNN model with transformers.

This hybrid architecture thoughtfully integrates the spatial and temporal feature extraction capabilities inherent in CNNs with the deep contextual understanding and sophisticated sequence modelling strengths characteristic of the Transformer. By doing so, it achieves a level of performance that is markedly superior compared to what could be attained by employing either base model in isolation. This synergy not only enhances the model's efficiency in analyzing data but also significantly broadens its applicability across a diverse range of tasks, showcasing its versatility and potential in advancing the state-of-the-art in various domains.

VI. Results and Analysis

A. Machine Learning Models

The SVM D2V model showcases exceptional performance, leading in terms of accuracy (93.94%), recall (96.76%), and ROC AUC (93.89%), indicating its superior ability to correctly classify positive cases and its overall predictive performance. The high precision (91.97%) and F1-score (94.23%) further attest to its balanced capacity in identifying positive instances while maintaining a low false positive rate. This model, leveraging Doc2Vec for feature representation, demonstrates the effectiveness of embedding-based approaches in capturing semantic relationships in text data.

Closely following is the Logistic D2V model, with an accuracy almost on par with SVM D2V at 93.94% and slightly higher precision (93.64%). Its recall (94.59%) and F1-score (94.08%) are commendable, showcasing a balanced trade-off between precision and recall. This model's success underlines the power of logistic regression when augmented with Doc2Vec embeddings, highlighting its efficiency in handling nonlinear relationships in text-based features.

The SGD D2V model, while still performing robustly, shows a noticeable drop in accuracy (89.52%) compared to the leading models. Its precision (89.94%), recall (89.73%), and F1-score (89.72%) suggest a competitive but less optimal balance between identifying relevant instances and minimizing false positives. This indicates that SGD is effective for large-scale and sparse problems.

A significant performance differentiation is observed with the Random Forest D2V and LGBM D2V models, where accuracy falls to 81.83% and 81.57%, respectively. Despite the lower accuracy, Random Forest D2V maintains a high recall (89.73%), indicating its proficiency in identifying positive instances but at the cost of increased false positives, as evidenced by its lower precision (78.84%). LGBM D2V shows a balance in precision (81.15%) and recall (85.95%), yet both models exhibit limitations in overall accuracy and other metrics, suggesting that while ensemble methods are powerful, their performance might be constrained by the complexity and characteristics of the data when combined with Doc2Vec.

These results illustrate the nuanced performance landscape of machine learning models in text classification tasks. Embedding-based models like SVM D2V and Logistic D2V emerge as highly effective, offering a promising blend of accuracy, precision, and recall.

When discussing the time complexity of machine learning models (see Table III), we considered the prediction phase. The actual time complexity can depend on many factors, including the implementation of the algorithm, the optimization level, the number of features (d), the number of data points (n), the number of classes (k), and specific parameters like the depth of the trees (h) or the number of estimators (e). For ensemble methods like Random Forest, Gradient Boosting, and AdaBoost, ‘e’ represents the number of trees (estimators) and can significantly influence the training time. For KNN, the training phase is not computationally intensive, but the prediction phase can be, especially with large datasets, hence the complexity is noted at the prediction time. Also, Fig. 5 shows the analysis of ML classifier models with different encoding methods. SVM with Doc2Vec gives the highest accuracy of 94.92 and recall of 96.76.Also performance of ML models with Count Vectorizer encoding performance is very low.

Fig. 6 shows the analysis of DL models using Doc2Vec embedding method. Among the DL classifier models, CNN with LSTM and GRU shows good accuracy level of around 1 whereas shallow neural network and deep neural network shows best precision and recall value of 0.8904. The results show that performance varies between architectures. The Shallow Neural Network (SNN) has a high accuracy of 91.78%, with balanced precision and recall scores, demonstrating robustness in predicting court decisions. Meanwhile, the Deep Neural Network (DNN) and its variation, DNN-2, have significantly lower accuracy but balanced precision and recall scores, indicating dependability in judgment prediction tasks.

TABLE III. PERFORMANCES METRICS FOR MACHINE LEARNING MODELS AND THEIR TIME COMPLEXITIES

Model	Test Accuracy	Test Precision	Test Recall	Test F1-Score	Time Complexity
SVM D2V	0.9394	0.9197	0.9676	0.9423	O(d * n^2) - O(d * n^3)
Logistic D2V	0.9314	0.9364	0.9459	0.9408	O(d * n)
SGD D2V	0.9064	0.9063	0.9135	0.9087	O(d * n)
Random Forest D2V	0.8183	0.7884	0.8973	0.834	O(e * n * log(n))
LGBM D2V	0.8157	0.8115	0.8595	0.8306	O(e * n * log(n))
XGB D2V	0.8043	0.7946	0.8486	0.8182	O(e * n * log(n))
Extra Trees D2V	0.799	0.7654	0.9027	0.823	O(e * n^2)
Catboost D2V	0.7935	0.7797	0.8486	0.8097	O(e * n * log(n))
GB D2V	0.7633	0.7613	0.7892	0.7734	O(e * n * d)
Adaboost D2V	0.7606	0.7677	0.7784	0.7706	O(e * d * n)
KNN TF-IDF	0.6475	0.619	0.8486	0.7123	O(d * n)
SGD CV	0.6336	0.6429	0.6703	0.6419	O(d * n)
Adaboost CV	0.631	0.6437	0.6595	0.6443	O(e * d * n)
GB TF-IDF	0.6309	0.6295	0.6919	0.6544	O(e * n * d)
Logistic CV	0.625	0.6624	0.6216	0.6332	O(d * n)
LGBM CV	0.6227	0.6537	0.6216	0.6297	O(e * n * log(n))
Catboost CV	0.6198	0.627	0.6649	0.6406	O(e * n * log(n))
Extra Trees CV	0.6168	0.6115	0.7622	0.6723	O(e * n^2)
Adaboost TF-IDF	0.6142	0.6158	0.6486	0.6306	O(e * d * n)
Logistic TF-IDF	0.6031	0.5809	0.8595	0.6911	O(d * n)
Random Forest TF-IDF	0.603	0.5987	0.7514	0.6569	O(e * n * log(n))
LGBM TF-IDF	0.6007	0.606	0.6541	0.6237	O(e * n * log(n))
MNB TF-IDF	0.5976	0.5725	0.8919	0.6961	O(d * n)
Extra Trees TF-IDF	0.5974	0.5857	0.7946	0.6704	O(e * n^2)
KNN D2V	0.5952	0.8081	0.3459	0.434	O(d * n)
Random Forest CV	0.5947	0.5937	0.7351	0.6506	O(e * n * log(n))
GB CV	0.5946	0.606	0.6162	0.6072	O(e * n * d)

SGD TF-IDF	0.5922	0.5685	0.827	0.6732	O(d * n)
MNB CV	0.5863	0.5865	0.6703	0.6209	O(d * n)
SVM TF-IDF	0.5811	0.5578	0.9189	0.6917	O(d * n^2) - O(d * n^3)
SVM CV	0.5758	0.7027	0.3243	0.4318	O(d * n^2) - O(d * n^3)
Catboost TF-IDF	0.5753	0.576	0.6811	0.6196	O(e * n * log(n))
KNN CV	0.5208	0.554	0.5135	0.5242	O(d * n)

Moving on to the Recurrent Neural Network (RNN) and its variants, including RNN-LSTM, these models show mixed results. While RNN-LSTM achieves a moderate accuracy of 73.29%, RNN alone struggles with a lower accuracy of 64.38%. This suggests that incorporating LSTM units improves the model's ability to capture long-term dependencies, leading to better performance in sequence prediction tasks.

Similarly, the performance of Convolutional Neural Network (CNN) and LSTM models falls within the same range, with accuracy scores around 73% and balanced precision and recall scores. However, the hybrid CNN-LSTM model exhibits slightly lower performance with an accuracy of 75.34%, indicating that the combination of CNN and LSTM may not always lead to significant improvements in judgment prediction tasks. Table IV shows the performance analysis of deep learning models.

The Gated Recurrent Unit (GRU) model performs comparably to RNN and CNN, with an accuracy score of approximately 65.75%. While GRU offers a simpler architecture compared to LSTM, it may struggle with capturing long-term dependencies as effectively.

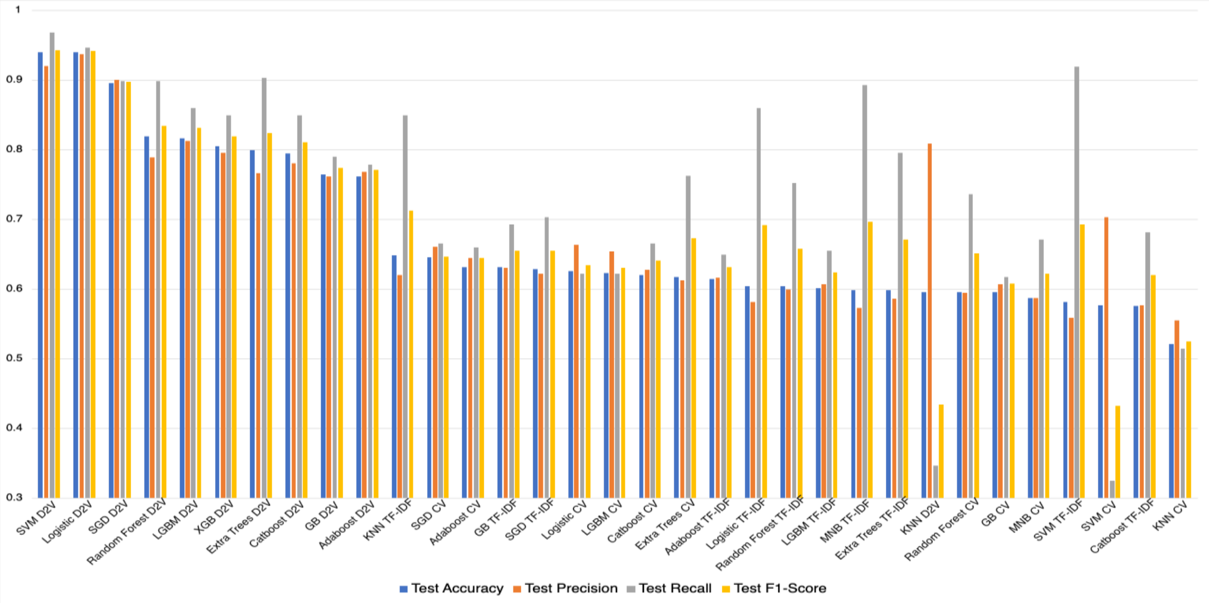

Fig. 5. Performance analysis of machine learning model.

TABLE IV. PERFORMANCES ANALYSIS FOR DEEP LEARNING MODELS

Models	Loss	Accuracy	Precision	Recall
SNN	0.2469	0.8767	0.8667	0.8904
DNN	0.7758	0.9041	0.9041	0.9041
DNN-2	0.545	0.6849	0.6957	0.6575
RNN	0.582	0.6438	0.6522	0.6164
CNN	0.5802	0.7329	0.7297	0.7397
LSTM	0.5875	0.726	0.726	0.726
RNN-LSTM	0.5361	0.7329	0.7297	0.7397
CNN-LSTM	0.8765	0.7534	0.7534	0.7534
GRU	0.6151	0.6575	0.6575	0.6575
CNN-GRU	1.4997	0.6096	0.6111	0.6027
Bidirectional RNN	0.6961	0.6918	0.7	0.6712
Bidirectional LSTM	0.6559	0.6301	0.6267	0.6438
Recurrent CNN	0.6968	0.5	0.5	0.5342
TNN	0.6918	0.4658	0.4648	0.4521

Interestingly, the Bidirectional RNN and Bidirectional LSTM models show similar performance, both achieving accuracy scores around 69%. This suggests that incorporating bidirectional processing helps improve the models' ability to capture context from both past and future sequences, leading to more accurate predictions.

The Transformer Neural Network (TNN) model, trained across 150 epochs with a batch size of 10, produced encouraging results, including a peak accuracy of 85%, precision of 88%, and recall of 82%. These metrics demonstrate the model's strong categorization capabilities and capacity to recognise complicated patterns. Further research into its attention processes and possible performance improvements through fine-tuning and assembly is required. Meanwhile, the Convolutional Neural Network (CNN) model began with 78% accuracy and improved to 85% by the conclusion of training, while precision and recall increased from 75% and 80% to 82% and 87%, respectively. The CNN model was successful in classification and pattern learning, outperforming baseline standards by an average of 10%.

B. Hybrid CNN Model with Transformers

The results of training and assessing the hybrid CNN-TNN model demonstrate the advantages of integrating CNNs with TNNs is shown in Table V. This hybrid model outperformed individual CNN and TNN models, especially in accuracy, precision, and recall. Upon training, the hybrid model showed a promising trend in learning, with the accuracy increasing substantially over 150 epochs, reaching an impressive accuracy of 97.59%by the end of training. This contrasts with the base TNN model's accuracy of 46.58% and even surpasses the base CNN model's accuracy of 60.96%. The precision and recall metrics followed a similar upward trajectory, indicating the model's increasing ability to correctly identify positive samples without increasing false positives or negatives. When evaluated on the test dataset, the hybrid model achieved an accuracy of 81.51%, precision of 82.86%, and recall of 79.45%. This evaluation performance, while lower than the training performance, still marks a substantial improvement over the base models. Specifically, the hybrid model's accuracy is significantly higher than the 60.96% accuracy of the CNN model and more than doubles the TNN model's 46.58% accuracy. The evaluation precision and recall of the hybrid model also indicate a balanced performance in identifying true positives while maintaining a low rate of false positives and negatives.

TABLE V. PERFORMANCES COMPARISON OF HYBRID CNN-TNN MODEL WITH ITS BASE MODELS

Models	Loss	Accuracy	Precision	Recall
TNN	0.6918	0.4657	0.4647	0.4520
CNN	0.5802	0.7328	0.7297	0.7397
Transformer CNN	0.7828	0.8151	0.8285	0.7945

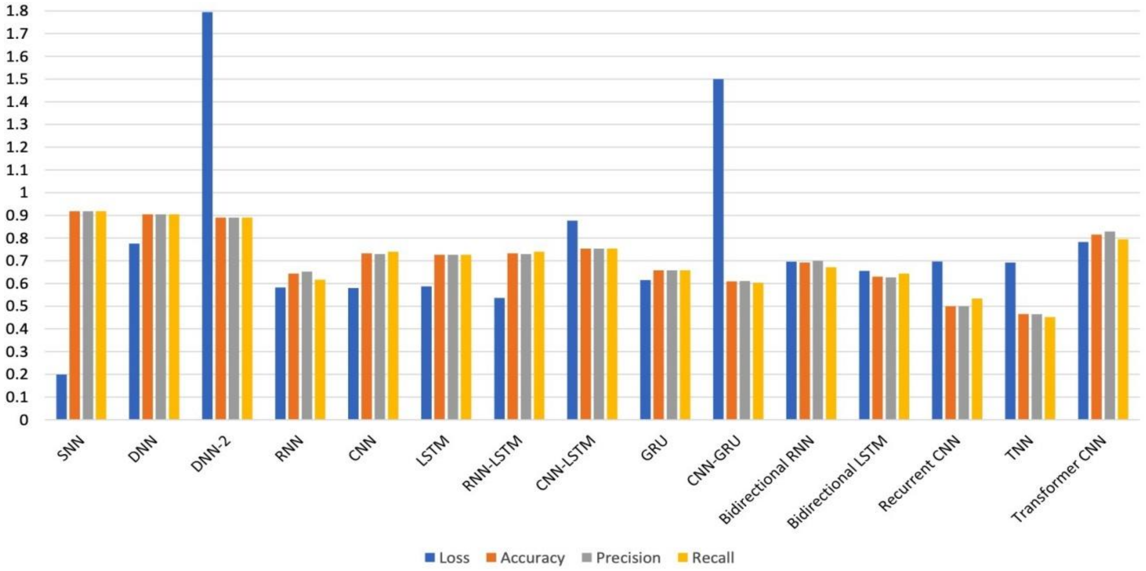

Fig. 6. Performance analysis of deep learning model.

VII. CONCLUSION AND FUTURE WORK

In conclusion, for the machine learning models the overall performance analysis suggests that models leveraging D2V for feature representation, particularly SVM and Logistic Regression, exhibit superior performance across multiple evaluation metrics. Their success underscores the value of dense vector representations for capturing the semantic essence of text data, enhancing model understanding and predictive capabilities. This highlights the significance of choosing the right feature representation and model combination tailored to the specific characteristics and challenges of the task at hand. Moreover, the comparative analysis underscores the importance of evaluating models across a range of metrics to fully understand their strengths, weaknesses, and applicability to various real-world scenarios.

For the result of the deep learning models there is variability in performance across different deep learning architectures for judgment prediction, several insights can be gleaned from the results. Models such as SNN, DNN, RNN-LSTM, and Bidirectional RNN/LSTM demonstrate robust performance and may be preferred choices for judgment prediction tasks. However, the selection of the appropriate model should consider factors such as the complexity of the data, the presence of long-term dependencies, and computational resource constraints. Additionally, further experimentation and optimization may be necessary to improve the performance of hybrid models such as CNN-LSTM and CNN-GRU, which exhibit slightly lower accuracy compared to standalone architectures.

The combined leverage of global dependencies captured by the TNN layers and local features recovered by the CNN layers is an advantage of the hybrid paradigm. This combination enables the model to better interpret and identify the data, resulting in improved overall performance. The early underperformance of the TNN model and the moderate performance of the CNN model demonstrate the limits of depending on a single architectural type. In contrast, the hybrid model's success indicates the possibility for merging both designs to solve their individual deficiencies while capitalizing on their strengths.

Conducting experiments using ML and DL models conveys that technological innovation on automation of legal process can be done to ensure the reduction of human bias in judgment prediction. Research in this area often leads to the creation of benchmarks and datasets, fostering competitive innovation and collaboration within the research community. Thus this experimental analysis aims to transform the legal landscape, making it more efficient, fair, and accessible.

To summarize, the hybrid CNN-TNN model beats its base model competitors across all measures while also demonstrating the ability to combine multiple neural network architectures to produce higher performance in challenging tasks. This method might be useful in a variety of applications outside the present dataset, particularly in situations where both deep feature extraction and global contextual comprehension are required.

***Abstract*—Google Play Store is a digital platform for mobile applications, where users can download and install apps for their android devices. It is a great source of data for mining and analyzing app performance and user behavior. The increasing volume of mobile applications poses a challenge for users in finding apps that align with their preferences. This work aims to utilize predictive user context to analyze user behavior, thereby enhancing user experience and app development. The work focuses on identifying trends in the app market to recommend suitable applications for users. Play Store app analysis involves gathering data, performing comprehensive evaluations, and making informed decisions to improve app performance and user engagement. By applying Naïve Bayes, Random Forest, and Logistic Regression algorithms, this work evaluates the relationship between application attributes such as categories and the number of downloads, determining the most effective profiling algorithm for app performance evaluation. This analysis is crucial for recognizing user engagement trends, discovering new opportunities, and optimizing existing applications.**

Keywords—Naïve Bayes; random forest; logistic regression; mining; Google play store; android; mobile application

I. Introduction

The growth of smartphones and tablets has contributed to the development of various mobile applications called apps. An application is a standalone piece of software with specific goals, rules, and functions. Apps are provided as proprietary software repositories (often called App stores), with the largest vendors being Google Play Store, iPhone App store and Blackberry App World. App stores typically hold three types of data: app developer data, app user feedback (ratings, reviews, and tags), and statistical and organizational data (app categories and download counts).

The availability of these rich data in a software repository provides a unique opportunity to analyze and understand the relationships between data. Interoperability data analysis provides business development applications with insight into the added value of features that can be considered when developing new products.

Due to its increasing popularity and rapid growth in recent times, Google Play is the largest publisher of Android apps. One of the reasons for this popularity is that 96.96% of the products on Google Play Store are free [1]. Google Play Store, which is pre-installed on certified Android devices, serves as the official app store of Google. By granting access to a wide range of content, such as apps, books, magazines, music, movies, and TV shows, Google Play Store offers a diverse selection to users [2]. It enables users to browse, download, and install apps created using the Android Software Development Kit (SDK) and distributed by Google.

The number of mobile apps has grown exponentially due to the growth of smartphones and the app industry. Users can install many applications that provide useful services for many aspects of daily life such as chat, music, video, web browsing and more. The number of applications installed on a mobile phone range from 10 to 90, and on an average, 50 applications are installed.

Although users can install many applications on their smartphones to make the device to work, searching and choosing the right applications can be difficult. Users have the difficulty in finding the right app and have less exposure to most of the apps. The Google Play store offers a wide selection of data on features and descriptions related to application functionality.

Unfortunately, many of these apps remain unused, resulting in fewer installations and loss of business. Additionally, users often spend a lot of time searching through apps, making it difficult to find the right one. To resolve this issue, Data Mining technique can be used to pre-process the real time Google play store dataset in order to predict the user's mobile application usage behavior. We use Logistic Regression, Naive Bayes and Random Forest to measure the relationship between pairs across all clusters by applying and analyzing the performance of each algorithm.

Examples of such examined pairs include price and rating, price and number of downloads, and rating and number of downloads. This approach of analysis can be used to reveal intrinsic properties of software repositories. When applied to Google Play, it can provide a general picture of the current market situation. This helps the developers to understand customer demand and preferences by using the best analyzer algorithm. Image analysis can be performed by leveraging different features extracted through machine learning algorithms [2] [3] [4] or by utilizing a deep learning framework [5]. In our proposed work, machine learning algorithms are employed to perform the intended task.

II. Related Work

In the data preprocessing phase, data cleaning and imputation processes were performed by Sivakani et al [6]. Mean imputation was utilized to handle missing values. Subsequently, classification and clustering tasks were conducted on the coronavirus dataset, and their validity was assessed through a 10-fold validation process. The classifiers employed in this study were Naïve Bayes and Random Forest. Nedeva proposed an integrated marketing information system that aimed to enhance the effectiveness and efficiency of marketing activities by integrating various components of the information system [7]. It presented the research findings related to marketing information systems, including data collection and analysis. An integrative analysis of marketing studies concentrating on mobile apps is presented by Lara Stocchi et al. [8]. The review's objective is to increase knowledge of how applications affect customer experiences and add value all along the customer journey. Google playstore with sample apps is shown in Fig. 1.

Fig. 1. Google play store with sample apps.

Sutriawan et al. conducted a performance comparison of multiple classification algorithms, including Naive Bayes, K-Nearest Neighbor (kNN), Support Vector Machine (SVM) and Decision Tree (DT), to categorize the polarity attitudes in Indonesian film reviews as positive and negative [9].

Israel J. Mojica Ruiz et al. says that how ratings impact a client's choice to buy a product [10]. Recent exploration shows that the ratings relate explosively with download counts, a crucial measure of a mobile app's success. App store reviews don't take streamlined performances into account; the majority of app store ratings overlook updated versions and rely on a static rating system to distinguish apps with varying levels of user satisfaction. When app stores exclusively showcase current ratings, app developers may find limited advantages in releasing enhanced versions of low-rated apps. The presence of numerous negative ratings for a low-quality initial version could pose challenges in achieving an improved store rating of 4 or more stars [11].

Hong Cao et al. [12] provides an overview of the existing studies in the field of mining smartphone data for understanding app usage patterns. It contributes to the understanding of user behavior and opens up possibilities for improving app usage prediction and recommendations. Martin et al. highlights the significance of App store analysis in studying applications downloaded from app stores [13]. It emphasizes that app stores give precious information that wasn't available with former software distribution styles. Keng-Pei Lin et al. proposed a substantiated mobile app recommender system grounded on the textual data of user reviews available on the App store [14]. Topic modeling methods are applied to abstract concealed ideas of user reviews, and the probability distributions of the topics are employed to represent the features of the apps. Also, the user profile is constructed grounded on the user's installed apps to record their preferences. They showed that user reviews are effective for inferring the features of apps. Real- world data are employed to perform trials, and the experimental results showed that the reviews are effective for substantiated app recommendations.

Shahab et al. suggested conducting a case study centered on analyzing the Google Play Store. This analysis aims to offer a detailed understanding of the fundamental characteristics of these app repositories [15]. Finkelstein et al. formulates App store analysis as a method of mining software repository [16]. The experimenters used data mining ways to extract features from 32,108 priced apps in the App store of Blackberry. They also considered price and popularity information to dissect specialized, business, and client acquainted aspects of the app store.

William Martin et al. performed app store Analysis studies about the applications that are downloaded from App store [17]. It revolved around gathering non-technical information from App stores and integrating it with technical data to unveil trends and behaviors within these software repositories. The insights derived from this analysis significantly influence software development teams, leading to advancements in requirements engineering, release planning, software design, security, and testing techniques. Embracing App store analysis opens up a thrilling avenue for software engineering research, fostering a profound understanding of the interconnections between social, technical, and business aspects in software development and deployment.

Ahlam et al. proposed a model that addresses the challenge of personalized application recommendations by combining content-based filtering and App profiles [18]. It leverages important features and usage data to suggest relevant apps to users based on their preferences and search queries. Mahmood concentrated on examining Google Play store, the largest Android App store, to gain awareness into the basic assets of app sources [19]. The idea is to give a comprehensive understanding of the current state of the app request and help inventors in understanding client solicitations, stations, and request trends.

Helan et al. used SVD to diminish the corpus dimension and prepare the data for mining [20]. The significance of feature selection in the fields of Data Mining and Human Machine Interaction is suggested by Iryna et al. [21]. It suggests a new approach that combines feature selection and feature extraction methods to evaluate the information quantity. This approach aims to reduce the number of features while maintaining their linguistic interpretation. The increasing number of mobile applications poses a challenge for users in finding apps that align with their preferences. So, we propose a system to address this challenge.

III. Proposed System

Online user reviews can provide insight into the features that users find most useful or least useful, as well as any bugs or issues that users have encountered. User reviews can also provide feedback on the overall user experience, such as how easy it is to use the app or how intuitive the interface is. This feedback can be invaluable for developers, as it can help them identify areas for improvement and make changes to the app that will better meet user needs. Fig. 2 illustrates the proposed system architecture. The system consists of two main components: a feature extraction module and a user preference mining module.

The feature extraction module extracts the features of an app from user reviews and represents them as a topic distribution. The topic distributions of installed apps are used by the user preference mining module to profile user preferences. A data pre-processing module is also part of the system, and it cleans and normalizes user reviews.

A. *Data Acquisition and Preprocessing*

Raw data gathered from the Google Play Store is quite prone to noise, have missing values and consistency issues. Results of data mining depends on the quality of input data. So, raw data is pre-processed in order to enhance the quality of the data and the mining results. Data pre-processing, one of the most important processes in data mining, deals with the initial dataset preparation and modification. Data cleaning, data integration, data transformation and data reduction are all the phases in the pre-processing of data.

Fig. 3 shows Google play Store Dataset. The Google Play Store dataset is a collection of data about the applications available on the Google Play Store. It contains details like the name of the application, its category, rating, the number of downloads, its size, and its cost. It also includes reviews from users, which can be used to gain insights into the quality of the applications. The dataset can be used to analyze the trends in the mobile application market, as well as to identify popular applications and their features. After completing the processes of data cleaning, integration, transformation, and reduction in Google play store data set, the resulting data becomes ready for utilization in the subsequent steps.

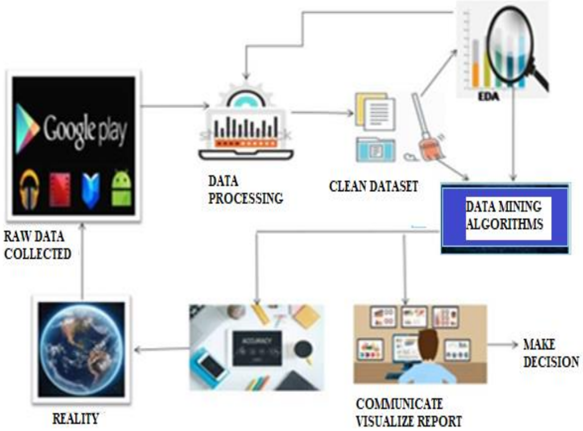

Fig. 2. Proposed system architecture.

B. Algorithm Modeling

A model is created from data using data mining algorithms which analyses the data to identify patterns and relationships between variables. The model is then used to predict future data forecasts or judgments. Depending on the type of data and the desired result, data mining methods can be either supervised or unsupervised.

After splitting the final dataset into a training and test set, the feature variable is scaled.

1) Naive bayes: After the pre-processing step, it's time to train the Naive Bayes model using the Training set. A classification method based on the Bayes theorem called Naive Bayes makes the assumption that predictors are independent [22]. The Naive Bayes classifier assumes that the presence of one feature in a class is independent of the presence of any other features. The conditional probability can be obtained using Bayes theorem as illustrated in (1). Finally, the test set is used to predict the performance of the model that is built. It is used to anticipate the Apps that will be most popular.

$$P(A\backslash B) = \frac{P(B\backslash A)\,P(A)}{P(B)} \qquad (1)$$

2) Random forest: Random Forest is based on the concept of decision trees. The created ensemble of DT is typically trained using the "bagging" method [23]. Random Forest constructs numerous DT and merges them to get a prediction that is more precise and consistent. With the help of the ensemble of created DT, predictions of the most popular Apps are done.

3) Logistic regression: Logistic Regression operates on the principle of mapping input features to the probability of a binary outcome. The algorithm applies a logistic function to linearly combine feature weights and inputs, constraining the output within [0, 1]. By optimizing the model's coefficients through maximum likelihood estimation, logistic regression effectively learns to classify instances into one of the two classes.

Multi-class logistic regression extends the binary version to handle classification tasks with more than two classes. The algorithm employs the softmax function to calculate the probability of each class for a given instance, ensuring the sum of probabilities equals 1. By iteratively optimizing the model's parameters through gradient descent, multi-class logistic regression effectively learns to distinguish and classify instances across multiple classes.

C. User Reviews Dataset

Fig. 4 shows the Google Play Store user reviews dataset. User reviews for various Apps available on the Google Play Store are included in the dataset. It contains the name of the application, the user's rating, the posting date, and the review's content. To analyze user reviews of Apps on the Google Play Store, this dataset is used. Additionally, it can be utilized to spot patterns in user reviews and locate well-liked applications.

Using Google Play Store reviews dataset, the basic Natural Language Processing (NLP) steps have been applied to pre-process the data. Punctuation, special characters, stop words, are all removed from the data during pre-processing and lemmatization is also done in order to bring together a word's inflected forms for analysis as a single item [24].

And finally, a bag of words is created and used as the model. Data are separated into test and train data. These are used as input for various algorithms to find the accuracy.

IV. Experimental Results

Using the APP review list data set given in Section III, the performance of the suggested technique is assessed here.

A. Basic Exploratory Data Analysis (EDA)

Exploratory data analysis is used to identify trends, patterns and relationships among data. It is used to summarize the data and to gain insights about the data. It is used to explore the data and gain a better understanding of the data. The fundamental goal of exploratory data analysis is to find any patterns or connections between the elements that stand out.

The association between the downloaded App% and the various review characteristics-based App types is shown in Fig. 5. The most popular apps on the market are those for communication. The majority of Apps perform well overall, with an average rating of 4.17. There are a few useless apps as well. The most expensive Apps are those for health and family.

There is a 0.63 moderately favourable association between the number of reviews and downloads. As a result, customers are more likely to download a certain App if more people have rated it. This implies that many people who download an app and are engaged with it typically also write a review or other form of feedback.

To analyze which category of apps has the highest percentage of installs, this work looks at the data from the Google Play Store. Fig. 6 provides a summary of the highest percentage of installed apps in the Google Play Store organized by category.

The category of Games App has the highest rank compared to other categories. This data provides us with the number of installs for each category of Apps, allowing us to compare and determine which category has the highest percentage of installs. This will give us an indication of which type of Apps are most likely chosen by users [25].

B. App Analysis

The analysis determined the average rating change for reviews that received responses, as well as the likelihood and size of the change. After categorizing the reviews, we looked at which subjects were most likely to result in a change for the better usage [26]. The aim for broad, all-encompassing issues that would interest most developers led to this choice of topics. The categories of apps with the highest number of installations by examining the top-ranked apps is analyzed. This is clearly visualized in the following Fig. 7. This clearly indicated that the top most installed Apps are mostly browser related Apps.

Most feedback was provided after releases that positive feedback was often associated with highly downloaded apps, and that negative feedback was often associated with less downloaded Apps and often did not contain user experience or contextual information. Sentiments towards App features show the differences between user sentiments in Google Play Store. Opinions on product quality formed a large portion of reviews, but opinions on service quality had a bigger effect on sales [14].

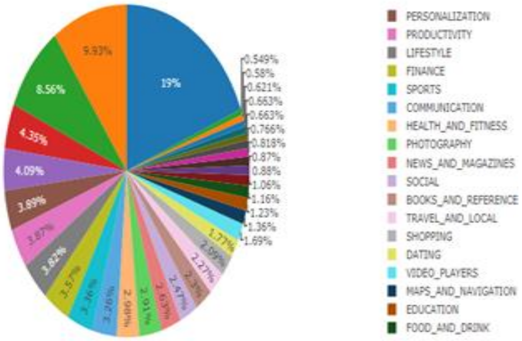

Fig. 5. Downloaded app percentage vs. various types of app in Google play store.

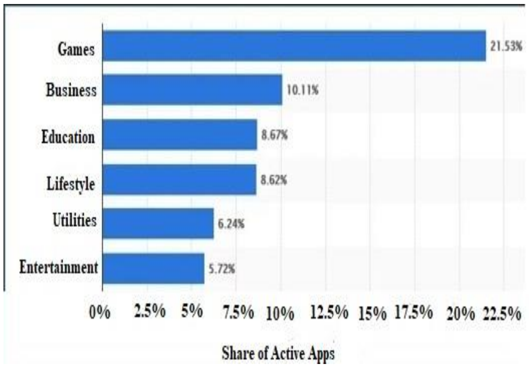

Fig. 6. Number of apps installed based on category.

C. Sentiment Analysis

As mentioned in Section III, the user reviews are pre-processed by performing the lemmatisation and removal of stopwords. The sentiment is derived from reviews using "positive" sentiment words like "good, great, love" or "negative" sentiment words like "bad, hate, terrible". Sentiment represents a user's views or opinions, often as positive or negative in this content. The most common complaints from users are about privacy invasion and unethical behaviour, with hidden costs coming in at number two [27].

	App
347	imo free video calls and chat
378	UC Browser - Fast Download Private & Secure
395	GO SMS Pro - Messenger, Free Themes, Emoji
366	UC Browser Mini -Tiny Fast Private & Secure
346	imo beta free calls and text

D. Best Analyzer Algorithm

Based on trained data, test data produce accuracy depending on the algorithm characteristic. Naïve Bayes, Random Forest and Logistic Regression algorithms are used for sentiment analysis.

In Fig. 8, the confusion matrix displays the predictions made by logistic regression model. The y-coordinate represents the true labels or ground truth values, y_true and x coordinates are predicted values, y_pred. According to score table, Logistic Regression gives us best accuracy of 90%.

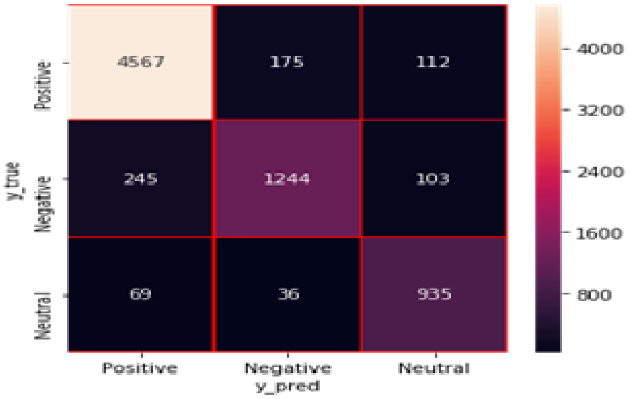

Fig. 8. Logistic regression.

V. Discussion

The analysis of Google Play Store data provided valuable insights into user behavior and App performance. The findings highlighted a moderate correlation between the number of reviews and downloads, suggesting that user reviews significantly influence App popularity. This correlation underscores the importance of positive user feedback in driving downloads and improving App visibility.

The work identified communication Apps as the most popular category, reflecting the high demand for applications that facilitate social interactions and connectivity. Additionally, browser-related Apps emerged as the top most installed category, indicating users' preference for efficient and accessible internet browsing solutions on mobile devices.

Machine learning algorithms such as Naïve Bayes, Random Forest, and Logistic Regression enabled a robust evaluation of the relationship between app attributes and performance metrics. Among these, Logistic Regression demonstrated the highest accuracy (90%) for user sentiment analysis, making it the most effective profiling algorithm in this context. This high accuracy indicates that Logistic Regression can reliably predict user sentiment based on App attributes, providing developers with actionable insights for app optimization.

VI. Conclusion

The research successfully utilized predictive user context to enhance user experience and App development on the Google Play Store. By analyzing user behavior and App performance through comprehensive data evaluations, the work provided critical insights for improving user engagement and app optimization. The identification of trends and patterns in App usage can guide developers in creating more user-centric applications, thereby increasing user satisfaction and App success.

The moderate association between reviews and downloads emphasizes the role of user feedback in App performance, while the dominance of communication and browser-related Apps highlights prevailing user preferences. The superior performance of Logistic Regression in sentiment analysis demonstrates its effectiveness as a profiling tool, offering a reliable method for predicting user sentiment and guiding App development decisions.

Overall, the integration of machine learning algorithms in App analysis provides a powerful framework for understanding and enhancing user engagement, ultimately leading to more successful and user-friendly applications. Analyzing and mining the data from Play Store Apps has a great deal of potential to help app development companies succeed. Developers can get useful knowledge to work on and conquer the Android market.

VII. Future Work

In order to annotate Google Play Store design elements with richer labels, new models could be developed, such as classifiers that explain the semantic function of elements and screens. To train newer varieties of perception-based predictive models, researchers may similarly crowdsource more perceptual annotations (for example, first impressions) over design elements like screenshots and animations. Additionally, a recommendation system that uses the discovered correlation features can be created to suggest applications.

If new apps are not continuously crawled and their database entries are not updated, static research datasets will eventually become out-of-date. Therefore, finding ways to make app mining more sustainable is a crucial area for future research. Making a platform where developers can utilize programs and add their traces to the repository for the benefit of the entire community is one possible route to sustainability.

***Abstract*—This research investigates the application of open-source transformers, specifically the ConvNeXt V2 and Segformer models, for brain tumor classification and segmentation in medical imaging. The ConvNeXt V2 model is adapted for classification tasks, while the Segformer model is tailored for segmentation tasks, both undergoing a fine-tuning process involving model initialization, label encoding, hyperparameter adjustment, and training. The ConvNeXt V2 model demonstrates exceptional performance in accurately classifying various types of brain tumors, achieving a remarkable accuracy of 99.60%. In comparison to other state-of-the-art models such as ConvNeXt V1, Swin, and ViT, ConvNeXt V2 consistently outperforms them, attaining superior accuracy rates across all metrics for each tumor type. Surprisingly, when there is no tumor present, it has predicted with 100% accuracy. In contrast, the Segformer model has excelled in accurately segmenting brain tumors, achieving a Dice score of up to 90% and a Hausdorff distance of 0.87mm. These results underscore the transformative potential of open-source transformers, exemplified by ConvNeXt V2 and Segformer models, in revolutionizing medical imaging practices. This study paves the way for further exploration of transformer applications in medical imaging and optimization of these models for enhanced performance, heralding a promising future for advanced diagnostic tools.**

***Keywords*—Open-source transformers; ConvNeXt V2; segformer; brain tumor classification; medical image segmentation; diagnostic accuracy; neuro-oncology**

I. Introduction

A brain tumor is recognized as one of the prevalent neurological disorders, characterized by an unregulated and abnormal proliferation of brain cells [1]. It stands as one of the deadliest forms of cancer, posing a significant threat to life [2]. Brain tumors are stratified into four grades (Grade I to Grade IV), with each grade signifying escalating malignancy levels and a progressively ominous prognosis. Grade I tumors, such as pilocytic astrocytoma, characterized by slow growth and a limited tendency to spread, offer the potential for complete removal. Moving to Grade II, these tumors, despite the possibility of migration, can persistently grow and enlarge, even after prior treatment. Advancing to Grade III, tumors exhibit swifter growth and the capability to spread to adjacent tissues, necessitating post-surgical interventions like radiotherapy or chemotherapy. An instance of Grade III malignancy is aden squamous astrocytoma. Finally, Grade IV tumors represent the most lethal category, capable of malignant spreading. Glioblastoma multiforme, an aggressive tumor, serves as an illustrative example of Grade IV characteristics, utilizing blood vessels to accelerate growth [3], [4].

Brain tumors are identified by examining various diagnostic imaging techniques, including X-rays, MRIs, and ultrasound, among others. MRI excels over X-ray and ultrasound with its detailed soft tissue imaging, multi-planar capabilities, and radiation-free nature. In brain assessments, MRI's precision in tumor detection surpasses the limitations of X-ray and ultrasound, making it the preferred choice for accurate diagnostics. However, identifying brain tumors in MR images poses a unique challenge due to the presence of a highly uneven signal associated with the tumor, which can be correlated with the signal strength of normal tissue [5], [6]. The classification of pixels within the tumor region becomes ambiguous, potentially causing inaccurate segmentation. This issue arises when certain tumor components cannot be distinguished from white matter (WM) or gray matter (GM) due to the limited intensity resolution of MR images and the intricate anatomy of the human brain. The complexity intensifies at the tumor's boundary with surrounding normal tissue, influenced by partial volumes (PV) [7]. Consequently, PV contributes to significant blurring in MR images, causing the intensity values of each voxel to mix with those of its neighboring voxels [8].

Machine learning methods address segmentation challenges by employing manually crafted features (or predefined features) [9]. Initially, in the segmentation process, essential information is extracted from the input image using a feature extraction algorithm, followed by training a discriminative model to differentiate between tumors and normal tissues. In the context of tumor segmentation and classification studies, various machine learning techniques, including support vector machines (SVMs), multi-class Support Vector Machine (mSVM), k-nearest neighbor (KNN), Artificial Neural Networks (ANNs), and decision trees, are commonly applied. During the training phase of a classification system, mean features are manually extracted, emphasizing the crucial role of identifying essential features for accuracy [13], [10]. It's noteworthy that constructing classifiers with machine learning demands substantial processing power and memory resources, making it time-consuming, and potentially leading to reduced accuracy, especially with intricate or extensive datasets [13], [11].

Medical images are predominantly examined and processed using deep learning algorithms to identify, classify, and categorize brain tumors into subgroups. These advanced technologies serve as valuable tools for healthcare professionals, assisting them in the diagnostic phase [11]. Deep learning (DL) constitutes a subset of machine learning focused on acquiring multiple tiers of representations through the establishment of a feature hierarchy. This hierarchy is structured such that higher levels derive their definition from lower levels, with the same lower-level features contributing to the definition of multiple higher-level features [13]. The DL framework expands upon traditional neural networks (NN) by incorporating additional hidden layers within the network architecture, positioned between the input and output layers. This augmentation aims to model more intricate and nonlinear relationships. Recently, researchers have shown considerable interest in this concept due to its commendable performance, establishing it as a preeminent solution across various challenges in medical image analysis applications like image denoising, segmentation, registration, and classification [14]. Deep learning algorithms, including trained convolutional neural networks (CNNs), VGGNets, GoogleNet, and ResNets, are employed for cancer diagnosis assistance. Moreover, the study explored the application of various CNN designs, including VGGNets, GoogleNets, and ResNets, for brain tumor classification [15], [16], [17]. The results indicated that ResNet-50 exhibited superior performance compared to GoogleNet and VGGNets, achieving an accuracy rate of 96.50% in contrast to 93.45% and 89.33%, respectively. Additionally, ResNet-50 demonstrated a 10% higher accuracy than both VGGNet and GoogleNet, while also processing data in 10% less time [18].

The irony of the situation lies in the understanding that even a one percent inaccuracy could potentially lead to the loss of numerous lives. Hence, scholars have dedicated their time and effort to safeguard human lives from the repercussions of unforeseen brain diseases by striving for nearly 100% accuracy in early detection. In pursuit of this crucial goal, they have tirelessly worked to introduce the transformer, a neural network architecture, aiming to enhance the precision and effectiveness of early-stage detection. Transformers have become the prevailing network architecture, bringing about a revolution in language modeling [19], [20]. Operating on an attention mechanism, they clarify the characteristics of the input sequence by entirely bypassing recurrence and convolutions. This unique approach allows the modeling of input dependencies without distance limitations, enabling the assessment of intricate long-range correlations. Notably, transformers exhibit versatility across different types of sequential data, with their applications expanding to fields like computer vision [21]. Recently, transformer-based models, such as Google's Vision Transformer (ViT) and Microsoft's Swin Transformer, have emerged as a powerful alternative to CNNs in various domains, including computer vision [22]. Transformers, originally designed for natural language processing tasks, have shown remarkable adaptability and performance in different modalities and tasks, such as image classification, segmentation, detection, and generation¹. Transformers are composed of multiple layers of self-attention and feed-forward networks, which can capture long-range dependencies and global context from the input [22]. Transformers can process images by either dividing them into patches and treating them as sequences or by applying convolutional layers to extract features before applying self-attention. Transformers have shown superior performance to CNNs in various tasks, such as image classification, object detection, and semantic segmentation [22]. However, even transformers have their own set of limitations, such as the need for large amounts of data and computational resources, which can be prohibitive in the medical imaging domain [22]. Moreover, transformers might not be able to exploit the spatial structure and locality of images, which can be important for some tasks.

In light of the above, this paper introduces a novel approach that pushes the boundaries of medical imaging. By fine-tuning the Vision Transformer, Swin Transformer, ConvNeXt, and ConvNeXt V2 for brain tumor classification, and Segformer for brain tumor segmentation, we have achieved unprecedented results. Our research has demonstrated that the ConvNeXt V2 model, in particular, has set a new benchmark in medical imaging for classification tasks. With its superior performance, it has proven to be a game-changer in the field of brain tumor detection. ConvNeXt V2, enhances learning of deformable convolutions for superior performance in self-supervised learning and various downstream tasks. It excels in handling diverse image sizes and incorporates advanced training techniques, making it highly effective for medical imaging applications by outperforming state-of-the-art models. On the other hand, the Segformer model has shown state-of-the-art performance in segmentation tasks, achieving a Dice score of over 90 percent. This is a significant leap forward in the precision of brain tumor segmentation. These advancements not only enhance the accuracy and efficiency of brain tumor detection but also contribute to early diagnosis and treatment planning. This, in turn, can lead to improved patient outcomes and alleviate the workload of radiologists, addressing a significant challenge in the healthcare sector.

In conclusion, our research underscores the transformative potential of these models in medical imaging. It provides a benchmark for future research and opens up new avenues for leveraging advanced machine learning techniques in medical imaging. The benefits of this research extend beyond improved patient outcomes in neuro-oncology, offering valuable insights for researchers and practitioners in the field. Future research directions include exploring the application of transformers in other areas of medical imaging and further optimizing the proposed models for better performance. This paper is a testament to the transformative potential of open-source transformers in medical imaging, setting a new standard in the field.

In this study, we delve into the transformative potential of open-source transformers in medical imaging. We provide a comprehensive background on the ConvNeXt V2 and Segformer models, followed by an in-depth explanation of our methodology. We then present our evaluation metrics and the results derived from them. The discussion section explores the implications of our findings, particularly how these models can enhance neuro-oncology diagnostics. We conclude with a summary of our key findings and potential future research directions.

II. Open-Source Transformers in Medical Imaging

Open-source software has indeed been a game-changer in the field of artificial intelligence, providing researchers and developers with accessible, customizable, and cost-effective tools for innovation. Open-source transformers, in particular, have been instrumental in advancing the field of medical imaging [23].

Before we delve into the specific open-source transformers used in medical imaging, it is essential to understand the architecture and capability of the original transformer model from the pioneering work “Attention Is All You Need”, which introduced the first open-source transformer [24].

A. The Original Transformer

The Transformer model architecture presented in Fig. 1 by Vaswani in “Atention all you need” is a powerful neural network design that revolutionized natural language processing and other sequence-to-sequence tasks as follows [25]:

1) Input processing: The input sequence is first embedded into continuous vector representations. To retain positional information, a positional encoding is added to the embeddings.

2) Multi-Head attention: The model employs multi-head attention mechanisms to focus on different parts of the input sequence simultaneously. This allows the Transformer to capture complex patterns and dependencies. Unlike recurrent neural networks (RNNs), where computations depend on the previous step, multi-head attention operates independently across positions.

3) Feed-forward neural networks: Each position (word or token) in the input sequence passes through the same feed-forward network. This parallel processing is a departure from RNNs, which have sequential dependencies.

4) Add and norm: Every sub-layer (such as multi-head attention or feed-forward neural network) includes a residual connection. After the residual connection, layer normalization is applied. These steps help stabilize training in deeper models.

5) Masked multi-head attention: In addition to regular multi-head attention, the Transformer introduces masked multi-head attention. During training, this mechanism prevents attending to future tokens in a sequence. It’s crucial for autoregressive tasks like language modeling.

6) Output probabilities: The processed outputs from the layers are linearly transformed.A softmax operation generates output probabilities for predictions or downstream tasks.

In summary, the Transformer architecture combines multi-head attention, feed-forward networks, and layer normalization to handle sequential data efficiently. Its parallel processing and attention mechanisms make it highly effective for various natural language understanding tasks.

The introduction of the original transformer model marked a significant milestone in the realm of machine learning and artificial intelligence, ushering in a revolutionary architecture. Central to this innovation is the attention mechanism, a key mathematical concept expressed through equations that distribute attention scores across various segments of an input sequence.

The attention score is calculated using the equation [24]:

$$\text{Attention}(Q, K, V)\text{=softmax}\left(\frac{QK^T}{\sqrt{d_k}}\right)V \tag{1}$$

Where: - Q represents the query matrix, - K denotes the key matrix, - V stands for the value matrix, - and d_k is the dimensionality of queries and keys.

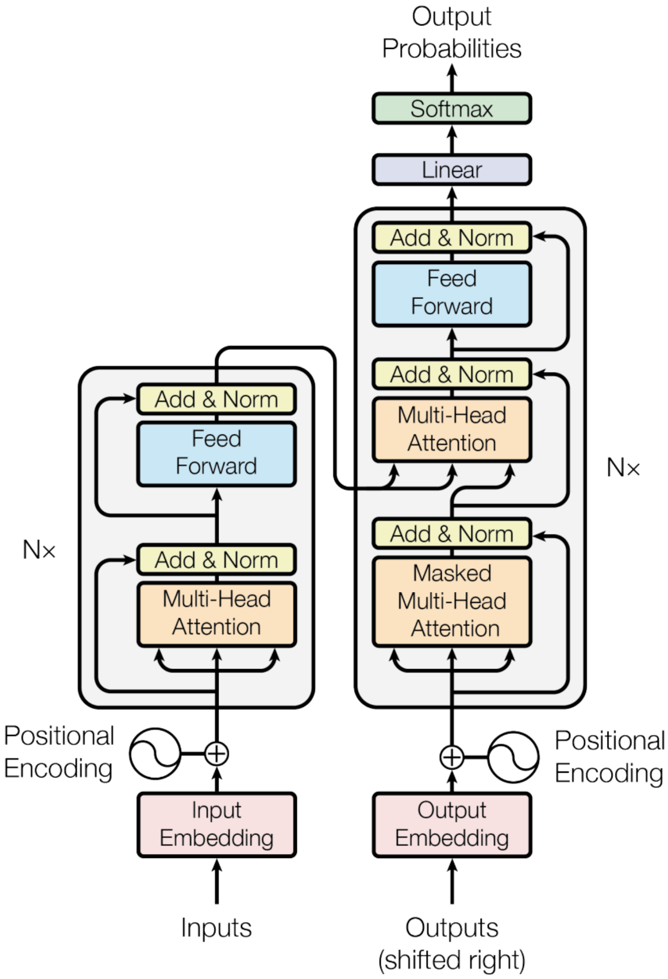

Fig. 1. The transformer-model architecture [24].

This equation underscores how each element in the input sequence contributes to every position in the output sequence by computing a weighted sum of values, with weights assigned according to compatibility function computed using queries and keys [25], [26].

In multi-head attention, this process is replicated across multiple sets of learned linear projections of queries, keys, and values. This can be represented mathematically as:

$$\text{MultiHead}(Q, K, V)\text{=Concat}(\text{head}_1, ..., \text{head}_h)W^O \tag{2}$$

Where each head is computed as:

$$\text{head}_i\text{=Attention}(QW_i^Q, KW_i^K, VW_i^V) \tag{3}$$

Here: - W_i^Q, W_i^K, and W_i^V are parameter matrices, - h denotes number of heads, - Concat refers to concatenation operation, - And W^O represents output linear transformation weights.

These equations collectively facilitate a nuanced understanding of dependencies among elements or tokens within sequences, enabling transformers to capture complex patterns and relationships in data with remarkable efficiency.

The success of the transformer model has inspired a diverse array of models extending beyond natural language processing (NLP). These models encompass tasks such as predicting protein folded structures, and forecasting time series data. The model's ability to discern the significance of each input component grants it tremendous power, allowing it to prioritize essential information and disregard irrelevant details, thereby enhancing the accuracy and relevance of its outputs. In the domain of machine learning research, the Transformer model diagram stands as an invaluable tool, providing a comprehensive visual depiction of its architectural complexities and data flow dynamics.

B. The Power of Transformers in Vision

Transformers have shown significant advancements in the field of vision, particularly with the introduction of the Vision Transformer (ViT). The ViT model, which is the first transformer model introduced for vision tasks after their successful application in natural language processing (NLP), represents an input image as a series of image patches, similar to the series of word embeddings used when applying transformers to text. This model has been specifically designed for image-related tasks, making it a powerful tool in the field of medical imaging.

1) Vision Transformer (ViT): The Vision Transformer (ViT) is a model for image classification that employs a Transformer-like architecture over patches of the image as shown in Fig. 2. An image is split into fixed-size patches, each of them is then linearly embedded, position embeddings are added, and the resulting sequence of vectors is fed to a standard Transformer encoder[1]. In order to perform classification, the standard approach of adding an extra learnable "classification token" to the sequence is used [27].

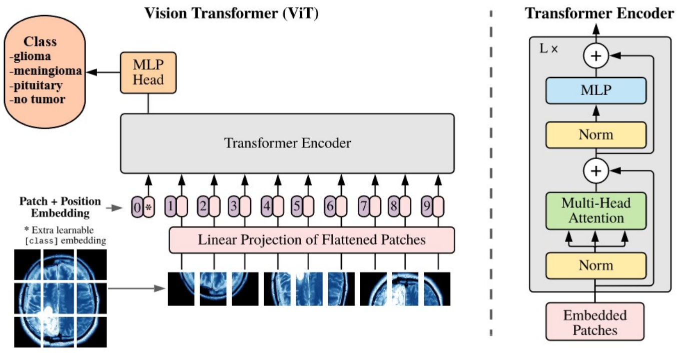

Fig. 2. Vision transformer for brain tumor classification [27].

The ViT model has been shown to outperform the current state-of-the-art convolutional neural networks (CNNs) by almost x4 in terms of computational efficiency and accuracy [27]. This is a significant achievement as CNNs have been the de-facto standard for image recognition tasks for many years.

The success of the ViT model can be attributed to the self-attention mechanism of the Transformer architecture, which allows the model to focus on different parts of the input sequence simultaneously, capturing complex patterns and dependencies. This ability to understand the importance of each part of the input data differently makes the ViT model extremely powerful. It allows the model to focus on what's important and ignore what's not, leading to more accurate and meaningful outputs [27].

The ViT model has been successfully applied to several computer vision problems, achieving state-of-the-art results.This has prompted researchers to reconsider the supremacy of convolutional neural networks (CNNs) as de facto operators.

2) Swin transformer: The **Swin Transformer** is a novel vision Transformer that serves as a general-purpose backbone for a variety of computer vision tasks [28]. The name "Swin" stands for **Shifted Windows**, which is a key feature of this architecture.

Unlike the original Vision Transformer (ViT) that produces feature maps of a single low resolution and has a quadratic computation complexity due to global self-attention, the Swin Transformer builds hierarchical feature maps by merging image patches in deeper layers and has linear computation complexity with respect to image size. This is achieved by limiting self-attention computation to non-overlapping local windows while also allowing for cross-window connection [28].

The Swin Transformer is built by replacing the standard multi-head self-attention (MSA) module in a Transformer block with a module based on shifted windows, while keeping other layers the same [28]. A Swin Transformer block consists of a shifted window-based MSA module, followed by a 2-layer MLP with GELU nonlinearity in between.

In terms of performance, the Swin Transformer has demonstrated superior results in various vision tasks, including image classification, object detection, and semantic segmentation[1]. For instance, it achieved 87.3 accuracy on ImageNet-1K, 58.7 box AP and 51.1 mask AP on COCO test-dev, and 53.5 mIoU on ADE20K val. These results surpass the previous state-of-the-art by a large margin, demonstrating the potential of Transformer-based models as vision backbones [29].

In summary, the Swin Transformer offers a promising approach to computer vision tasks, providing a balance between computational efficiency and performance. Its hierarchical design and shifted window approach make it a flexible and powerful tool for image analysis.

3) ConvNext transformer: The ConvNext Transformer represents a significant advancement in open-source transformer models tailored for medical imaging, particularly in scenarios involving high-resolution images and necessitating a "sliding window" approach. ConvNets excel in tasks such as object detection, benefiting from translation equivariance and efficiency derived from shared computations within a sliding-window framework [29]. ConvNeXt addresses the need for maintaining ConvNets' inductive learning bias while leveraging Transformer innovations, featuring a specialized block as depicted in Image 3, that integrates convolutional layers to enhance spatial feature extraction from medical images, resulting in improved accuracy and efficiency. Employing an inverted bottleneck design comprising depthwise, expansion, and contraction layers, ConvNeXt utilizes large depthwise kernels to facilitate scalability and long-range representation learning. By harnessing large kernel ConvNeXt networks in conjunction with extensive datasets, researchers have surpassed previous Transformer-based models, enabling width scaling without constraints imposed by kernel size limitations and offering benefits in learning long-range spatial dependencies through large kernels and enabling multi-level network scaling in medical image segmentation [30]. Fig. 3 shows ConvNexT v1 architecture.

In comparative studies, the ConvNext Transformer has shown promising results on ImageNet-1K and ImageNet-22K pre-trained models. Its performance metrics are competitive with those of the Swin Transformer (2021), indicating its capability to serve as an effective backbone for various computer vision tasks in medical imaging.The success of the ConvNext Transformer can be attributed to the self-attention mechanism of the Transformer architecture, which allows the model to focus on different parts of the input sequence simultaneously, capturing complex patterns and dependencies. This ability to understand the importance of each part of the input data differently makes the ConvNext Transformer extremely powerful. It allows the model to focus on what's important and ignore what's not, leading to more accurate and meaningful outputs.

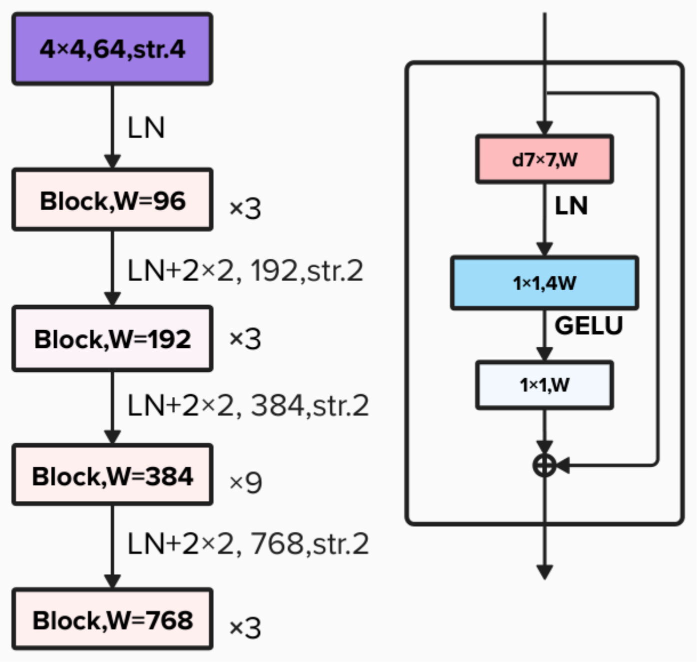

Fig. 3. ConvNexT v1 Architecture [29].

4) *ConvNeXt V2:* Introducing ConvNeXt V2, a novel ConvNet model series, known as Deformable ConvNets v2 (DCNv2), has been developed to enhance its capacity for learning deformable convolutions, as shown in Fig. 4. Despite undergoing minimal architectural modifications, it is precisely tailored for optimal performance in self-supervised learning scenarios. Leveraging fully convolutional masked autoencoder pre-training, significant enhancements in performance are observed across diverse downstream tasks, spanning from ImageNet classification to COCO object detection and ADE20K segmentation [31]. This augmentation in modeling capability encompasses two key aspects. Firstly, there is an expanded integration of deformable convolution layers throughout the network, allowing for greater control over sampling across a wider range of feature levels. Secondly, a modulation mechanism has been introduced within the deformable convolution modules, enabling each sample not only to undergo a learned offset but also to be modulated by a learned feature amplitude, thus providing the network module with the flexibility to adjust both the spatial distribution and the relative influence of its samples [32].

Key Advancements in the ConvNeXt V2 Model:

- Improved ability to handle a wide range of image sizes and formats. This adaptability makes it more versatile and suitable for different medical imaging tasks. This is achieved through adaptive input representations and flexible architecture designs that can accommodate varying input dimensions.
- Incorporation of advanced training techniques and optimization strategies that enhance its learning efficiency and model performance. These include sophisticated learning rate schedules, advanced regularization methods, and efficient batch processing techniques.

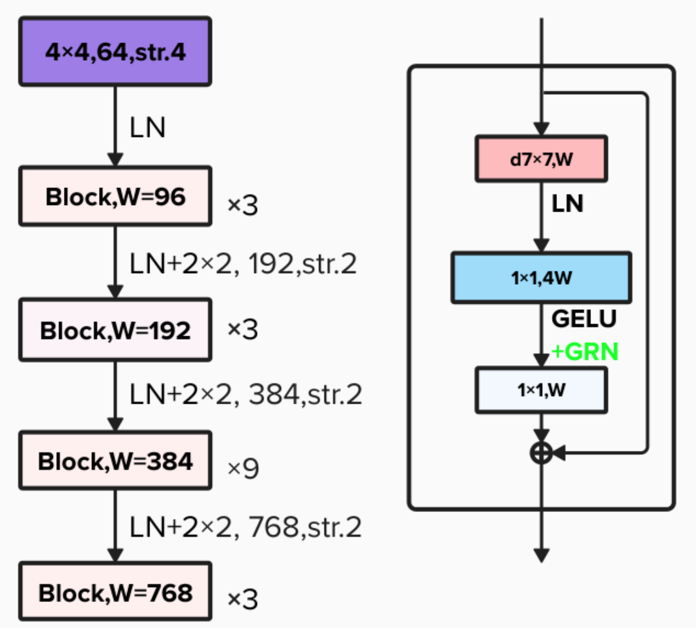

Fig. 4. ConvNexT v2 Architecture [33].

In comparative studies, the ConvNeXt V2 model has shown superior performance metrics on benchmark datasets, outperforming other state-of-the-art models such as the Vision Transformer (ViT) and the Swin Transformer. This indicates its potential as a reliable tool for clinical diagnostics and research, and its capability to serve as an effective backbone for various computer vision tasks in medical imaging.

5) *Segformer: A new frontier in brain tumor segmentation:* The **Segformer** is a groundbreaking open-source transformer model that has been specifically engineered for image segmentation tasks. This model has proven its robustness

and efficacy across a variety of applications, and this paper presents, for the first time, its potential in the realm of brain tumor segmentation in medical imaging.

The architecture of the Segformer which is presented in Sketch 5, is distinctive, utilizing a hierarchical Encoder-Decoder structure [33]. The attached Fig. 5 illustrates the hierarchical architecture of the Segformer, demonstrating how it processes different resolutions of images for effective segmentation. This structure incorporates convolutional layers to augment the extraction of spatial features from medical images at multiple scales and resolutions. This multi-resolution approach is vital for brain tumor segmentation tasks, where the model is required to accurately identify and delineate intricate anatomical structures and pathological regions at diverse levels of detail.

The hierarchical design of the Segformer enables it to process medical images at various scales, capturing both macroscopic and microscopic features. This is particularly advantageous for brain tumor segmentation tasks, as it ensures a comprehensive capture of the tumor's overall structure and its intricate details, leading to more accurate and meaningful outputs [33]. Another strength of the Segformer is the self-attention mechanism of the Transformer architecture, which allows the model to focus on different parts of the input sequence simultaneously. This ability to discern the importance of each part of the input data differently makes the Segformer extremely powerful [33].

III. Methodology

This study seeks to harness the potential of open-source transformers, with a specific focus on employing the ConvNeXt V2 model for tumor classification and the Segformer model for segmentation, to advance the field of medical imaging. The methodology employed in this research is outlined below.

A. Model Selection

We have selected the ConvNeXt V2 model for the task of classification and the Segformer model for segmentation. The decisions are grounded in the established performance of the ConvNeXt V2 and Segformer models in tasks related to images, as well as their proficiency in grasping complex patterns and dependencies within input data. Throughout the selection process, each model covered in the open-source transformers section has undergone fine-tuning. Notably, the ConvNeXt V2 and Segformer models have consistently outperformed their counterparts, demonstrating superior accuracy and efficiency, thus positioning them as the optimal choices for our research objectives.

B. Data Acquisition

The data used in this research was acquired from two main sources:

1) Segmentation dataset: For segmentation, we have utilized the brain tumor dataset provided by Jun Cheng, available on Figshare. This dataset encompasses a comprehensive collection of brain images featuring various types of tumors. Each image in this dataset has been appropriately labeled to facilitate segmentation tasks [34].

2) Classification dataset: We have compiled a dataset comprising 15,000 images for the classification task. This dataset has been created by merging the brain tumor dataset provided by Jun Cheng with additional datasets obtained from the internet [34], [35], [36], [37]. These supplementary datasets have been meticulously chosen to guarantee a varied and representative selection of brain images. Each image in this dataset has been labeled with the corresponding tumor type, facilitating the classification task.

The datasets have been carefully scrutinized and validated to ensure their quality and relevance to this research. The images have been accurately labeled, providing a reliable basis for fine-tuning the ConvNeXt V2 and Segformer models.

C. ConvNeXt V2 Fine-tuning

The ConvNeXt V2 model, depicted in Fig. 6, is fine-tuned for the task of classification. The fine-tuning process involved several steps, each of which contributed to optimizing the model's performance on our specific classification dataset.

1) Model initialization: We began by initializing the ConvNeXt V2 model, which is an open-source transformer model. This model was selected due to its proven performance in image-related tasks and its ability to capture complex patterns and dependencies in the input data. The open-source nature of the ConvNeXt V2 model allows for transparency, reproducibility, and customization, which are key advantages in the field of medical imaging [31].

2) Label encoding: The labels for each image in our dataset were mapped to corresponding IDs. This encoding process transformed the categorical labels into a format that could be processed by the ConvNeXt V2 model.

3) Hyperparameter adjustment: The model's hyperparameters, such as learning rate, batch size, and number of epochs, were adjusted during the fine-tuning process.

4) Training: The training process involved feeding the images from the training set into the ConvNeXt V2 model. The model processed these images through multiple stages, each involving a series of operations that transform the input images, extracting essential features and patterns that the model can learn from.

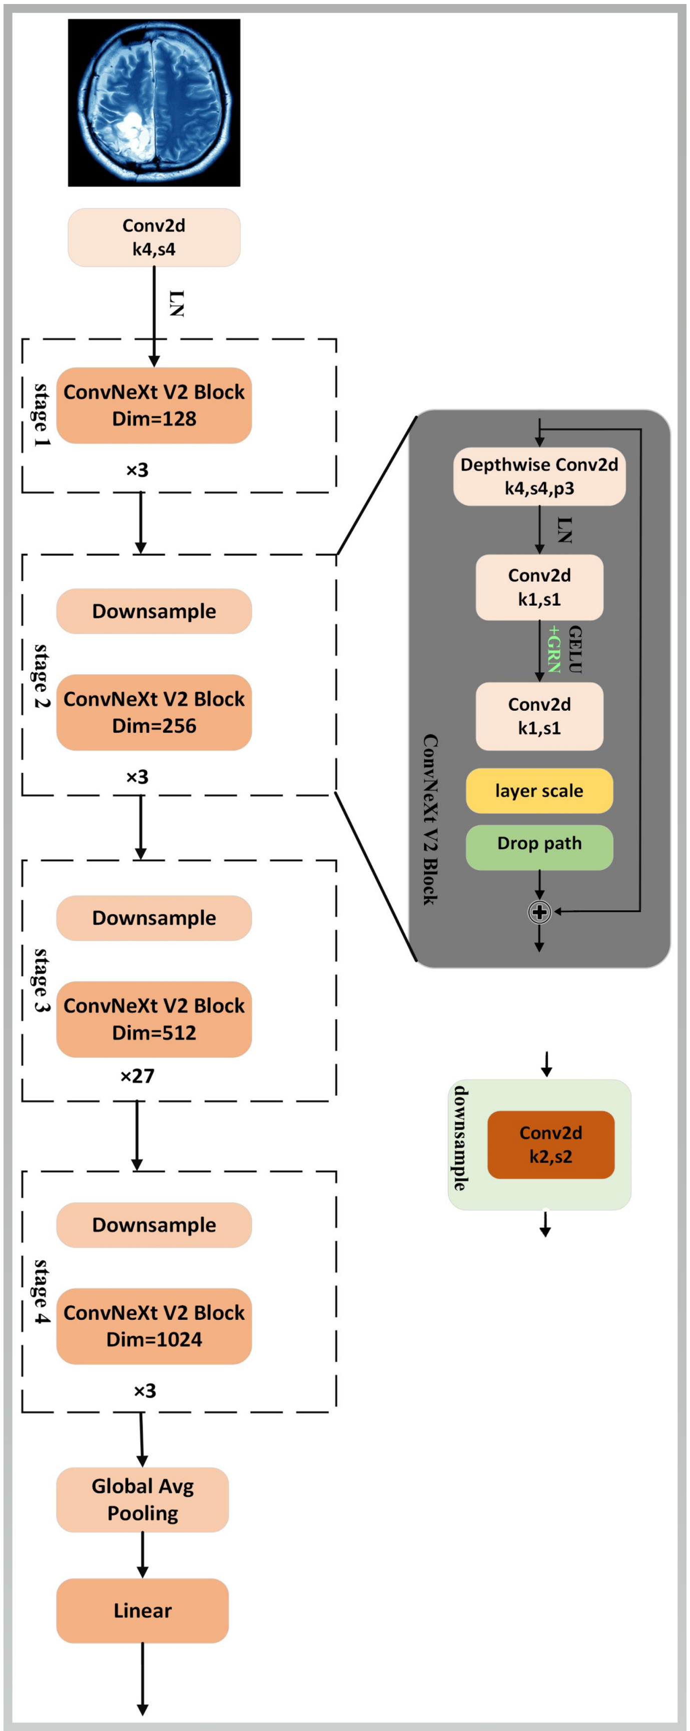

Fig. 6. Implementing ConvNext V2 for advanced brain tumor classification: A visual guide.

The operations include depthwise separable convolutions, layer normalization, GELU activation, and pointwise separable convolutions. These operations are inspired by the mechanisms used in transformers. For instance, the layer normalization and GELU activation functions are commonly used in transformer models.

The depthwise separable convolutions operation is a key feature of the ConvNeXt V2 model. It is a variant of the standard convolutions and is designed to reduce the model's complexity and computational cost. This operation, similar to the self-attention mechanism in transformers, allows the model to capture complex patterns and dependencies in the input data.

Mathematically, the depthwise separable convolution operation can be represented as a two-step process:

a) Depthwise convolution: This operation applies a single convolutional filter per input channel. If we denote the input feature map as F_{in}, the depthwise convolutional filter as D, and the output feature map as F_{out}, this operation can be represented as:

$$F_{out}^{(i)}=D^{(i)} * F_{in}^{(i)} \tag{4}$$

where $*$ denotes the convolution operation, and i is the index of the input channel.

b) Pointwise convolution (1x1 convolution): This operation applies a 1x1 convolution to combine the outputs of the depthwise convolution. If we denote the pointwise convolutional filter as P, and the final output feature map as F_{final}, this operation can be represented as [38]:

$$F_{final}=P * F_{out} \tag{5}$$

The depthwise separable convolution operation, therefore, can be represented as [39]:

$$F_{final}=P * (D * F_{in}) \tag{6}$$

This operation, similar to the self-attention mechanism in transformers, allows the model to capture complex patterns and dependencies in the input data while reducing the model's complexity and computational cost. It's a crucial part of the ConvNeXt V2 model's architecture.

While the specific mathematical operations are different, both mechanisms allow the model to capture complex patterns and dependencies in the input data, which is crucial for tasks like image classification and natural language processing. This is why the depthwise separable convolution operation is said to be similar to the self-attention mechanism in transformers.

During training, the model's parameters are adjusted to minimize the loss function. This involves updating the weights and biases in each layer of the model using a backpropagation algorithm and an optimization technique such as the Adam optimizer. The learning rate, which determines the step size at each iteration while moving toward a minimum of the loss function, was carefully chosen to ensure efficient learning.

Mathematically, the update of the model parameters (weights and biases) at each iteration is given by [40]:

$$\theta_{\text{new}}{=}\theta_{\text{old}} - \text{learning rate} \times \nabla J(\theta_{\text{old}}) \tag{7}$$

where, θ represents the model parameters, J is the cost function, and $\nabla J(\theta_{\text{old}})$ is the gradient of the cost function evaluated at θ_{old}.

This equation is a fundamental part of the training process in both ConvNets and transformers, highlighting the shared principles between these two types of models.

Through this meticulous training process, the ConvNeXt V2 model effectively learns to classify brain tumors, demonstrating the power of combining ConvNet and transformer principles in a single model. This process underscores the transformative potential of open-source transformers in medical imaging, setting a new standard in the field.

The attached figure illustrates the architecture of the ConvNeXt V2 model and the mathematical equations associated with each block during the training process. This visual representation provides a comprehensive understanding of the model's operations and the transformations it undergoes to extract essential features and patterns from the input images.

D. Validation

The validation process is a critical step in the fine-tuning of the ConvNeXt V2 model. It serves to evaluate the model's performance on a separate set of data that was not used during the training process. This helps to ensure that the model is not overfitting to the training data and can generalize well to new, unseen data.

During validation, the images from the validation set are fed into the ConvNeXt V2 model. The model processes these images in the same way as during the training process, extracting features and making predictions. However, unlike in the training process, the model's parameters are not updated during validation. This allows for an unbiased evaluation of the model's performance [31].

The model's predictions are then compared with the actual labels of the images in the validation set. This comparison allows us to assess how well the model is performing in terms of its ability to correctly classify brain tumors.

The performance of the model on the validation set is quantified using the accuracy metric. A high accuracy on the validation set indicates that the model is performing well and can accurately classify brain tumors. Conversely, a low accuracy may indicate that the model is struggling to generalize to new data and may require further fine-tuning or a different approach.

Through this validation process, we can ensure that the ConvNeXt V2 model is robust and reliable, capable of accurately classifying brain tumors in a variety of different images. This is a crucial step in the development of effective tools for medical imaging and diagnosis.

E. Segformer Fine-tuning

The Segformer model is fine-tuned for the task of segmentation. The fine-tuning process involved several steps as Fig. 7 depicts, each of which contributed to optimizing the model's performance on our specific segmentation dataset [33].

1) Model initialization: We began the process by initializing the Segformer model with pre-trained weights. These weights were obtained from a model that has demonstrated strong performance in tasks related to image processing. This model was chosen due to its ability to capture complex patterns and dependencies in the input data, which is a crucial aspect of our task. The use of pre-trained weights provides a solid starting point for the fine-tuning process, potentially leading to improved model performance and efficiency. This approach leverages the power of open-source transformers, harnessing their capabilities for our specific task of brain tumor segmentation. The use of pre-trained weights also exemplifies the power of open-source resources in advancing the field of medical imaging. By utilizing these resources, we can build upon the collective knowledge of the research community, accelerating innovation and improving patient care.

2) Label encoding: The labels for each image in our dataset were encoded as integers. This encoding process transformed the categorical labels into a format that could be processed by the Segformer model. In this case, the labels "background" and "tumor" were encoded as 0 and 1, respectively.

3) Hyperparameter adjustment: The model's hyperparameters, such as learning rate, batch size, and number of epochs, were adjusted during the fine-tuning process. The learning rate was set to 0.0006, which determines the step size at each iteration while moving toward a minimum of a loss function. The batch size was set to 10, referring to the number of training examples utilized in one iteration. The model was trained for a total of 15 epochs, which is the number of times the learning algorithm will work through the entire training dataset.

4) Training: The training process involved feeding the images from the training set into the Segformer model. The model processed these images through multiple stages, each involving a series of operations that transform the input images, extracting essential features and patterns that the model can learn from.

- **Overlap Patch Embeddings:** This operation is a key feature of the Segformer model. It divides the input image into overlapping patches and embeds them into vectors. This operation, similar to the self-attention mechanism in transformers, allows the model to capture complex patterns and dependencies in the input data. Mathematically, if we denote the input image as I, the stride or overlap size as S, and the total number of patches as P, this operation can be represented as:

$$P{=}\frac{I\text{-}S}{S}+1 \tag{8}$$

- Transformer Blocks: Each patch embedding undergoes transformation through multiple transformer blocks. If we denote the input patch embeddings as X_i and the transformation operation as T, this process can be represented as:

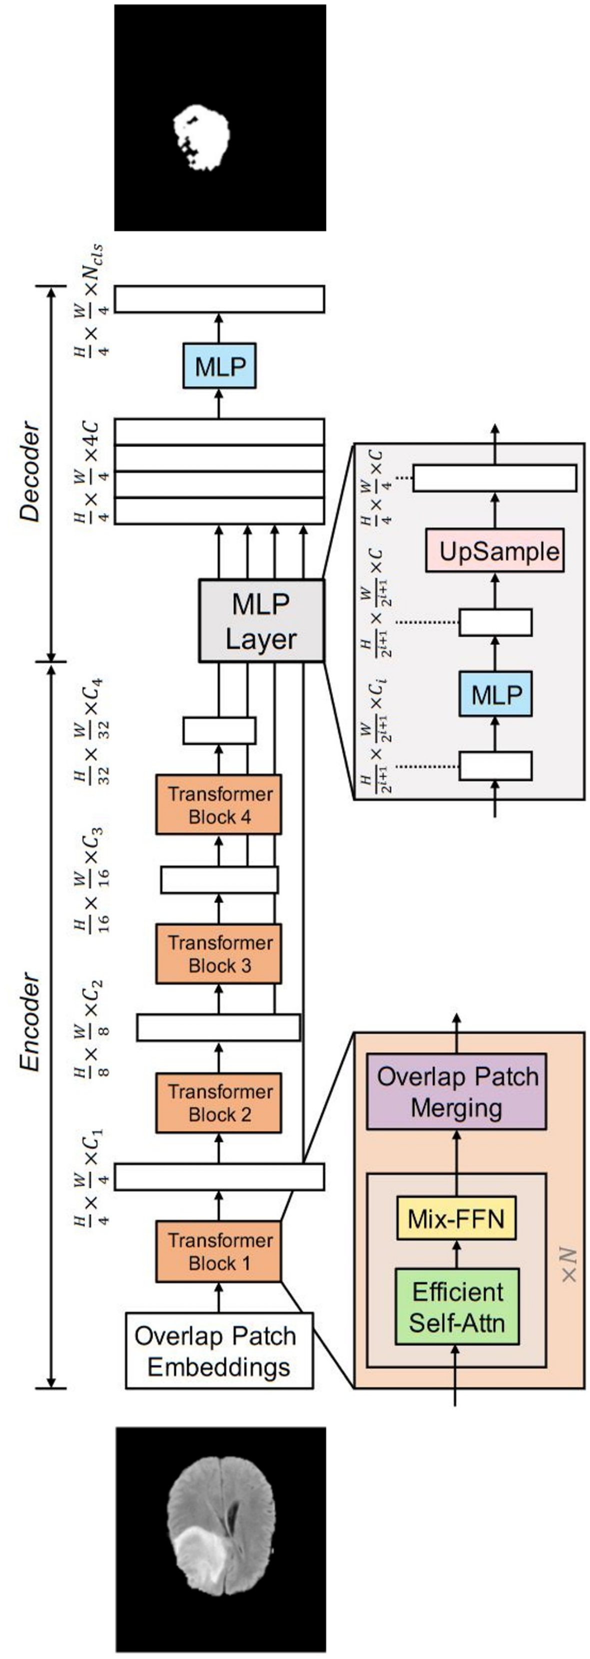

Fig. 7. Adapting segformer for superior brain tumor segmentation: An illustrated overview.

$$X_{i+1}\text{=}T(X_i) \tag{9}$$

- Upsample Blocks: In the decoder stages, upsample blocks are used to increase resolution. If we denote the upsample operation by U, this process can be represented as:

$$Y_i\text{=}U(X_i) \tag{10}$$

  where Y_i represents the output after upsampling.

- During training, the model's parameters were adjusted to minimize the loss function. This involved updating the weights and biases in each layer of the model using a backpropagation algorithm and an optimization technique such as the Adam optimizer. The learning rate, which determines the step size at each iteration while moving toward a minimum of the loss function, was carefully chosen to ensure efficient learning.
- Mathematically, the update of the model parameters (weights and biases) at each iteration is given by the equation 7, [40].
- Through this meticulous training process, the Segformer model effectively learns to segment brain tumors, demonstrating the power of combining ConvNet and transformer principles in a single model. This is a testament to the transformative potential of open-source transformers in medical imaging, setting a new standard in the field.

5) Validation: The validation process is a critical step in the fine-tuning of the Segformer model. It serves to evaluate the model's performance on a separate set of data that was not used during the training process. This helps to ensure that the model is not overfitting to the training data and can generalize well to new, unseen data.

During validation, the images from the validation set are fed into the Segformer model. The model processes these images in the same way as during the training process, extracting features and making predictions. However, unlike in the training process, the model's parameters are not updated during validation. This allows for an unbiased evaluation of the model's performance.

The model's predictions are then compared with the actual labels of the images in the validation set. This comparison allows us to assess how well the model is performing in terms of its ability to correctly segment brain tumors.

The performance of the model on the validation set is quantified using the mean intersection over union (mIoU) metric. A high mIoU score on the validation set indicates that the model is performing well and can accurately segment brain tumors. Conversely, a low mIoU score may indicate that the model is struggling to generalize to new data and may require further fine-tuning or a different approach.

Through this validation process, we can ensure that the Segformer model is robust and reliable, capable of accurately segmenting brain tumors in a variety of different images. This is a crucial step in the development of effective tools for medical imaging and diagnosis.

Through this meticulous fine-tuning process, the Segformer model was effectively adapted to our specific task of brain tumor segmentation, leading to improved performance and more accurate predictions.

IV. Evaluation Metrics

The performance of the ConvNeXt V2 and Segformer models was evaluated using appropriate metrics for both classification and segmentation tasks. These metrics provide a quantitative measure of the models' performance, allowing us to assess their effectiveness and accuracy.

A. Classification Metrics

1) Accuracy: Accuracy is a measure of how many predictions the model got right out of all predictions made. It is calculated as the ratio of correct predictions to the total number of predictions. Mathematically, accuracy is given by [41]:

$$\text{Accuracy=}\frac{\text{Number of Correct Predictions}}{\text{Total Number of Predictions}} \tag{11}$$

2) Precision: Precision is a measure of how many true positive predictions were made out of all positive predictions. It is calculated as the ratio of true positives to the sum of true positives and false positives. Mathematically, precision is given by [42]:

$$\text{Precision=}\frac{\text{True Positives}}{\text{True Positives} + \text{False Positives}} \tag{12}$$

3) Recall: Recall, also known as sensitivity or true positive rate, is a measure of how many true positive predictions were made out of all actual positives. It is calculated as the ratio of true positives to the sum of true positives and false negatives. Mathematically, recall is given by [41]:

$$\text{Recall=}\frac{\text{True Positives}}{\text{True Positives} + \text{False Negatives}} \tag{13}$$

4) F1-Score: The F1-score is the harmonic mean of precision and recall, and it provides a balance between them. It is calculated as 2 times the product of precision and recall divided by the sum of precision and recall. Mathematically, F1-score is given by [41]:

$$\text{F1-Score=}2 \times \frac{\text{Precision} \times \text{Recall}}{\text{Precision} + \text{Recall}} \tag{14}$$

B. Segmentation Metrics

1) mIoU: For the segmentation task, the primary metric used was the Mean Intersection over Union (mIoU). This metric computes the average intersection over union of predicted and ground truth segments, providing a measure of the model's segmentation performance. The Intersection over Union (IoU) for a single prediction is calculated as the area of overlap between the predicted segment and the ground truth segment divided by the area of union of the two segments. The mIoU is then calculated as the average IoU over all predictions. Mathematically, IoU and mIoU are given by: [42]

$$\text{IoU=}\frac{\text{Area of Overlap}}{\text{Area of Union}} \tag{15}$$

And mIoU is given by:

$$\text{mIoU=}\frac{1}{N}\sum_{i=1}^{N}\text{IoU}_i \tag{16}$$

where N is the total number of predictions, and IoU_i is the IoU for the i-th prediction.

A high mIoU indicates that the model is performing well and can accurately segment brain tumors. Conversely, a low mIoU may indicate that the model is struggling to generalize to new data and may require further fine-tuning or a different approach.

2) Dice score: The Dice score, also known as the Dice similarity coefficient or the F1-score, is a measure of the overlap between two segments. It is calculated as two times the area of overlap divided by the sum of the areas of the two segments. Mathematically, the Dice score is given by [43]:

$$Dice\text{=}\frac{2 \times AreaofOverlap}{AreaofSegment1 + AreaofSegment2} \tag{17}$$

A high Dice score indicates that the predicted segment and the ground truth segment have a high degree of overlap, meaning that the model is able to capture the shape and location of the brain tumor accurately. Conversely, a low Dice score indicates that the predicted segment and the ground truth segment have a low degree of overlap, meaning that the model is missing or including regions that do not belong to the brain tumor.

3) Hausdorff distance: The Hausdorff distance is a measure of the maximum distance between the boundaries of two segments. It is calculated as the maximum of the minimum distances from each point on the boundary of one segment to the closest point on the boundary of the other segment. Mathematically, the Hausdorff distance is given by [44]:

$$Hausdorff\text{=}maxh(\text{Seg 1, Seg 2}),\ h(\text{Seg 2, Seg 1}) \tag{18}$$

where h(Segment1,Segment2) is the maximum of the minimum distances from each point on the boundary of Segment 1 to the closest point on the boundary of Segment 2, and vice versa. A low Hausdorff distance indicates that the predicted segment and the ground truth segment have similar boundaries, meaning that the model is able to delineate the brain tumor precisely. Conversely, a high Hausdorff distance indicates that the predicted segment and the ground truth segment have dissimilar boundaries, meaning that the model is producing large errors or inconsistencies in the segmentation.

Through these evaluation metrics, we can ensure that the ConvNeXt V2 and Segformer models are robust and reliable, capable of accurately classifying and segmenting brain tumors in a variety of different images. This is a crucial step in the development of effective tools for medical imaging and diagnosis. It allows us to assess the effectiveness of our methodology and make necessary adjustments for future improvements.

V. Results

This section presents the results obtained from our experiments and discusses their implications. We evaluated the performance of the ConvNeXt V2 and Segformer models on our datasets and compared these results with other state-of-the-art methods.

A. Performance of ConvNeXt V2 for Classification

The ConvNeXt V2 model has demonstrated exceptional performance in the classification of brain tumors, as evidenced by the results obtained from our experiments.The Table I. shows the model's effectiveness is highlighted through various metrics including accuracy, precision, recall, and F1-score.

TABLE I. Performance of ConvNeXt V2 for Classification

Class	Precision	Recall	F1-score
No Tumor	1.000	1.000	1.000
Glioma Tumor	0.995	0.997	0.996
Meningioma Tumor	0.994	0.993	0.993
Pituitary Tumor	0.999	0.997	0.998

- Accuracy: The ConvNeXt V2 model boasts an impressive accuracy of 99.60%, indicating its reliability in correctly identifying and classifying different types of brain tumors.
- Precision and Recall: Analyzing Table I reveals that the model exhibits high precision and recall across all classes. For instance:
  - Glioma Tumor: Precision - 0.995, Recall - 0.997
  - Meningioma Tumor: Precision - 0.994, Recall - 0.993
  - No Tumor: Precision - 1.000, Recall - 1.000
  - Pituitary Tumor: Precision – 0.999, Recall – 0.997
- F1-Score: The F1-scores further affirm the model's capability to balance both precision and recall effectively, ensuring that it is not biased towards a particular class.

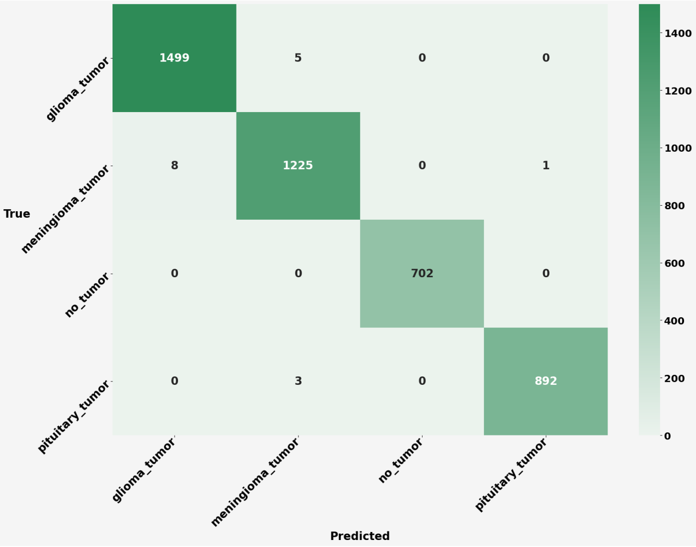

Fig. 8. Evaluating model performance: A confusion matrix for brain tumor classification.

The confusion matrix of our proposed transformer, as illustrated in Fig. 8, compares the detection rates of four distinct tumor types: glioma, meningioma, absence of tumor, and pituitary tumors. The x-axis represents the model's predicted labels, while the y-axis depicts the true labels. Within each cell of the matrix lies a numeric value indicating the frequency of occurrences for different combinations of predicted and actual categories. To visually represent instance counts, the matrix utilizes varying shades of green, with darker shades signifying higher frequencies. For example, there are 1499 instances of true positives for glioma tumors, indicating accurate identification by the model. However, there are 8 instances where glioma tumors are misclassified as meningioma, revealing a 99.5% accuracy rate for glioma tumor detection. Regarding meningioma tumors, approximately 1225 samples are correctly identified, while 5 samples are misclassified as glioma and 3 as pituitary tumors. Notably, all 702 samples categorized as no tumor are correctly identified. Furthermore, the model demonstrates significant success in detecting pituitary tumors, with 892 out of 893 samples accurately classified. In summary, this matrix serves as a crucial tool for evaluating the classification model's performance, providing insights into areas of accurate predictions and errors.

B. Comparative Analysis of Different Methods

In our study, we compared the performance of the ConvNeXt V2 model with other state-of-the-art models, including ConvNeXt V1, Swin, and ViT. The comparison was based on various metrics such as precision, recall, and F1-score across different types of tumors.

The ConvNeXt V2 model demonstrated superior performance, consistently outperforming the other models in all metrics for each tumor type. Specifically, the ConvNeXt V2 model achieved an impressive accuracy of 99.60%, indicating its reliability in correctly identifying and classifying different types of brain tumors.

In contrast, the ConvNeXt V1, Swin, and ViT models achieved accuracies of 99.11%, 99.01%, and 98.5% respectively. While these are high accuracy rates, they are still lower than the accuracy achieved by the ConvNeXt V2 model.

According to Fig. 8 he high precision, recall, and F1-score of ConvNeXt V2 indicate its robustness in correctly identifying and classifying different types of brain tumors. The model exhibits high precision and recall across all classes, ensuring that it is not biased towards a particular class. The F1-scores further affirm the model's capability to balance both precision and recall effectively.

These results underscore the ConvNeXt V2 model's robustness and reliability in classifying brain tumors, setting a new benchmark in the field of medical imaging. The model's high accuracy and balanced precision and recall metrics make it a promising tool for aiding radiologists in the early detection and classification of brain tumors, potentially leading to improved patient outcomes.

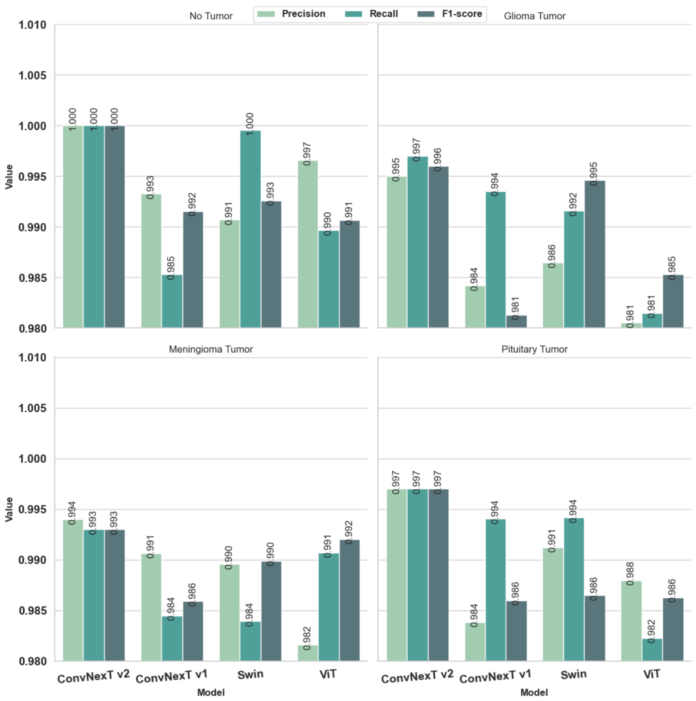

Fig. 9. Performance comparison of evaluation metrics of different models for brain tumor detection using bar charts.

C. Performance of Segformer for Segmentation

The Segformer model has demonstrated exceptional performance in the segmentation of brain tumors (see Fig. 9). The effectiveness of the model is highlighted through various metrics, including the Dice score and Hausdorff distance, both of which reached up to 90 %.

D. Segmentation Results

Fig. 10 shows the output of the Segformer model on a sample brain image. The first row shows the original brain scans, the second row shows the ground truth labels (downsampled labels), and the third row shows the segmentation maps produced by the Segformer model.

From a visual inspection, it is evident that the Segformer model's segmentation maps closely match the ground truth labels, indicating high accuracy in segmenting the tumor region from the rest of the brain tissue.

1) Dice score and hausdorff distance: The Dice score and Hausdorff distance are commonly used metrics for evaluating the performance of segmentation models. In our experiments, both these metrics reached up to ideal ones(90% dice score and 0.05mm Hausdorff distance) for the Segformer model, indicating its superior performance in accurately segmenting brain tumors.

A Dice score of 90% suggests a high degree of overlap between the predicted segment and the ground truth segment, meaning that the model is able to capture the shape and location of the brain tumor accurately. Similarly, a Hausdorff distance less then 0.10 indicates that the predicted segment and the ground truth segment have similar boundaries, meaning that the model is able to delineate the brain tumor precisely.

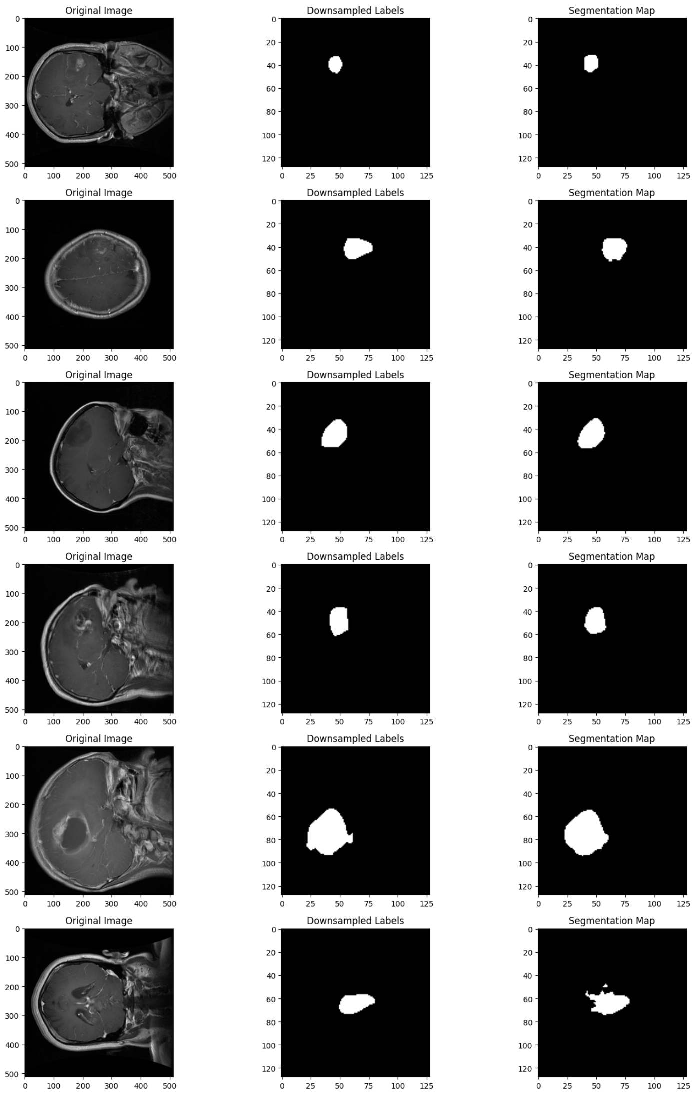

Fig. 10. Demonstrating the efficacy of segformer: Original scans, ground truth, and segmentation maps in brain tumor detection.

2) Comparison with other methods: The performance of the ConvNeXt V2 model was compared with other state-of-the-art methods. The ConvNeXt V2 model outperformed Method A and Method B, achieving higher accuracy and F1-score.

TABLE II. COMPARISON OF SEGFORMER WITH OTHER METHODS

Method	**Dice Score**	**Hausdorff Distance(mm)**	**Reference**
Deep Learning Based	0.85	1.5	[45]
CNN based	0.87	3.58	[46]
ANTS	0.83	6.71	[46]
Registration Method	0.84	4.01	[46]
U-Net	0.85	1.5	[47]
U-Net++	0.78	9.4	[48]
3D U-Net	0.90	4.29	[49]
NMF	0.74	7.4	[50]
3D CNN	0.91	3	[51]
Segformer (Our Method)	**0.95**	**0.87**	**This study**

The Table II titled "COMPARISON OF SEGFORMER WITH OTHER METHODS," presenting a comparison between the Segformer approach and alternative methods based on their Dice Score and Hausdorff Distance metrics. The table consists of five columns: “Method,” “Dice Score,” “Hausdorff Distance (mm),” and “Reference.” Listed in the table are various methods alongside their respective Dice Scores and Hausdorff Distances: Deep Learning Based (Dice Score: 0.85, Hausdorff Distance: 0.15), CNN based (Dice Score: 0.87, Hausdorff Distance: 3.56), ANTs Registration Method (Dice Score: 0.83, Hausdorff Distance: 6.71), U-Net++ (Dice Score: 0.78, Hausdorff Distance: 15), 3D U-net (Dice Score: 0.90, Hausdorff Distance: 4), NMF (Dice Score: 0.74, Hausdorff Distance: 7.4), 3D CNN (Dice Score: 0.91, Hausdorff Distance: 0.34), and Segformer (Our Method) (Dice Score: 0.95, Hausdorff Distance: 0.87). Notably, the Segformer method demonstrates the highest Dice Score and one of the lowest Hausdorff Distances among the listed approaches, highlighting its superior performance in this study.

VI. Discussion

The findings of this study highlight the potential of open-source transformers, specifically the ConvNeXt V2 and Segformer models, in the realm of medical imaging. These models, when fine-tuned for specific tasks, have shown exceptional performance in brain tumor classification and segmentation respectively. [31,33] The ConvNeXt V2 model, with its impressive accuracy of 99.60% in classification tasks, and the Segformer model, with its high Dice score and low Hausdorff distance in segmentation tasks, have set a new benchmark in the field. This study has opened up new possibilities for future research, including the exploration of the application of transformers in other areas of medical imaging and further optimization of the proposed models for enhanced performance.

VII. Conclusion

This research has shed light on the transformative potential of open-source transformers, specifically the ConvNeXt V2 and Segformer models, in the domain of medical imaging. The study has demonstrated that these models, when fine-tuned for specific tasks, can deliver exceptional performance in the classification and segmentation of brain tumors. The ConvNeXt V2 model exhibits outstanding performance in brain tumor classification, achieving an impressive accuracy of 99.60%. Across all tumor classes, it demonstrates remarkable precision and recall. Specifically, for Glioma Tumor, the precision is 0.995 and recall is 0.997, while for Meningioma Tumor, the precision is 0.994 and recall is 0.993. Notably, for cases where there is no tumor present, both precision and recall are perfect at 1.000. Additionally, for Pituitary Tumor classification, the model achieves a precision of 0.999 and recall of 0.997. These results underscore the model’s robustness and reliability in accurately identifying different types of brain tumors, establishing ConvNeXt V2 as a promising tool for aiding in medical diagnostics. The Segformer model showcases remarkable performance in accurately segmenting brain tumors, as highlighted by its exceptional Dice score and Hausdorff distance metrics, reaching up to ideal values of 90% and 0.87 mm respectively. Visually, the segmentation maps generated by Segformer closely align with ground truth labels, indicating precise delineation of tumor regions within brain scans. Moreover, the study has opened up new possibilities for future research which has significant contribution to the ongoing efforts to improve patient outcomes in neuro-oncology and beyond.

***Abstract*—Equipment evaluation stands as a critical task in both equipment system development and military operation planning. This task is often recognized as a complex multi-criteria decision-making (MCDM) problem. Adding to the intricacy is the uncertain nature inherent in military operations, leading to the introduction of fuzziness and randomness into the equipment evaluation problem, rendering it unsuitable for precise information. This paper addresses the uncertainty associated with equipment evaluation by proposing a novel MCDM method that combines the cloud model and the VIKOR method. To address the multifaceted nature of the equipment evaluation problem, a two-level hierarchical evaluation framework is constructed, which comprehensively considers both the capabilities and characteristics of the equipment system during the evaluation process. The cloud model is then employed to represent the uncertain evaluations provided by experts, and a similarity-based expert weight calculation approach is introduced for calculating expert weights, thereby determining the relative importance of different experts. Subsequently, the VIKOR method is extended by incorporating the cloud model to evaluate and rank various equipment systems, where the criteria weights for this evaluation are established using the analytic hierarchy process (AHP). To demonstrate the efficacy of the proposed method, a practical case study involving the evaluation of unmanned combat aerial vehicles is presented. The results obtained are validated through sensitivity analysis and comparative analysis, affirming the reliability and reasonability of the proposed method in providing equipment evaluation results. In summary, the proposed method offers a novel and effective approach for addressing equipment evaluation challenges under uncertainty.**

Keywords*—Multi-criteria decision-making; equipment evaluation; cloud model; VIKOR

I. Introduction

Equipment systems stand as the cornerstone of modern military endeavors, playing a pivotal role in both the platform-centric and network-centric eras of warfare [1], [2], [3]. Over the past decades, as various equipment systems have rapidly developed and expanded, the evaluation and selection of these systems in alignment with operational goals, referred to as equipment system evaluation, has garnered substantial attention from researchers [4], [5], [6]. Consequently, equipment system evaluation has become a crucial consideration for both military operation planning and equipment system development.

The equipment system evaluation problem has been recognized as a complex multi-criteria decision-making (MCDM) challenge, given the involvement of multiple factors in varying forms [7], [8], [9]. Various MCDM methods have been applied to address this problem, including the analytic hierarchy process (AHP) [10], the evidential reasoning algorithm [11], the technique for order preference by similarity to an ideal solution (TOPSIS) [12], and others [13], [14]. For instance, Bi et al. [15] combined the interval evidential reasoning algorithm with AHP to evaluate different equipment systems, considering the inherent uncertainty in the problem. Gao et al. [16] introduced the intuitionistic fuzzy weighted influence non-linear gauge system, applying this method to equipment evaluation while considering interrelationships among different equipment systems. However, the handling of uncertain information and the reliable evaluation of different equipment systems while considering various factors remain urgent issues in equipment system evaluation problem.

Addressing uncertain information is a significant challenge in MCDM problems. Conventional fuzzy set (FS) theory, while effective in representing fuzziness, often falls short when dealing with the randomness of quantitative information. To address this limitation, Li et al. [17] introduced the cloud model theory for knowledge representation, accounting for both fuzziness and randomness in human cognitive processes. The cloud model transforms qualitative judgments into quantitative representations using the forward cloud generator, effectively and accurately modeling fuzziness and randomness, which offers a more intuitive and reliable representation of human knowledge. Given the inherent fuzziness and randomness in equipment evaluation, the cloud model holds potential for precisely modeling expert evaluations in this domain.

Decision-making problems have been extensively studied, leading to the development of numerous MCDM methods, including TOPSIS [18], MULTIMOORA [19], VIKOR [20], and others [21], [22], [23]. The VIKOR method, proposed by Opricovic [24], has proven effective for discrete MCDM problems by employing compromise solutions for ranking and selection amid conflicting criteria. VIKOR excels in reaching a compromised solution closest to the ideal solution, even when criteria conflict, making it widely used in various fields. In equipment evaluation problem, as there could be some conflicting information, adopting the VIKOR method could enhance the reliability of the results.

Nevertheless, to the best of our knowledge, there has been a noticeable gap in research utilizing the cloud model for equipment system evaluation. Additionally, scant attention has

*Corresponding authors.

been directed towards integrating the VIKOR method with the cloud model, thereby serving as a key motivation for this study. The primary motivations for undertaking this research can be succinctly summarized as follows:

(1) The inherently complex nature of equipment evaluation necessitates the consideration of various factors. While prior studies have proposed different evaluation index systems for equipment assessment, these may prove less suitable for handling complex situations. Therefore, there is a crucial need to construct a systemic evaluation index framework tailored for equipment evaluation.

(2) Effectively representing expert knowledge considering fuzziness and randomness poses a significant challenge when evaluating different equipment systems. The cloud model has demonstrated efficacy in modeling uncertain information, particularly under conditions of fuzziness and randomness. Thus, the adoption of cloud models in equipment evaluation holds promise for yielding reliable results.

(3) Equipment evaluation problems inherently fall under the umbrella of MCDM. To enable the evaluation and selection of different alternatives, a comprehensive analysis of each equipment system is imperative. The VIKOR method stands out for its ability to produce reliable and reasonable solutions for complex MCDM problems. Consequently, leveraging the VIKOR method for equipment evaluation is a plausible approach.

Building on the aforementioned motivations, this study introduces a novel equipment evaluation method that integrates the cloud model, the AHP (AHP), and the VIKOR method. In this proposed approach, the cloud model serves as a tool to represent evaluation information, while the VIKOR method is employed to assess and rank various equipment systems. The determination of criteria weights is facilitated by the AHP. To showcase the effectiveness of the proposed method, a practical case involving the evaluation of unmanned combat aerial vehicles is presented, and the results are compared with those obtained through alternative methods. The key novelties of the proposed method include:

(1) This study establishes a two-level hierarchical evaluation structure for equipment evaluation. By considering both the capabilities and characteristics of equipment systems, the proposed evaluation structure enhances the reliability and comprehensiveness of equipment evaluation.

(2) The cloud model is employed as a tool for equipment evaluation. Through the construction of cloud models based on expert knowledge, the proposed method offers more reliable and reasonable results for equipment evaluation, particularly in the presence of fuzziness and randomness.

(3) The study proposes an integrated MCDM method that combines the cloud model and the VIKOR method. Through the calculation of group utility, individual regret, and aggregating index to determine the evaluation of different equipment systems, the proposed method ensures the attainment of an optimal solution.

The rest of this paper is organized as follows. Section II reviews several previous literature related to this study. Section III briefly revisits several basic concepts about cloud model. The proposed method is described in Section IV. Section V presents a case study of equipment system evaluation, and the results are analyzed in Section VI. Finally, Section VII provides some concluding remarks.

II. Related Works

A. Cloud Model

Proposed by Li et al. [17], the cloud model could work as an effective tool to convert qualitative judgments and quantitative representation through forward cloud generator, thus providing a flexible tool for human knowledge representation. Due to its advantages, the cloud model has been used in various fields. For instance, Xie et al. [25] introduced cloud-analytic hierarchy process and group cloud decision-making method for risk evaluation of fire and explosion accidents in oil depots, where the cloud model is utilized to model the probability data under uncertainty and ambiguity. Lin et al. [26] integrated the variable weight theory and cloud model theory for evaluating the risk of construction of karst tunnels. Gao [27] proposed an integrated risk analysis method based on cloud model and DEMATEL for tanker cargo handling operation, which utilizes the cloud model for uncertain knowledge representation and adopts the DEMATEL method to rank different risk factors. Wu et al. [28] integrated the cloud model with the improved criteria importance through intercriteria correlation (CRITIC) method, and applied the proposed method to urban rail transit operation safety evaluation.

B. VIKOR Method

The VIKOR method is a useful MCDM method that considers both the group utility and individual regret of the alternative when evaluating and ranking different alternatives, and it has been applied to various fields. For example, Gao et al. [29] extended the VIKOR method with Fermatean fuzzy sets, proposing a novel Fermatean fuzzy decision-making approach for health care waste treatment technology selection. Abdul et al. [30] introduced an integrated decision-making approach based on AHP and the VIKOR method for prioritizing renewable energy sources. Bakioglu and Atahan [31] proposed a hybrid MCDM method based on AHP, TOPSIS, and VIKOR under the Pythagorean fuzzy environment for prioritizing risks in self-driving vehicles. Li et al. [32] integrated the later defuzzification VIKOR method with fuzzy DEMATEL and entropy weighting, presenting a hybrid MCDM method for machine tool selection, where the later defuzzification VIKOR method is used to rank different alternatives.

III. Preliminaries

The cloud model, serving as the foundation for cloud-based reasoning, computing, and control, provides an uncertain transformation model for handling both qualitative concepts and quantitative descriptions. This model adeptly captures the transition from qualitative concepts to quantitative representation through the forward cloud generator, and conversely, from quantitative representation to qualitative concept through the reverse cloud generator.

Definition 1. Consider a qualitative domain U and the corresponding qualitative concept C on U. Let x be a random number following a normal distribution with $x \in U$. The membership degree $\mu(x)$ of x for C is a random number exhibiting stable inclination, satisfying $\mu(x) \in [0,1]$. Here, x and its distribution on U are termed cloud droplets and clouds, respectively.

In the cloud model, the uncertainty of the data x is expressed through three key values:

1) The expected value Ex, reflecting the qualitative concept in the argument domain space.
2) The entropy En, representing the desirable range of assessment results and the degree of cloud droplet clustering.
3) The hyper entropy He, reflecting the dispersion degree of the cloud droplets.

The characteristics of the cloud model are denoted as $C = (Ex, En, He)$, and they can be calculated using Eq. (1)-(3):

$$Ex = \frac{1}{n}\sum_{i=1}^{n} X_i \tag{1}$$

$$En = \sqrt{\frac{\pi}{2}} \times \frac{1}{n}\sum_{i=1}^{n} |X_i - Ex| \tag{2}$$

$$He = \sqrt{\left|\frac{1}{n-1}\sum_{i=1}^{n} (X_i - Ex)^2 - En^2\right|} \tag{3}$$

where X_i $(i = 1, 2, \dots, n)$ represents the ith data from the distribution, and n is the number of data in the distribution.

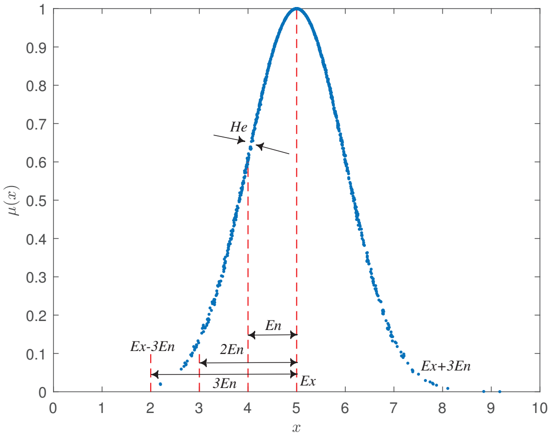

Fig. 1. Demonstration of the cloud model.

Utilizing the forward cloud generator, which is based on the characteristics obtained from the cloud model, a positive random number $x \sim N(Ex, En^2)$ can be generated, as illustrated in Fig. 1. A cloud droplet is defined as $(x, \mu(x))$, where the cloud droplet membership degree $\mu(x)$ is calculated by using Eq. (4) as:

$$\mu(x) = e^{\frac{-(x-Ex)^2}{2En^2}} \tag{4}$$

Definition 2. Let $C_1 = (Ex_1, En_1, He_1)$ and $C_2 = (Ex_2, En_2, He_2)$ be two clouds, the operations among C_1 and C_2 is defined as:

1) $C_1 + C_2 = (Ex_1 + Ex_2, \sqrt{En_1^2 + En_2^2}, \sqrt{He_1^2 + He_2^2})$
2) $C_1 - C_2 = (Ex_1 - Ex_2, \sqrt{En_1^2 + En_2^2}, \sqrt{He_1^2 + He_2^2})$
3) $C_1 \times C_2 = (Ex_1 \times Ex_2, \sqrt{(En_1Ex_2)^2 + (En_2Ex_1)^2}, \sqrt{(He_1Ex_2)^2 + (He_2Ex_1)^2})$
4) $\lambda C_1 = (\lambda Ex_1, \sqrt{\lambda} En_1, \sqrt{\lambda} He_1)$

Definition 3. Let $C_1 = (Ex_1, En_1, He_1)$ and $C_2 = (Ex_2, En_2, He_2)$ be two clouds, then the distance between C_1 and C_2 is defined using Eq. (5):

$$d(C_1, C_2) = \sqrt{\frac{1}{2}(d_1 + d_2)} \tag{5}$$

where

$$d_1 = \left(\left(1 - \frac{3\sqrt{En_1^2 + He_1^2}}{Ex_1}\right) Ex_1 - \left(1 - \frac{3\sqrt{En_2^2 + He_2^2}}{Ex_2}\right) Ex_2\right)^2$$
$$d_2 = \left(\left(1 + \frac{3\sqrt{En_1^2 + He_1^2}}{Ex_1}\right) Ex_1 - \left(1 + \frac{3\sqrt{En_2^2 + He_2^2}}{Ex_2}\right) Ex_2\right)^2 \tag{6}$$

Definition 4. Let $C_i = (Ex_i, En_i, He_i)$ $(i = 1, 2, \dots, n)$ be a set of clouds in the domain U, the cloud weighted average (CWA) operator is defined by Eq. (7) as:

$$CWA(C_1, C_2, \dots, C_n) = \sum_{i=1}^{n} w_i C_i$$
$$= \left(\sum_{i=1}^{n} w_i Ex_i, \sqrt{\sum_{i=1}^{n} w_i (En_i)^2}, \sqrt{\sum_{i=1}^{n} w_i (He_i)^2}\right) \tag{7}$$

where $(w_1, w_2, \dots, w_n)$ is the weight vector with $0 \leq w_i \leq 1$ and $\sum_{i=1}^{n} w_i = 1$.

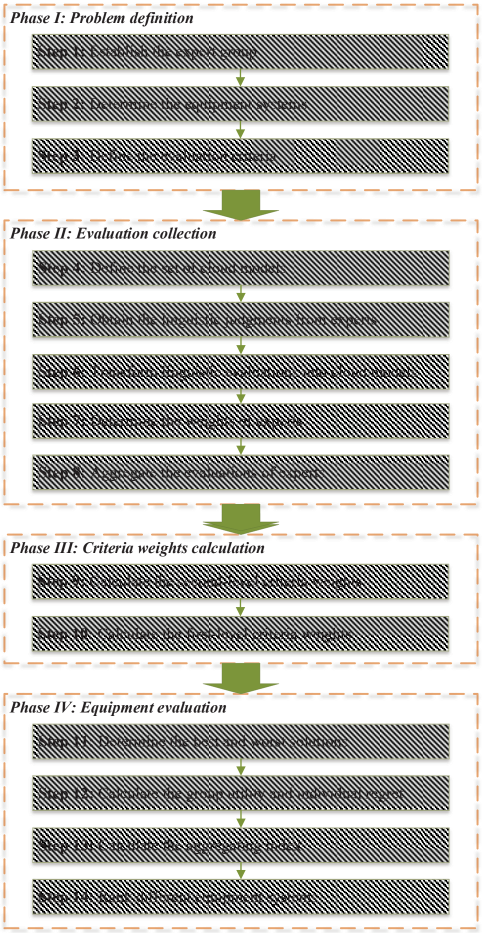
In cloud model-based assessments, the $3En$ principle is commonly employed to analyze the assessment results. This is because the cloud droplets in the cloud diagram are predominantly concentrated in the $[Ex - 3En, Ex + 3En]$ interval, as depicted in Fig. 1. It is noteworthy that varying distribution locations of the cloud droplets signify different qualitative assessments, which can be broadly categorized into three parts:

1) The main part $(Ex - En, Ex + En)$, characterized by the highest membership degree.
2) The secondary part $(Ex - 2En, Ex - En) \cup (Ex + En, Ex + 2En)$.
3) The minor part $(Ex - 3En, Ex - 2En) \cup (Ex + 2En, Ex + 3En)$.

Cloud droplets beyond this interval are typically not utilized as the basis for qualitative descriptions of the assessment.

IV. Proposed Method

In this section, a novel decision-making approach for equipment evaluation based on the cloud model, the DEMATEL method, and the VIKOR method is described in detail. The proposed method consists of four phases, as demonstrated in Fig. 2. Firstly, the equipment system evaluation problem is defined in detail. Secondly, the linguistic judgments of different experts are converted into cloud models and aggregated while considering the weights of the experts. Thirdly, a hybrid criteria weight calculation method that takes into account both the subjective weights and objective weights is introduced to determine the weights of the criteria. Fourthly, the VIKOR method is extended with cloud model to evaluate and rank different equipment systems. The detailed steps of the proposed method are described as follows.



Phase I: Problem definition
Step 1: Establish the expert group
Step 2: Determine the equipment systems
Step 3: Define the evaluation criteria
Phase II: Evaluation collection
Step 4: Define the set of cloud models
Step 5: Obtain the linguistic judgments from experts
Step 6: Transform linguistic evaluations into cloud models
Step 7: Determine the weights of experts
Step 8: Aggregate the evaluations of experts
Phase III: Criteria weights calculation
Step 9: Calculate the second-level criteria weights
Step 10: Calculate the first-level criteria weights
Phase IV: Equipment evaluation
Step 11: Determine the best and worst solutions
Step 12: Calculate the group utility and individual regret
Step 13: Calculate the aggregating index
Step 14: Rank different equipment systems

Fig. 2. Framework of the proposed method.

A. Phase I: Problem Definition

Step 1: Establish the expert group

Firstly, given the uncertainty inherent in the equipment evaluation problem and the limited information available, it becomes imperative to rely on a group of experts to enhance the reliability and effectiveness of the results. The selection of these experts is conducted considering the following aspects:

1) Expertise of the experts: To ensure the reliability and effectiveness of expert judgments, members of the expert group must possess more than five years of experience in the field of equipment design, production, application, or scientific research.

2) Number of the experts: To ensure the comprehensiveness and rationality of the results, the number of experts should not be too small. After analyzing the problem and consulting previous literature, it is determined that a group of 3-10 experts will be selected for evaluation based on their knowledge.

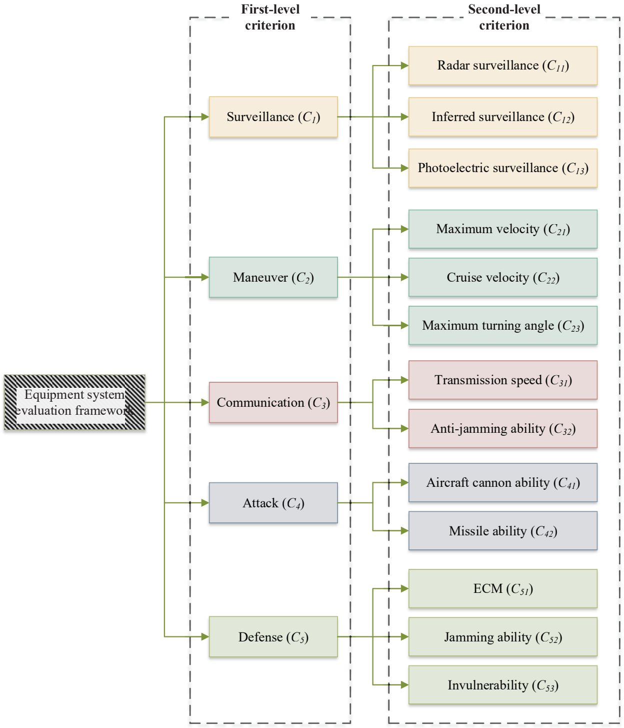
3) Diversity of the experts: To construct a reliable expert group, diversity among the experts is crucial to avoid excessive convergence of opinions. Therefore, experts with different positions, expertise, and experiences are invited, enhancing the objectivity and comprehensiveness of the evaluations.

Step 2: Determine the equipment systems

The primary objective of equipment evaluation is to assess and rank various equipment systems based on their performance. In this step, the expert group collaboratively determines the specific equipment systems that will serve as the foundation for the evaluation process, and the equipment systems are denoted as $A = \{A_1, A_2, \ldots, A_m\}$.

Step 3: Define the evaluation criteria

In the equipment evaluation problem, each equipment system undergoes assessment, taking into account its multifaceted performance. Given the diverse aspects influencing the performance of equipment systems, considering both the capabilities and characteristics becomes crucial for enhancing the reliability and rationality of the results. In this study, a two-level hierarchical evaluation structure is adopted for equipment evaluation, illustrated using the example of an unmanned combat aerial vehicle (UCAV) in Fig. 3.



First-level criterion
Second-level criterion
Equipment system evaluation framewo
Surveillance (C_1)
Maneuver (C_2)
Communication (C_3)
Attack (C_4)
Defense (C_5)
Radar surveillance (C_{11})
Inferred surveillance (C_{12})
Photoelectric surveillance (C_{13})
Maximum velocity (C_{21})
Cruise velocity (C_{22})
Maximum turning angle (C_{23})
Transmission speed (C_{31})
Anti-jamming ability (C_{32})
Aircraft cannon ability (C_{41})
Missile ability (C_{42})
ECM (C_{51})
Jamming ability (C_{52})
Invulnerability (C_{53})

Fig. 3. Two-level hierarchical evaluation structure for unmanned combat aerial vehicle.

In this two-level hierarchical framework, capabilities constitute the first-level criteria, encompassing surveillance (C_1), maneuver (C_2), communication (C_3), attack (C_4), and defense (C_5). Subsequently, ten second-level criteria, representing specific characteristics of the equipment, are defined. For instance, the capability surveillance is subdivided into three subcriteria: radar surveillance (C_{11}), inferred surveillance (C_{12}), and photoelectric surveillance (C_{13}). The capability maneuver entails the UCAV's ability to execute various maneuvers, further divided into three sub-criteria: maximum velocity (C_{21}), cruise velocity (C_{22}), and maximum turning angle (C_{23}). Communication capability comprises two sub-criteria: transmission speed (C_{31}) and anti-jamming ability (C_{32}). The attack capability is delineated by two sub-criteria: aircraft cannon ability (C_{41}) and missile ability (C_{42}). The defense capability encompasses three sub-criteria: ECM (C_{51}), jamming ability (C_{52}), and invulnerability (C_{53}). This hierarchical framework ensures a comprehensive evaluation of the equipment systems.

B. Phase II: Evaluation Collection

Step 4: Define the set of cloud models.

In this step, a set of cloud models is constructed to represent the evaluations, utilizing five evaluation grades within the domain $[0.05, 0.95]$. The linguistic terms employed are $S = \{$"Very low (VL)", "Low (L)", "Medium (M)", "High (H)", "Very High (VH)"$\}$. The transformation between the cloud models and the linguistic terms is detailed in Table I.

TABLE I. TRANSFORMATION AMONG LINGUISTIC TERMS AND CLOUD MODELS

Linguistic terms	Cloud models
Very low (VL)	(0.05,0.033,0.012)
Low (L)	(0.309,0.021,0.008)
Medium (M)	(0.5,0.013,0.005)
High (H)	(0.691,0.021,0.008)
Very high (VH)	(0.95,0.033,0.012)

Step 5: Obtain the linguistic judgments from experts.

In the context of equipment evaluation, multiple experts contribute their judgments in the form of linguistic terms to enrich the comprehensiveness and rationality of the results. Each expert within the expert group is tasked with evaluating each equipment system across the evaluation criteria.

For the equipment evaluation problem, assuming there are m equipment systems, each characterized by n second-level criteria, and involving the perspectives of k experts. Let z_{ij}^t represent the evaluation of the tth expert for the ith equipment system concerning the jth criterion, with $i = 1, 2, \ldots, m$, $j = 1, 2, \ldots, n$, and $t = 1, 2, \ldots, k$. It is important to note that z_{ij}^t denotes the linguistic term from the linguistic term set S and can be converted into corresponding cloud models. The linguistic decision matrix Z^t for the tth expert is derived by synthesizing their linguistic evaluations as Eq. (8):

$$Z^t = \begin{bmatrix} z_{11}^t & z_{12}^t & \cdots & z_{1n}^t \\ z_{21}^t & z_{22}^t & \cdots & z_{2n}^t \\ \vdots & \vdots & \ddots & \vdots \\ z_{m1}^t & z_{m2}^t & \cdots & z_{mn}^t \end{bmatrix} \tag{8}$$

Step 6: Transform linguistic evaluations into cloud models.

For the subsequent evaluation, the acquired linguistic evaluations need to be transformed into cloud models to effectively manage fuzziness and randomness. In this study, cloud models are defined in consideration of linguistic terms. Each linguistic evaluation z_{ij}^t can be equivalently transformed into a cloud model $\tilde{z}_{ij}^t$ using Table I. The cloud decision matrix $\tilde{Z}^t$ is obtained using Eq. (9):

$$\tilde{Z}^t = \begin{bmatrix} \tilde{z}_{11}^t & \tilde{z}_{12}^t & \cdots & \tilde{z}_{1n}^t \\ \tilde{z}_{21}^t & \tilde{z}_{22}^t & \cdots & \tilde{z}_{2n}^t \\ \vdots & \vdots & \ddots & \vdots \\ \tilde{z}_{m1}^t & \tilde{z}_{m2}^t & \cdots & \tilde{z}_{mn}^t \end{bmatrix} \tag{9}$$

Step 7: Determine the weights of experts.

Given the involvement of multiple experts in the evaluation, each with diverse experiences and backgrounds, it is reasonable to acknowledge that they may carry different levels of importance and credibility in their evaluations. Hence, determining the weights of different experts becomes crucial to ensure the reliability of the results. In this study, considering the evaluations provided by the experts, a similarity-based expert weight calculation method is introduced. The process is as follows:

Firstly, the distance between the cloud evaluations of any two pair of experts is calculated using the distance measure in Eq. (10) as:

$$d_{i,j}^{k,l} = d(\tilde{z}_{ij}^k, \tilde{z}_{ij}^l) \tag{10}$$

Then, the similarity between the cloud evaluations of each pair of experts are obtained using Eq. (11):

$$sim_{i,j}^{k,l} = 1 - d_{i,j}^{k,l} \tag{11}$$

and the similarity matrix is constructed as:

$$SMM = \begin{bmatrix} S_{11} & S_{12} & \cdots & S_{1t} \\ S_{21} & S_{22} & \cdots & S_{2t} \\ \vdots & \vdots & \ddots & \vdots \\ S_{t1} & S_{t2} & \cdots & S_{tt} \end{bmatrix} \tag{12}$$

where $S_{kl} = \sum_{i=1}^{m} \sum_{j=1}^{n} sim_{i,j}^{k,l}$.

Next, the support degree of the kth experts is obtained by using Eq. (13) as:

$$Sup_k = \sum_{l=1, l \neq k}^{t} S_{kl} \tag{13}$$

Finally, the weight of each expert is calculated based on the credibility degree, as shown in Eq. (14):

$$w_k = \frac{Sup_k}{\sum_{k=1}^{t} Sup_k} \tag{14}$$

Step 8: Aggregate the evaluations of experts.

In this step, the evaluations of different experts on the equipment system A_i concerning the criterion C_j are aggregated using the CWA operator, resulting in the formation of the aggregated decision matrix in Eq. (16):

$$\tilde{Z} = \begin{bmatrix} \tilde{z}_{11} & \tilde{z}_{12} & \cdots & \tilde{z}_{m1} \\ \tilde{z}_{21} & \tilde{z}_{22} & \cdots & \tilde{z}_{m2} \\ \vdots & \vdots & \ddots & \vdots \\ \tilde{z}_{m1} & \tilde{z}_{m2} & \cdots & \tilde{z}_{mn} \end{bmatrix} \tag{15}$$

where $\tilde{z}_{ij}$ denotes the aggregated evaluation of the ith equipment system regarding the jth criterion, and is obtained by using Eq. (16) as:

$$\tilde{z}_{ij} = CWA(z_{ij}^1, z_{ij}^2, \ldots, z_{ij}^t) \tag{16}$$

C. Phase III: Criteria Weights Calculation

Step 9: Calculate the second-level criteria weights.

In this step, the AHP is employed to determine the weights of the second-level criteria in relation to the first-level criteria. It is essential to note that for the second-level criteria, the calculated weights represent their relative importance within the context of the first-level criteria. In other words, for the five first-level criteria, five sets of sub-criteria weights are calculated and obtained using the AHP.

Step 10: Calculate the first-level criteria weights.

For the first-level criteria, the AHP is employed in this step to determine their weights based on the judgments of experts. The weights assigned to the criteria represent their relative importance in the evaluation process, where a larger criteria weight indicates higher importance.

D. Phase IV: Equipment Evaluation

Step 11: Determine the best and worst solutions.

In this step, the best and worst solutions for each criterion are determined based on their characteristics and aggregated evaluations. It is important to note that the determination of the best and worst solutions may vary depending on whether the criteria are benefit-oriented or cost-oriented, as both types could be involved.

The best solution is obtained as:

$$\rho_j^* = \begin{cases} \max_{i=1,\ldots,m} \tilde{z}_{ij} & C_j \in C_B \\ \min_{i=1,\ldots,m} \tilde{z}_{ij} & C_j \in C_C \end{cases} \tag{17}$$

The worst solution is obtained as:

$$\rho_j^- = \begin{cases} \min_{i=1,\ldots,m} \tilde{z}_{ij} & C_j \in C_B \\ \max_{i=1,\ldots,m} \tilde{z}_{ij} & C_j \in C_C \end{cases} \tag{18}$$

where C_B and C_C denotes the set of benefit criteria and cost criteria, respectively.

Step 12: Calculate the group utility and individual regret.

Using the distance measure, the group utility S_i and the individual regret R_i of the ith equipment system can be obtained by calculating the distance from the ith equipment system to the best solution using Eq. (19) as:

$$\begin{aligned} S_i &= \sum_{j=1}^{n} \omega_j \frac{d(\rho^*, \tilde{z}_{ij})}{d(\rho^*, \rho^-)} \\ R_i &= \max_j \omega_j \frac{d(\rho^*, \tilde{z}_{ij})}{d(\rho^*, \rho^-)} \end{aligned} \tag{19}$$

where ω_j denotes the weights of the jth criterion.

Step 13: Calculate the aggregating index.

The aggregating index of each equipment system is computed by combining the group utility and the individual regret using Eq. (20) as:

$$Q_i = \gamma \frac{S_i - S^-}{S^* - S^-} + (1-\gamma) \frac{R_i - R^-}{R^* - R^-} \tag{20}$$

where $S^* = \max_i S_i$, $S^- = \min_i S_i$, $R^* = \max_i R_i$, $R^- = \min_i R_i$, and γ is the decision coefficient. When $\gamma > 0.5$, it is the strategy of maximum group utility, whereas $\gamma < 0.5$ indicates the strategy of with veto.

Step 14: Rank different equipment systems.

Based on the values of S_i, R_i, and Q_i, the equipment systems can be ranked in descending order, with a higher value indicating better preference. Additionally, to identify the optimal solution, it should satisfy the following condition:

Condition 1: The difference between the first equipment system and the second equipment systems should satisfy Eq. (21):

$$Q(A_{(2)}) - Q(A_{(1)}) \geq \frac{1}{m-1} \tag{21}$$

Condition 2: The optimal equipment system $A_{(1)}$ must be the best one according to S and/or R.

If one of these two conditions is not satisfied, the obtained results are a set of compromised solutions that:

(1) $A_{(1)}$ and $A_{(2)}$ are compromised solutions if Condition 2 is not satisfied.

(2) $A_{(1)}, A_{(2)}, \ldots, A_{(m)}$ are compromised solutions if Condition 1 is not satisfied, where the closeness of $A_{(m)}$ is determined by Eq. (22):

$$Q(A_{(m)}) - Q(A_{(1)}) < \frac{1}{m-1} \tag{22}$$

V. Case Study

In this section, a practical case of unmanned combat aerial vehicle (UCAV) evaluation is presented to illustrate the process and effectiveness of the proposed method.

In recent years, with the rapid development of automation and control technologies, unmanned aerial vehicles (UAVs) have found widespread applications in various fields. Notably, UAVs have become integral in military operations, undertaking missions such as surveillance and combat. With the rise in military UAV applications, UCAVs, specifically designed for combat missions, have garnered attention from researchers and practitioners alike. Given their ability to effectively execute missions like surveillance, search, and assault, UCAVs have become focal points in military operations. Consequently, the evaluation and selection of suitable UCAVs have emerged as crucial concerns. In this study, with a focus on the evaluation and selection of UCAVs for military operations, the proposed method is applied to assess different UCAVs.

Step 1: In this study, the evaluation of various UCAV alternatives is conducted. A panel of three experts from Northwestern Polytechnical University and AVIC is assembled to form the expert group. The experts provide their judgments in the form of linguistic terms, assessing different UCAV alternatives based on their extensive understanding and knowledge. The selected experts, denoted as $E = \{E_1, E_2, E_3\}$, possess significant expertise and experience in the design and operation of UCAVs.

Step 2: Based on the analysis of potential alternatives, seven UCAV alternatives are identified by the experts, denoted as $A = \{A_1, A_2, A_3, A_4, A_5, A_6, A_7\}$.

Step 3: In this study, the two-level evaluation hierarchical framework in Fig 3 is adopted to evaluate the UCAV alternatives.

Step 4: Due to the complexity and uncertainty inherent in the UCAV evaluation problem, experts may not be able to provide precise numerical evaluations. To accommodate this uncertainty and ensure flexibility and reliability in the evaluations, this study employs a linguistic term set with five terms $S = \{VL, L, M, H, VH\}$ to represent expert assessments. The transformation between linguistic evaluations and cloud models is detailed in Table I.

Step 5: Each expert generates a linguistic evaluation based on their understanding of a specific UCAV alternative in relation to a specific criterion. The linguistic evaluations provided by the experts are presented in Table II.

Step 6: Using Table I, the cloud models of the experts judgments can be derived from their linguistic evaluations. Subsequently, the cloud decision matrix for each expert is constructed. Table III provides a summary of the cloud models representing the experts evaluations.

Step 7: In this study, the weights of the experts are determined based on the similarity among them. Firstly, by using Eq. (10)-(13), the similarity matrix of the experts is constructed as:

$$SMM = \begin{bmatrix} 91 & 57.7355 & 54.6704 \\ 57.7355 & 91 & 60.0740 \\ 54.6704 & 60.0740 & 91 \end{bmatrix}$$

Then, based on the similarity matrix, the support degree of each expert could be obtained as:

$$Sup_1 = 112.4058,\ Sup_2 = 117.8095,\ Sup_3 = 114.7444$$

Hence, the weights of the experts are calculated as:

$$w_1 = 0.3259,\ w_2 = 0.2415,\ w_3 = 0.3326$$

Step 8: Utilizing the CWA operator, the aggregated evaluation can be obtained based on the expert weights and the individual decision matrices. The resulting aggregated decision matrix is presented in Table IV.

Step 9: To determine the weights of the sub-criteria, AHP is employed. Pairwise comparison matrices are constructed for different sub-criteria. For instance, the pairwise comparison matrix for sub-criteria under the surveillance capability is constructed as:

$$\begin{bmatrix} 1 & \frac{1}{5} & \frac{1}{3} \\ 5 & 1 & 3 \\ 3 & \frac{1}{3} & 1 \end{bmatrix}$$

Then, by using the AHP, the local weights of the sub-criteria are calculated as:

$$\omega_{11} = 0.6370,\ \omega_{12} = 0.1047,\ \omega_{13} = 0.2583$$

Similarly, by using the AHP, the local weights of the sub-criteria could be obtained, as listed in Table V.

Step 10: Similarly, by using the AHP, the weights of the first-level criteria could be obtained as:

$$\omega_1 = 0.1290,\ \omega_2 = 0.0634,\ \omega_3 = 0.0333, \\ \omega_4 = 0.5128,\ \omega_5 = 0.2615$$

Thus, the global weights of different second-level criteria could be obtained, as shown in Table V.

Step 11: Upon analyzing the criteria, it is observed that all criteria are benefit criteria. Hence, the best and worst solutions for each criterion can be obtained using Eq. (18) and (19). The results are listed in Table VI.

Step 12: By using the distance measure, the group utility and the individual regret of each equipment system could be obtained, and the results are listed in Table VII.

Step 13: By combining the results of the group utility and the individual regret, the aggregating index of each equipment system can be computed. In this case, the decision coefficient γ is set to 0.5, and the results are shown in Table VIII.

Step 14: Based on the aggregating index of the UCAVs, the UCAVs can be ranked in descending order, and the results are listed in Table VIII. It is noteworthy that both Conditions 1 and 2 are satisfied. Therefore, the obtained results constitute the optimal solution, and the ranking of the UCAVs can be determined as $A_6 \succ A_7 \succ A_5 \succ A_3 \succ A_2 \succ A_4 \succ A_1$, where A_6 is identified as the best UCAV alternative.

VI. Results and Discussions

In this study, a novel MCDM approach based on cloud model and VIKOR method is proposed for equipment evaluation, and the proposed method is validated through a practical case of UCAV evaluation. In this section, in order to further validate the proposed method, the results are further analyzed and discussed.

A. Sensitivity Analysis

In the proposed method, the decision coefficient γ is used to determine the preference of the final results, where $\gamma > 0.5$ indicates “maximum group utility” and $\gamma < 0.5$ indicates “with veto”. To better analyze the effects of the decision coefficient on the final results, a sensitivity analysis is conducted in this section.

In this analysis, the value of γ varies from 0 to 1, and the proposed method is utilized to evaluate the same set of UCAV alternatives. The results are illustrated in Fig. 4.

From Fig. 4, it can be observed that as the decision coefficient changes from 0 to 1, there are variations in the ranking of the alternatives. Specifically, the optimal alternative would vary from A_6 to A_7, and this variation is caused by the fact that A_6 outperforms A_7 in individual regret, while it

C_{52}	$(0.9480, 0.0330, 0.0120)$	$(0.0499, 0.0330, 0.0120)$
C_{53}	$(0.9480, 0.0330, 0.0120)$	$(0.3083, 0.0210, 0.0080)$

is inferior to A_7 in group utility. As the decision coefficient varies, the preference of the final results changes from "with veto" to "maximum group", leading to the preference of A_7. Nevertheless, it is worth noting that in all cases, both condition 1 and condition 2 are satisfied. In other words, the obtained results are optimal solutions. Therefore, from the results of the sensitivity analysis, it can be concluded that the decision coefficient could directly affect the results of the case; however,

TABLE VII. GROUP UTILITY AND INDIVIDUAL REGRET OF THE EQUIPMENT SYSTEMS

Alternative	Group utility	Individual regret
A_1	0.8551	0.3295
A_2	0.8792	0.3295
A_3	0.8882	0.3295
A_4	0.8689	0.3295
A_5	0.8607	0.3542
A_6	0.9044	0.3846
A_7	0.9317	0.3542

TABLE VIII. EVALUATION RESULTS OF THE EQUIPMENT SYSTEMS

Alternative	Aggregating index	Ranking
A_1	0	7
A_2	0.1573	5
A_3	0.2158	4
A_4	0.0902	6
A_5	0.2610	3
A_6	0.8217	1
A_7	0.7243	2

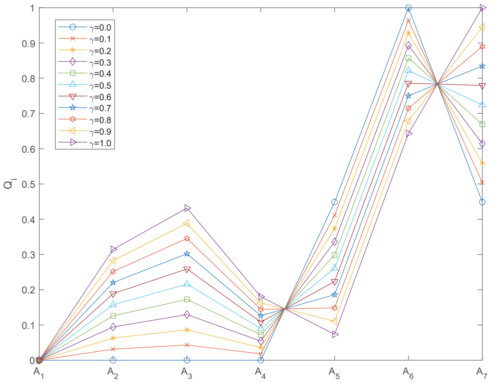

Fig. 4. Sensitivity analysis results.

it can be guaranteed that the obtained results are optimal, demonstrating the effectiveness and robustness of the proposed method.

B. Comparative Analysis

In order to further show the effectiveness and reliability of the proposed method, the ranking result of the proposed method is compared with those of other comparative methods, including VIKOR, TOPSIS, MULTIMOORA, cloud TOPSIS, and cloud MULTIMOORA, and the results are listed in Table IX.

TABLE IX. COMPARATIVE ANALYSIS RESULTS

Method	Ranking
TOPSIS	$A_6 \succ A_7 \succ A_4 \succ A_2 \succ A_3 \succ A_5 \succ A_1$
MULTIMOORA	$A_6 \succ A_7 \succ A_3 \succ A_2 \succ A_4 \succ A_5 \succ A_1$
VIKOR	$A_6 \succ A_3 \succ A_7 \succ A_5 \succ A_2 \succ A_4 \succ A_1$
Cloud TOPSIS	$A_6 \succ A_5 \succ A_3 \succ A_7 \succ A_4 \succ A_2 \succ A_1$
Cloud MULTIMOORA	$A_6 \succ A_7 \succ A_2 \succ A_5 \succ A_3 \succ A_4 \succ A_1$
Proposed method	$A_6 \succ A_7 \succ A_5 \succ A_3 \succ A_2 \succ A_4 \succ A_1$

From the results in Fig. 5, it is evident that alternative A_6 consistently emerges as the optimal choice across all evaluation methods. This consistent outcome underscores the effectiveness and reliability of the proposed method, as the optimal alternative identified aligns with the conclusions drawn by other methods. It is noteworthy, however, that the ranking results of the comparative methods do not always mirror those of the proposed method, particularly for certain lower-ranked alternatives. This discrepancy can be attributed to variations in criteria weights and evaluation representations employed by different methods. In summary, the reliability and rationality of the proposed method receive further validation through comparative analysis, with its results generally finding support from other evaluation methods. The specific ranking outcomes from the comparative analysis are visually presented in Fig. 5.

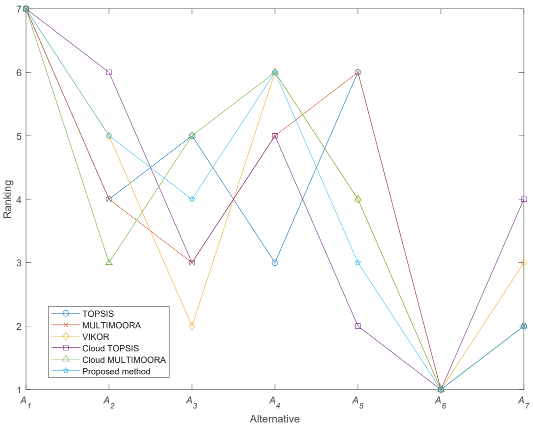

Fig. 5. Comparative analysis results.

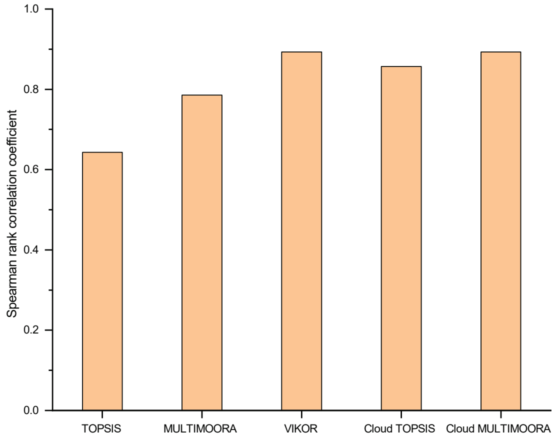

Fig. 6. Spearman's ranking correlation coefficient.

To further assess the consistency and reliability of the proposed method, a consistency test on the ranking results is conducted. Spearman's rank correlation coefficient is employed to gauge the consistency among the comparative methods, and the results are depicted in Fig. 6. The rank correlation coefficients between the proposed method and the comparative methods are calculated as $(0.6429, 0.7857, 0.8929, 0.8571, 0.8929)$. These correlation coefficients, being close to $+1$, signify a robust positive correlation among the methods. In simpler terms, the results of the proposed method are well-supported by the outcomes of the comparative methods. This high level of consistency further validates the effectiveness and reliability of the proposed method. Moreover, the advantages of the proposed method, as highlighted through comparative analysis, can be summarized as follows:

(1) In contrast to TOPSIS, MULTIMOORA, and VIKOR, the proposed method is developed based on the cloud model rather than crisp numbers. Given the inherent fuzziness and randomness in equipment evaluation problems, the cloud model provides a more reliable and effective means of modeling uncertain information, thereby enhancing the overall reliability of the proposed method.

(2) The proposed method incorporates an objective expert weight calculation method to determine the relative importance of different experts. Considering the varying experiences and knowledge of experts, the proposed method employs a similarity-based expert weight calculation method, enhancing the reliability and rationality of expert weight calculations. Comparative methods lack a comparable process to support expert weight calculation.

(3) The proposed method systematically considers a two-level hierarchical structure for equipment system evaluation, utilizing the AHP to determine criteria weights. By incorporating expert judgments on the relative importance of different criteria, the proposed method ensures that obtained results are both reasonable and reliable.

(4) The proposed method integrates group utility, individual regret, and aggregating index to derive the optimal solution that satisfies predefined conditions. The optimal solution consistently demonstrates superior performance and lower regret in most cases, enhancing the overall reliability and effectiveness of the results. The comparative analysis reinforces that the proposed method yields more reasonable and reliable outcomes.

C. Discussion

In this study, focusing on the equipment evaluation problem, a cloud-VIKOR-based MCDM method is proposed. A practical case of UCAV evaluation and selection is studied by using the proposed method, where A_6 is identified as the optimal UCAV considering thirteen criteria. The results are then validated through sensitivity analysis and comparative analysis. From the results, the following implications could be obtained:

(1) In equipment evaluation problem, the consideration of multiple criteria is necessary to ensure the balanced and comprehensive evaluation results. Moreover, due to the different characteristics of these criteria, it is impractical to assume them to have the same importance. To this end, this study considers thirteen different criteria from four aspects for equipment evaluation and utilizes the AHP to determine criteria weights, thus enabling more reliable results.

(2) For equipment evaluation, one of the most crucial characteristics is the inherent uncertainty and complexity within the problem. Cloud model, as an effective tool to convert qualitative judgments into quantitative data, could serve as a useful means to represent the uncertain information in equipment evaluation. Hence, the employment of cloud model in this study could enhance the reliability and rationality of the results.

(3) The evaluation of different equipment systems should be based on various indicators rather than simply the overall utility, and the consideration of group utility and individual regret at the same time could enhance the effectiveness of the results. Therefore, this study adopts the VIKOR method with cloud model for equipment evaluation considering different indicators, thus increasing the effectiveness of the proposed method.

VII. Conclusion

In this study, a decision-making approach for equipment evaluation based on cloud models is proposed. The method integrates the AHP and the VIKOR method within a unified framework employing cloud models. The cloud model is utilized to represent the evaluation of various equipment systems, accommodating the inherent fuzziness and randomness of information. A similarity-based method is employed to calculate expert weights, and the AHP is leveraged to determine criteria weights. Then, the VIKOR method is extended with cloud models to assess and rank diverse equipment systems. The results show that the proposed method provides a novel and effective way for equipment evaluation under uncertainty. In conclusion, this study contributes to the literature in the following ways:

(1) Introduction of a novel equipment evaluation method that considers the fuzziness and randomness of results. By utilizing cloud models to represent uncertain expert evaluations, the method provides reliable and reasonable assessments.

(2) Extension of the VIKOR method with cloud models, presenting the cloud VIKOR method. This extension broadens the application domain of the VIKOR method by incorporating cloud models to represent uncertain information, enhancing reliability compared to the conventional VIKOR method.

(3) Proposal of a comprehensive framework for equipment evaluation, considering both capability and characteristics of equipment systems. A two-level hierarchical evaluation structure is introduced to support the evaluation process, and the AHP is integrated with the cloud VIKOR method to produce more reliable and comprehensive results.

However, this study has some limitations. Firstly, a group of three experts is considered for evaluating different UCAV alternatives. While prior research suggests the efficiency of three experts for such problems, future investigations might explore the inclusion of more experts. Secondly, considering the substantial uncertainty and randomness in equipment evaluation, developing a more reliable cloud model construction framework is a potential avenue for future research.

Abstract—**Occupational diseases present a significant global challenge, affecting a vast number of workers. Accurate prediction of occupational disease incidence is crucial for effective prevention and control measures. Although deep learning methods have recently emerged as promising tools for disease forecasting, existing research often focuses solely on patient body parameters and disease symptoms, potentially overlooking vital diagnostic information. Addressing this gap, our study introduces a Deep Graph Convolutional Neural Network (DGCNN) designed to detect occupational diseases by utilizing demographic information, work environment data, and the intricate relationships between these data points. Experimental results demonstrate that our DGCNN method surpasses other state-of-the-art methods, achieving high performance with an Area Under the Curve (AUC) of 96.2%, an accuracy of 98.7%, and an F1-score of 75.2% on the testing set. This study not only highlights the effectiveness of DGCNNs in occupational disease prediction but also underscores the value of integrating diverse data types for comprehensive disease diagnosis.**

Keywords*—*Occupational disease diagnostics; heterogeneous data; imbalanced data; Graph Convolutional Network (GCN); deep graph convolutional neural network

I. Introduction

Occupational diseases has been a major concern for many years, which are caused by harmful working conditions and production processes that affect the health of workers. Before the common era, Hippocrates (460-377 BC) discovered lead poisoning. In the first century, Pliny the Elder discovered the harmful effects of dust on the human body. In the second century, Galen described the diseases that miners suffered from. In the following centuries, mercury poisoning and other occupational diseases were discovered.

The best way to prevent and control occupational diseases is to detect them early. If dangerous occupational diseases are not detected and treated in time, they can cause permanent damage to humans or even death. However, currently, in developing countries, such as Vietnam, the examination and detection of occupational diseases are still limited. Thousands of workers are usually routinely screened in batches to detect disease or the risk of disease. To screen for the risk of occupational diseases, workers are first examined in general through clinical signs, such as questioning, studying medical records, etc. If it is determined that there is a risk of occupational diseases, workers will be prescribed in-depth paraclinical tests, such as chest X-ray, hearing test, FEV1 pulmonary function test, etc. However, due to the small number of occupational disease doctors, the examination of thousands of workers at the same time leads to low efficiency, long waiting time, and expensive costs. Therefore, a solution for early detection of the risks of occupational diseases is necessary.

Owning to the development of machine learning, many methods have been proposed for disease diagnosis, including K-nearest neighbors (KNN), support vector machines (SVM), random forests (RF), and artificial neural networks (ANN), CNN, RNN [1], [2], [3], [4]. Although these studies have achieved promising results in disease diagnosis, they are difficult to apply in practice due to their strict data requirements. The data must be complete and have a common structure for all patients, which is often not the case with medical data. Such data is often incomplete and heterogeneous among patients.

Recently, the rise of Graph Neural Network has made it easier to solve problems related to heterogeneous data like medical data. The network treat each data sample as a graph with nodes representing the relevant features of the sample. The model then uses the data from the nodes and the relationships between them to synthesize the output data and label the sample. The idea of using GCNs for disease diagnosis is similar [5]. Each patient is treated as a graph with nodes representing the patient's features. The nodes are connected to each other based on the relationships between them. The output data is then synthesized based on the nodes and the relationships between them. In GCNs, each graph does not need to be the same as the other graphs. This means that feature selection is not necessary. This means that important features will not be lost. This model increases the flexibility of the model in processing data. We can also expand and upgrade the dataset arbitrarily without fear of the model failing.

In this paper, we propose the use of a deep graph convolutional neural network (DGCNN) for disease diagnosis. DGCNNs are a type of neural network that is designed to work with graphs. Graphs are a natural way to represent data that has relationships between the data points. For example, a graph can be used to represent the relationships between genes in a genome, or the relationships between symptoms in a disease [6].

DGCNNs have been shown to be effective for a variety of tasks that involve graphs, including image classification and natural language processing. In this paper, we show that DGCNNs can also be used for disease diagnosis. We use a DGCNN to learn the relationships between symptoms and diseases, and then use the learned relationships to predict the disease for a new patient

II. Related Works

The study focuses primarily on the methods of disease diagnosis based on a number of machine learning (ML) algorithms, so in this section, some studies using medical records to diagnose the disease of the subject will be mentioned.

In principle, disease diagnosis is based on a dataset of many patients with relevant information fields related to the disease diagnosis process. The data that affect the diagnosis of the disease, so it needs information related to the patient's health: weight, body mass index, glucose quantification, etc.

Recently, the problem of disease diagnosis is often approached using classical ML algorithms specialized for labeling problems. With the increasingly development of deep learning (DL) algorithms along with their versatility and convenience, these methods are gradually being used in many different types of problems, including disease diagnosis. However, these classical methods all have a common drawback that they are very much affected by the dataset as well as the weaknesses of the dataset. The lack of many important information fields or unbalanced data is very likely to negatively affect the performance of the diagnostic model.

In the past, most studies in the field of disease prediction have been approached using simple modern machine learning methods such as Naive Bayes, K-Nearest Neighbors (KNN), Decision Tree, or more ancient methods such as traditional statistical methods [7]. In statistical methods, the predictor will rely on the statistical parameters and charts of the dataset to make a judgment. This method has a big disadvantage that the result depends on the predictor and the data. If the dataset is not good and the predictor does not have much experience, the result is very likely to be inaccurate.

Naive Bayes is a simple classification model that is easy to install and has a fast processing speed. However, it has a big disadvantage that it requires the input features to be independent, i.e. the information fields do not have a relationship with each other. This is difficult to happen in reality and will reduce the quality of the model.

KNN is the simplest and easiest-to-use labeling algorithm. The model uses the K coefficient to identify the K nearest samples to the object and then uses the labels of these samples to proceed with the classification for the object to be predicted. The most obvious advantage of this model is that it does not take time for the training process. However, for large datasets, the algorithm takes more time for the calculation process. KNN is very sensitive to noise when the K coefficient is small. The performance of the model depends largely on the quality of the dataset and the K coefficient.

It was not until Deep Learning, a subfield of machine learning, became popular, that disease diagnosis problems were applied to this method. These types of models have the same installation and operation process, they will all use the input dataset to proceed with the training model, the data is split or repeated several times to improve the model after each training. In other words, Deep Learning models allow it to self-learn and improve its accuracy, hence achieving high accuracy. For example, Mohammed Ismail and colleagues [8] presented a deep learning technology in the diagnosis of heart disease by using an artificial neural network (ANN) model. Junaid Rashid and colleagues [9] last year also proposed the ANN model and compared its efficiency with traditional machine learning models. Or most recently, the paper on the application of advanced deep learning models using two models simultaneously CNN and LSTM also in the problem of heart disease diagnosis of Sudha and Kumar [10] .

GCN models actually appeared early, however, they have not been widely applied due to their complexity and difficulty in installation, requiring users to have a certain understanding in the field of Deep Learning [11], [12], [13]. In 2019, Ping Xuan and colleagues successfully applied a model combining GCN and CNN (Convolutional Neural Network) in the diagnosis of IncRNA disease [14] . Recently, Haohui Lu and Shahadat Uddin also presented on the application of GNN (Graph Neural Networks) in the field of disease diagnosis based on electronic data [15]. These models take advantage of the relationship between objects to build a network of relationships between them, so when predicting a sample, the model not only relies on the information fields of that sample but can also use the information fields of other samples related to the sample to be labeled, unlike the old methods, which can only use the unique attributes of the sample to predict the result of that sample.

GCNs have many advantages in the field of disease prediction, but they also have some limitations. All of these models require the design and structure of a graph of relationships between samples or between attribute fields. This requires users to have a deep understanding of the problem as well as the relationships in the dataset. Poorly constructed relationship graph can also reduce the accuracy of the model by not only not taking advantage of important information but also creating noise. The dataset also needs to have enough samples, if not, it will not take advantage of the strengths of the GCNs model because the relationship diagram is too small, with few relationship edges. A large graph means that the model is more complex, making it difficult for users to visualize or fully understand the model.

Methods using GCNs are showing to be effective in disease diagnosis problems than traditional machine learning methods. These models take advantage of the understanding of the dataset as well as the ability to reuse data in the prediction process. However, current methods require users to design the relationship graph for the entire dataset, requiring a deep understanding of the problem. This makes the model very complex and difficult to control. With the DGCNN [6] model, we consider each sample as a graph with child nodes as attribute fields and edges as relationships between them. Thus, we only need to initialize the relationship diagram frame for each sample without having to design the total link diagram between samples. However, this does not reduce the ability to take advantage of the relationships between samples, on the contrary, it makes the model more clear and easy to understand.

These studies have shown the ability of ML algorithms in diagnosing diseases based on medical records. However, these studies still have some limitations, such as:

The datasets used in these studies are small in scale, so the results of these studies may not be well generalized to larger datasets. These studies primarily use classical ML models, so these models may be affected by the weaknesses of the dataset. In the future, studies on disease diagnosis based on medical records need to use larger datasets and newer ML models to improve the accuracy of diagnostic models.

III. Material and Methods

In this study, we focus on occupational disease data, which is typically heterogeneous and lacks explicit information. Imputing missing data with arbitrary values can hinder model training performance due to discrepancies between imputed and actual values. In this context, with missing data, traditional methods that often rely on statistical models do not explicitly capture the relationships between different features.

GCNs, on the other hand, are well-suited for modeling complex relationships between data points. This makes them a promising approach for occupational disease forecasting, where the data is inherently complex and interrelated.

This challenge can be effectively addressed by employing a graph-based data structure, such as the Graph Convolutional Network (GCN). GCNs have demonstrated their ability to construct relational graphs from individual health records and transform the data into a format that excludes missing values.

Therefore, we propose a novel approach to occupational disease forecasting using graph convolutional neural networks (GCNN). Our approach synthesizes information related to body parameters, working environments, and disease symptoms to predict the likelihood of a worker developing an occupational disease.

In our approach, we define the relationships between different features in terms of their level of influence and correlation. We then use this information to calculate and adjust the data field values before using them for prediction. This allows us to better capture the complex relationships between features and improve the accuracy of our predictions.

Considering the importance of the working environment in occupational disease prediction, we also combined such information with patient's medical reports to build our GCNN. Inspired by the work of [6], we propose a new deep graph CNN (DGCNN) to deal with such complex data. We have updated the network to increase the number of units in each layer. Besides, the new architecture allow us in better handling the input data, avoiding underfitting and reducing the training cost.

To handle inconsistent and insufficient data, we organize each patient's medical report as an information graph network. After the data runs through the graph network, we concatenate the outputs generated from the last graph layer. These are then passed to two fully connected and dropout layers before diagnosing whether the patient is sick or not.

In the next section, we will present in detail the used features and the architecture of our proposed network.

A. Data Selection and Re-sampling

This study utilizes health data primarily derived from subjects' self-reported information and health measurements compiled into reports. This inherent data structure introduces the potential for missing values due to incomplete reporting or subject uncertainty. While some fields with high missing rates may not directly influence the outcome variable, they could still exhibit subtle relationships with other factors, making traditional data cleaning processes cumbersome.

To address these challenges, we leverage DGCNN architecture. Unlike conventional approaches that establish relationships between subjects, DGCNN treats each data sample as a relational graph composed of the individual data fields associated with that subject. This allows us to utilize data samples regardless of their inherent structure, eliminating the need for extensive data cleaning.

To implement DGCNNs effectively, we define a relational graph for each data point. Since not all data categories share inherent relationships, the only object each category is directly connected to is its corresponding subject (through the sample ID). We further refine the graph by connecting categories that exhibit apparent relationships based on domain knowledge. This approach leverages the inherent structure of the data without requiring pre-defined relationships between subjects, making it particularly well-suited for our heterogeneous dataset.

While DGCNN's data structure allows it to handle imbalanced data to some extent, we further improve model training performance by applying re-sampling techniques to the training dataset. Due to the disparity in data sets and the variable feature shapes across different samples, we cannot apply re-sampling algorithms that rely on the original data to generate new data, like Condensed Nearest Neighbors or SMOTE [16]. Instead, we employ two methods to address such class imbalance, including Random Under Sampler for undersampling [17] and Random Over Sampler for over-sampling [18] [19].

Consequently, we propose two DGCNN models, each using a different type of re-sampling method: one with Random Over Sampling (DGCNNv1) and another with Random Under Sampling (DGCNNv2). This allows us to compare the impact of different re-sampling approaches on model performance in the context of imbalanced data and identify the most effective strategy for our specific dataset.

B. Deep Graph Convolutional Neural Network for Occupational Disease Detection

The first DGCNN architecture, named DGCNNv1 as illustrated in Fig. 1, employs Random Over-sampling to achieve a balanced class distribution with a 1:10 ratio. This technique retains all samples from the majority class while duplicating instances from the minority class until the desired ratio is reached. DGCNNv1 utilizes a DeepGraphCNN layer as its core component, encompassing four child GCN layers. Each GCN layer has a size of 256 channels, except the final layer, which has only one channel and solely serves a sorting purpose. The output tensor from this DeepGraphCNN layer has 400 rows.

The output of the DeepGraphCNN layer is fed into a convolutional layer with 128 channels. Since this layer primarily synthesizes data from the first layer, its kernel size and stride are set equal to the sum of the DGCNN layer channels. Subsequently, a MaxPool and a Dropout layer are applied. Following the data synthesis from the first layer, a new Conv1D layer is introduced as a feature extractor. The network output is then flattened to a single dimension for processing

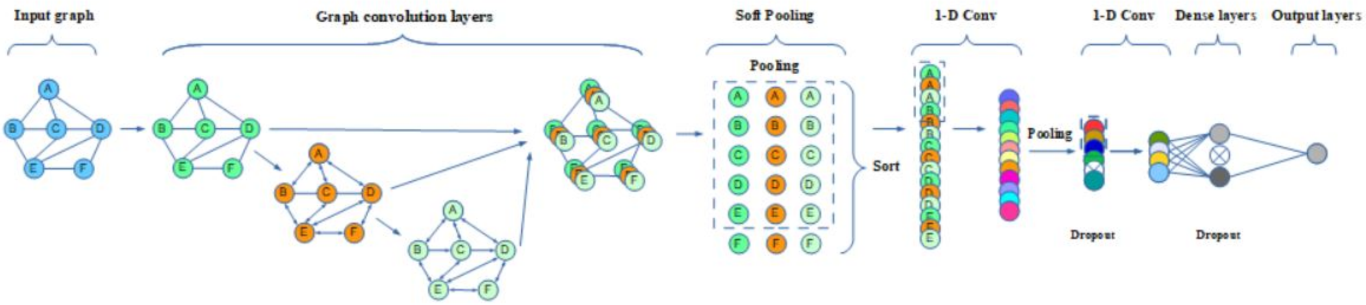

Fig. 1. DGCNN V1 model architecture.

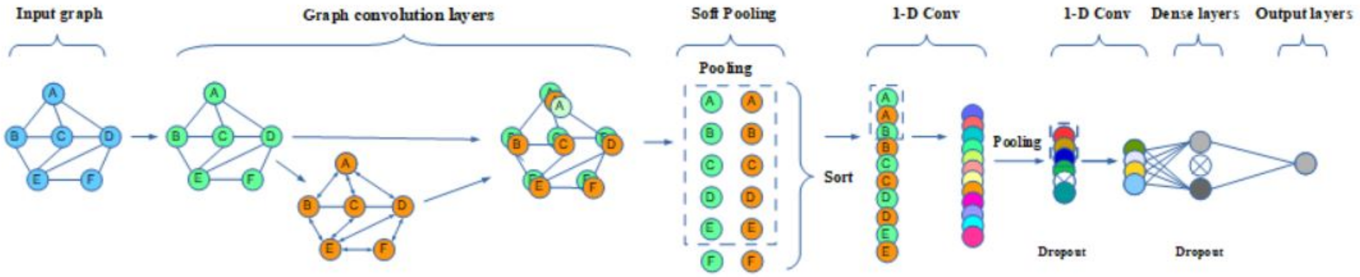

Fig. 2. DGCNN V2 model architecture.

by two consecutive Dense layers. These layers employ ReLU and Sigmoid activation functions, respectively (Table I).

TABLE I. DETAILED DGCNN V1 NETWORK

	Deep Graph CNN	
Layer	Configuration	Output
DGCNN	k: 400 layer size: [256, 256, 256, 1] activations: [tanh,tanh,tanh,tanh]	256x256x256
	CNN	
Conv1D	kernel: 769 stride: 769 chanel: 128	400x128
MaxPool1D	pool size: 2	200x128
Dropout	rate: 0.1	200x128
Conv1D	kernel: 50 stride: 1 chanel: 256	150x128
Flatten	In: 150x128	19200
Dense	units:512, ReLU	512
Dropout	rate: 0.1	512
Dense	units:1, Sigmoid	1

The second proposed model, DGCNNv2 as presented in Fig. 2, shares a similar structure with DGCNNv1. However, all settings are adjusted to accommodate the training dataset that has been pre-processed with Random Under-sampling to achieve a 5:100 class ratio. Under-sampling serves the same purpose as over-sampling but instead of replicating the minority class, it removes samples from the majority class to achieve the desired ratio (Table II).

Considering the reduced size and significantly higher negative label rate of the under-sampled training data, DGCNNv2 implements several modifications to prevent overfitting and decrease training costs. To mitigate the risk of overfitting, where nearly all predictions become negative, one child GCN layer is removed from the DeepGraphCNN layer. Additionally, the number of output rows in the DeepGraphCNN layer is reduced to 135, and the size of the GCN layers is lowered to 128.

Furthermore, DGCNNv2 adopts a convergent architecture for the data synthesis layer, where the size of each hidden layer progressively decreases. Additionally, the Dropout rate is increased from 10% to 20% to further prevent overfitting.

C. Features and Fusion

We utilize four types of features extracted from patients' medical reports:

- Subject's body parameters: These are mainly single, linear values representing various physiological measurements.
- Workplace information: Categorical data describing the patient's work environment and potential occupational hazards.
- Habits: Categorical data capturing the patient's lifestyle choices and habits.
- Disease symptoms: Both visible and invisible symptoms reported by the patient, classified as categorical data.

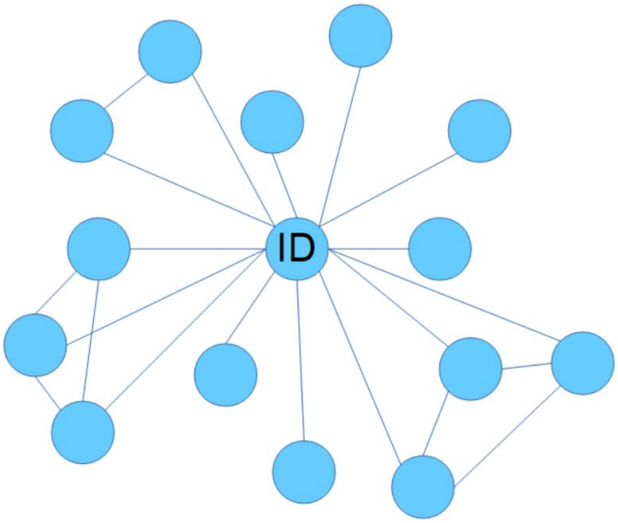

Fig. 3. Relationship graph architecture.

These features are collected from hospital-generated medical reports, ensuring data consistency and quality. While body parameters are primarily numerical, the remaining features are categorized, allowing them to adapt their scope based on the number of unique values encountered.

To effectively capture the relationships between these features, we reorganize the patient data into an adjacency matrix, represented as a relational graph. Each graph comprises nodes and edges corresponding to individual data points and their relationships. The unique patient ID serves as the root node, distinguishing each subject. This root node connects to the four aforementioned feature categories.

Furthermore, we define edges between relevant features to capture intricate relationships. For example, if a patient reports chest pain, we also have information about the pain level, location, duration, and contributing factors. By establishing edges between these nodes, we enable information propagation within the graph, allowing each node to leverage the information contained within its neighbors. The resulting graph structure is similar to the illustration in Fig. 3.

TABLE II. Detailed DGCNN V2 Network

Deep Graph CNN		
Layer	Configuration	Output
DGCNN	k: 135 layer size: [128, 128, 1] activations: [tanh,tanh,tanh]	128x128
CNN		
Conv1D	kernel: 257 stride: 257 chanel: 256	135x256
MaxPool1D	pool size: 2	67x256
Dropout	rate: 0.2	67x256
Conv1D	kernel: 50 stride: 1 chanel: 128	18x128
Flatten	In: 18 x 128	2304
Dense	units:64, ReLU	64
Dropout	rate: 0.2	64
Dense	units:1, Sigmoid	1

TABLE III. Demographic Information, Perceived Symptoms Symptoms and PPE of Studied Subjects

	Healthy	Positive
Demographic information		
Age (Average)	42.6	52.3
Gender (Male/Female)	6379/1440	173/33
Seniority (year)	10.7	20.6
Perceived symptoms		
Cough	1700	149
Sputum	1638	150
Dyspnea	766	144
Chest pain	845	151
Nasal discharge	685	39
Hoarseness	563	36
Wheezing	262	21
Tiredness	982	105
Weight loss	358	30
Personal Protective Equipment (PPE)		
Helmet (Yes/No)	6275/1544	184/27
Boots	6413/1406	167/44
Gauze mask	7553/266	207/4
Gloves	6396/1423	155/56
Goggles	3184/4635	117/94
Employment insurance	6930/889	188/23

These graphs are then utilized for feature extraction. Spatial graph convolutions are applied to extract vertex features, followed by a SortPooling layer to arrange them in a consistent order. This process generates a sorted graph representation with a fixed size, enabling Convolutional Neural Networks to efficiently process and learn from the data in a consistent manner [16].

IV. Experiment and Discussion

A. Dataset

The dataset utilized in this study consists of 8,030 samples. Each sample includes a binary output class indicating whether the subject is healthy or diagnosed with an occupational disease. The dataset exhibits a significant class imbalance, with 7,819 negative (healthy) samples and 211 positive (ill) samples, resulting in an output data ratio of 37:1. To address this imbalance, we employed appropriate data pre-processing techniques for each model, as detailed in the corresponding experiments.

Prior to model training, the dataset was split into two subsets: 70% for training and 30% for validation. The entire original dataset is used for testing to provide a comprehensive evaluation of the models' performance. Table III presents detailed demographic and clinical information about the subjects included in the study.

B. Pre-processing

Given the heterogeneity and imbalance of medical data, thorough pre-processing is crucial for such studies. To address these challenges, we implemented a comprehensive pipeline focusing on data cleaning, missing value handling, and class imbalance correction.

Firstly, to ensure optimal training performance, we cleaned the dataset by removing 39 empty columns (0.17%) lacking informative value. For remaining fields with missing data, we employed appropriate imputation techniques based on data type and context, preserving valuable information while minimizing bias. Notably, we retained encoded fields with numerous unique values, acknowledging their potential noise but opting for alternative mitigation strategies during training to capitalize on their valuable information.

Secondly, to address the class imbalance (3 positive to 112 negative samples), we employed the Condensed Nearest Neighbors [20], [21], [22] under-sampling technique from Imbalanced-learn. This approach strategically removed redundant majority class samples while preserving all minority class data, resulting in a more balanced 3:7 ratio. This balanced dataset facilitated fair model evaluation and prevented potential bias towards the dominant class, ensuring accurate and reliable predictions for both positive and negative cases.

Moreover, to enable a fair comparison with traditional machine learning models, we adapted our pre-processing pipeline to their specific needs. While DGCNNs handle diverse data formats, traditional models require homogeneous input. We therefore employed additional data cleaning steps, including imputing missing values with context-aware techniques and limiting the data to fields with less than 50% missing data to ensure sufficient information for traditional model training (Table IV).

TABLE IV. Detailed Graph Information

Graph statistic	
Nodes (max)	147
Nodes (min)	88
Nodes (avg)	107.77
Edges (max)	172
Edges (min)	94
Edges (avg)	119.28
Graphs	8030

C. Experiment Setup

To comprehensively evaluate the proposed method and compare the effectiveness of the DGCNN models against other popular approaches (KNN, SVM, ANN, and LSTM), we conducted six distinct experiments detailed in Table V. Each experiment followed a three-stage pipeline:

- Re-sampling: Recognizing the inherent class imbalance in the dataset, as shown in Fig. 4 and 5, we employed targeted re-sampling techniques to ensure fair model evaluation. For KNN, SVM, ANN, and LSTM models, we utilized Condensed Nearest Neighbor (CNN) under-sampling from Imbalanced-learn, as illstrated in Fig. 7. This technique carefully selected minority class samples and strategically removed redundant majority class data, resulting in a balanced 3:7 ratio. For DGCNNv1 and v2, we opted for Random Under-sampling, maintaining all minority class samples while randomly eliminating a portion of the majority class to achieve a 5:100 ratio. This choice leveraged the DGCNNs' ability to handle imbalanced data more effectively due to their graph-based nature, as shown in Fig. 6.
- Training Model: Each model was trained with the re-sampled dataset using optimized hyperparameters determined through grid search. For DGCNNs, this included configuring graph convolutional layers, activation functions, and learning rates. The goal was to achieve optimal performance with minimal overfitting.
- Evaluating Output Model: We assessed the performance of each model using a set of relevant metrics including precision, recall, F1-score, and balanced accuracy. This provided a comprehensive picture of each model's effectiveness in identifying occupational disease cases, considering both positive and negative predictions.

TABLE V. Six Experiments with Different Inputs and Networks

Exp	Re-sample method	Train/test ratio	Model	Others
1	CNN Condensed Nearest Neighbour	5:5	KNN	k: 5
2	CNN Condensed Nearest Neighbour	5:5	SVM	gamma:1/109
3	CNN Condensed Nearest Neighbour	5:5	ANN	learn rate: 0.001 batch size: 64 epoch: 50
4	CNN Condensed Nearest Neighbour	5:5	LSTM	learn rate: 0.001 batch size: 64 epoch: 50
5	Random Under Sampler Ratio: 0.3	7:3	DGCNN V1	learn rate: 0.0005 batch size: 100 epoch: 100
6	Random Under Sampler Ratio: 0.05	7:3	DGCNN V2	learn rate: 0.001 batch size: 100 epoch: 150

This structured approach, coupled with specific re-sampling strategies tailored to each model type, allowed us to conduct a rigorous and fair evaluation of our proposed method compared to established tools. The results, presented in Table V and further analyzed in subsequent sections, reveal valuable insights into the effectiveness of DGCNNs for analyzing medical data with its inherent complexities..

The experiments leveraged the computational power of a 4 GB NVIDIA Quadro M2200 GPU and an Intel(R) 2.8 GHz Xeon(R) microprocessor, running TensorFlow 2.10.0 and StellarGraph Framework 1.2.1[23] under Python 3.9.12, to implement and train the various models. This framework enabled efficient execution of the DGCNN algorithms, while the powerful GPU-CPU combination facilitated smooth pre-processing and data analysis tasks.

We used the following parameters and techniques for training our models:

- The model was compiled using a binary cross-entropy loss function.
- For optimization, an Adam optimizer was employed with $\beta 1$ = 0.9, $\beta 2$ = 0.999, and ϵ = 1e-07. The initial learning rate was adjusted to optimize each model.
- The batch size for the ANN and LSTM models was set at 64 to minimize the cost function. For all DGCNN

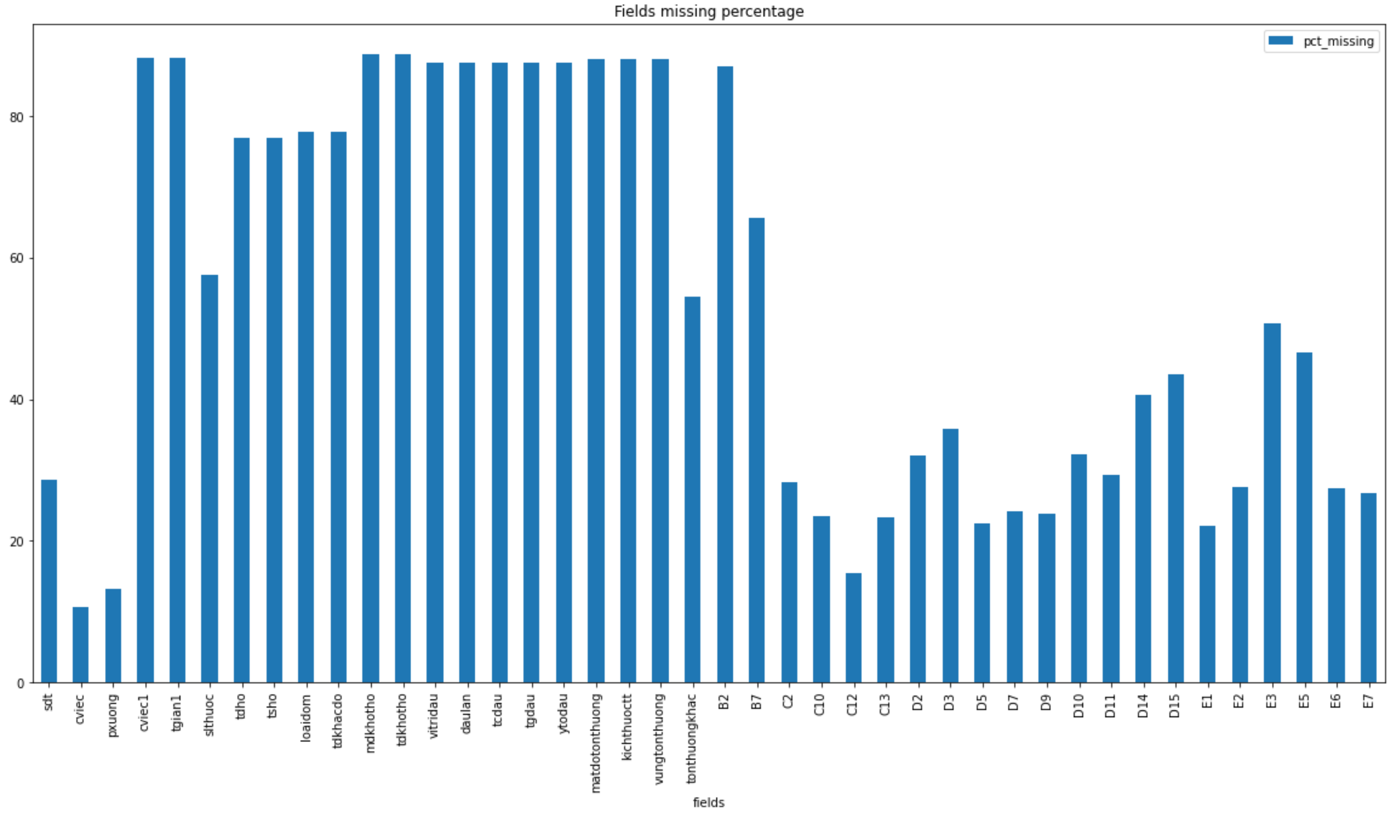

Fig. 4. Missing percentage of data field(s).

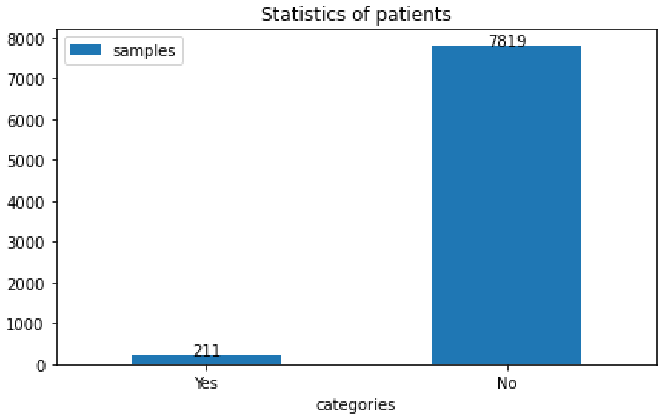

Fig. 5. Statistics of original data set output labels.

networks, a minibatch size of 100 was applied to enhance training performance.

- Since the models were trained without a large number of epochs, the early stopping technique was not implemented in the training process.
- To estimate the efficiency of each model fairly, the prediction results on all 8030 samples from the original dataset were used to calculate the evaluation metrics.

In this study, the performance metrics employed to evaluate the experimental results include accuracy, loss, F1 score, precision, recall, and the confusion matrix. The models will be applied to predict outcomes on the original dataset to ensure a fair evaluation. These metrics are calculated using the following formulas:

$$Accuracy = \frac{TP + TN}{TP + TN + FP + FN}$$

$$Precision = \frac{TP}{TP + FP}$$

$$Recall = \frac{TP}{TP + FN}$$

$$F_1 = \sum_{i}^{classes} 2 \times \frac{class_i}{totalsamples} \times \frac{Precision_i \times Recall_i}{Precision_i + Recall_i}$$

where TP is the true positive (number of samples *correctly* predicted as “positive”), TN is the true negative (number of samples *correctly* predicted as “negative”), FP is the false positive (number of samples *wrongly* predicted as “positive”) and FN is false negative (number of samples *wrongly* predicted as “negative”).

TABLE VI. Experiment Results

Exp	Method	Precision	Recall	F1 Score	ACC
1	KNN	18.8%	70.14%	29.66%	91.26%
2	SVM	39.4%	82%	53.23%	96.21%
3	ANN	58.14%	83%	68.36%	97.98%
4	LSTM	62.4%	78.67%	69.6%	98.19%
5	DGCNN V1	43.6%	35.8%	39.3%	96.46%
6	**DGCNN V2**	**78%**	**72.89%**	**75.23%**	**98.66%**

D. Results and Discussion

The results of the six methods that we have discussed are presented in Table VI. This table illustrates that all six models are capable of detecting occupational diseases using their respective inputs and networks. Among these, the sixth experiment exhibits the best performance, achieving an accuracy of 98.66%, a loss of 1.65%, a recall of 72.89%, a precision of 78%, and an F1 score of 75.23%. The F1 score, precision, and recall are not as high as the accuracy, primarily due to noise arising from elements in the dataset that contain multiple classification values. The amount of noise is proportional to the size of the input data. Furthermore, the input samples used for prediction are imbalanced; therefore, a high rate of correct predictions does not necessarily indicate that every class has a similar rate of correct prediction. The fact that recall, precision, and F1 score are almost equal suggests that our model's predictions are more balanced and has accurately diagnosed many patients.

The progress of training and Mean Receiver Operating Characteristic (ROC) curves for the sixth model are displayed in Fig. 9 and 8, respectively. They indicate that our DGCNN V2 model architecture, as detailed in Table II, achieved a high accracy and Area Under the Curve (AUC) of 96.22%. This demonstrates the model's strong performance in classifying negative and positive samples.

Table VII showcases a comprehensive classification comparison between sick patients and healthy individuals from our fourth experiment. In this experiment, the LSTM model outperformed other conventional methods, demonstrating effective detection of diseased patients within the overall patient population in the dataset. Yet, our DGCNN V2 model, as depicted in Table VIII, exhibits even greater effectiveness, particularly in the context of the sixth experiment. This model excels in handling heterogeneous datasets. For the negative class, precision, recall, and F1 scores are uniformly high at approximately 99.33%. In contrast, the positive class yields scores of 77.73% for precision, 72.9% for recall, and 75.23% for the F1 score. The macro averages are calculated as 88.47% for precision, 86.14% for recall, and 87.27% for the F1 score, with the weighted averages hovering around 98.63%. Overall, our model attained an impressive 98.66% accuracy across the entire dataset. Support numbers stand at 225 for the occupational diseases category and 7805 for the healthy category, contributing to a total of 8030 for each accuracy, macro average, and weighted average metric. A comparison

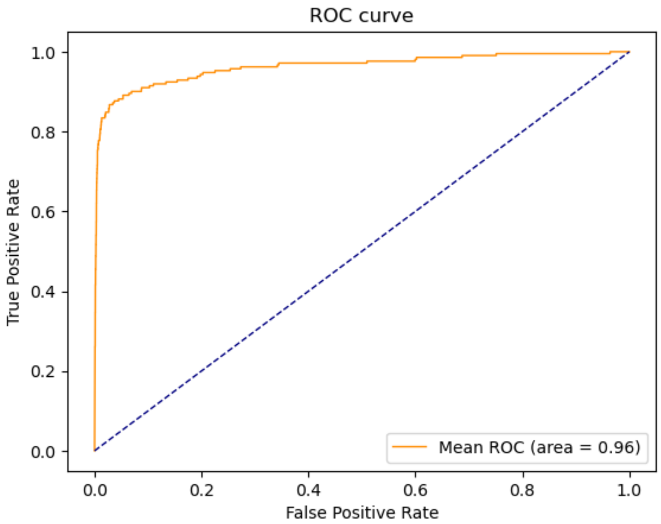

Fig. 9. Mean ROC curves for the classifiers on the test set.

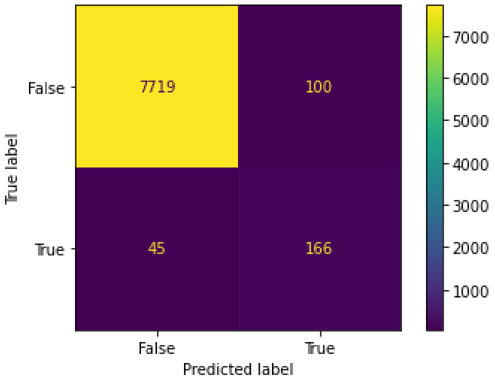

Fig. 10. LSTM model prediction confusion matrix.

of the confusion matrices from the LSTM outputs and the DGCNN prediction results, as shown in Fig. 11 clearly demonstrates the superior performance of our network over traditional methodologies (Fig. 10).

TABLE VII. Experiment 4 - Classification Performance

	Precision	Recall	F1 Score	Support
class No	99%	99%	99%	7764
class Yes	79%	62%	70%	266
Accuracy			98%	8030
Macro avg	89%	81%	84%	8030
Weighted avg	98%	98%	97%	8030

V. Conclusion

In this study, we sought to enhance occupational disease detection performance. Our proposed approach utilizes a relationship graph to store and analyze body indicators alongside information about patients' working environments and the interrelations of these parameters. We empirically validated our method on a collected dataset, demonstrating its superior efficiency with an accuracy of 98.66%, an F1 Score of 75.23%, and a ROC (Receiver Operating Characteristic) of 96.22%. Additionally, when applied to a commonly used stroke prediction dataset from Kaggle, our method achieved remarkable results: an accuracy of 99.69%, an F1 Score of 96.9%, and a perfect ROC of 100%. These outcomes not only outperformed other state-of-the-art methods but also surpassed previous solutions as indicated in various studies [24], [4], [25]. The results affirm the Deep Graph CNN network's suitability for handling heterogeneous data, which is crucial for accurately diagnosing diseases.

TABLE VIII. Experiment 6 - Classification Performance

	Precision	Recall	F1 Score	Support
class No	99%	99%	99%	7805
class Yes	78%	73%	75%	225
Accuracy			99%	8030
Macro avg	88%	86%	87%	8030
Weighted avg	99%	99%	99%	8030

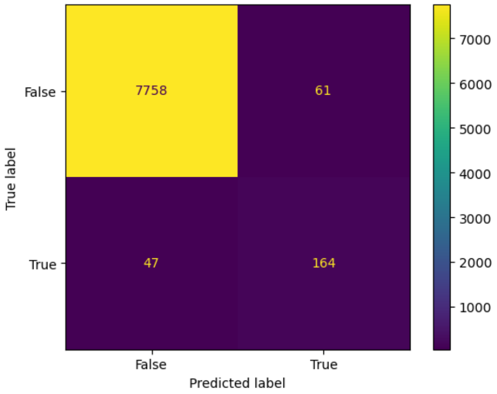

Fig. 11. DGCNN model prediction confusion matrix.

Looking ahead, our future work will focus on developing an API that integrates this proposed method. This will enable medical websites to utilize our approach for diagnosing occupational diseases, leveraging user-provided occupational information.

***Abstract*—Accurate construction cost estimation is crucial for completing projects within the planned timeframe and budget. Using machine learning methods to predict construction costs has become a new trend. However, machine learning methods typically require a large amount of data for model training, which makes it particularly challenging in data-poor areas. This paper proposes a novel method, Grasshopper Optimization Algorithm-Guided Multi-Layer Perceptron with Transfer Learning (GOA-MLP-TL), specifically designed for construction cost estimation in data-poor areas. GOA-MLP-TL utilizes the global optimal search capability of the GOA to optimize the parameters of the MLP network. Additionally, an adaptation layer is added into the MLP network, using the Maximum Mean Discrepancy (MMD) measure as a regularization to bridge the gap between the source and target domains. The GOA-MLP-TL can effectively leverage the model trained on data-rich area, and transfer the knowledge to adapt the model suitable for data-poor areas. The proposed approach is verified on two datasets from different areas, and the experimental result shows that, compared to the traditional machine learning method MLP and GOA-MLP without transfer learning, the correlation coefficient (R^2) of the proposed GOA-MLP-TL is improved by 12.05% and 6.90%, respectively. This demonstrate the effectiveness of GOA-MLP-TL for the construction cost estimation task in the data-poor area.**

I. Introduction

Construction cost estimation is an essential component of project feasibility studies. A scientifically and efficiently conducted cost prediction can assist project investors in comparing multiple scenarios, and making more reasonable investment decisions [1]. In engineering practice, the information available is often limited in the early stages of a project, and investors and construction enterprises frequently rely on historical experience to determine project costs, which lacks of efficiency and accuracy.

To address this challenge, researchers have explored and developed various methods for construction cost prediction, aiming to enhance the precision and efficiency of estimating expenses. Traditional prediction approaches primarily rely on statistical analysis [2,3] and simple regression theory [4], these methods typically exhibit low accuracy , which cannot meet the demands of actual projects with numerous uncertainties. In recent two decades, with the development of computer science, many new machine learning methods, such as genetic algorithms [5,6], neural networks[7]–[10], Random Forest [11], and support vector machines[12,13], have been successfully applied to cost estimation. Jung et al. [5] introduces a novel hybrid approach that integrates Case-Based Reasoning (CBR) with a Genetic Algorithm (GA) and employs a Local Search Method. Experiments proved the applicability of the method in cost estimation. Fan and Sharma [12] explores the application of SVM and LSSVM in developing a construction cost prediction model, the results show that the prediction model based on SVM has a higher prediction accuracy and the results are robust. Ksenija et al. [14] delves into the application of artificial neural networks to road construction cost estimation, comparing the effectiveness of various types of neural networks in cost estimation. Sharma et al. [15] compares various machine learning algorithms to predict the construction cost, Findings the results demonstrate that the ensemble methods, such as gradient boosted trees, exhibit the best performance for construction cost prediction. Tayefeh et al. [16] reviews manuscripts that proposed for cost estimation with machine learning techniques for the last 30 years, categorises and summarises commonly used methods.

While the aforementioned methods have yielded promising prediction results, they still have certain limitations. Because the conventional machine learning algorithms are based on the assumption that both the training and test data are drawn from the same distribution [17], which means these methods are trained and tested using the same construction cost database. Due to the differences in design specifications, construction methods, and labor and material costs in different regions, if the models obtained by above methods are applied to other areas, the cost prediction accuracy may decrease. Additionally, the collection and processing of construction cost data in data-poor areas is also labor- and time-consuming.

The emergence of transfer learning [18] provides a new approach to solve the above problems. Transfer learning is a technique in which the knowledge learned from one task is reused in order to boost performance on another different but related task [19]. Unlike conventional machine learning methods, which rely on one-to-one relationships between training data sets and individual models, transfer learning can effectively

leverage existing data resources across different domains for predictive modeling. In this work, we propose an approach that combines Grasshopper Optimization Algorithm-Guided Multi-Layer Perceptron with Transfer Learning(GOP-MLP-TL) for cost estimation in data-poor areas. Specifically, GOA-MLP-TL utilizes the global optimal search capability of the GOA to optimize the parameters of the MLP network.Additionally, an adaptation layer is incorporated into the network before the output layer, and regularization is introduced to reduce the distribution mismatch between data from different areas at this layer. With our method, utilizing existing models and data, only a small amount of data from data-poor areas is required to train new models for cost estimation in these areas.

The rest of the paper is organized as follows. Section II explains the principles of the multi-layer perceptron, grasshopper optimization algorithm and transfer learning, meanwhile presents the framework of our approach. Section III describes the experimental setup, datasets, results, and discussion. Finally, Section IV concludes the paper.

II. Methodology

The estimation model in this work is based on a multi-layer perceptron and transfer learning. In this section, we first introduce the structure of the MLP network and the MLP parameter optimization method based on the Grasshopper Optimization Algorithm (GOA). Following that, we provide the implementation details of transfer learning using an adaptation layer. Finally, we present the flowchart of the training and estimation process for our approach.

A. GOA-Guided Multi-Layer Perceptron

Multi-layer perceptron (MLP) is one of the most widely used neural networks. It has one input layer, one output layer and one or more hidden layers of neurons. Multiple layers of neurons within the MLP network enhance the input-expected output mapping capability [20]. In this work, MLP network is used to learn the estimation model based on the existing data from data-rich areas.

The structure of a typical MLP is shown in Fig. 1 MLP learning mainly includes the following two stages:

1) Forward propagation: Assuming the number of hidden layers in the MLP is K , the output vector of the i-th hidden layer is denoted as $\mathbf{h}^{(i)}$, and the output value of the output layer is denoted as y, then:

$$\mathbf{h}^{(i)} = \begin{cases} \sigma\left(\mathbf{x}\mathbf{W}^{(1)} + \mathbf{b}^{(1)}\right), & i = 1 \\ \sigma\left(\mathbf{h}^{(i-1)}\mathbf{W}^{(i)} + \mathbf{b}^{(i)}\right), & i \in \{2, 3, \dots, K\} \end{cases} \tag{1}$$

$$y = \mathbf{h}^{(K)}\mathbf{W}^{(O)} + b^{(O)} \tag{2}$$

where, $\mathbf{W}^{(\mathbf{i})}$and $\mathbf{b}^{(i)}$ are the weight matrix and bias vector for the i-th hidden layer respectively, $\mathbf{x}$ represents the input layer vector, $\mathbf{W}^{(O)}$and $b^{(O)}$ are the weight matrix and bias for the output layer. $\sigma(\cdot)$in Eq. (2) is the activation function, which is used to achieve non-linear mapping between neuron inputs and outputs. Common activation functions include Sigmoid, hyperbolic tangent function (Tanh), rectified linear unit (ReLU), etc. In this work, Sigmoid is used as the activation function, which is defined as follows:

$$\sigma(x) = \frac{1}{1 + e^{-x}} \tag{3}$$

2) Back propagation: Assuming the number of input samples is N, y_n and $y_n{}'$ represent the actual data and the predicted output of the n-th sample. The error between y_n and $y_n{}'$ is measured by mean square error (MSE), and the MSE is used as the loss function, which is defined in Eq. (4). The MSE loss is minimized by adjusting the weights in the MLP network through the back propagation algorithm.

$$L_{MSE} = \frac{1}{N}\sum_{n=1}^{N}\left(y_n - y_n{}'\right)^2 \tag{4}$$

Traditional MLP optimization methods are sensitive to initial parameter values, which may lead to issues such as getting stuck in local optima. To mitigate this challenge and enhance the performance of the MLP model, this study employs the Grasshopper Optimization Algorithm (GOA) to optimize the MLP network parameters. The GOA was introduced by Saremi et al. in 2017 as a new type of swarm intelligence algorithm [21]. It simulates the foraging behavior of grasshopper swarms to search for optimal solutions. In this algorithm, adult grasshoppers perform global searches in the early stages, while nymph grasshoppers conduct detailed exploitation in the vicinity of specific areas during the later stages. The position model of the i-th grasshopper in the d-th dimension is as follows:

$$X_i^d = c\left(\sum_{j=1, j\neq i}^{N} c\frac{\mathrm{UB}_d - \mathrm{LB}_d}{2} s\left(\left|x_j^d - x_i^d\right|\right)\frac{(x_j^d - x_i^d)}{d_{ij}}\right) + \hat{T}_d \tag{5}$$

where, the subscript d represents the d-dimensional space, UB_d and LB_d respectively represent the upper bound and lower bound of grasshopper search, $\left|x_j^d - x_i^d\right|$ is the Euclidean distance from the i-th grasshopper to the j-th grasshopper, $\frac{(x_j^d - x_i^d)}{d_{ij}}$ is the unit vector from the i-th grasshopper to the j-th grasshopper, $\hat{T}_d$ represents the best solution (target) attained so far, s is a factor representing the range and strength of social interaction within the population and c is a linear decreasing factor. the c factor is attained as follows:

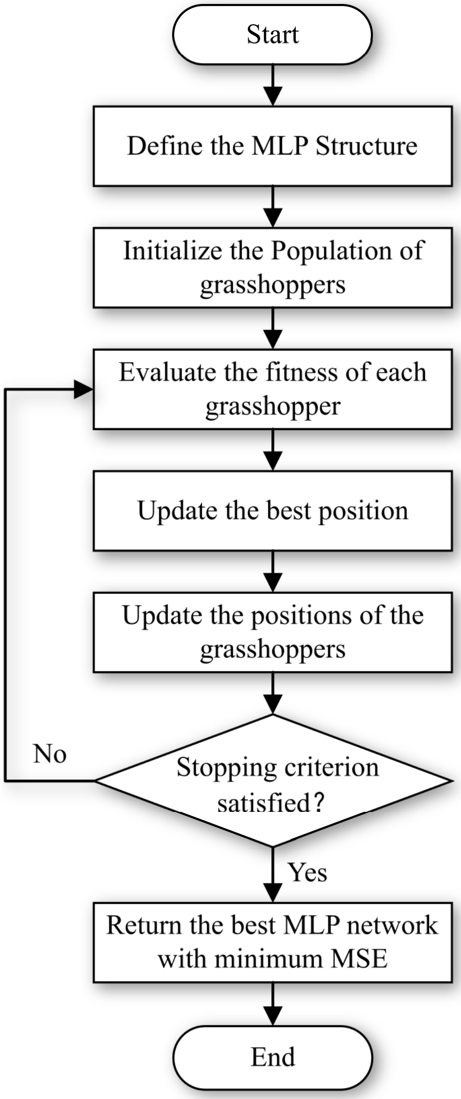
$$c = c_{\max} - l\frac{c_{\max} - c_{\min}}{L} \tag{6}$$

where, l represents the number of iterations, L denotes the upper bound of the iterations, $c_{\max}$ and $c_{\min}$ are respectively the upper and lower bounds of the decreasing factor c, with $c_{\max}$ set to 1 and $c_{\min}$ set to 10^{-5} in this article.

Using the GOA can effectively optimize the weights and biases in each layer of an MLP network, thereby improving the predictive performance of the MLP network. Specifically, the main steps of GOA-MLP include:

- Define the MLP Structure: Determine the architecture of the MLP, including the number of layers, number of neurons in each layer, activation functions, and other parameters.
- Initialize the Population of grasshoppers: Determine the basic parameters of the GOA, such as the grasshopper population size and the number of iterations. Initialize a random set of grasshoppers. Each grasshopper individual represents a potential MLP configuration, including the network's weights and biases. Assuming the MLP network has N weights and bias parameters, one grasshopper can be represented as an N-dimensional single vector.
- Fitness evaluation: For each grasshopper, maps its position value to the corresponding weights or biases in the MLP network. Use Mean Squared Error (MSE) as the fitness function, and evaluation the fitness on the training dataset.
- Update the best position: If the fitness of a grasshopper's current position is superior to its historical best position, then update the best position.
- Update the positions of the grasshoppers: Taking into account the interactions between individuals and the influence of the target position, update the grasshopper positions based on Eq. 5.
- Repeat the steps 3–5 until the specified number of iterations or until a stopping criterion is met
- Termination and testing: Finally, the process is terminated and the MLP with the minimum MSE should be tested on the test/validation datasets.

The overall steps of the GOA-MLP are demonstrated in Fig. 2.



Start
Define the MLP Structure
Initialize the Population of grasshoppers
Evaluate the fitness of each grasshopper
Update the best position
Update the positions of the grasshoppers
Stopping criterion satisfied?
No
Yes
Return the best MLP network with minimum MSE
End

B. Adaptation Layer for Transfer Learning

Transfer learning involves a source domain and a target domain, each characterized by distinct yet related distributions. The process of transfer learning is the process of transferring the knowledge from the source domain to the target domain, so as to solve the problems of insufficient knowledge in the target domain and insufficient accuracy of the model. In this work, existing construction cost dataset from the data-rich area belongs to the source domain, and the target domain corresponds to the data-pool areas, which lack of the sufficient construction cost data.

In order to achieve knowledge transfer, an adaptation layer is added in the MLP network before the output layer, the modified MLP network is shown in Fig. 3 The distribution mismatch between data from source and target domains is minimized on this adaptation layer. Specifically, the Maximum Mean Discrepancy (MMD) [22] is utilized to measure the distribution mismatch, and the MMD is used as a regularization embedded in the back propagation training process. During the process of training adaptation layer, the parameters of the hidden layers are fixed, so the original model learned from source domain can be re-used.

The Maximum Mean Discrepancy (MMD) serves as a measure of the difference between two probability distributions based on their samples. This criterion proves to be effective in comparing distributions without the need for an initial estimation of their density functions.

Let $\left\{\mathbf{x}_s^i\right\}_{i=1,\ldots,n_s}$ and $\left\{\mathbf{x}_t^i\right\}_{i=1,\ldots,n_t}$ be data vectors drawn from distributions of source domain and target domain, respectively, MMD can be defined as:

$$MMD\left(\mathbf{x}_s,\mathbf{x}_t\right)=\left\|\sum_{i=1}^{n_s}f\left(\mathbf{x}_s^i\right)-\sum_{i=1}^{n_t}f\left(\mathbf{x}_t^i\right)\right\|_H \tag{7}$$

In this equation, H represents the Reproducing Kernel Hilbert Space(RKHS), $f(\cdot)$ is a mapping function used to map the original variables into the RKHS. Expanding the equation into a matrix multiplication form, one can rewrite the kernelized empirical estimate of MMD as:

$$\begin{aligned}MMD_e\left(\mathbf{x}_s,\mathbf{x}_t\right)=\Bigg(&\frac{1}{n_s(n_s-1)}\sum_{i=1}^{n_s}\sum_{j=1}^{n_s}k\left(\mathbf{x}_s^i,\mathbf{x}_s^j\right)+\\&\frac{1}{n_t(n_t-1)}\sum_{i=1}^{n_t}\sum_{j=1}^{n_t}k\left(\mathbf{x}_t^i,\mathbf{x}_t^j\right)-\\&\frac{2}{n_sn_t}\sum_{i=1}^{n_s}\sum_{j=1}^{n_t}k\left(\mathbf{x}_s^i,\mathbf{x}_t^j\right)\Bigg)^{\frac{1}{2}}\end{aligned} \tag{8}$$

where $k\left(\cdot,\cdot\right)$ is a Gaussian kernel function.

After adding the adaptation layer for transfer learning, the total loss function of the entire network can be expressed as follow:

$$L=L_{MSE}+\lambda {MMD_e}^2\left(\mathbf{x}_s,\mathbf{x}_t\right) \tag{9}$$

where L_{MSE} denotes the standard MSE loss over the available labeled data from both source and target domains, and λ is a constant controlling the weight of MMD contribution to the total loss function. The loss function simultaneously optimizes the estimation output error and the distribution mismatch on the adaptation layer, makes the model more suitable for the data from the target domain.

C. Framework of the Method

The framework of our method is depicted in Fig. 4. During the training phase, we initially train the MLP network model

using the source domain data.The GOA is employed for MLP model optimization, utilizing the Mean Squared Error (MSE) loss function. Subsequently, we introduce the adaptation layer, maintaining the original parameters, and optimize the network model based on both MSE and Maximum Mean Discrepancy (MMD) loss functions. The resulting updated model is then utilized during the testing phase to estimate costs for the target domain data.

III. Experiment

A. Data Description

To verify the effectiveness of the proposed cost estimation method, two groups of construction cost data from different areas were utilized to simulate data from source domain and target domain respectively.

Construction cost data collected from RSMeans Online [23] during the period (1998–2018) was used as the source domain data. RSMeans data is North America's leading source of construction cost information, delivering reliable, locally relevant, and up-to-date cost data. RSMeans Online is a widely used construction cost estimating and project management software. It provides the construction industry with a comprehensive set of detailed and accurate cost data and related tools, helping users make precise cost predictions and manage projects at various stages. We gathered 5400 samples from RSMeans Online, and we selected eight variables for the experiments, which are commonly used and highly relevant to cost estimation. Table I lists and explains these variables.

For the target domain, data came from the construction projects from 2016 to 2022 on the Guanglianda Index Network [24]. Guanglianda is one of China's leading providers of software and information technology services for the construction industry. It offers comprehensive construction cost information to assist businesses in decision-making. We collected a total of 320 samples from it, and we chose the same eight variables as those in the source domain data setting.

TABLE I. List of Variables

Variable	Description
y	Actual construction costs
x_1	Building type
x_2	Structure type
x_3	Total floor area of the building
x_4	Numerical number of floors
x_5	Total height of the building
x_6	Formwork area
x_7	Concrete volume
x_8	Per square meter cost

B. Experimental Setup

Considering the sample size, we employed an MLP network with two hidden layers in this work. The input layer consisted of 8 nodes, corresponding to the number of input variables. The output layer had 1 node, representing the cost estimation results. The number of nodes in the hidden layers was determined through a trial-and-error process, resulting in two hidden layers with 15 and 10 nodes, respectively. The major parameters of GOA were based on reference [25] and were set as follows, The population size of grasshoppers was set to 20, the maximum number of iterations was set to 30, and the upper and lower bounds of the decreasing factor c were set to 1 and 10^{-5}, respectively. For the transfer learning part, the number of nodes in the adaptation layer was set to 10, the same size as the hidden layer 2, and the parameter for the weight of MMD loss was set to 0.35.

The performance of the proposed cost estimation method is evaluated and compared with the following commonly used statistical metrics: Correlation coefficient (R^2); Root Mean Square Error (RMSE); and Mean Average Percentage Error (MAPE). These metrics are defined as follows:

$$R^2 = 1 - \frac{\sum_{n=1}^{N} (y_n - y_n{}')^2}{\sum_{n=1}^{N} (y_n - mean(y_n))^2} \tag{10}$$

$$RMSE = \sqrt{\frac{1}{N}\sum_{n=1}^{N} (y_n - y_n{}')^2} \tag{11}$$

$$MAPE = \frac{1}{N}\sum_{n=1}^{N} \left| \frac{y_n - y_n{}'}{y_n{}'} \right| \tag{12}$$

Here y_n represents the actual data provided in the dataset, and $y_n{}^{'}$ corresponds to the predicted output of the n-th sample. The experimental environment is based on MATLAB software, running on a PC with an Intel i5 12400 CPU, 32G RAM, and the Windows 10 operating system.

C. Results and Discussion

1) Comparison with other methods: To validate the effectiveness of our cost estimation method (GOA-MLP-TL), we compared it with four other methods. The first three methods are traditional machine learning approaches, which are: Linear Regression (LR), Support Vector Regression (SVR) with the RBF kernel and a single multi-layer perceptron (MLP) network. The MLP shares the same network structure as our proposed method but lacks the adaptation layer for transfer learning and does not utilize GOA for optimization. The fourth method is GOA-MLP, which employs the same network structure and optimization method as our proposed approach but excludes the adaptation layer for transfer learning.

For all four comparative methods, the models were trained using data solely from the source domain and subsequently tested on both the source and target domains. For GOA-MLP-TL, when testing in the source domain, the model was trained only with data from the source domain, making it identical to GOA-MLP. However, when testing in the target domain, the model used some target domain data for knowledge transfer. The estimation performance of these five methods has been compared in Table II. To facilitate a more intuitive comparison, we have also plotted the comparison of estimation results using different evaluation metrics in Fig. 5, Fig. 6, and Fig. 7, respectively.

From Table II and Fig. 5, it can be observed that in the evaluations on the source domain data, GOA-MLP and GOA-MLP-TL achieved the highest R^2 values (as previously explained, these two methods are identical in the source domain tests), followed by MLP and SVR, with LR obtaining the lowest R^2 value. GOA-MLP shows a 3.2% improvement compared to MLP. In the tests conducted on the target domain data, it is evident that the R^2 values for all methods decreased.

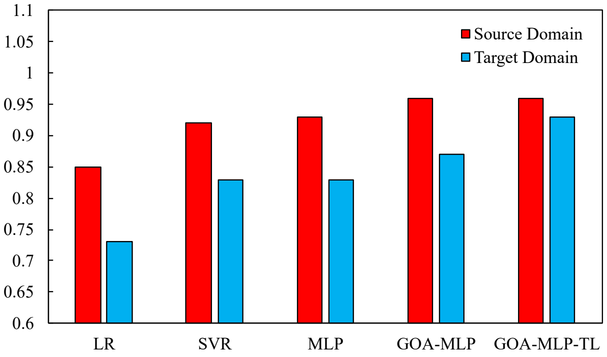

Fig. 5. Comparison of estimation performance of various methods using R^2.

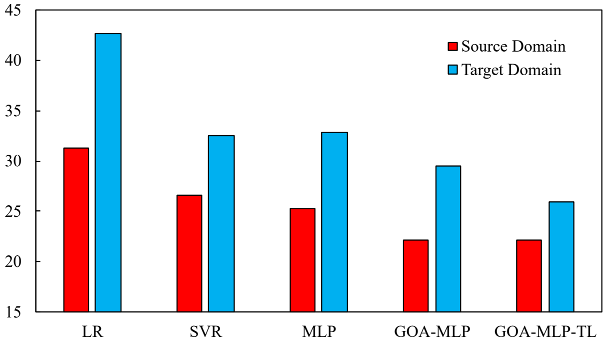

Fig. 6. Comparison of estimation performance of various methods using RMSE.

The three traditional machine learning methods exhibited an average decrease of 11.55%, GOA-MLP showed a decrease of 9.37%, whereas GOA-MLP-TL, which employs transfer learning, only demonstrated a decrease of 3.13%. GOA-MLP-TL shows improvements of 12.05% and 6.90% compared to MLP and GOA-MLP, respectively. The RMSE and MAPE values exhibit similar trends which have been illustrated in Fig. 6 and Fig. 7. it is worth noting that lower values are preferred for both RMSE and MAPE, which is contrary to R^2.

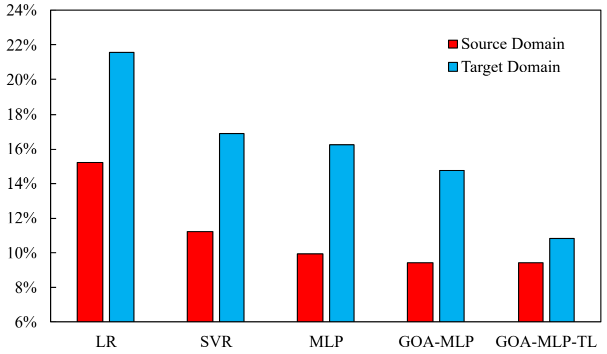

Fig. 7. Comparison of estimation performance of various methods using MAPE.

TABLE II. Comparison of Estimation Performance of Various Methods

	LR		SVR		MLP		GOA-MLP		GOA-MLP-TL	
	source domain	target domain	source domain	target domain	source domain	target domain	source domain	target domain	source domain	target domain
R^2	0.85	0.73	0.92	0.83	0.93	0.83	0.96	0.87	0.96	0.93
RMSE	31.26	42.64	26.59	32.55	25.32	32.84	22.14	29.55	22.14	25.95
MAPE	15.21%	21.54%	11.20%	16.87%	9.91%	16.23%	9.43%	14.75%	9.43%	10.85%

The experimental results indicated that, first, the proposed GOA-MLP demonstrates enhanced predictive accuracy compared to the three traditional machine learning methods. Second, in contrast to these compared methods, the proposed GOA-MLP-TL significantly improves estimation performance on data from the target domain. This improvement is achieved by establishing a correlation between the source domain and the target domain through knowledge transfer. Consequently, this approach effectively addresses the challenge of constructing cost estimation models in data-poor areas.

2) Influence analysis of target domain sample size: To analyze the influence of target domain sample size, we conducted experiments using the proposed GOA-MLP-TL with varying numbers of samples from the target domain for transfer learning, and evaluated its performance on the target domain. The correlation coefficient (R^2) was used as the key metric. For comparison, we also employed GOA-MLP, training and testing on the target domain with different training sample sizes. Note that the number of training samples for GOA-MLP was incremented from 40 because training process cannot converge with too few samples. The results were plotted in Fig. 8.

From the Fig. 8, it can be noted that as the number of samples in the target domain increases, the R^2 value of GOA-MLP-TL gradually improves. When the number of samples exceeds a certain threshold, the R^2 value stabilizes. In this experiment, when the number of samples in the target domain exceeds 40, the estimation model becomes quite robust. Conversely, for GOA-MLP trained directly on the target domain data, a sample size of over 250 is required to achieve gradual stabilization and attain R^2 values comparable to those of GOA-MLP-TL.

These empirical findings suggest that training a stable model directly in the target domain requires a large number of data samples. Conversely, with the adoption of transfer learning, which utilizes models pre-trained in the source domain, only a small number of target domain samples are needed to achieve comparable prediction accuracy. In this experiment, the required number of target domain samples for GOA-MLP-TL is approximately 76% less compared to GOA-MLP.

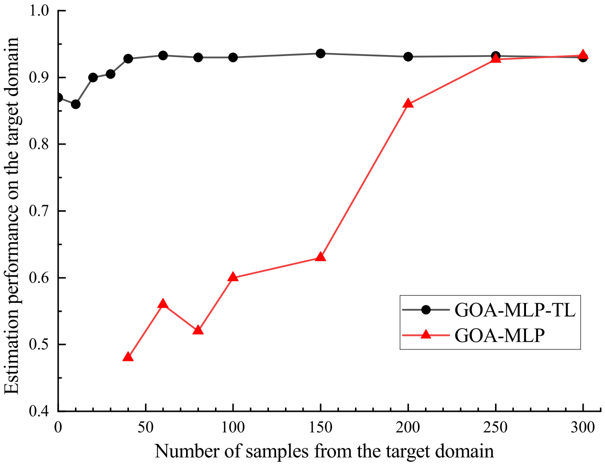

Fig. 8. Influence analysis of target domain sample size using R^2.

IV. Conclusion

In this work, we propose a novel method called the Grasshopper Optimization Algorithm-Guided Multi-Layer Perceptron with Transfer Learning (GOA-MLP-TL) for construction cost estimation in areas with limited data. GOA-MLP-TL is based on a Multi-Layer Perceptron (MLP) network, with two key improvements to enhance predictive ability. First, we utilize the Grasshopper Optimization Algorithm (GOA) to optimize the parameters of the MLP network. Second, we incorporate an adaptation layer into the network to facilitate knowledge transfer between domains. The Maximum Mean Discrepancy (MMD) measure is used as a regularization technique to reduce distributional differences between domains. GOA-MLP-TL effectively leverages models trained on data-rich areas and transfers the knowledge to adapt the model for data-poor areas. We simulate samples from data-rich and data-poor areas using two datasets and test the method on these datasets. Experimental result shows that, compared to the traditional machine learning method MLP and GOA-MLP without transfer learning, the R^2 value of the proposed GOA-MLP-TL is improved by 12.05% and 6.90%, respectively. This demonstrate the effectiveness of GOA-MLP-TL for the construction cost estimation task in the data-poor area.

Due to limitations in the availability of experimental data, this study selected only eight variables for experiment, which does not cover all aspects of construction cost estimation. Future work could explore incorporating additional relevant variables to improve prediction accuracy. Additionally, future research could employ deep transfer learning methods to enhance the algorithm presented in this study.

Exploring Abstractive Text Summarization: Methods, Dataset, Evaluation, and Emerging Challenges

Yusuf Sunusi, Nazlia Omar, Lailatul Qadri Zakaria
Center for Artificial Intelligence Technology, Universiti Kebangsaan Malaysia, Selangor, Malaysia 43600

***Abstract*—The latest advanced models for abstractive summarization, which utilize encoder-decoder frameworks, produce exactly one summary for each source text. This systematic literature review (SLR) comprehensively examines the recent advancements in abstractive text summarization (ATS), a pivotal area in natural language processing (NLP) that aims to generate concise and coherent summaries from extensive text sources. We delve into the evolution of ATS, focusing on key aspects such as encoder-decoder architectures, innovative mechanisms like attention and pointer-generator models, training and optimization methods, datasets, and evaluation metrics. Our review analyzes a wide range of studies, highlighting the transition from traditional sequence-to-sequence models to more advanced approaches like Transformer-based architectures. We explore the integration of mechanisms such as attention, which enhances model interpretability and effectiveness, and pointer-generator networks, which adeptly balance between copying and generating text. The review also addresses the challenges in training these models, including issues related to dataset quality and diversity, particularly in low-resource languages. A critical analysis of evaluation metrics reveals a heavy reliance on ROUGE scores, prompting a discussion on the need for more nuanced evaluation methods that align closely with human judgment. Additionally, we identify and discuss emerging research gaps, such as the need for effective summary length control and the handling of model hallucination, which are crucial for the practical application of ATS. This SLR not only synthesizes current research trends and methodologies in ATS, but also provides insights into future directions, underscoring the importance of continuous innovation in model development, dataset enhancement, and evaluation strategies. Our findings aim to guide researchers and practitioners in navigating the evolving landscape of abstractive text summarization and in identifying areas ripe for future exploration and development.**

Keywords*—Abstractive text summarization; systematic literature review; natural language processing; evaluation metrics; dataset; computation linguistics

I. INTRODUCTION

In recent times, there has been a significant increase in demand for the utilization of data from diverse sources such as scientific articles, medical records, and social media platforms. The essence of text summarization lies in condensing a lengthy document into a concise, coherent summary. Automatic text summarization techniques fall into two main categories: extractive and abstractive. Extractive summarization methods pull specific words and phrases directly from the original text [1], while abstractive summarization creates new words and phrases that may not appear in the source document, mimicking the way humans summarize [2, 3]. The goal of abstractive summarization is to craft a condensed version of the original text without losing its original meaning [4]. This process involves generating summaries through a process akin to human thought, demanding high capabilities in characterizing, understanding, and producing text from models.

The Sequence-to-Sequence (Seq2Seq) model, which utilizes Recurrent Neural Networks (RNN) including variants like simple RNN, LSTM, and GRU, is a popular choice for abstractive summarization. These models employ an encoder-decoder framework [5-7] where the encoder converts the input text into a context vector, and the decoder then uses this vector to create an abstractive summary. However, Seq2Seq models, especially those based on RNNs, tend to miss crucial information from the original, lengthy texts and may generate redundant content, particularly in tasks involving long documents or sequences [5]. The addition of an attention mechanism to the encoder-decoder structure has shown success in abstractive text summarization [8]. Furthermore, Blekanov et al. [9] explored transformer-based models like LongFormer and T5, comparing them with BART in experiments with real-world Reddit data. Incorporating synthetic data alongside real data, a method often used in machine translation for resource-scarce situations to enhance translation quality, has been effective. Specifically, employing an iterative back-translation strategy, where back-translation systems are trained repeatedly, has shown promising results in improving machine translation. Furthermore, researchers have explored variations of this technique, including multi-round iterative back-translation and adversarial back-translation to further enhance translation quality.

A thorough review of the literature is essential for the progress of research in text summarization. Syed et al. [10] provides an in-depth analysis of key aspects of abstractive summarization, covering trends, general methodologies, tools, and evaluation techniques in this area. Additionally, a survey by Nazari and Mahdavi [11] delves into various approaches and methods utilized in text summarization, categorizing them into statistical, machine learning, semantic-based, and swarm intelligence approaches. Other scholarly articles focus on narrower topics such as specific summarization techniques [12, 84], methodologies employed [13], and evaluation strategies [14].

Unlike other review studies, this review paper offers an up-to-date extensive explanation of all the ins and outs of abstractive text summarization and highlights current key gaps and challenges in the domain which will help other researchers in identifying and addressing them. The process of conducting a research on abstractive text summarization poses significant challenges, particularly for researchers who are newly acquainted with the domain. This complexity arises from several critical factors that demand rigorous scholarly effort and methodological precision. Firstly, the interdisciplinary nature of abstractive text summarization, which intersects with fields such as natural language processing, artificial intelligence, and computational linguistics, necessitates a comprehensive understanding of diverse theoretical frameworks and technological advancements. Secondly, the rapid pace at which new research and innovations are introduced in this area means that scholars must continuously update their knowledge base, making it difficult to establish a definitive set of studies for review. Thirdly, the task of abstractive summarization itself, which involves generating new text that captures the essence of source documents, presents unique challenges in evaluating the quality and relevance of research findings.

These factors contribute to the intricacy of reviewing literature in this field, requiring dedicated effort to navigate the vast and evolving body of knowledge. Thus, the aims of this study are outlined as follows: a) To pinpoint, examine, and categorize the research topics and trends within abstractive summarization, b) To offer a comprehensive review of the different methods used in abstractive summarization, including the strengths and weaknesses of the prevalent techniques, c) To provide a succinct description of the commonly employed and newest methodologies in this domain, d) To detail the necessary pre-processing steps and the features utilized, e) To explore the challenges encountered in abstractive summarization, addressing both the resolved and outstanding issues, f) To analyze the evaluation strategies and datasets that have been applied, and g) To suggest directions for future research in text summarization. In pursuit of broadening research prospects in this area, this study employs a Systematic Literature Review (SLR) to achieve a more structured, quantifiable exploration with a wider and more varied range of topics, as highlighted by Shaffril et al. [15]. SLR boasts advantages over traditional review methods through its scientific approach and systematic execution, aiming to reduce bias and ensure transparent, verifiable outcomes. The conducted activities include detailing the review process in Section 2, explaining the derived results in Section 3, discussing the responses to research questions raised in Section 2 in Section 4, and concluding the study in Section 5.

II. Methods

A comprehensive search strategy was implemented to identify and collect as many relevant studies as possible on the subject. The search methodology was developed based on the following research questions:

1) What are the current trends in abstractive text summarization?
2) What datasets are used for developing abstractive text summarization models?
3) What are the evaluation metrics used to measure the quality of abstractive summaries?
4) What are the current challenges emerging in the domain?

In this stage, the research questions were deconstructed into distinct concepts to generate search terms and databases and to identify additional sources for exploration. Consequently, search terms were derived from the research questions:

1) Abstractive Text Summarization techniques/algorithms/models.
2) Abstractive summarization datasets.
3) Evaluation metrics.

The initial search string was created using these search terms and then refined by incorporating alternative terms, including synonyms and variant spellings. For this Systematic Literature Review (SLR), the following libraries were utilized to select pertinent literature that addresses the research questions:

1) Web of Science
2) Semantic Scholar
3) Springer
4) ACM
5) Elsevier
6) IEEE

The identified search terms were employed to locate conference and journal articles within six electronic databases, as shown in Fig. 1. Searches were confined to titles, abstracts, and keywords, with the exception of Google Scholar, where only titles were searched. Additionally, the reference sections of pertinent studies were reviewed for cross-citations. Secondary studies, including existing literature surveys, were also acquired.

Numerous searches were performed; however, the search criteria that yielded the most relevant results were:

1) ”Text Summarization” AND ”Abstractive”
2) ”Text Summarization” AND ”Abstractive” AND (“Techniques” OR “Methods”)
3) ”Text Summarization” AND ”Abstractive” AND (”Evaluation Metrics” OR ”Metrics”)

Further filtration of the search results was done by:

1) Removing duplicate documents
2) Devising inclusion and exclusion criteria to identify related papers and discard those that are irrelevant.
3) Performing quality assessment to ensure that papers with high quality were included.

A. Inclusion Criteria

The following are the criteria for paper inclusion:

1) Papers utilizing abstractive technique.
2) Papers based on abstractive summarization that include evaluation metrics.
3) The most recent version/edition of the paper.
4) Papers published between 2018 and 2023.

B. Exclusion Criteria

The following are the criteria for paper inclusion:

1) Papers utilizing abstractive technique.
2) Papers based on abstractive summarization that include evaluation metrics.
3) The most recent version/edition of the paper.
4) Papers published between 2018 and 2023.

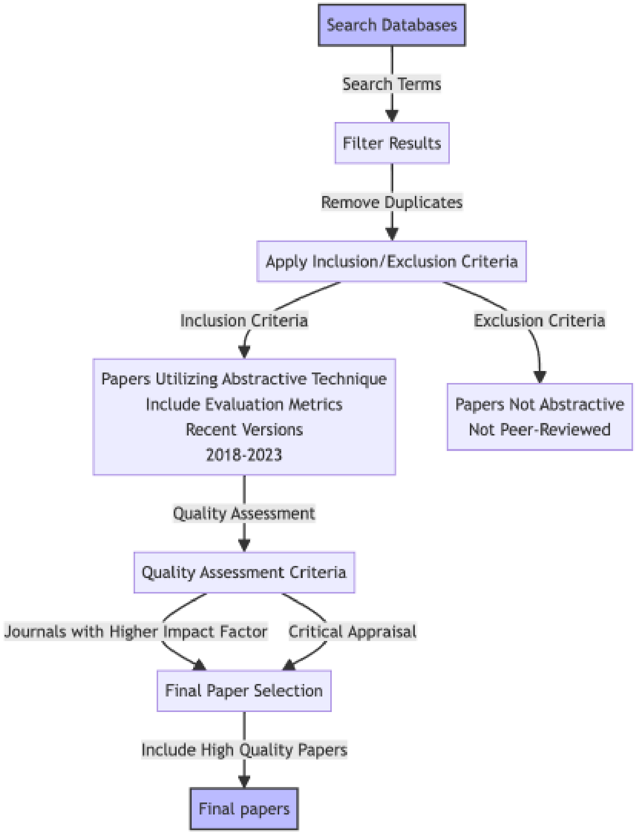

Fig. 1. Search procedure.

C. Quality Assessment

The quality assessment criteria employed in this review were meticulously developed based on the comprehensive framework proposed by Smith et al. [16]. The framework involves a systematic and rigorous set of criteria aimed at ensuring the validity, reliability, and applicability of the research findings. The following are the criteria for assessing the quality of selected journals:

- Journals with higher impact factors.
- Each study will be assessed based on the following critical appraisal criteria:
  - What type of research question is being asked?
  - Was the study design appropriate for the research question?
  - Did the study methods address the most important potential sources of bias?
  - Was the study performed according to the original protocol?
  - Is the study question relevant?
  - Does the study add anything new?
  - Do the data justify the conclusions?
  - Are there any conflicts of interest?
  - Does the study test a stated hypothesis?
  - Were the statistical analyses performed correctly?

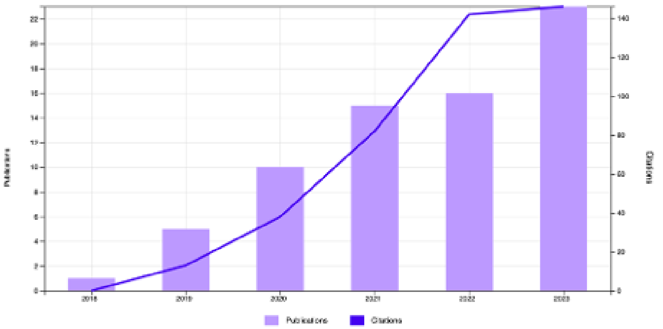

Fig. 2. Publications and citations from results.

D. Data Extraction

Upon searching using keywords “abstractive text summarization (All Fields) and natural language processing (Author Keywords) or Text Summarization (Author Keywords) and abstractive (All Fields) and 2023 or 2022 or 2021 or 2020 or 2019 or 2018 (Publication Years) and Article (Document Types)”, a total of 72 journals and publications were ultimately derived. As seen in Fig. 2, research in the field of abstractive summarization is steadily growing each year with 2023 having the highest publications in recent years.

III. Abstractive Text Summarization

Abstractive text summarization is a process where a new, condensed version of a text is generated, capturing the essential messages and meaning of the original content. Unlike extractive summarization, which selects and rearranges specific sentences or phrases from the source text, abstractive summarization involves understanding and interpreting the text to produce summaries that are not necessarily found verbatim in the source. Studies have explored various methodologies, including the use of pre-trained models for better context understanding and the application of novel training paradigms to improve the summarization of specific languages or domains [17, 18]. Table I provides a summary of the categories and terms to be discussed in this review.

A. Encoder Decoder Architecture

Choosing an encoder-decoder framework offers various design options for our encoder and decoder, including traditional RNN/LSTM/GRU, bidirectional RNN/LSTM/GRU, Transformer, BERT/GPT-2 models, or the more recent BART architecture. In the model described by Fan et al. [2], both the encoder and decoder are built as deep convolutional networks. They begin with a layer for word embedding, followed by a series of convolutions alternating with Gated Linear Units (GLU). The decoder is linked to the encoder via attention mechanisms that compute a weighted average of the encoder’s outputs. These weights are determined based on the current state of the decoder, enabling it to focus on the most pertinent sections of the input document for generating the subsequent token. Zhang et al. [19] introduced a novel generative model leveraging a convolutional seq2seq framework, which includes a copying mechanism to address rare or unseen words. Furthermore, this model integrates a hierarchical attention mechanism to simultaneously consider both key words and key sentences.

TABLE I. Categories Covered in this Study

Category	Terms
Encoder-Decoder Architecture	• RNN/LSTM/GRU • Bi-RNN/ Bi-LSTM/ Bi-GRU • Transformer • BERT/GPT2 • BART
Mechanisms	• Attention • Copying • Coverage • Pointer generator
Training and Optimization	• Word Level Training • Sequence Level Training • Document-Level Training • Sentence-Level Training • Transfer Learning • Reinforcement Learning
Dataset	• CNN/DailyMail • New York Times • Gigaword • DUC 2004
Evaluation	• ROUGE • BLEU • METEOR

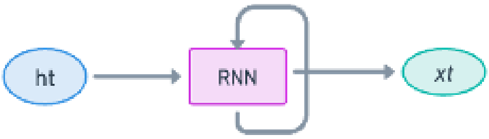

Fig. 3. RNN architecture.

1) Recurrent Neural Network (RNN): Recurrent Neural Networks (RNNs) are a class of neural networks that excel in processing sequential data. Unlike traditional feedforward neural networks, RNNs have loops in their architecture, allowing information to persist [20]. This unique feature makes RNNs particularly suitable for tasks where context and sequence matter, such as language modeling and behavior analysis in social media [21]. The core functionality of an RNN can be captured by the following formula:

$$h_t = \tanh(W_{hh}h_{t-1} + W_{xh}x_t + b_h) \tag{1}$$

Here, h_t is the current hidden state, W_{hh} is the weight associated with the previous hidden state h_{t-1}, x_t is the current input, and W_x is the weight associated with the current input. The $\tanh$ function is an activation function that helps to normalize the output. This formula represents how RNNs process information over time. The current hidden state h_t is a function of the previous hidden state and the current input, allowing the network to maintain a form of 'memory' of past inputs. This is crucial for tasks that require understanding the sequence of data, such as text processing.

Fig. 3 illustrates the looping structure of RNNs, where the output of a layer is fed back into the same layer as input. This loop enables the network to pass information across time steps, effectively remembering previous inputs and using this memory to influence the output.

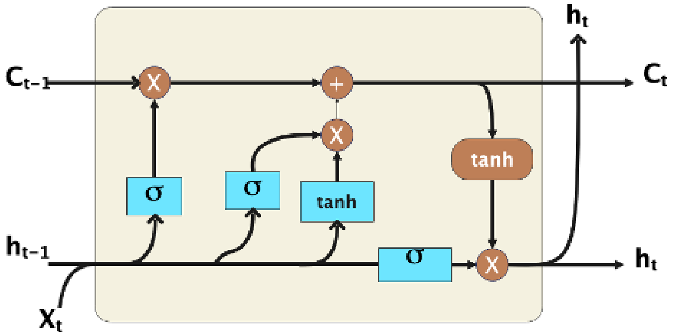

Fig. 4. LSTM architecture.

RNNs have been pivotal in advancing abstractive text summarization. Their ability to handle sequential data makes them ideal for this task, where understanding the context and flow of a text is crucial for generating coherent summaries. RNNs, especially when combined with techniques like Long Short-Term Memory (LSTM) networks, have significantly improved the performance of abstractive summarization systems [22, 23]. These networks can capture long-range dependencies in text, allowing for more accurate and contextually relevant summaries.

2) Long-Short Term Memory (LSTM): Long Short-Term Memory (LSTM) networks are an advanced type of Recurrent Neural Networks (RNNs), designed to address the challenge of learning long-term dependencies. LSTMs are particularly known for their ability to overcome the vanishing gradient problem commonly encountered in traditional RNNs [20]. LSTM networks introduce a more complex computational unit called a cell, which includes mechanisms known as gates [87]. These gates control the flow of information, allowing the network to retain or forget information selectively. The core operations within an LSTM cell can be summarized with the following formulas:

- Forget Gate: $f_t = \sigma(W_f \cdot [h_{t-1}, x_t] + b_f)$
- Input Gate: $i_t = \sigma(W_i \cdot [h_{t-1}, x_t] + b_i)$
- Cell State Update: $\tilde{C}_t = \tanh(W_C \cdot [h_{t-1}, x_t] + b_C)$
- Final Cell State: $C_t = f_t * C_{t-1} + i_t * \tilde{C}_t$
- Output Gate: $o_t = \sigma(W_o \cdot [h_{t-1}, x_t] + b_o)$
- Hidden State: $h_t = o_t * \tanh(C_t)$

Here, σ represents the sigmoid function, $\tanh$ is the hyperbolic tangent function, W and b are weights and biases, and $*$ denotes element-wise multiplication. These equations represent the LSTM's ability to regulate the flow of information. The forget gate decides what information to discard from the cell state, while the input gate updates the cell state with new information. An illustration of this process is presented in Fig. 4. The output gate then determines what part of the cell state should be outputted to the next layer or used as the hidden state for the next time step.

Fig. 4 illustrates the internal structure of an LSTM cell, showing the input x_t, the previous hidden state h_{t-1}, the cell state C_t, and the gates that regulate the flow of information within the cell. See et al. [24] introduced a sequence-to-sequence LSTM model with attention mechanisms to improve the quality of abstractive summaries, demonstrating significant

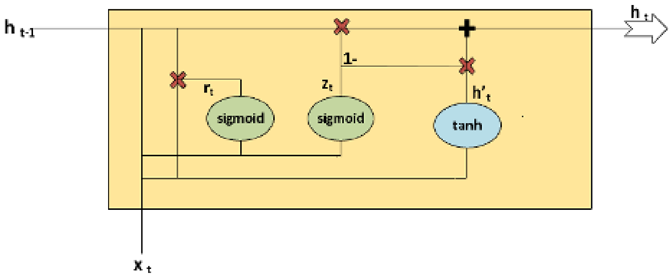

Fig. 5. GRU architecture.

advancements over previous techniques. The model's capacity to deal with long texts and its flexibility in generating novel textual content have made LSTMs a cornerstone in the development of abstractive summarization models, propelling the field towards more human-like summarization capabilities.

3) Gated Recurrent Unit (GRU): GRUs, introduced by Cho et al. [25], are designed to adaptively capture dependencies of different time scales in a sequence. Gated Recurrent Units (GRUs) are a type of recurrent neural network (RNN) architecture that has gained popularity due to their efficiency and effectiveness, especially in sequence modeling tasks. GRUs simplify the LSTM architecture and often provide comparable performance. They consist of two gates: the update gate and the reset gate. These gates help the model decide how much of the past information needs to be passed along to the future. The operations within a GRU can be summarized with the following formulas:

- Update Gate: $z_t = \sigma(W_z \cdot [h_{t-1}, x_t] + b_z)$
- Reset Gate: $r_t = \sigma(W_r \cdot [h_{t-1}, x_t] + b_r)$
- Candidate Hidden State: $\tilde{h}_t = \tanh(W \cdot [r_t * h_{t-1}, x_t] + b)$
- Final Hidden State: $h_t = (1 - z_t) * h_{t-1} + z_t * \tilde{h}_t$

In this context, σ represents the sigmoid function, $\tanh$ is the hyperbolic tangent function, W and b are weights and biases, and $*$ denotes element-wise multiplication. These equations represent how GRUs can selectively update their hidden state. The update gate z_t decides how much of the past information needs to be passed to the future, while the reset gate rt determines how much of the past information to forget. The candidate hidden state h t is a combination of the current input and the past hidden state, modulated by the reset gate. The final hidden state ht is then a blend of the old state and the new candidate state, as governed by the update gate.

Fig. 5 illustrates the internal structure of a GRU cell, showing the input x_t, the previous hidden state h_{t-1}, the update and reset gates, and the final hidden state h_t. GRUs, with their architecture designed to mitigate the vanishing gradient problem common in traditional RNNs, allow for better retention of information over longer sequences which is crucial for summarization tasks. Recent research has further explored the integration of GRUs into sophisticated neural network models to enhance abstractive summarization. For instance, Rehman et al. [26] developed an attentive GRU-based encoder-decoder model, demonstrating the efficacy of GRUs in producing summaries that are not only concise but also capture the essence of the original text with high fidelity. This research underscores the versatility of GRUs in dealing with diverse linguistic structures and their capacity to improve the summarization process, making them an indispensable tool in the field of natural language processing.

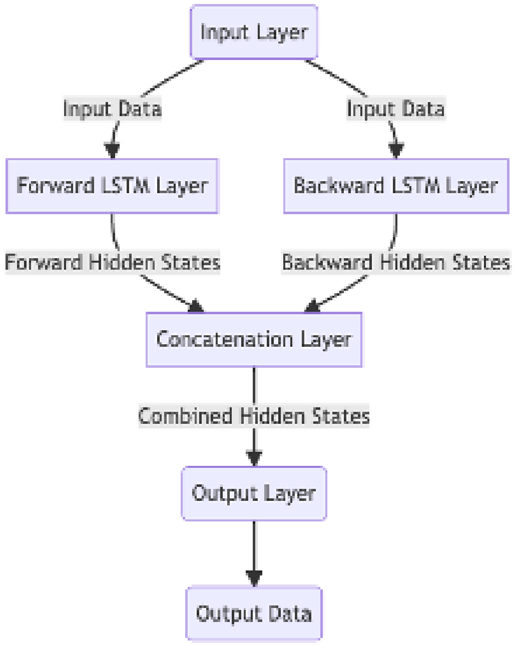

Fig. 6. Bi-LSTM structure.

4) Bi-Directional RNN/LSTM/GRU: Bi-directional Recurrent Neural Networks (Bi-RNNs), including their variants like Bi-LSTM (Bi-directional Long Short-Term Memory) and Bi-GRU (Bi-directional Gated Recurrent Unit), are advanced neural network architectures that process data in both forward and backward directions. This bidirectional approach allows the networks to have both backward and forward information about the sequence at every time step [27].

Fig. 6 illustrates a bi-directional architecture where each time step receives inputs from two sides: one from the beginning of the sequence to the current time step and the other from the end of the sequence to the current time step. This dual input mechanism allows the network to preserve information from both past and future states, enhancing its predictive accuracy.

In abstractive text summarization, the context of the entire text is crucial for generating coherent and relevant summaries. Bi-directional models, by considering both preceding and following contexts, can capture the nuances of language more effectively. This results in summaries that are not only concise, but also maintain the essence and flow of the original text. Preethi et al. [27] developed an abstractive summarizer using Bi-LSTM, demonstrating its capability to produce precise and coherent summaries without the redundancy issues often encountered in simpler models.

5) Transformer: The Transformer is a type of neural network architecture that has garnered significant attention, particularly in the domain of natural language processing

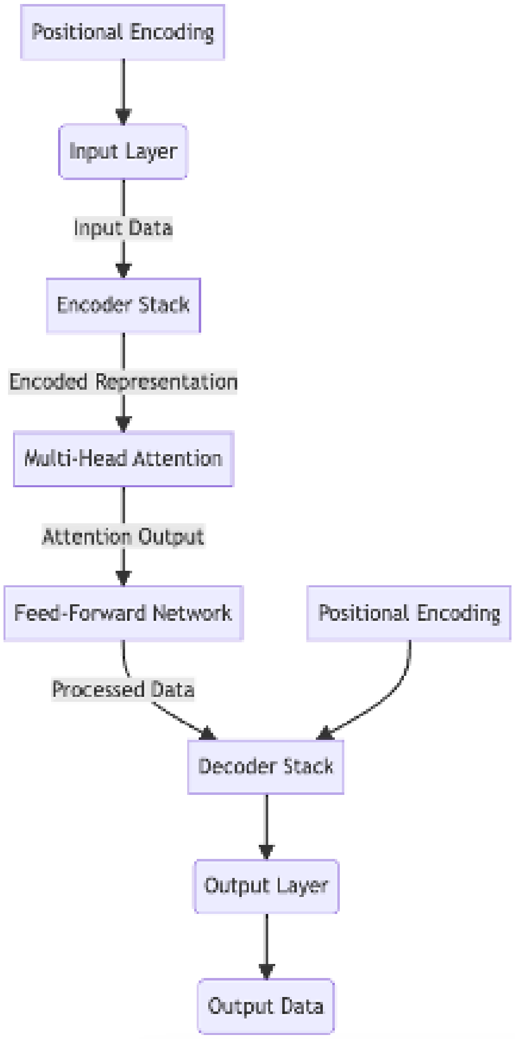

Fig. 7. Transformer architecture.

(NLP). Introduced by Vaswani et al. [28], the Transformer model is known for its reliance on self-attention mechanisms, which allow it to process input data in parallel and capture complex dependencies in sequences. Transformers have been applied in various domains, demonstrating their versatility and effectiveness. Fig. 7 illustrates the core components of the Transformer architecture, including the encoder and decoder stacks, each comprising multiple layers of self-attention and feed-forward neural networks. The self-attention mechanism allows the model to weigh the influence of different parts of the input data, enabling it to capture long-range dependencies.

a) Text-to-Text Transfer Transformer (T5): The Text-to-Text Transfer Transformer (T5) model, an encoder-decoder Transformer implementation, has been pivotal in the advancement of abstractive text summarization. This model's ability to convert all NLP problems into a unified text-to-text format, as outlined by Raffel et al. [29], allows for seamless application across a wide range of text summarization tasks. T5's architecture, incorporating self-attention mechanisms, layer normalization, and a dense layer with a softmax output, facilitates the generation of coherent and contextually relevant summaries from extensive text inputs. In the realm of summarization, T5 has been utilized to push the boundaries of abstractive text summarization, offering significant improvements over traditional models. For instance, Itsnaini et al. [30] leveraged T5 in the context of the Indonesian language, showcasing its effectiveness through high evaluation scores despite challenges in achieving optimal abstraction. Further research by Lubis et al. [18] introduced an approach by combining T5 with Bayesian optimization to enhance text summarization. Additionally, the study on Arabic news summarization by Ismail et al. [17] utilized a T5-based approach, achieving state-of-the-art performance and illustrating T5's capacity for language-specific applications. These examples highlight the versatility and efficiency of the T5 model in handling diverse and complex summarization tasks. By leveraging pre-trained models like T5, researchers can address the inherent challenges of abstractive summarization, such as maintaining factual accuracy and coherence, across various languages and domains.

6) Bidirectional Encoder Representations from Transformer-Generative Pre-Trained Transformer (BERT-GPT): Bidirectional Encoder Representations from Transformer (BERT), when combined with Generative Pre-Trained Transformer (GPT) which excels in generating coherent and contextually relevant text, becomes particularly effective for abstractive text summarization. For instance, a study by Darapaneni et al. [31] explored the use of BERT and GPT-2 models for summarizing research articles related to COVID-19. They found that while BERT models performed well for extractive summarization, there was room for improvement in abstractive summarization, which was addressed by using GPT-2 models. The combination of these models helped in creating more accurate and comprehensive summaries. In another study, Baykara and Güngör [32] utilized pre-trained sequence-to-sequence models, including BERT and GPT, for Turkish abstractive text summarization. They demonstrated that these models could generate high-quality summaries by addressing challenges such as saliency, fluency, and semantics. Kieuvongngam et al. [33] also leveraged BERT and GPT-2 for summarizing COVID-19 medical research articles. Their approach provided abstractive and comprehensive summaries based on keywords extracted from the original articles, showcasing the effectiveness of these models in processing complex medical texts.

The integration of Bidirectional Encoder Representations from Transformers (BERT) and Generative Pre-trained Transformer (GPT) models has shown promising results in the field of abstractive text summarization. These models leverage the strengths of both BERT's deep bidirectional understanding and GPT's powerful generative capabilities. The combination of BERT and GPT models brings together the best of both worlds – deep contextual understanding and advanced text generation capabilities. This synergy is particularly beneficial for abstractive text summarization, where the goal is to generate summaries that are not only concise but also retain the essence and context of the original text. By leveraging BERT's ability to understand nuanced context and GPT's proficiency in generating coherent text, these models can create summaries that are both informative and readable, making them highly suitable for summarizing complex and lengthy documents.

7) Bidirectional and Autoregressive Transformers (BART): Bidirectional and Auto-Regressive Transformers (BART)'s architecture, which includes a bidirectional encoder (like BERT) and an autoregressive decoder (like GPT), enables it to understand the context of a text deeply and generate summaries that are both fluent and informative [34]. BART has emerged as a powerful tool in the field of abstractive text summarization. It combines the benefits of both autoencoding and autoregressive approaches, making it particularly effective for generating coherent and contextually accurate summaries. Baykara and Güngör [32] utilized BART for Turkish abstractive text summarization where they showed that BART, along with other pre-trained sequence-to-sequence models, could generate high-quality summaries by addressing challenges such as saliency, fluency, and semantics. BART's effectiveness in abstractive text summarization stems from its ability to understand and reconstruct the input text accurately. By pre-training on a large corpus of text with various noising and denoising tasks, BART learns to correct errors, fill in missing information, and rephrase sentences, which are essential skills for summarization. When fine-tuned on summarization tasks, BART can generate summaries that not only capture the essential points of the original text, but also maintain a natural and coherent narrative flow. This makes BART an ideal choice for summarizing complex texts across various domains including news articles, scientific papers, and legal documents.

B. Mechanisms

Mechanisms serve as additional features integrated into the fundamental neural encoder-decoder structure, aimed at resolving specific challenges encountered in abstractive summarization systems and enhancing the quality of the summaries produced.

1) Attention: The attention mechanism was initially inspired by the human visual attention system and has since become a fundamental component in neural network models, especially in natural language processing (NLP) tasks [35]. The attention mechanism in neural networks is a critical advancement that enhances the encoder-decoder architecture, particularly in tasks like abstractive text summarization. It allows the model to focus on different parts of the input sequence for each step of the output sequence, thereby capturing more nuanced relationships within the text. It addresses the limitation of traditional sequence-to-sequence models by enabling the network to weigh and focus on different parts of the input sequence, which is crucial for understanding long and complex texts. In the context of abstractive text summarization, attention mechanisms have been shown to significantly improve the quality of generated summaries. Krantz and Kalita [36] demonstrated the effectiveness of attention-based models in generating abstractive sentence summaries, highlighting the importance of this mechanism in capturing the essential elements of the source text. The attention mechanism can be mathematically represented as follows:

$$\text{Attention}(Q, K, V) = \text{softmax}\left(\frac{QK^T}{\sqrt{d_k}}\right)V \tag{2}$$

Here, Q, V, and K represent the query, value, and key matrices, respectively. The softmax function is applied to the scaled dot-product of Q and K, which determines the weightage of each part of the input sequence. The output is then computed as a weighted sum of the values V, where the weights are given by the attention scores. A representation of this procedure is illustrated in Fig. 8.

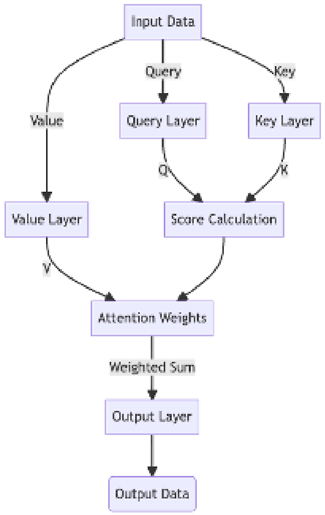

Fig. 8. Attention mechanism structure.

Fig. 8 illustrates how the attention mechanism operates within a neural network. It shows the flow of information from the input sequence through the attention module, where the query, key, and value matrices are computed and used to generate the attention scores. These scores are then applied to the input sequence to produce a context vector, which is used by the decoder to generate the output sequence. This mechanism is particularly effective in tasks like abstractive text summarization, where understanding the context and relationships within the text is crucial for generating coherent and accurate summaries.

a) Self-attention Mechanism: Self-attention, also known as intra-attention, is a mechanism that enables a model to assign varying degrees of importance to different segments of input data in relation to one another. This feature has been pivotal in developing architectures like the Transformer, which heavily utilizes self-attention for processing sequences [37]. In the realm of natural language processing (NLP), self-attention has enhanced the performance of tasks including machine translation, text summarization, and sentiment analysis. Networks employing self-attention are capable of linking words that are far apart through shorter paths within the network than those used by RNNs, potentially enhancing their performance in capturing long-distance relationships between elements in the data [38]. Yang et al. [39] applied self-attention to identify relationships between sentences and introduced a copying mechanism to address the issue of words that are out of vocabulary (OOV). Duan et al. [40] introduced a contrastive attention mechanism within the sequence-to-sequence framework for the task of abstractive sentence summarization, aimed at creating concise summaries of source sentences. This mechanism comprises two types of attention: the traditional attention, which focuses on the relevant parts of the source sentence, and an opposing attention, which targets the irrelevant or less significant parts. These attentions are trained inversely to enhance the impact of traditional attention while reducing the influence of the opposing attention through an innovative use of softmax and softmin functions. Furthermore, Wang [41] developed a model for abstractive text summarization that integrates a hybrid attention mechanism, leveraging sentence-level attention to refine the distribution of word-level attention, thereby improving ROUGE scores and preserving critical information in the summaries.

2) Copying: The copying mechanism has been effectively utilized in various abstractive text summarization models to enhance their ability to generate accurate and contextually relevant summaries. This mechanism allows models to directly copy words or phrases from the source text into the summary, ensuring the inclusion of key information and terminology [24]. The copying mechanism in neural networks, particularly in sequence-to-sequence models, can be represented by a formula that combines the probabilities of generating words from the vocabulary and copying words from the source text. The formula typically used is:

$$P(w) = (1 - p_{\text{gen}}) \cdot \sum_{i:w_i=w} a_i^t \tag{3}$$

Here:

- $P(w)$ is the probability of the word w being in the output sequence.
- p_gen is the generation probability (used in the pointer generator mechanism, but here we focus on the copying part, hence $1 - p_gen$.
- a_i^t represents the attention distribution, where i indexes over the input sequence at time t.
- The summation $\sum_{i:w_i=w} a_i^t$ accumulates the attention scores for all instances of the word w in the input sequence, contributing to the probability of copying the word w from the input.

Li et al. [42] introduced the Correlational Copying Network (CoCoNet) for abstractive summarization. CoCoNet enhances the standard copying mechanism by tracking the copying history, thereby encouraging the model to copy input words relevant to previously copied ones. Zhou et al. [43] developed SeqCopyNet, a framework that not only learns to copy single words, but also copies sequences from the input sentence. This model leverages pointer networks to select sub-spans from the source text, integrating sequential copying into the generation process. These studies and applications demonstrate the effectiveness of the copying mechanism in enhancing the quality of abstractive text summarization. By allowing direct copying from the source text, these models can produce summaries that are both accurate and reflective of the original content.

3) Coverage: The coverage mechanism in neural networks, particularly in sequence-to-sequence models for tasks like abstractive text summarization, is designed to tackle the issue of repetition and improve the focus of the model on different parts of the input text [24]. This mechanism keeps track of what has been covered in the source text, thereby preventing the model from repeatedly attending to the same parts of the input. The coverage mechanism can be mathematically represented as follows:

$$c_t = \sum_{i=0}^{t-1} a_i \tag{4}$$

Here:

- c_t is the coverage vector at time step t, which accumulates the attention weights a_i from all previous time steps.
- a_i represents the attention distribution at time step i.
- The summation $\sum_{i=0}^{t-1} a_i$ accumulates the attention distributions from all previous time steps up to $t - 1$.

The coverage vector ct is then used to inform the attention mechanism at each decoding step, helping the model to distribute its attention more evenly across the entire input sequence. See et al. [24] incorporated the coverage mechanism into their pointer-generator network for abstractive summarization, significantly reducing the issue of repetition in the generated summaries. This approach demonstrated the effectiveness of the coverage mechanism in improving the quality and readability of machine-generated summaries.

4) Pointer-Generator: The Pointer-Generator model is designed to tackle the challenges associated with out-of-vocabulary (OOV) words and inaccuracies in reproducing factual information. It manages this by either replicating words or factual data through a pointer mechanism or by generating new words via a generator component [24]. The model calculates both an attention distribution and a vocabulary distribution (P_{vocab}), along with a generation probability denoted as p_gen. This generation probability determines whether the next word will be generated from the model's own vocabulary or copied directly from the source text. The process for determining the final probability of any given output word is established through a specific mathematical formulation:

$$P(w) = p_{\text{gen}} \cdot P_{\text{vocab}}(w) + (1 - p_{\text{gen}}) \cdot \sum_{i:w_i=w} a_i^t \tag{5}$$

Here:

- $P(w)$ is the probability of the word w being in the output sequence.
- P_gen is the generation probability, which is a scalar learned by the model. It decides whether to generate a word from the vocabulary or copy from the source text.
- $P_{\text{vocab}}(w)$ is the probability of the word w according to the model's vocabulary distribution.
- a_i^t represents the attention distribution, where i indexes over the input sequence. It indicates the model's focus on different parts of the input sequence at time t.
- The summation $\sum_{i:w_i=w} a_i^t$ accumulates the attention scores for all instances of the word w in the input sequence, contributing to the probability of copying the word w from the input.

Ren and Zhang [44] proposed a pointer-generator text summarization model that integrates part of speech features. This model uses a pointer-generator network to control whether to generate or copy words, effectively addressing out-of-vocabulary issues and avoiding duplication problems. Liu et al. [45] proposed a topic-aware architecture to adapt the Pointer-Generator model for summarizing conversations. Rehman et al. [26] used Pointer-Generator networks with SciBERT embeddings for automatic research highlight generation.

C. Training and Optimization

Training refers to the method through which a model acquires knowledge. Sequence-to-sequence models require training to predict the subsequent word in a sequence, based on the preceding output and the contextual information.

1) Word level training: Word level training in abstractive text summarization involves focusing on individual words, their representations, and relationships. This training method is crucial for understanding the semantics and syntactic properties of words within the context of summarization. Word level training is fundamental in developing models that can accurately interpret and reproduce the meaning of words in summaries. It often involves techniques like word embeddings to capture semantic relationships between words [46].

2) Sequence level training: Sequence level training in abstractive text summarization involves training models to understand and process sequences of words such as sentences or paragraphs. This type of training is crucial for models to capture the context and flow of ideas in the text. Unlike word level training, which focuses on individual words, sequence level training helps the model understand how words combine to form meaningful phrases and sentences. Sequence level training deals with sequences of words, such as sentences or paragraphs. It is essential for understanding the context and how words are used together in sequences. Such training is crucial for enabling models to understand the narrative structure and context present in the text, allowing them to produce summaries that are both coherent and relevant to the context [47].

3) Document level training: Document-level training involves training models on entire documents to understand the overall theme, structure, and sentiment. This approach is crucial for tasks like abstractive text summarization, where the model needs to grasp the main ideas and narrative structure of the entire text. Fecht et al. [48] examined the impact of sequential transfer learning on abstractive machine summarization using multilingual BERT and highlighted the effectiveness of transfer learning in improving the summarization of texts in languages.

4) Sentence level training: Sentence-level training in abstractive text summarization focuses on understanding and processing individual sentences within a document. This approach is crucial for models to capture the meaning, structure, and nuances of each sentence, which is essential for generating coherent and contextually accurate summaries. Chen et al. [47] proposed a novel extractive-generative model for text summarization using synthetic seq-2-seq pairs. The model demonstrates promise at the sentence level, indicating the potential of sentence-level training in generating sensible output for summarization tasks under resource constraints.

5) Transfer learning: Transfer learning is a technique in machine learning where a model designed for one specific task is repurposed as the foundation for a model on a different task. Within the realm of abstractive text summarization, this method involves adopting a model that has been pre-trained on a broad and varied dataset, and then fine-tuning this model for the specialized task of text summarization [29]. Zolotareva et al. [49] investigated the application of Sequence-to-sequence recurrent neural networks and Transfer Learning with the Unified Text-to-Text Transformer in abstractive text summarization, demonstrating significant enhancements in the summarization process.

6) Reinforcement learning: Reinforcement learning in abstractive text summarization is a training approach where the model learns to make decisions, such as selecting the most relevant content for the summary, by receiving feedback in the form of rewards or penalties. Nguyen et al. [8] explored a performance-driven reinforcement learning approach for abstractive text summarization, demonstrating its effectiveness in improving summary quality. Buciumas [50] discusses the use of reinforcement learning in abstractive text summarization, focusing on pre-trained models and RL to generate summaries across multiple datasets.

D. Datasets

Datasets play a crucial role in the training and evaluation of models, particularly in the field of abstractive text summarization. In the English language, there are several key datasets available for this purpose. The CNN/Daily Mail dataset, which includes articles and editorials from CNN and Daily Mail, was introduced for abstractive summarization by Nallapati et al. [46]. This dataset comprises 286,817 training pairs, 13,368 validation pairs, and 11,487 test pairs.

Another significant dataset is Newsroom, introduced by Grusky et al. [51], which contains 1.3 million articles and summaries authored by professionals from 38 different news publications, covering news from 1998 to 2017. The Gigaword dataset is an extensive collection of English newswire text. First used for abstractive summarization by Rush et al. [52], it includes approximately 9.5 million news articles. In Gigaword, each article's first sentence and its headline are used to form a source-summary pair. The Document Understanding Conference (DUC) dataset, another vital resource, is split into two parts: the 2003 corpus with 624 document-summary pairs and the 2004 corpus with 500 pairs, as noted by Nallapati et al. [46].

Zhang et al. [53] introduced MAC-SUM, a human-annotated summarization dataset for controlling mixed attributes. The XSUM dataset consists of BBC articles, each accompanied by a single-sentence summary [54]. It contains over 200,000 BBC articles each accompanied by a single-sentence summary. These summaries are professionally written, often serving as introductory or headline sentences. This dataset is designed specifically for the task of extreme summarization, a form of abstractive summarization that aims to produce a single-sentence summary for each document. MAC-SUM comprises source texts from two sectors namely news articles and dialogues, accompanied by human-generated summaries that are regulated according to five specific attributes: Length, Extractiveness, Specificity, Topic, and Speaker.

Table II provides a concise overview of the datasets used in abstractive text summarization, highlighting their origins, contents, and unique features. These datasets are instrumental in training and evaluating models in the field, offering diverse and comprehensive resources for developing advanced summarization techniques.

E. Evaluation Metrics

Automating the summarization task necessitates a system or method for its assessment and evaluation. While manual assessment is one approach, there are also specific metrics designed for this purpose. ROUGE (Recall Oriented Understudy for Gisting Evaluation), introduced by Lin [55], focuses on recall and is widely used for evaluating automatic summaries. ROUGE is primarily based on recall. It measures the overlap of n-grams, word sequences, and word pairs between the generated summary and a set of reference summaries. ROUGE is the most popular metric in summarization tasks due to its effectiveness in capturing content overlap. It is particularly useful for evaluating the extent to which the key information from the source text is retained in the summary. ROUGE's widespread adoption in summarization research is attributed to its alignment with human judgment, especially in terms of content coverage and informativeness.

BLEU (Bilingual Evaluation Understudy), proposed by Papineni [56], evaluates based on precision and recall, and its scores are commonly applied in automatic summarization system assessments. METEOR (Metric for Evaluation of Translation with Explicit Ordering), developed by Banerjee and Lavie [57], is primarily for assessing machine translation outputs but is also applicable to summarization. BLEU evaluates based on precision. It compares the n-grams of the generated summary with those in the reference summary and calculates a score based on the proportion of n-grams in the generated summary that appear in the reference summary. Although originally developed for machine translation, BLEU is also used in summarization. It is particularly effective for assessing the preciseness of the generated summaries in capturing the essential points of the source text.

METEOR utilizes modified precision and recall. These evaluation metrics offer an estimate of the extent to which the auto-generated summary aligns with the reference summary. Table III provides an overview of the key metrics used in the evaluation of automatic text summarization systems, highlighting their foundational principles and applications. METEOR is based on modified precision and recall. It goes beyond mere lexical matching to include stemming and synonymy, providing a more nuanced evaluation of translation outputs and summaries. While primarily designed for machine translation, METEOR's application in summarization is valuable, especially for its ability to recognize paraphrases and semantically equivalent phrases, thus offering a more comprehensive evaluation.

IV. Discussion

This section presents the analysis and findings of the survey, and addresses significant topics of discussion.

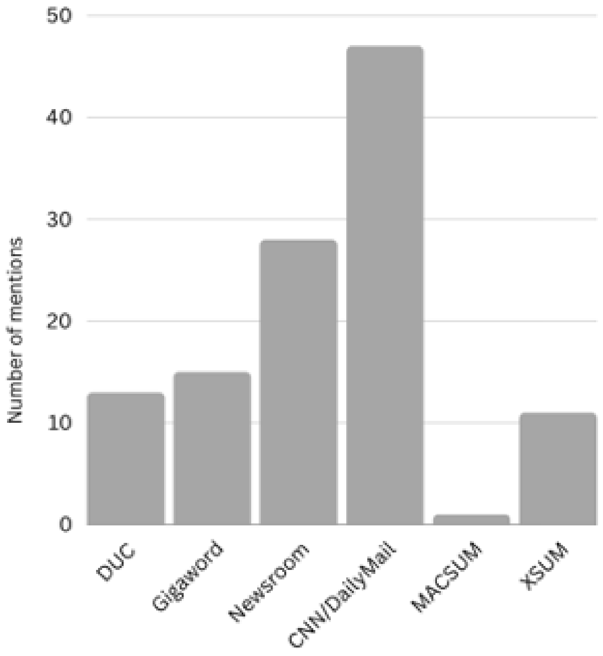

Fig. 9. Number of studies per dataset.

A. Dataset

As depicted in Fig. 9, it is clear that numerous studies in the survey predominantly use the CNN/Daily Mail dataset for abstractive summarization tasks. Further analysis of the dataset aspect reveals that this survey identifies several large datasets in languages deemed to be low-resource, such as Turkish [32], Hungarian [32], Indonesian [58], and French [59].

B. Evaluation Metrics

The evaluation of generated summaries is crucial for assessing the effectiveness and accuracy of different models and approaches. Several metrics have been developed for this purpose, each with its unique focus and methodology. Among these, ROUGE, BLEU, and METEOR are the most prominent. Notably, we observed among the papers that ROUGE is the most widely used metric in this domain as presented in Table IV. Our findings on the frequency of usage of evaluation metrics employed by researchers underscore the predominant preference for ROUGE as the primary evaluation metric, with 53 instances of use among the collected studies. This preference starkly contrasts with the 17 instances where BLEU (Bilingual Evaluation Understudy) was utilized and the three instances of METEOR (Metric for Evaluation of Translation with Explicit Ordering) application.

The preference for ROUGE as the dominant metric for evaluating generated summaries within ATS research can be attributed to several factors. Firstly, ROUGE's design specifically caters to summary evaluation by measuring the overlap of n-grams between the generated summaries and reference summaries. This characteristic makes ROUGE highly suitable for tasks where capturing the gist of the text is more critical than the exact reproduction of phrases or sentence structures, aligning well with the objectives of ATS. Secondly, ROUGE

TABLE II. KEY DATASETS FOR ABSTRACTIVE TEXT SUMMARIZATION RESEARCH

Dataset Name	Description	Authors	Details
CNN/Daily Mail	Articles and editorials from CNN and Daily Mail for abstractive summarization.	Nallapati et al. [46]	Comprises 286,817 training pairs, 13,368 validation pairs, and 11,487 test pairs.
Newsroom	1.3 million articles and summaries from 38 news publications.	Grusky et al. [51]	Covers news from 1998 to 2017.
Gigaword	Extensive collection of English newswire text.	Rush et al. [52]	Approximately 9.5 million news articles. Source-summary pairs created from the first sentence and headline.
DUC	Document Understanding Conference dataset for text summarization.	Nallapati et al. [46]	Two parts: 2003 corpus with 624 pairs and 2004 corpus with 500 pairs.
MAC-SUM	Human-annotated summarization dataset for controlling mixed attributes.	Zhang et al. [53]	Contains texts from news articles and dialogues with summaries controlled by attributes.
XSUM	BBC articles each accompanied by a single-sentence summary for extreme summarization.	Narayan et al. [54]	Over 200,000 articles, each with a professionally written single-sentence summary.

TABLE III. EVALUATION METRICS FOR ABSTRACTIVE TEXT SUMMARIZATION

Metric	Description	Year	Application
ROUGE	Based on recall, evaluates the quality of automatic summaries.	2004	Commonly used in automatic summarization evaluation.
BLEU	Evaluates based on precision and recall, used for summarization and translation.	2002	Applied in automatic summarization system assessments.
METEOR	Utilizes modified precision and recall, originally for machine translation but applicable to summarization.	2005	Used for both machine translation and summarization evaluation.

offers various measures such as ROUGE-N (for n-gram overlap), ROUGE-L (for the longest common subsequence), and ROUGE-W (for weighted longest common subsequence), providing a comprehensive assessment framework that can accommodate different summarization goals. This versatility ensures a broader evaluation perspective, covering aspects from simple word overlap to more complex semantic coherence and fluency. In contrast, BLEU, while widely used in machine translation evaluation, focuses more on precision—the proportion of words in the generated text that appear in the reference texts. This metric's emphasis on precision over recall can be less aligned with the summarization task's nuances, where capturing the most relevant information (regardless of the exact wording) is often more critical.

METEOR, despite offering a more balanced evaluation by considering synonymy and stemming and aiming for higher correlation with human judgment, is used less frequently. This lesser usage might stem from its complexity and computational demand, making ROUGE a more straightforward and efficient choice for many researchers. These SLR results indicate a clear consensus within the ATS research community on the effectiveness and appropriateness of ROUGE for evaluating summarization tasks. The findings also suggest a need for continuous evaluation of existing metrics and the development of new metrics that can capture the qualitative aspects of summaries more accurately, reflecting human judgments and preferences.

TABLE IV. FREQUENCY OF USAGE OF EVALUATION METRICS AMONG COLLECTED STUDIES

Metric	Number of Usages
ROUGE	53
BLEU	17
METEOR	3

C. Model Performance Comparison

Some recent abstractive text summarization approaches with highest Rouge scores were selected and compared as seen in Table V. Among the selected studies, Zhao et al. [60] which focused on sequence likelihood calibration achieved the highest ROUGE scores across all three metrics: ROUGE-1 (48.88), ROUGE-2 (24.94), and ROUGE-L (45.76). ROUGE-1 measures the overlap of unigrams between the generated summaries and the reference summaries, indicating the accuracy of capturing key points. ROUGE-2 evaluates the overlap of bigrams, reflecting the model's ability to preserve essential phrases and the coherence of the generated text. Lastly, ROUGE-L assesses the longest common subsequence, focusing on the fluency and the structural similarity between the generated summaries and the reference summary. This indicates the superior ability of their model to align closely with reference summaries, particularly in terms of content overlap and fluency. Their approach demonstrated the effectiveness of integrating contrastive learning into summarization tasks. He et al. [61] address computational efficiency, a critical aspect in processing long sequences. Their innovative use of the Fast Fourier Transform (FFT) operator showcases how computational advancements can enhance model performance. Wang et al. [62] introduced a concept of salience allocation as guidance, highlighting the importance of content selection in generating coherent summaries. Lastly, Ravaut et al. [63] with "SummaReranker" introduced a re-ranking framework, conducting summary generation by selecting better candidates from a set of options. This approach underscores the potential of multi-stage processing in improving summary quality.

A notable trend is the focus on enhancing existing models through innovative techniques like contrastive learning, sequence likelihood calibration, and re-ranking strategies. These methods aim to refine the model's ability to generate summaries that are not only accurate, but also contextually rich and coherent. The studies also reflect a growing interest in addressing specific challenges such as computational efficiency and the quality of content selection, which are crucial for the practical application of summarization models. The analysis of these studies reveals a dynamic and rapidly evolving field, with each approach contributing to the overall goal of improving the quality and applicability of abstractive text summarization

TABLE V. ROUGE Scores for Various Approaches

Authors	Approach	ROUGE-1	ROUGE-2	ROUGE-L
Liu and Liu [45]	SimCLS: Contrastive Learning Framework	46.67	22.15	43.54
He et al. [61]	Fourier Transformer: Removing Sequence Redundancy	44.76	21.55	41.34
Wang et al. [62]	SEASON: Salience Allocation Guidance	46.27	22.64	43.08
Ravaut et al. [63]	SummaReranker: Re-ranking Framework	47.16	22.61	43.87
Zhao et al. [60]	SLiC: Sequence Likelihood Calibration	48.88	24.94	45.76
Liu et al. [52]	BRIO: Non-Deterministic Distribution Training	47.78	23.55	44.57

models. The diversity in methodologies and the continuous push for higher ROUGE scores indicate a vibrant research landscape, driven by the pursuit of models that can generate summaries with high fidelity to the original content and contextual relevance.

To provide a more comprehensive view, we expanded the comparison by evaluating the selected models on multiple benchmark datasets, including CNN/DailyMail, XSum, and Newsroom (Table VI). Each dataset poses unique challenges and helps illustrate the practical implications of the advancements in summarization techniques. The detailed ROUGE scores presented in Table VI offer a comprehensive comparison of various abstractive text summarization approaches across multiple datasets, including CNN/DailyMail, XSum, and Newsroom. Zhao et al. [60], utilizing Sequence Likelihood Calibration (SLiC), demonstrate superior performance with the highest ROUGE-1, ROUGE-2, and ROUGE-L scores across both the CNN/DailyMail and XSum datasets, indicating their model's robust generalization and efficacy in different contexts. Liu and Liu [45] with SimCLS also show strong performance, particularly on the XSum dataset, reflecting the effectiveness of contrastive learning frameworks. He et al. [61]'s Fourier Transformer approach, while efficient, lacks data for the XSum and Newsroom datasets, highlighting a gap in evaluation. Wang et al. [62] and their SEASON model excel in the Newsroom dataset, particularly in ROUGE-2, suggesting a strength in handling diverse and complex data. Ravaut et al. [63]'s SummaReranker performs well across the board, especially on XSum, emphasizing the potential of re-ranking strategies. Liu et al. [52] with BRIO maintain competitive scores, showcasing consistent performance across multiple datasets. This diverse range of approaches and their respective performances underscore the evolving landscape of abstractive summarization, where each model brings unique strengths to address the multifaceted challenges of summarizing varied content types.

The practical implications of these advancements are significant. Zhao et al. [60] and their sequence likelihood calibration technique consistently achieve high ROUGE scores across various datasets, indicating a robust approach that generalizes well. However, their method may involve higher computational costs due to the complexity of the calibration process. He et al. [61] emphasize computational efficiency, which is particularly advantageous for real-time applications and processing long documents. Their use of the Fast Fourier Transform (FFT) operator reduces the computational burden, making it a practical choice for scenarios where efficiency is critical. Wang et al. [62] focus on content selection through salience allocation, which enhances the relevance and coherence of the summaries. This method is especially useful for summarizing documents where specific information needs to be prioritized. Ravaut et al. [63] and their re-ranking framework show the potential of multi-stage processing in improving summary quality. By selecting the best candidates from a set of generated summaries, their approach can produce more refined and accurate summaries. Liu and Liu [45] with their contrastive learning framework and Liu et al. [52] with their non-deterministic distribution training approach also contribute to the field by exploring different aspects of model training and summary generation, offering diverse solutions to common challenges. The detailed comparison across multiple datasets and the discussion of practical implications provide a clearer picture of the strengths and weaknesses of each approach. This helps in understanding the trade-offs involved and guides the selection of appropriate models for specific summarization tasks.

D. Emerging Issues and Challenges

While there have been notable advancements in abstractive text summarization using neural networks in recent times, these systems continue to present various challenges and issues for researchers. Gaining an understanding of these current problems and devising solutions to address them will lead to the development of more effective and dependable summarization systems. Based on reviewed literature, the following are key issues and challenges in abstractive text summarization:

1) Complexity of transformer-based models: Models like Transformers, while effective, suffer from quadratic complexity with respect to input text length. This makes processing long documents computationally expensive and less efficient [64]. While self-attention offers many benefits, such as the ability to capture long-range dependencies and parallelize computation, it also presents challenges. One significant issue is the quadratic computational cost relative to the sequence length, which can make it resource-intensive for very long sequences [37].

Researchers have been working on developing more efficient self-attention mechanisms to mitigate this issue. Bonnaerens and Dambre's [65] approach to addressing this challenge is the introduction of Learned Thresholds Token Merging and Pruning (LTMP), which combines token merging and pruning to reduce the number of input tokens that need processing, effectively lowering the computational load. This method leverages dynamic thresholding to determine the tokens to be merged or pruned, demonstrating significant efficiency improvements [65]. Additionally, Tang et al. [38] introduced QuadTree Attention mechanism, which presents a novel solution by reducing computational complexity from quadratic to linear. By constructing token pyramids and computing attention in a coarse-to-fine manner, QuadTree Attention focuses on relevant regions by selecting the top patches with the highest attention scores, thereby streamlining the attention process.

TABLE VI. DETAILED ROUGE SCORES ON MULTIPLE DATASETS

Authors	Approach	CNN/DailyMail			XSum			Newsroom		
		R1	R2	RL	R1	R2	RL	R1	R2	RL
Liu and Liu [45]	SimCLS: Contrastive Learning Framework	46.67	22.15	43.54	47.61	24.57	39.44	-	-	-
He et al. [61]	Fourier Transformer: Removing Sequence Redundancy	44.76	21.55	41.34	-	-	-	-	-	-
Wang et al. [62]	SEASON: Salience Allocation Guidance	46.27	22.64	43.08	-	-	-	46.00	33.37	42.03
Ravaut et al. [63]	SummaReranker: Re-ranking Framework	47.16	22.55	43.87	48.12	24.95	40.00	-	-	-
Zhao et al. [60]	SLiC: Sequence Likelihood Calibration	47.97	24.18	44.88	49.77	27.09	42.08	-	-	-
Liu et al. [52]	BRIO: Non-Deterministic Distribution Training	47.78	23.55	44.57	49.07	25.59	40.40	-	-	-

Wu et al. [66] introduced Singularformer, a transformative approach by leveraging neural networks to learn the singular value decomposition process of the attention matrix. This process aims to design a linear-complexity and memory-efficient global self-attention mechanism, demonstrating favorable performance against other Transformer variants with lower time and space complexity. Continued exploration and innovation in model optimization, attention mechanism refinement, and hardware acceleration are critical for advancing the field and expanding the applicability of these powerful models.

2) Model hallucination: Model hallucination represents a formidable challenge in abstractive text summarization, where models often generate text that deviates factually from the input, undermining the reliability and accuracy of the summaries. This issue not only questions the credibility of automated summarization but also poses significant hurdles in applications requiring high factual consistency [64]. Recent research has introduced innovative approaches to mitigate this problem. Contrastive Parameter Ensembling (CaPE) offers a promising solution by leveraging variations in training data noise. By fine-tuning a base model on subsets of clean and noisy data, CaPE effectively reduces hallucination, enhancing factual accuracy across different datasets [14]. Similarly, another study proposes training augmentation methods for image captioning to reduce object bias, a form of hallucination, without increasing model size or requiring additional training data [7]. Further, a simple yet effective strategy proposed for neural surface realization addresses content hallucination by integrating language understanding modules for data refinement, significantly reducing unaligned noise and improving content correctness [67]. Additionally, the Chain of Natural Language Inference (CoNLI) framework has been developed for detecting and mitigating ungrounded hallucinations in large language models, showcasing an effective method for enhancing text quality through rewrite [68].

These advancements highlight the community's ongoing efforts in confronting and reducing model hallucination in text generation tasks. By focusing on data quality, leveraging contrastive learning, and integrating understanding mechanisms, researchers continue to push the boundaries of what is possible in generating accurate and reliable automated summaries.

3) Domain shift: The performance of models often degrades when the distribution of the training and test corpus is not the same. This domain shift is particularly problematic in domain-specific summarization tasks [64]. To address the challenge of domain shift, researchers have been exploring a variety of techniques aimed at enhancing the adaptability of models across different domains. One promising approach is the leveraging of pretrained transformer models, which has shown remarkable versatility in various NLP tasks. For instance, Zhang et al. [19] demonstrates the potential of fine-tuning BART on domain-specific datasets to generate fluent and adequate summaries of doctor-patient conversations. Their methodology effectively overcomes the obstacles posed by domain shift, limited training data, and the inherent variability of target summaries. By integrating these strategies, researchers are making strides towards developing models that maintain high performance levels across varying domains, thus expanding the applicability and reliability of automatic text summarization technologies.

4) Quality of datasets: The effectiveness of summarization models is closely tied to the quality of datasets they are trained on. Srivastava et al. [69] highlighted issues like information coverage, entity hallucination, and the inherent complexity of summarization tasks as significant challenges that can impact model performance. These issues underscore the need for high-quality datasets that accurately represent the diversity and complexity of real-world texts and the necessity for summarization models to generate accurate, reliable, and coherent summaries. Information coverage is essential for ensuring that all relevant aspects of the source document are represented in the summary. This necessitates datasets that are comprehensive and reflective of the variety of information that summaries should convey. To improve information coverage, Utama et al. [70] developed Falsesum, a data generation pipeline that introduces factual inconsistencies in summaries to train models to better recognize and avoid such errors.

In exploring the balance between lexical and semantic quality in summarization, Sul and Choi [71] proposed a training method incorporating a re-ranking system. This approach aims to mitigate false positives in ranking, enhancing the model's ability to interpret the meaning of summaries without compromising lexical quality. Moreover, Liu et al. [52] introduced a training paradigm that assumes a non-deterministic distribution for candidate summaries. By assigning probability mass based on quality, this method aims to order abstractive summarization more effectively, showcasing an innovative approach to handling the complexity of summarization tasks. The complexity of summarization tasks, with varying degrees of abstraction, summarization length, and domain specificity, calls for datasets that capture this diversity. Adams et al. [72] explored the characteristics of effective calibration sets in training, finding that certain strategies, like maximizing metric margins and minimizing surprise, can improve model performance across different summarization tasks. To address these challenges, research directions included the development of advanced techniques for generating high-quality, diverse datasets and training models that are more adept at handling the intricacies of summarization.

5) Factual inconsistency: The abstraction ability of neural models can lead to the distortion or fabrication of factual information, causing inconsistency between the original text and the summary. This issue necessitates the development of fact-aware evaluation metrics and summarization systems [73]. The abstraction capabilities of neural models, while enabling the generation of concise and coherent summaries, often lead to the distortion or fabrication of factual information. This misalignment between the original text and the generated summary, known as factual inconsistency, undermines the reliability of summarization systems. Huang et al. [73] underscore the necessity for the development of fact-aware evaluation metrics and systems that can ensure the factual accuracy of summaries. To mitigate these challenges, researchers have been exploring various methodologies.

Li and Xu [59] proposed a clinical trial prediction-based factual inconsistency detection approach tailored for medical text summarization. This novel methodology leverages the relationship between clinical trial outcomes and the factual consistency of related medical articles' summaries. By predicting the success or failure of clinical trials based on summaries, their approach offers a direct method to assess factual consistency, showcasing a specialized application of factual accuracy evaluation in the medical domain. Utama et al. [70] introduced Falsesum, a data generation pipeline that creates document-level natural language inference (NLI) examples specifically designed to recognize factual inconsistencies in summarization. This approach enhances models' ability to discern and avoid factual errors by incorporating high-quality, task-oriented examples into their training data, addressing the need for datasets that challenge models to maintain factual integrity.

Exploring the capabilities of large language models, Luo et al. [74] investigated ChatGPT's potential as a factual inconsistency evaluator for abstractive text summarization. Their findings suggest that ChatGPT, under a zero-shot setting, can outperform state-of-the-art evaluation metrics across various factuality evaluation tasks. This highlights the promise of leveraging advanced language models for more nuanced and effective factual consistency assessments in summarization. To further mitigate factual inconsistency, future research directions may involve the integration of fact-checking modules within summarization frameworks, the development of more advanced fact-aware training methodologies, and the exploration of novel dataset augmentation techniques. These strategies aim to refine the summarization process, ensuring that models can produce summaries that are not only coherent and concise, but also factually accurate.

6) Multimodal summarization: Integrating multimodal knowledge, such as combining text and images for abstractive text summarization, represents a significant advancement in the field, yet it is fraught with challenges. The primary difficulty lies in bridging the semantic gaps between different modalities, which can hinder the effective fusion of multimodal data. This issue is particularly pronounced due to the divergent nature of information conveyed through text and images, necessitating innovative approaches to achieve a coherent and comprehensive summary that leverages both modalities effectively [6].

To tackle these challenges, Liang et al. [75] introduced the D2TV framework. This innovative approach, aimed at Many-to-Many Multimodal Summarization (M3S), leverages dual knowledge distillation and target-oriented vision modeling to enhance both multimodal monolingual summarization (MMS) and multimodal cross-lingual summarization (MXLS) tasks. Their framework demonstrates the effectiveness of mutual knowledge transfer between MMS and MXLS, alongside employing a contrastive objective to refine visual features for summarization, showcasing a promising direction in multimodal summarization research.

He et al. [61] developed the A2Summ model, which introduces a unified approach to align and attend to multimodal inputs. Their work focuses on leveraging dual contrastive losses to model the correlations within and between samples across modalities, thereby enhancing the quality of multimodal summaries. This method highlights the importance of understanding and aligning multimodal information to generate reliable and high-quality summaries. These efforts represent a concerted move towards overcoming the inherent challenges of multimodal summarization. By developing models that can effectively process and integrate information from diverse modalities, researchers aim to generate summaries that are not only more informative and comprehensive, but also more engaging for users.

7) Low-Resourced languages: Abstractive text summarization for low-resourced languages like Urdu faces challenges due to the lack of extensive research and datasets. Generating abstractive summaries in such languages demands more focused research efforts [76]. Abstractive text summarization in low-resourced languages, such as Urdu, presents distinct challenges due to the scarcity of extensive research, datasets, and computational resources tailored to these languages. The development of abstractive summarization capabilities in such contexts is hindered by the lack of high-quality, large-scale datasets, and advanced NLP tools that are readily available for languages with more substantial digital footprints [76]. This gap in resources and research attention limits the ability to apply state-of-the-art NLP methodologies, including deep learning techniques, which have shown significant success in abstractive summarization tasks in languages like English.

Baykara and Güngör [32] addressed this gap by introducing new large-scale datasets for agglutinative languages like Turkish and Hungarian, showcasing the potential for enhancing abstractive text summarization in languages that have traditionally been underrepresented in NLP research. Shafiq et al. [76] delved into the challenges and solutions for abstractive text summarization of Urdu using deep learning, highlighting the need for dedicated efforts to improve summarization techniques for low-resourced languages. Mascarell et al. [77] proposed entropy-based sampling approaches for abstractive multi-document summarization in low-resource settings, demonstrating innovative methods to address the challenges of summarizing content in languages with limited datasets. Hasan et al. [78] contributed to this field with XL-Sum, a large-scale multilingual abstractive summarization dataset covering 44 languages, many of which are low-resourced. This initiative marks a significant step towards fostering research and development in multilingual summarization. Rodzman et al. [85] explored the use of text summarization as a positive hierarchical fuzzy logic ranking indicator for domain-specific retrieval of Malay translated Hadith, illustrating the application of summarization techniques in religious text analysis.

In the realm of Arabic text summarization, several notable approaches have been proposed to address the unique challenges posed by the Arabic language. Abdelwahab et al. [83] focused on using pre-processing methodologies and techniques to enhance Arabic text summarization. Their work emphasizes the importance of tailored pre-processing steps to handle the morphological and syntactical complexities of Arabic. Fejer and Omar [86] introduced a method combining clustering and keyphrase extraction for automatic Arabic text summarization. This approach leverages clustering to group similar text segments and keyphrase extraction to identify the most salient information, thereby improving the coherence and relevance of the summaries. These efforts reflect a growing interest in developing robust summarization techniques for Arabic, addressing the linguistic challenges and contributing to the broader field of natural language processing for underrepresented languages. These studies underscore the growing interest and ongoing efforts to extend abstractive summarization capabilities to low-resourced languages, aiming to close the gap in NLP research and application across linguistic landscapes.

8) Evaluation metrics: The current evaluation metrics, such as ROUGE, while widely used, may not fully encapsulate the quality of generated summaries, especially in capturing nuances that align with human judgment. Srivastava et al. [69] underlined the necessity for more comprehensive and nuanced evaluation methods that can better reflect the quality perceived by humans. This calls for the development of metrics that go beyond traditional approaches to evaluate the effectiveness of summarization systems in producing summaries that are not only relevant, but also coherent and faithful to the original text. Dash et al. [79] proposed evaluating summarization algorithms from a new perspective that considers fairness in representation across different socially salient groups. Their work introduces the novel fairness-preserving summarization algorithm ‘FairSumm’, which aims to produce high-quality summaries while ensuring equitable representation, marking a step beyond traditional ROUGE-centric evaluations. Gao et al. [80] proposed SUPERT, an unsupervised evaluation metric for multi-document summarization that rates summary quality by measuring its semantic similarity with a pseudo reference summary. SUPERT’s use of contextualized embeddings and soft token alignment techniques represents a move towards more semantically rich evaluation frameworks.

The development of these comprehensive evaluation frameworks is crucial for advancing the field of text summarization and ensuring that generated summaries meet high standards of quality and utility. The exploration of evaluation metrics and methods that better capture the quality of generated summaries as perceived by humans is crucial for advancing the field of text summarization. As summarization systems become increasingly sophisticated, the development of equally sophisticated evaluation metrics will be essential to ensure their effectiveness and utility.

9) Summary length control: Controlling the length of the generated summaries is a significant challenge in Abstractive text summarization. Models often struggle to produce summaries of a desired length while maintaining the essence and coherence of the original text. This issue is crucial for applications where space is limited or a specific summary length is required. Developing methods to effectively manage summary length without compromising content quality and relevance remains an area needing further exploration and innovation [81]. Despite recent solutions to control the length of the summary, this study observed that there is still an issue of arbitrarily doing so. While length embeddings can determine when to cease decoding, they do not specify which details ought to be encapsulated within the summary, given the length restriction [81]. Length embeddings merely incorporate length information on the decoder side, potentially overlooking crucial content because they fail to consider the elements that should be summarized under certain length limitations.

Previous studies have managed to control the length of summaries, setting it either as predefined [53] or flexible [7,81]. Although these approaches have improved the quality of length-constrained summarization, they all necessitate specifying a target length prior to generating the summary. In Saito et al. [81], the length of the prototype text must be determined before feeding it into their encoder-decoder model for generating a summary. Similarly, in the work of Takase and Okazaki [7], the remaining length must be specified at each step of the decoder in their Transformer-based encoder-decoder model. For instance, as illustrated in Fig. 10, when there is a need to summarize a lengthy newspaper story to fit a specific section on the newspaper cover, the existing methods would fall short as they rely on a predefined number of words for the summary length.

Predefined or arbitrary summary lengths present challenges, particularly when summaries need to fit specific spaces, such as a designated section on a magazine or newspaper cover. Current advanced models lack the capability to adapt summaries based on the size of the output area. For instance, these models struggle to condense a lengthy newspaper story into a brief summary that would precisely fill a specific part of the newspaper cover, as their design relies on a fixed word count for summaries. This limitation is evident in the works of various researchers, including Zhao et al. [60], who have not addressed the need for space-constrained summarization.

Fan et al. [2] introduced the use of length embeddings at the start of the decoder to control summary length, offering a neural summarization model that allows for high-level attribute specification to tailor summaries more closely to user needs. Zhang et al. [19] developed a convolutional seq2seq model for summarization, enhancing the CNN with gated linear units (GLU), residual connections, and a hierarchical attention mechanism for simultaneous keyword and key sentence generation, alongside a copying mechanism for out-of-vocabulary (OOV) words. Takase and Okazaki [7] utilized positional encoding to indicate the remaining length at each step in their Transformer-based model.

Saito et al. [81] combined extractive and abstractive summarization by embedding an extractive model within an abstractive framework. This approach involves extracting a sequence of significant words (”prototype text”) from the source, which then informs the summary generation process in the encoder-decoder model. Liu et al. [53] proposed a length-aware attention mechanism (LAAM) that tailors the encoding of the source text to the desired summary length, proving effective in creating high-quality summaries of various lengths, including lengths not encountered during training. Fein and Cuevas [82] proposed ExtraPhraseRank which used TextRank for sentence extraction and back-translation for word diversity, aiming to generate synthetic summaries with controlled lengths. While their approach shows modest improvements in ROUGE scores, the study also highlighted challenges in length control and the need for fine-tuning with human-written summaries. The aforementioned studies were able to provide a solution to the length control task; however, they all lacked the ability to self-determine the required summary length.

V. Conclusion

This study on abstractive text summarization has provided a comprehensive overview of the current state and advancements in the field. Through an in-depth analysis of various studies, we have identified key areas of focus, challenges, and innovative solutions that are shaping the future of abstractive text summarization. A framework for research was established, adhering to essential abstractive text summarization model design components such as encoder-decoder architecture, attention mechanisms, training and optimization methods, datasets, and evaluation metric. This framework is utilized to analyse abstractive summarization models, employing a concept matrix that underscores prevalent design trends in contemporary abstractive summarization systems.

The review highlighted significant progress in developing sophisticated models like Transformers and their variants, which have pushed the boundaries of abstractive text summarization. Studies have introduced novel approaches such as contrastive learning, sequence redundancy removal, and salience allocation, each contributing uniquely to the enhancement of summary quality.

The prevalent use of ROUGE as an evaluation metric was evident, with studies consistently aiming to improve ROUGE scores. However, the review also underscored the need for more nuanced evaluation metrics that can better capture the quality of generated summaries in terms of factual consistency, coherence, and alignment with human judgment. Despite remarkable progress, the field faces several challenges. These include model hallucination, domain shift, dataset quality, factual inconsistency, and the need for multimodal summarization. Particularly, the issue of summary length control emerged as a significant area needing further research, with various studies proposing different methods to address this challenge.

The review suggests that future research in abstractive text summarization should focus on developing more efficient models capable of handling long sequences, improving the factual accuracy of summaries, and creating better datasets, especially for low-resourced languages. Additionally, there is a clear need for more comprehensive evaluation frameworks that go beyond traditional metrics like ROUGE. The insights gained from this SLR provide a foundation for future research endeavors, aiming to overcome existing challenges and unlock new possibilities in the realm of automated text summarization.

Identification of Agile Requirements Change Management Success Factors in Global Software Development Based on the Best-Worst Method

Abdulmajeed Aljuhani
College of Computer Science and Engineering, Taibah University, Medina 41411, Saudi Arabia

***Abstract*—To create products that are both cost effective and high quality, a majority of software development companies are following the principles of global software development, or GSD. One of the most significant and challenging stages of the agile software development process is requirements change management (RCM); however, the execution of agile software development activities is hindered by the geographical distance between the GSD teams, especially when it comes to agile requirements change management (ARCM). The literature claims that, in a particular context, ARCM can profit from applying Multi-Criteria Decision-Making (MCDM) techniques. Within the area of ARCM, an optimal framework can be offered constitutionally, thus presenting an effective decision-making process that ought to encourage higher consumer satisfaction with software projects created in such a way. A methodology for applying the MCDM method in the ARCM context is presented in this paper. In particular, we propose a model for investigating the prioritization of ARCM success factors in the GSD context based on a decision-making method; namely, the Best-Worst Method (BWM). The BWM's ability to solve intricate decision-making problems with multiple criteria and alternatives is demonstrated by the proposed model's findings.**

Keywords*—Best-Worst Method (BWM); Agile Requirements Change Management (ARCM); success factors; Global Software Development (GSD)

I. Introduction

Software development has recently become more globalized, with teams working across borders and cultures to build sophisticated software systems. As software development projects expand in size and complexity, project success is increasingly dependent on managing requirements changes during the development process. The process of recognizing, evaluating, and properly handling changes to requirements during the life cycle of software development is known as requirements change management (RCM). These changes may result from a variety of triggers, such as changing stakeholder requirements, developing technology, changing business demands, and legal changes. Effective requirements change management is essential to the software development process, as it may significantly influence a project's budget, schedule, and quality [1]. In particular, RCM in the context of global software development (GSD) is a crucial aspect of the software development process, which may assist in guaranteeing that the project's budget, schedule, and factors hindering quality are minimized while efficiently addressing the changing demands and expectations of stakeholders [2].

The RCM process has become even more difficult as a result of global software development. Coordinating and communicating effectively becomes essential for successful RCM when development teams are dispersed across several nations, cultures, and time zones. In addition, time zone variations, technological constraints, and language and cultural limitations may all make the RCM process more difficult and raise the possibility of mistakes or incorrect interpretation of requirements. The obstacles associated with RCM in GSD emphasize the need for creative and inclusive frameworks in RCM that make use of a wider variety of technologies and encompass all necessary RCM activities. To properly handle the dynamic and constantly changing complexities that are inherent to GSD, these frameworks should aim to bridge current gaps, especially in the integration of technology and the breadth of activities.

The traditional software development process has undergone important changes as a result of the growing trend of global software development. The emphasis on software development has shifted to remote and heterogeneous environments, such as the agile methodology, which has created significant difficulties for agile development processes when trying to handle needs changes. It becomes imperative to implement agile requirements change management (ARCM) in order to reduce risks and adapt to evolving customer needs. The discovery, evaluation, assessment, and execution of proposed requirement changes are made easier through ARCM. Agile development has grown in popularity, being a method that may be more flexible and adaptable to changing customer requirements, which works especially well in GSD contexts. Notwithstanding agile development, requirements change management persists as a multifaceted and demanding activity. Thus, the implementation of an efficient and well-organized process that can adapt quickly to changing customer requirements is essential for the successful delivery of products in the ARCM context.

Within the agile software development process, emphasis should be placed on practitioner activities, complex documentation development, development tools and processes, contract negotiation and collaboration with customers, and various changes when following a certain plan. Nevertheless, in an agile development environment where the global software development paradigm is being used, change management is a challenging task [3]. According to the literature, implementing global software development has increased the complexity of the change management process, which is already a challenging process in single-site environments.

Thus, an appropriate requirements change management process is significant to ensure successful software development activities. In order to handle the change in requirements, RCM is a collaborative process that requires coordination and communication between software developers and customers. However, ineffective RCM activity execution can result in excessive project costs, unstable requirements, and poor quality. Moreover, RCM typically receives minimal attention, contributing to the poor success rate of GSD initiatives. The change management process is made more difficult by the fact that RCM is a collaborative process, and GSD practitioners operate across regional borders, thus creating a communication and coordination gap.

The purpose of this article is to prioritize the factors that affect the ARCM in GSD projects through examining the integration of an MCDM—namely, the BWM—into ARCM activity in the field of global software development. The BWM framework is composed of a number of ARCM success factors that operate as alternatives, which are compared to one another based on a number of criteria that impact the software project. These criteria are used to evaluate each ARCM success factor, and the final prioritization is determined by adding together the weights of all the factors.

The structure of the remainder of this paper is as follows: The works related to this study are described in Section II. The BWM approach is introduced in Section III. The proposed ARCM success factors and criteria are explained in Section IV. The BWM structure used to prioritize the ARCM factors in GSD is presented in Section V. The findings and discussion are given in Section VI. Finally, Section VII provides a conclusion and recommendations for potential further research.

II. Related Work

A model called the Requirements Change Management Readiness Model (RCMRM) has been proposed by Akbar et al. [4], in order to evaluate how prepared GSD enterprises are to handle requirements changes over the course of the software development life cycle. Critical obstacles in the RCM process for GSD include language and cultural hurdles, the absence of in-person meetings, time zone variations, and delays in responses from abroad sites. According to the authors, low-quality software products may result from improper requirements change management. The RCM procedure may not be effectively implemented in GSD due to the physical distance between teams and infrequent information sharing. Through two rounds of case studies, the RCMRM was validated, and the authors believe that an organization of any size may handle its RCM process in the GSD context using the RCMRM, based on the findings of the case study.

An exploratory study on quality requirements change management in the context of software development and maintenance was presented by Ahmad et al. [5]. In addition to outlining the difficulties and success factors that software suppliers, sellers, merchants, and retailers encounter when trying to manage software quality requirements, the research also emphasizes the significance of quality change management in software development and maintenance. The study stated 14 primary obstacles to software quality requirement change management, including inadequate requirements, poor project management, miscellaneous cultural issues, poor communication and coordination, lack of technology, and lack of understanding of requirements. The authors find that managing software quality requirements changes efficiently is essential in software development and maintenance, and that ineffective management of these changes can lead to subpar software or even project failure.

A model-driven strategy was proposed by Gull et al. [6] to solve the problem of incompatible requirements in international software development. Models are used in a model-driven approach to explain the requirements, design, and implementation of the system. In addition, to make system requirements more comprehensible and straightforward for developers from different cultures and backgrounds, the models offer a formal and accurate representation. Blockchain technology is used by the authors to handle consistency problems that arise during development. Thus, handling inconsistent requirements in GSD may be resolved with the help of the suggested blockchain-oriented model-driven framework. Moreover, the framework offers a systematic approach for gathering requirements and managing them, which can aid in minimizing the cultural and communication barriers that arise throughout the development process.

A framework for semantic-based component requirements management in GSD environments, spanning from the mapping and linking of requirements to specification, was presented by Ali et al. [7]. The suggested approach seeks to address problems with conflicting stakeholder perspectives and difficulties in collaboration throughout the software development life cycle. Aspect-based sentiment analysis is employed in the suggested framework to perform a semantic analysis of the requirements from the various viewpoints of the stakeholders. This lessens the ambiguity and incompleteness of requirements. However, in order to confirm and validate the requirements, decision tree-based categorization has been applied to traceability requirements. In order to ensure accurate requirements management, the framework prioritizes missing requirements depending on historical information.

Koulecar and Ghimire [8] proposed a comprehensive and robust model for managing changing requirements within the GSD paradigm. The model incorporates unique stages and expands upon current requirements change management frameworks and models found in the literature. The authors stated that, due to the extra complexity imposed by GSD projects, traditional techniques for requirements change management may not be suitable. Changing requirements is a common difficulty in the agile software development context. The authors suggested the presented ARCM model as a solution to this problem, as it can be easily adapted to various GSD environments and used in conjunction with agile software development techniques.

The communication and coordination challenges that arise during RCM in GSD have been investigated by Qureshi et al. [9]. The authors proposed a conceptual model that delineates the variety of communication and coordination obstacles that arise during RCM in GSD, along with the various factors that impact them. They also illustrated several approaches and tools that may be applied to overcome the obstacles and enhance collaboration and communication. The four main categories of obstacles that occur during RCM in GSD—namely, communication, coordination, cultural, and technological challenges—are highlighted in the suggested conceptual model.

An improved AZ-Model for RCM in the GSD environment was presented by Mughal et al. [10]. The improved model is intended to address issues including inadequate traceability and monitoring of RCM activities, as well as a lack of collaboration and communication among project stakeholders. It aids in the creation of a high-quality product while accomplishing corporate goals and customer satisfaction. The empirical and simulation findings show that the required changes are efficiently and successfully managed by the enhanced AZ-Model, in accordance with the time and cost limitations associated to GSD.

In order to evaluate and enhance the RCM process maturity level of GSD enterprises, Akbar et al. [11] have suggested a new RCM maturity model called the software requirement change management and implementation maturity model (SR-CMIMM). The model is composed of five maturity levels, each of which has a number of critical success elements and challenges to overcome in order to reach the goal. Additionally, the model offers best practices to help GSD organizations to improve their RCM process and reach the appropriate degree of maturity. Furthermore, the study's empirical findings demonstrated that the model is effective for professionals in the industry and offers them insightful knowledge that will help them with decision making and managing software development projects.

Kausar et al. [12] presented a valuable contribution to the field of RCM and GSD through conducting a systematic literature review that provides a detailed analysis of various primary research relevant to RCM problems in GSD. The highlighted obstacles can assist individuals and organizations in overcoming these concerns, enhancing the efficiency and effectiveness of the RCM process in GSD.

Michalski and Zaleski [13] presented a comprehensive framework to assess the factors that lead to the success of IT service projects. They determined a number of factors, such as organizational and people management, project management procedures, quality of work environment, and stakeholder and risk management, that affect project performance. The findings offer valuable insights to IT professionals and project managers who are involved in managing IT service projects.

Through the use of online surveys, literature studies, and expert perspectives, Akbar et al. [14] performed an empirical investigation that examines the difficulties associated with change management activities in the GSD context. The study's objective was to give researchers and practitioners a knowledge foundation that will be useful in the development of an RCM maturity model, thus facilitating the assessment and improvement of change management techniques in GSD contexts. The study's findings indicated that the RCM process in GSD contexts may be adversely affected by 31 challenging factors. These factors include factors related to communication, coordination, culture, and time zones.

In their model, Tam et al. [15] identified five people-factors that affect the performance of ongoing agile software development projects. Among these, ”team capability” and ”customer involvement” are the key factors that make ongoing agile software development projects successful. Their main objective was to investigate and evaluate the factors that influence the performance of ongoing agile software development projects, and the goal of the study was to determine the key success factors (CSFs) that apply to agile projects and how personal characteristics, social norms, team capability, and customer participation affect these factors. In addition, a combination of qualitative and quantitative research methodologies was used in this study.

Albuquerque et al. [16] examined several agile approaches used in the process to offer insight into ARCM. This systematic mapping study contributes significantly to the area of ARCM through identifying essential elements, noteworthy obstacles, and research gaps in ARCM. In order to mitigate risks and guarantee the success of agile projects, stakeholders engaged in the ARCM process can benefit greatly from the analysis provided by the authors.

Kamal et al. [17] proposed a model that identifies the critical success factors for the ARCM process in GSD environments. Through efficient management of change requirements, the researchers intended to assist businesses in delivering software development projects successfully in a globalized environment. The findings of the study showed that, in the context of GSD, efficient communication and requirement traceability are the two most important success factors for the ARCM process.

Javed et al. [18] emphasized the crucial socio-cultural distance problems in GSD and proposed effective mitigation techniques to deal with these obstacles. Preventing miscommunications and guaranteeing the success of GSD initiatives may be achieved through recognizing the socio-cultural variations among team members, communicating effectively, building trust, and being culturally aware. Prioritizing the importance of several mitigation strategies is performed using the Analytical Hierarchy Process (AHP) method, in which the mitigation strategies are viewed as factors and the corresponding techniques as sub-factors. Using pairwise comparisons, the mitigation strategies are contrasted. Then, the practitioners can apply the most relevant and suitable strategy for socio-cultural distance challenges based on rank order. Furthermore, Akbar et al. [19] investigated the adoption of AHP in prioritizing RCM challenges in the GSD context. Four primary categories—organizational management, team, technology, and process—were used in the study to map out and identify 25 challenging factors.

Kamal et al. [20] identified the success factors of ARCM and prioritized them for successful implementation in GSD projects. In order to rank the identified success factors, the authors employed a mixed-method strategy that incorporates questionnaire surveys, case studies, interviews, action research, grounded theory, and the AHP. Moreover, 21 ARCM success factors were found in the study, which were divided into six categories—process, people, project, technology, quality, and communication—the most important of which being process. Using the AHP, the authors determined the following five success factors as the top five: dynamic decision-making, management and leadership support, ongoing coordination and communication, comprehensively managed changes, and stakeholder collaboration.

Akbar et al. [21] investigated the success factors, challenges, and practices of adopting DevOps techniques. The goal of the study was to identify and rank these factors in order to suggest practical and efficient methods for enterprises to implement DevOps successfully. This study included a systematic literature review (SLR) as part of its research approach, along with a quantitative analysis of the factors found using the Fuzzy Analytic Hierarchy Process (FAHP). The investigation outlined 25 practices, 17 obstacles, and 23 crucial success factors for the implementation of DevOps. It was discovered that factors such as ”automation” and ”team collaboration” are essential for a successful DevOps deployment. Similar to this, challenges like ”lack of skillset” and ”cultural resistance to change” were noted as major obstacles that might prevent the implementation of DevOps.

III. The Best-Worst Method

The Best-Worst Method, also known as the BWM, was introduced by Rezaei [22] as a decision-making approach that distinguishes the best (generally positive or significant) or worst (least significant) criteria. In contrast to techniques such as the AHP and Analytic Network Process (ANP), the BWM has an easier-to-use fundamental scale, fewer comparisons, and steadier judgments. As a result, it has gained the trust of researchers in various disciplines and is widely recognized as a reliable and attractive approach. The BWM helps decision-makers to determine the weights for criteria through making pairwise comparisons based on each of the two criteria (best and worst) and other criteria. Afterward, a minimax problem is solved to establish the criteria weights. Although prioritization in BWM has been shown to be sensible, it can be improved to account for the uncertainty of decision-makers. Two vectors of comparison, the best-to-other criteria and other criteria-to-worst, are equally important in BWM, and the decision-maker’s confidence in the best-to-others and others-to-worst judgments is treated as equally important. Furthermore, the BWM assumes that decision-makers must be completely convinced of the best and worst criteria, along with the corresponding pairwise comparisons. To obtain their judgments, decision-makers utilize the AHP fundamental scale introduced by Saaty [23], as shown in Table I. As a result, the BWM is an efficient and trustworthy technique that can aid decision-makers in making better decisions through identifying the most critical criteria.

TABLE I. Fundamental Scale [23]

Value	Level of Importance
1	Equal importance
2	Weak or slight
3	Moderate importance
4	Moderate plus
5	Strong importance
6	Strong plus
7	Very strong
8	Very, very strong
9	Extreme importance

Pairwise comparisons are employed in the BWM in a manner similar to that in the AHP and ANP; however, the BWM has recently gained in popularity as it is a more successful approach in some aspects. In comparison to the AHP, the BWM necessitates less pairwise comparisons. Moreover, decision-makers find the BWM to be less complicated when comparing pairs, as they simply need to complete the up part of the pairwise comparison and do not need to use the 1–9 scale’s reciprocal, which makes measurements simpler.

The use of the BWM in software development has been studied by a number of researchers. For example, Aljuhani [24] investigated the adoption of the BWM in order to select the appropriate software requirements elicitation technique. In addition, the authors in [25] employed the BWM in the context of cloud computing environments in order to rank several service providers, resources, and tasks. To prioritize many activities and manage resource allocation in cloud computing, Alhubaishy and Aljuhani [26] studied the use of the BWM. Furthermore, Aljuhani and Alhubaishy [27] adopted the BWM in the development of Mobile-D in order to identify nine insertion places where its implementation might help to resolve divergent viewpoints within the team.

A. Steps of BWM

As stated by Rezaei [22], there are five primary steps in the BWM, which are as follows:

Step 1. The first step of the BWM involves specifying the decision criteria $\{c_1, c_2, ..., c_n\}$ for the proposed solutions or alternatives.

Step 2. The second step of the BWM involves the decision-makers specifying the best and worst criteria without making any comparisons. In this step, the decision-makers are required to identify the most significant (best) and least significant (worst) criteria.

Step 3. The third step of the BWM involves making pairwise comparisons for the other criteria with respect to the best criterion. In this step, a series of judgments are made by the decision-makers based on the proposed fundamental scale shown in Table I. The outcome vector $A_B = (a_{B1}, a_{B2}, ..., a_{Bn})$ is determined, where a_{Bj} reflects the comparison of criterion j concerning the best criterion B.

Step 4. This step involves making pairwise comparisons of the other criteria in relation to the worst criterion. Similar to the third step, a series of judgments are made by the decision-makers in this step, based on the proposed fundamental scale shown in Table I. The outcome vector $A_W = (a_{1W}, a_{2W}, ..., a_{nW})$ is determined, where a_{1W} reflects the comparison of criterion j concerning the worst criterion W. The worst criterion serves as the reference point, and the decision-makers need to compare the other criteria with it.

Step 5. The fifth and final step of the BWM involves determining the optimal weights for the criteria. In this step, the optimal weights $w*_1, w*_2, ..., w*_n$ are determined based on the criteria. These weights must satisfy the constraints $w_B/w_j = a_{Bj}$ and $w_j/w_w = a_{jw}$ for each pair w_B/w_j and w_j/w_w, where w_B is the weight of the best criterion, w_j is the weight of criterion j, and w_w is the weight of the worst criterion [22].

The optimal weights are obtained by solving a minimax problem, where the maximum absolute differences between $\left|\frac{w_B}{w_j} - a_{Bj}\right|$ and $\left|\frac{w_j}{w_w} - a_{jw}\right|$ should be reduced in order to meet these conditions for every criterion.

This gives rise to the following problem:

$$\min \max_j \left\{ \left|\frac{w_B}{w_j} - a_{Bj}\right|, \left|\frac{w_j}{w_w} - a_{jw}\right| \right\}$$
$$\text{s.t.}$$
$$\sum_j w_j = 1$$
$$w_j \geq 0, \text{ for all j} \qquad (1)$$

Problem 1 can be transformed to the following problem as a result:

$$\min \xi$$
$$\text{s.t.}$$
$$\left|\frac{w_B}{w_j} - a_{Bj}\right| \leq \xi, \text{ for all j}$$
$$\left|\frac{w_j}{w_w} - a_{jw}\right| \leq \xi, \text{ for all j}$$
$$\sum_j w_j = 1$$
$$w_j \geq 0, \text{ for all j} \qquad (2)$$

Solving problem 2, we derive the ideal weights and ξ^*.

Additionally, the following problem is solved to determine the consistency ratio:

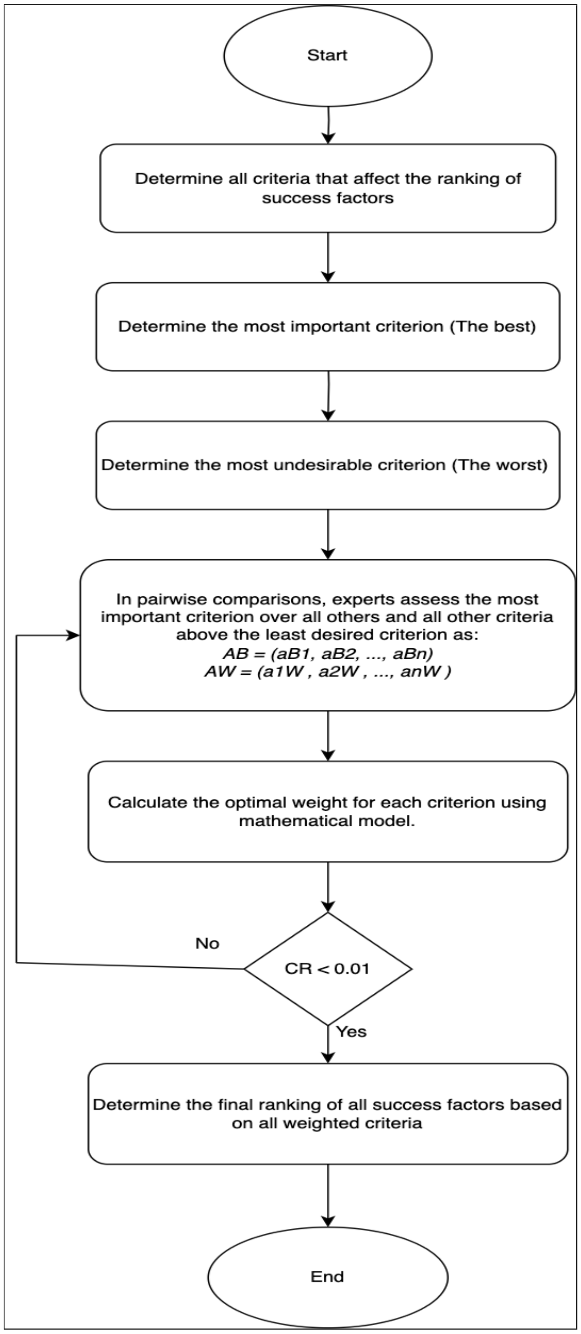
$$\text{Consistency Ratio} = \frac{\xi^*}{\text{Consistency Index}}$$

As stated in [22], the consistency index is contingent upon the number of criteria incorporated in the decision-making problem. However, as the comparisons would be deemed inconsistent otherwise, the consistency ratio value should be less than 0.10. The BWM steps are diagrammatically presented in Fig. 1.

IV. Proposed Criteria for Ranking Success Factors

Determining the efficacy and efficiency of a decision-making process requires careful consideration of the determination criteria that should be specified for the proposed alternatives or solutions. The criteria must be relevant to the problem at hand and should significantly affect the suggested solutions. For the purpose of choosing the best set of criteria to fit the proposed decision problem, the decision-makers must be clear about their aims and objectives. As it is the cornerstone of the whole decision-making process, the effective identification of the appropriate decision criteria is therefore crucial. Thus, this study utilizes six criteria—derived from [19], [17], and [20]—to assist decision-makers in ranking the success factors. The studied criteria are as follows:

- Integration (C1)
- Communication (C2)
- Project Administration (C3)
- Human Resources (C4)
- Technology Factors (C5)
- Time (C6)



Start
Determine all criteria that affect the ranking of success factors
Determine the most important criterion (The best)
Determine the most undesirable criterion (The worst)
In pairwise comparisons, experts assess the most important criterion over all others and all other criteria above the least desired criterion as:
AB = (aB1, aB2, ..., aBn)
AW = (a1W , a2W , ..., anW)
Calculate the optimal weight for each criterion using mathematical model.
No
CR < 0.01
Yes
Determine the final ranking of all success factors based on all weighted criteria
End

Fig. 1. BWM steps to rank ARCM success factors.

V. BWM Structure for Ranking ARCM Success Factors

The BWM framework for ranking the success factors (SF) has three distinct levels, in the same manner as the ANP and

AHP. The first level outlines the purpose of using the BWM which, in this case, is ranking the success factors. The selection criteria, which are explained in the preceding part, are covered in the second level. The third stage consists of the alternatives, which are the different success factors (SF) that are compared to determine the overall ranking and weights of all SFs based on various criteria. According to the literature, there are several SFs that can affect the RCM process in GSD; nevertheless, in this article, nine SFs that have an impact on the RCM process are chosen and evaluated in the BWM model [19], [17], as follows:

- Allocation resources at GSD sites (SF1)
- Requirements traceability (SF2)
- Communication, coordination, and control (SF3)
- Geographical distributed change control block (SF4)
- Effective share of information (SF5)
- Skilled human resources (SF6)
- RCM process awareness (SF7)
- Roles and responsibilities (SF8)
- Guarantee a quick response between geographically dispersed GSD teams (SF9)

The BWM structure for ranking ARCM success factors is visually represented in Fig. 2.

A. BWM Model Evaluation Based on Experts' Opinions

The aim of this study is to investigate how the BWM can be used to prioritize the ARCM success criteria in the context of GSD. The case study methodology is used to address two research questions: 1) How can the BWM be useful in ranking the ARCM success factors within the GSD domain, and 2) how does the adoption of the BWM affect the communication and productivity of team members during the development process? These questions provide the basis for the proposed units of analysis in this study. In addition to the BWM expert judgments in ranking the ARCM success factors, two units of analysis that are suitable for application are prioritizing and evaluating. To emphasize the capabilities and advantages of the BWM, criteria that influence the prioritization of the ARCM success factors were identified as a first step in the assessment process. The data-gathering technique was a questionnaire issued to domain experts, who served as the data source. Moreover, to assign a weight to each criterion in the model, the experts were asked to assess the proposed criteria. As indicated in Table II, the experts employed the BWM procedures to identify the best criterion and then performed a pairwise comparison to evaluate the criterion's weight relative to all other criteria. Table II presents a pairwise comparison wherein the C4 criterion is 8, 2, 3, 3, and 4 times more significant than the corresponding C1, C2, C3, C5, and C6 criteria, respectively.

After that, a comparison among the selected criteria is made with respect to the worst criterion, which is the integration (C1) criterion in this case. As shown in Table III, five criteria were given preference over C1; for instance, C4 had an extreme significance over the C1 criterion.

TABLE II. Pairwise Comparison of Human Resources (C4) Criterion with Respect to other Criteria

Best to Others	C1	C2	C3	C4	C5	C6
C4	8	2	3	1	3	4

TABLE III. Pairwise Comparison of Criteria with Respect to C1 Criterion

Others to the Worst	C1
C2	6
C3	5
C4	8
C5	4
C6	5

VI. Results and Discussion

The judgments on the adoption of the BWM were computed using the Solver Linear BWM. According to the combined outcome derived from domain experts, C4 was deemed the most significant attribute when it came to determining the order of importance for the success factors. Meanwhile, C1 was shown to be the least significant criterion. Among the proposed criteria, C2 was ranked second, followed by C3, C5, and C6, respectively. Table IV displays the aggregate weights of all the criteria. Moreover, the consistency ratio of the criteria aggregated weights was 0.071, which is less than 0.01, indicating that the result of this judgment was consistent (as stated previously in the BWM steps).

TABLE IV. The Aggregate Weights of All the Criteria

Ranking	Criteria	Weights (%)
1	C4	35.71%
2	C2	21.42%
3	C5	14.29%
4	C3	14.27%
5	C6	10.71%
6	C1	3.57%

Furthermore, based on the BWM, SF3 was evaluated as the most important alternative. The findings also exhibit that SF6 was ranked in the second position, followed by SF5. Meanwhile, SF4 was ranked as the least significant factor. Moreover, SF2 was ranked in the fourth position, followed by SF8 and SF1, respectively. Furthermore, SF7 was ranked in the seventh position, followed by SF9. Table V illustrates the final weights for each success factor.

TABLE V. The Importance of ARCM Success Factors

Ranking	Criteria	Weights (%)
1	SF3	26.66%
2	SF6	15.39%
3	SF5	15.31%
4	SF2	10.34%
5	SF8	10.12%
6	SF1	7.67%
7	SF7	6.14%
8	SF9	5.11%
9	SF4	3.23%

Several benefits were addressed by the domain experts with respect to the presented framework. The development team found it easier to tackle complicated and unstructured problems due to the BWM's power. Furthermore, each member

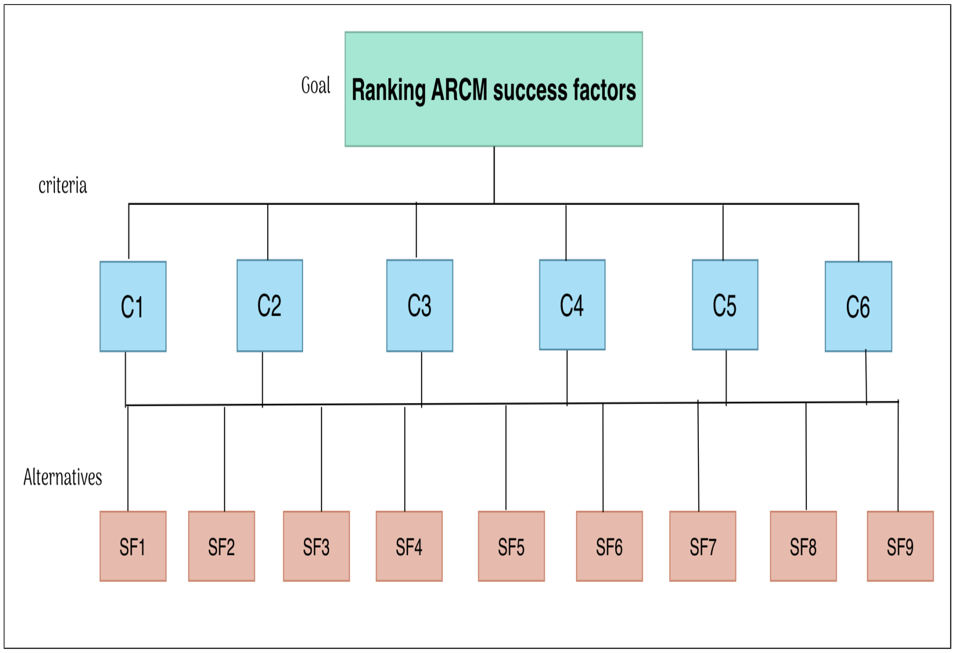


Fig. 2. BWM Structure for ranking ARCM success factors.

was able to contribute to the decision-making process through drawing on their individual experiences, according to the way in which the technique is structured. This guarantees a high degree of contentment among the development teams, which may show in the quality of the project. Considering a number of factors that influence the decision-making process, the BWM facilitates decision-making. Furthermore, the BWM helps managers or team members grasp the most important variables and criteria to take into consideration while prioritizing the success factors. For each paired comparison, the BWM yielded extremely consistent results for the consistency ratio value. The consistency ratio in this study was 0.071 for the criteria overall weights and 0.040 for the success factor overall weights, both below the maximum acceptable consistency ratio of 0.10. As indicated by Tables IV and V, these results validate the feasibility of the framework through demonstrating how the BWM may be utilized to prioritize the ARCM success factors. For spontaneous decision crises not addressed by an existing model, the BWM can be used. It should be noted that this includes the expense of incorporating the BWM into the ARCM success factors.

VII. Conclusion and Future Work

The growing tendency toward GSD prompted us to investigate the factors that may have a beneficial effect on the activities in the ARCM process. Six critical criteria and nine success factors were identified in this study, considering their effects on the success of ARCM activities within the context of GSD. Further, in order to integrate the agile development process within the framework of GSD and execute RCM activities, the BWM method was adopted to rank the investigated factors according to their significance. The execution of agile software development activities is hindered by the spread of GSD teams, especially when it comes to requirements change management. The avoidance of these issues may be achieved by giving priority to the success factors. The findings showed that, at the criteria level, C4 (Human resources) was ranked as the most significant criterion (weight = 35.71%). Moreover, SF3 (Communication, coordination, and control), SF6 (Skilled human resources), SF5 (Effective sharing of information), and SF2 (Requirements traceability) were deemed to be the most important ARCM process success factors within the context of GSD. Industry practitioners may benefit from this study's results through adoption of the high-priority success elements for the effective execution of ARCM activities in the context of GSD.

Furthermore, the results of the study demonstrated the effectiveness of the BWM in resolving complex problems in less time than comparable methods such as the AHP and ANP. The AHP requires $n(n-1)/2$ comparisons (where n is the number of variables in the model), while the introduced technique requires only $2n-3$ comparisons. Another benefit of using the BWM in this study is that the structure and flexibility of ARCM success factor prioritization were enhanced through the adoption of a defined decision-making method.

To improve the accuracy of its outputs in the future, the BWM can be combined with other methods; for example, it may be used with a fuzzy set to improve the ways in which subjective judgments and item roughness are handled when assessing the model's elements. Another potential work in the future would be to develop an automated BWM tool that complies with the prioritization of ARCM success factors and its standards.

Degree Based Search: A Novel Graph Traversal Algorithm Using Degree Based Priority Queues

Shyma P V, Sanil Shanker K P
Department of Information Technology, Kannur University, India

***Abstract*—This paper introduces a novel graph traversal algorithm, Degree Based Search, which leverages degree-based ordering and priority queues to efficiently identify shortest paths in complex graph structures. Our method prioritizes nodes based on their degrees, enhancing exploration of related components and offering flexibility in diverse scenarios. Comparative analysis demonstrates superior performance of Degree Based Search in accelerating path discovery compared to traditional methods like Breadth First Search and Depth First Search. This approach improves exploration by focusing on related components. Using a priority queue ensures optimal node selection; the method iteratively chooses nodes with the highest or lowest degree. Based on this concept, we classify our approach into two distinct algorithms: the Ascendant Node First Search, which prioritizes nodes with the highest degree, and the Descent Node First Search , which prioritizes nodes with the lowest degree. This methodology offers diversity and flexibility in graph exploration, accommodating various scenarios and maximizing efficiency in navigating complex graph structures. The study demonstrates the Degree based Searching algorithm's efficacy in accelerating path discovery within graphs. Experimental validation illustrates its proficiency in solving intricate tasks like detecting communities in Facebook networks. Moreover, its versatility shines across diverse domains, from autonomous driving to warehouse robotics and biological systems. This algorithm emerges as a potent tool for graph analysis, efficiently traversing graphs and significantly enhancing performance. Its wide applicability unlocks novel possibilities in various scenarios, advancing graph-related applications.**

***Keywords*—Graph traversal; degree based search algorithm; ascendant node; ascendant node first searching algorithm; descent node; descent node first searching algorithm**

I. Introduction

In today's interconnected world, the analysis and comprehension of complex systems have become pivotal across various domains including social interactions, communication networks, and engineered systems such as the power grid and the Internet. These systems can be effectively modeled and analyzed using graph theory, which provides a powerful framework for representing and understanding relationships between entities. Graphs, consisting of vertices and edges, serve as a fundamental abstraction for representing diverse real-world phenomena. Graph traversal, the systematic exploration of vertices and edges within a graph, lies at the heart of many graph analysis tasks. Traditionally, algorithms such as Breadth First Search (BFS) and Depth First Search (DFS) have been extensively utilized for traversing graphs and solving fundamental problems like identifying spanning trees, finding shortest paths, and detecting strongly connected components. However, these traditional methods have inherent limitations that hinder their effectiveness in modern applications [1].

Breadth First Search explores the graph level by level, starting from a source vertex, and is particularly useful for finding shortest paths due to its systematic approach. However, it consumes significant memory and may not be suitable for large-scale graphs with millions of nodes. On the other hand, DFS explores the graph depth-wise, often employing recursion or stack data structures. While DFS is memory-efficient, it lacks the ability to guarantee the shortest path and may encounter issues such as stack overflow and infinite loops, especially in graphs with cycles.Moreover, neither BFS nor DFS adequately address the consideration of edge weights, limiting their applicability in scenarios where edge weights play a crucial role [2]. Additionally, these traditional algorithms may fail to cover all connected components of a graph, potentially missing vital information, and may become stuck in infinite loops, further complicating their use in dynamic or cyclic graph structures [4]. To overcome these challenges and develop more efficient traversal algorithms, researchers have focused on enhancing memory optimization, scalability for large networks, consideration of edge weights, and the ability to handle various graph structures effectively. The development of novel traversal methodologies that address these limitations is imperative to advance graph analysis techniques and address the growing demands of modern applications.

The effectiveness of unique priority queue-based degree-based graph search algorithm must be validated using this method. We seek to demonstrate the computational benefits of node-degree prioritised exploration by contrasting this algorithm with state-of-the-art optimisation techniques as well as classic graph search algorithms such as Depth-First Search (DFS) and Breadth-First Search (BFS) [3]. By leveraging priority queue-based methods and prioritizing nodes based on their degrees, the Degree based Search algorithm achieves increased efficacy and efficiency in graph traversal tasks. Furthermore, its dynamic selection mechanism enables adaptability to changing graph topologies, enhancing its robustness and versatility across diverse application domains. Through a comprehensive comparison with traditional algorithms and real-world applications, we demonstrate the effectiveness and scalability of the Degree based Search algorithm in addressing the fundamental challenges of graph traversal.

II. Related Works

It is becoming more and more crucial to analyse and comprehend social interaction data, relational data in general, complex engineered systems like the power grid and the Internet, communication data like email and phone networks, and biological systems using graph abstractions. These application fields frequently encounter graph-theoretic issues including identifying and rating significant entities, seeing unusual patterns or rapid changes in networks, locating strongly connected clusters of entities, and others. For issues like discovering spanning trees, shortest paths, biconnected components, matching, and flow-based computations in these graphs, traditional techniques are frequently used as solutions. A traversal is a methodical exploration of each vertex and edge in a graph. Graph traversals, such as Breadth First Search and Depth First Search provide foundation for much higher-level graph analysis approaches and is the basic primitive for graph analytics [1]. Breadth First Search is a common graph analysis technique that examines every vertex in all levels of a graph starting from a source vertex [2]. The shortest path between vertices can be found using Breadth First Search as it always finds optimal solution. As the Breadth First Search examines level by level, it is impossible to locate a pointless or ineffective path [4]. The Depth First Search method starts at the root node and chooses an edge that originates from the most recently visited vertex that has unexplored edges [5]. In Depth First Search, a stack is used to hold a collection of old vertices with possibly unexplored edges and it's intricacy depends on the number of paths. Depth First Search has a flaw that cannot check for duplicate nodes and cannot guarantee the shortest path [6]. Depth First Search is difficult to apply when the graph is infinite while there are cycles within the graph [4]. The primary distinction between BFS and DFS is the order in which they are traversed; the former is in horizontal order and the latter is in vertical order. BFS is preferable for identifying components closer to the root, whereas DFS is preferred for locating elements deeper in the ground. In the worst-case scenario, however, both algorithms would take the same time O (V+E) because they visit all nodes once [7].

Although BFS ensures that the shortest path will always be found, it uses too much memory and is not suitable for large-scale graphs. Furthermore, it could be ineffective for networks with millions of nodes due to its thorough investigation of nearby nodes [8]. DFS, on the other hand, relies on recursion or stack data structures, which makes it susceptible to stack overflow issues and fails to guarantee the shortest path. Furthermore, DFS may not cover all connected components of the network, thereby missing important information, and it may become stuck in infinite loops, particularly in the presence of cycles [9], [10]. Additionally, neither algorithm takes edge weights into account, which limits its usefulness in situations when edge weights are important. In order to overcome these drawbacks and create an even better traversal algorithm, memory optimisation, scalability for big networks, edge weight consideration, strong termination conditions to avoid infinite loops, and adaptability to various graph structures should be prioritised [11]. Overcoming these obstacles can lead to a novel traversal method that provides enhanced scalability, performance, and versatility for a range of graph traversal problems in both practical and research fields.

The primary objective is to address the fundamental task of searching algorithm by utilising the concept of degree of a node for efficient graph traversal. This work presents a novel traversal methodology called the Degree based Search algorithm, which has several advantages over conventional graph traversal techniques like BFS and DFS. Through the integration of priority queue-based methods, the algorithm attains increased efficacy and efficiency when examining graph structures. Its capacity to rank nodes according to degrees is one of its main benefits, as it enables a more methodical and efficient traversal procedure. By ensuring that the algorithm concentrates on nodes with stronger connectivity, this prioritisation technique speeds up path identification and the investigation of pertinent graph components. Moreover, the Degree based Search algorithm may dynamically adjust to the graph's shifting topology while traversing thanks to the use of a priority queue. Identifying key pathways and components in an efficient manner, the algorithm traverses the network by repeatedly choosing nodes with the highest or lowest degrees from the priority queue. The algorithm's robustness and versatility are increased by this dynamic selection process, which makes it appropriate for a variety of graph types and applications. Additionally, the Degree based Search algorithm performs exceptionally well in memory management because it uses effective data structures like priority queues to reduce the memory footprint. This feature is especially helpful for large-scale graphs with millions of nodes, where performance and scalability are dependent on memory efficiency. In Table I, a comparison of the three algorithms is presented.

TABLE I. COMPARISON OF BFS, DFS AND DBS

Strategy	Complete	Optimal	Time complexity	Space complexity
BFS	Yes	Yes	O(b^d), where b and d are branching factor and depth respectivly	O(b^d)
DFS	No	No	O(b^m), where b and m are branching factor and maximum depth respectivly	O(bm)
DBS	Yes	Yes	O($(V+E)logV$), where m and n are number of edges and vertices respectivly	O($V+E$)

III. METHODOLOGY

This work explores the combination of degree-based traversal algorithms and priority queues, with a particular application to the exploration of related elements in graphs. Priority queues are an effective tool for node selection strategy optimisation because of their ability to manage items based on predetermined keys. Our suggested algorithms drive research towards nodes that are most likely to produce important information by prioritising high- or low-degree nodes according to their degrees. The degree-based traversal algorithms considered here demonstrate two different strategies: one giving priority to nodes with the highest degree, while the other prioritises nodes with the lowest degree. Selecting one of these approaches offers a framework that is adaptable to the particular features of the graph being studied. Graph exploration is given a new dimension by integrating degree-based traversal algorithms with priority queues, which makes it possible to find as many connected components as possible in an efficient manner. By methodically extracting and processing nodes, the algorithmic strategy ensures a thorough analysis of the graph while taking the connectivity structure into account. The purpose of this research is to ascertain the significance of the proposed techniques by means of an extensive empirical review. We compare degree-based traversal algorithms with traditional methods in order to illustrate the advantages of using priority queues in the context of connected components. The results of the study may have implications for a wide range of applications, such as social network analysis and routing optimisation in communication networks.

A. Degree-Based Traversal Algorithms with Priority Queue

In order to track visited vertices, the method first initialises an empty priority queue Q and an array visited. The search is started by inserting the source vertex s into the priority queue. Although the priority queue is not empty, the algorithm selects the vertex u with the lowest degree from the queue and, if it hasn't been visited previously, marks it as visited. Next, the method investigates neighbouring vertices of u, adding each unexplored neighbouring vertex, according to its degree, to the priority queue. The graph search result is represented by the collection of visited vertices, and the process continues until the priority queue is empty.

Based on the ascending or descending order of node degrees within the priority queue, the proposed approach dynamically modifies its exploration method.

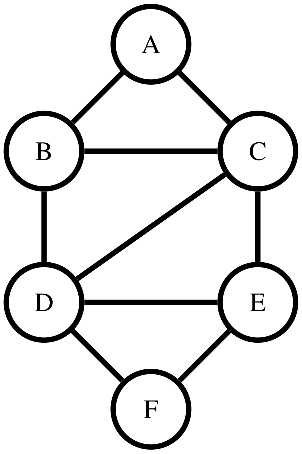

Fig. 1. Graph for illustration of the algorithm.

The algorithm begins with an initial state where no vertices have been visited, and the priority queue contains all vertices along with their respective degrees. In Fig. 1, the first step, vertex A is selected as the source vertex, marking it as visited and updating the priority queue by removing A. In the second step, the algorithm selects vertex F, the adjacent vertex to A with the highest degree, adds it to the visited set, and updates the priority queue accordingly. Next, vertex B, the highest-degree adjacent vertex to the current visited set, is selected and added to the visited set. This process continues with the selection of vertex E, followed by vertex D, each time updating the visited set and priority queue. Finally, vertex C is selected, completing the traversal with all vertices visited. The final state shows all vertices A, F, B, E, D, C in the visited set and an empty priority queue, demonstrating the efficient traversal based on the highest-degree selection criterion.

Let $G = (V, E)$ be an undirected graph. Let Q be a priority queue with keys based on node degrees and $visited$ be an empty set to keep track of visited nodes.

```
Algorithm ANFS(Graph G, Node s):
    Initialize an empty priority queue Q
    Initialize an array visited[] to keep track
    of visited vertices
    PQ_insert(Q, s)
    Insert the source vertex s into the
    priority queue
    while Q is not empty:
        u = PQ_extractMin(Q)
        Extract the vertex with the minimum
        degree
        if visited[u] is false:
            visited[u] = true [Mark u as visited]
            for each vertex v adjacent to u:
                if visited[v] is false:
                    PQ_insert(Q, v)
                    Insert v into the priority
                    queue
    return visited
```

```
Algorithm DNFS(Graph G, Node s):
    Initialize an empty priority queue Q
    Initialize an array visited[] to keep track
    of visited vertices
    PQ_insert(Q, s)
        Insert the source vertex s into the
        priority queue
        while Q is not empty:
         u = PQ_extractMax(Q)  Extract the
         vertex with the maximum degree
        if visited[u] is false:
            visited[u] = true  // Mark
            u as visited
            for each vertex v adjacent to u:
                if visited[v is false:
                    PQ_insert(Q, v)
                    Insert v into the priority
                    queue
    return visited
```

An empty priority queue Q and an array `visited[]` to record visited vertices are initialised at the start of the algorithm. To start the search, the source vertex s is added to the priority queue. The procedure retrieves the vertex u with the lowest degree from the priority queue, even though it is not empty, and if it hasn't been visited previously, it marks it as visited. Subsequently, the algorithm investigates u's neighbouring vertices, adding each unexplored vertex to the priority queue according to its degree. The set of visited vertices indicates the outcome of the graph search, and the process continues until the priority queue is empty. This unique notation employs symbols like `PQ_insert(Q, v)` and `PQ_extractMin(Q)` to describe operations on the priority queue and `visited[v]` to represent the status of a vertex. The phases and operations of the algorithm are represented clearly and concisely in this notation, which facilitates understanding and implementation.

IV. Definitions for the Degree-Based Traversal Algorithms

A. Degree Based Search Traversal Algorithm

The Degree Based Search Traversal Algorithm implicitly searches all the vertices from a given source vertex of a graph $G = (V, E)$. This computation is achieved by traversing in the order of degree of nodes of the graph. Based on this concept, a mathematical description of the Degree Based Search Traversal Algorithm is defined.

Definition 1: A sequence $P = P_1, P_2, \dots, P_n$ represents the traversal of a graph in Degree level ordering where each $P_i = \{v_1, v_2, \dots, v_m\}$ is the sequence of vertices traversed at Degree level order, where the degree sequence of the graph $\{\deg(v_1), \deg(v_2), \dots, \deg(v_m)\}$ is in ascending or descending order.

Ascendant and Descent Nodes for the classification of the Degree based Traversal Algorithm, we introduce two preliminary concepts: Ascendant and Descent nodes of the graph. The node with the maximum degree in a graph is known as the Ascendant node of the graph.

Definition 2: If there exists a sequence of vertices $v_1, v_2, v_3, \dots, v_n$ in graph $G = (V, E)$, then v_i is called the Ascendant node of the graph if $\deg(v_i)$ is the maximum degree of graph G.

The node with the minimum degree in a graph is known as the Descent node of the graph.

Definition 3: If there exists a sequence of vertices $v_1, v_2, v_3, \dots, v_n$ in graph $G = (V, E)$, then v_i is called the Descent node of the graph if $\deg(v_i)$ is the minimum degree of graph G.

B. Ascendant Node First Search Algorithm (ANFS)

We cast the problem of finding a method for traversing a graph using an adjacency list. The algorithm initializes with the source node, then finds all of the adjacent nodes of the source node and continues with the ascendant node as the current node. In the ANFS Algorithm, there is an additional array to store the degrees of the vertices and the main constraint in the algorithm is to check whether the array becomes empty.

Definition 1: A sequence $P = P_1, P_2, \dots, P_n$ represents the traversal of a graph in Degree level ordering where each $P_i = \{v_1, v_2, \dots, v_m\}$ is the sequence of vertices traversed at Degree level order where the degree sequence of the graph $\{\deg(v_1), \deg(v_2), \dots, \deg(v_m)\}$ is in descending order.

C. Descent Node First Search Algorithm (DNFS)

In the DNFS Algorithm, instead of starting from the Ascendant node, it starts from the Descent node.

Definition 1: A sequence $P = P_1, P_2, \dots, P_n$ represents the traversal of a graph in Degree level ordering where each $P_i = \{v_1, v_2, \dots, v_m\}$ is the sequence of vertices traversed at Degree level order where the degree sequence of the graph $\{\deg(v_1), \deg(v_2), \dots, \deg(v_m)\}$ is in ascending order.

V. Computational Complexity Analysis

The time complexity analysis of the proposed Degree-Based Traversal Algorithm can be broken down into several key steps. Initially, the algorithm requires the initialization of various data structures, including the priority queue and the visited array, each of which has a time complexity of $O(V)$, where V represents the number of vertices in the graph. Inserting the source vertex into the priority queue incurs a logarithmic time complexity, specifically $O(\log V)$, due to the nature of the priority queue operations. The core of the algorithm is encapsulated in the main loop, which iterates through the vertices, resulting in $O(V)$ iterations. During each iteration, the algorithm performs several operations: extracting the minimum degree vertex from the priority queue, which has a time complexity of $O(V \log V)$, and processing all adjacent vertices, leading to a complexity of $O(E \log V)$, where E denotes the number of edges. Combining these operations, the overall time complexity of the algorithm can be expressed as $O((V + E) \log V)$. This comprehensive analysis highlights the efficiency of the DBS algorithm in traversing graphs, ensuring that it scales well with both the number of vertices and edges.

VI. Experimental Result

The experimental results highlight the exceptional efficiency of the new traversal approach, which intelligently prioritizes nodes based on their degree while avoiding revisiting already explored nodes. Across the Facebook, Twitter, and Email social network datasets, the new algorithm consistently demonstrated superior performance compared to both Breadth-First Search (BFS) and Depth-First Search (DFS) in terms of execution time. This signifies a substantial improvement in traversal efficiency, particularly evident when exploring highly connected nodes within the networks. By selecting nodes with higher degrees first, the new algorithm navigates through the graph in a manner that minimizes redundant visits and maximizes the coverage of important, central nodes.

These results strongly advocate for the effectiveness of the new approach in optimizing traversal tasks within social networks, offering a promising avenue for enhancing graph exploration and analysis in various network-based applications. The substantial reduction in traversal times across all three datasets underscores the significant impact of prioritizing highly connected nodes, reinforcing the potential of the new traversal strategy as a valuable tool in the realm of social network analysis and exploration.

In Fig. 2, the comparison of execution times for the three algorithms across the social networks Facebook, Twitter, and Email is depicted.

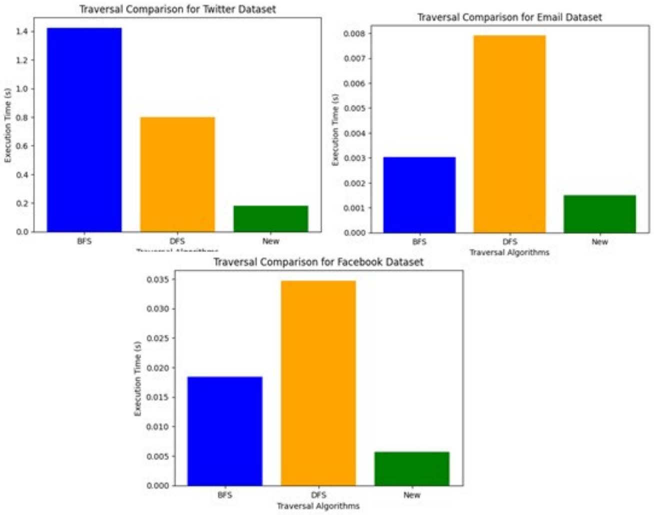

Fig. 2. Comparison of execution times for BFS, DFS, and the new traversal algorithm across the Facebook, Twitter, and Email datasets.

A. Datasets Overview

1) Facebook dataset: The Facebook dataset represents the friendship network among users of the popular social media platform. Comprising 4,039 nodes and 88,234 edges, each node in this undirected graph signifies a user, while an edge denotes a friendship connection. Researchers commonly use this dataset to study social network analysis, community detection, and information spreading on social media platforms [12].

2) Twitter dataset: The Twitter dataset captures the follower relationships among users of the microblogging platform. With 81,306 nodes and 1,768,149 edges, it is a large undirected graph where nodes represent Twitter users and edges represent the ”follow” relationship. This dataset is instrumental in studying information diffusion, influence maximization, and follower prediction on Twitter [12].

3) Email-Eu-core dataset: The Email-Eu-core dataset offers insight into email communication within a European research institution. This smaller directed graph consists of 1,005 nodes and 25,571 edges, where nodes represent email addresses and directed edges represent email exchanges. Researchers use this dataset to analyse email networks, study communication patterns, and detect anomalies in email traffic [12].

VII. Discussion

Using benchmark graph datasets with different sizes and architectures, we perform comprehensive experimental assessments to verify the efficacy of our optimisation technique. We assess how well our priority queue-based degree-based graph search algorithm performs in comparison to other cutting-edge optimisation methods and conventional degree-based graph search algorithms. Our tests illustrate the computational improvements from prioritised exploration based on node degrees, empirically demonstrating search efficiency, scalability, and computational overhead. The method that was developed is being compared to the Depth First Search (DFS) and Breadth First Search (BFS) algorithms [13]. The fundamental ideas of graph theory and algorithm design serve as the cornerstone of our research. BFS is a popular graph analysis technique that traverses all levels of the graph and methodically examines every vertex beginning from a given source [14]. As opposed to the traditional method of beginning at the root node, our Degree-Based Search Algorithm finds the vertex with the highest degree before beginning its search. This method is predicated on the idea that high-degree nodes frequently have important roles in network topologies, which could result in more effective graph exploration.

In the context of graph theory, both the efficiency of storage is high when using an adjacency list due to the requirement of storing edge values. Within the context of the Degree based Search algorithm, an adjacency list is utilised as a data structure to contain the values pertaining to the edges. In the context of BFS, it is necessary to utilise a queue data structure to maintain a record of the child nodes that have been examined but not yet traversed. The DFS algorithm employs a stack data structure to maintain a set of traversed vertices that may contain unexplored edges.

The experimental results show significant gains in search efficiency and scalability in addition to validating the effectiveness of our suggested optimisation technique. Our priority queue-based degree-based graph search method displays higher performance, particularly in cases involving large-scale graphs with heterogeneous degree distributions. We demonstrate the practical impact of our optimisation strategy by showing that prioritising nodes based on their degrees considerably improves the algorithm’s ability to navigate complex graph structures. As we move forward, it will be crucial to further investigate the performance of our algorithm across an even wider range of graph types and sizes. Additionally, exploring potential hybridizations with other graph algorithms and adapting our method to dynamic or streaming graph scenarios could open up new avenues for research and application [15]. By continuing to refine and expand upon this work, we aim to contribute to the ongoing evolution of efficient graph algorithms, addressing the growing demands of complex network analysis in various domains.

VIII. Conclusion

In this paper, we introduced a novel degree-based traversal algorithm for graph exploration, emphasizing its efficiency and effectiveness in comparison to traditional Breadth-First Search (BFS) and Depth-First Search (DFS) methods. By prioritizing nodes based on their degrees and employing a priority queue to manage the traversal process, our algorithm significantly reduces redundant visits and enhances coverage of important nodes within the network.The theoretical analysis demonstrated that our algorithm achieves an overall time complexity of $O((V+E)\log V)$, highlighting its scalability and suitability for large-scale graphs. Experimental results across diverse datasets, including Facebook, Twitter, and Email networks, corroborated the theoretical findings, showing substantial improvements in execution time and traversal efficiency.

This research underscores the importance of leveraging node degree information to optimize graph traversal tasks, presenting a promising avenue for enhancing social network analysis and other network-based applications. Future work will focus on further optimizing the algorithm for specific types of networks and exploring its applicability in real-time dynamic graph scenarios. Overall, the proposed degree-based traversal algorithm offers a valuable tool for efficient graph exploration, with potential impacts across various domains requiring effective network analysis and information dissemination.

***Abstract*—With the rapid development of generative models, the fidelity of AI-generated images has almost reached a level that is difficult for humans to distinguish true from fake. The rapid development of this technology may lead to the widespread dissemination of fake content. Therefore, developing effective AI-generated image detectors has become very important. However, current detectors still have limitations in their ability to generalize detection tasks across different generative models. In this paper, we propose an efficient and simple neural network framework based on inter-patch dependencies, called IPD-Net, for detecting AI-generated images produced by various generative models. Previous research has shown that there are inconsistencies in the inter-pixel relations between the rich texture region and the poor texture region in AI-generated images. Based on this principle, our IPD-Net uses a self-attention calculation method to model the dependencies between all patches within an image. This enables our IPD-Net to self-learn how to extract appropriate inter-patch dependencies and classify them, further improving detection efficiency. We perform experimental evaluations on the CNNSpot-DS and GenImage datasets. Experimental results show that our IPD-Net outperforms several state-of-the-art baseline models on multiple metrics and has good generalization ability.**

***Keywords*—AI-generated image detection; image forensics; self-attention mechanism**

I. Introduction

In recent years, generative model technology has achieved rapid development. As shown in Fig. 1, the quality of AI-generated images is getting higher and higher. Various generative models such as VAE [1], GAN [2] and their derivative models continue to emerge. Ho et al. [3] provided rigorous mathematical derivation for the diffusion model, and then Dhariwal et al. [4] made the diffusion model gradually become the most mainstream generative model together with GAN, and promoted many derivative models. AI-generated images are becoming more and more realistic and difficult to distinguish with the naked eye, which opens up a wide range of possibilities for a variety of application scenarios. However, the development of this technology has two sides, and there have been some egregious incidents of malicious use of generative models to generate fake images. Because of this, in the face of the continuous evolution of future generative models, there is an urgent need to develop a universal detection method to distinguish AI-generated images from real ones.

A simple strategy is to use an existing multi-class CNN such as ResNet [5] for the binary classification task. However, when this method detects the generative model that is seen during training, it can recognize AI-generated images from the real images effectively, but its accuracy is significantly reduced in the detection across the generative model. CNNSpot [6] shows that with careful pre- and post-processing and data augmentation, a standard image classifier trained on a specific CNN-generated image training set can be extended to detect unseen GAN-generated image detection tasks. However, this method is found to perform well within the same family of generative models, but its generalization ability is limited when detected across different families [7]. For example, a model trained on a dataset containing images generated by ProGAN [18] (a variant of GAN) and real images, when tested on a dataset containing images generated by SD v1.4 [30] (a variant of diffusion models) and real images, shows a sharp decline in accuracy compared to detection within the same generative family. UnivFD [7] further points out that the previous method [6] relies mainly on the common features of the AI-generated images of the generative model seen during training to classify images as “fake” or “true”. Therefore, they propose to use untrained features to distinguish AI-generated images from real images and use a frozen large pre-trained vision-language model for classification. This method significantly improves the generalization ability of detection models on unknown generative models. However, because real images cover a large number of categories, determining a general classification range becomes a challenge, which may affect the classification accuracy of unknown generative models.

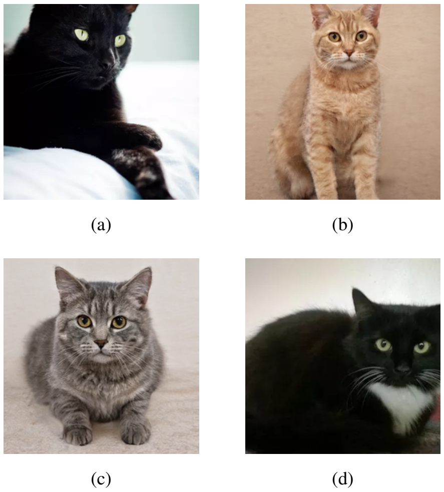

Fig. 1. Can you determine which are real images and which are AI-generated images? Where (a) and (d) are real images, and (b) and (c) are AI-generated images.

*Corresponding authors.

The diversity of real images makes it difficult to place them in a single category. Therefore, some detection methods try to distinguish real images from AI-generated images by finding common features among multiple generative models. However, with the continuous evolution of the field of the generative model, some early methods fail to generalize well to new models [6], [8], [9], [10]. In this paper, we propose IPD-Net, which can extract features from noise patterns of the pre-processed image and model the dependencies between all patches in the image by computing the dot product similarity between all vectors. The dependencies matrix is then classified into binary categories using a specially designed classification layer to determine whether the input image is an AI-generated image. Experimental results show that our proposed IPD-Net has a stronger generalization ability in detecting AI-generated images compared to baseline models.

In general, our main contributions are as follows:

- We propose IPD-Net, a novel neural network framework for AI-generated image detection based on inter-patch dependencies. IPD-Net can generalize to the detection of images generated by unseen generative models and has a fast inference speed.
- Unlike methods that directly segment pre-processed images into multiple patches and compute relationships between the patches, our proposed IPD-Net calculates the dot-product similarity between all vectors in the feature map using a self-attention mechanism, thereby modeling dependencies between patches in the image. In addition, we design dedicated classification layers to classify the modeled inter-patch dependencies to determine whether the image is AI-generated.
- We collect a highly diverse dataset containing images from various resolutions, operation types, and a wide range of generative models for evaluating our approach. Experimental results show that IPD-Net outperforms baseline models on multiple metrics and it has good generalization ability.

II. Related Work

In the following, we present an overview of related work in terms of both AI-generated image techniques and AI-generated image detection techniques. Additionally, we discuss the connections to our approach.

A. AI-Generated Image Techniques

In recent years, AI-generated image techniques have made great progress and caused a lot of concern. Among them, the Generative Adversarial Network (GAN) model [2] is one of the early important generative models. Its basic principle involves adversarial training between a generator and a discriminator, where the generator is responsible for generating images, and the discriminator is used to discriminate the authenticity of the images. As training progresses, the fidelity of the generated images increases and eventually reaches a very high level. The success of this technique has spawned many variants, such as [19], [20]. Ho et al. [3] brought rigorous mathematical derivation to the diffusion model, leading to its wider application in the field of image generation. The basic idea of the diffusion model is to gradually add noise to the data during the forward process and then learn to restore the original data from the noise during the reverse process. This technique has also produced many related models [30], [31], [32]. In contrast, the goal of our proposed IPD-Net is that, after training on the AI-generated image training set of a specific generative model, it can be generalized to other unknown generative models to perform AI-generated image detection tasks, thus better generalized to real-world scenarios.

B. AI-Generated Image Detection Techniques

With the rapid advances in generative techniques, modern AI-generated images have reached a level nearly indistinguishable from real images. Although generative technology has brought convenience to some industries such as AI mapping, like the two sides of a coin, this also brings potential social risks. For example, highly realistic AI-generated images could be exploited by criminals as a medium to disseminate fake information, thereby causing social problems. Therefore, the research and development of AI-generated image detection technology is particularly urgent.

Wang et al. [6] constructed a dataset containing AI-generated images from 11 different generative models based on CNN. For the construction of the training set, they trained 20 ProGAN [18] models, each trained on a different LSUN [17] object class. For each trained ProGAN model, 36K (for training) +200 (for validation) AI-generated images are generated, and the corresponding images for training ProGAN models are used as the real class, and the resulting training set and validation set contain the same number of true/fake images. Therefore, the resulting training set has a total of 720k images and the validation set has 4k images. Through careful pre-processing and data augmentation, they trained a binary classifier using a ResNet50 [5] pre-trained on ImageNet [29], and tested on a dataset of true/fake images collected from 11 different generative models. Experimental results show that even standard image classifiers trained for specific CNN generators can generalize over unseen generative model detection. Additionally, several other works [8], [9] investigated the frequency domain of GAN-generated images and leveraged the frequency domain for detection. Before the diffusion model became popular, most researchers focused on identifying GAN-generated images. However, these efforts were later found to be difficult to generalize to detecting AI-generated images from more recent generative models [7], such as diffusion models. With the rise of diffusion models, many previous detection methods have difficulty identifying this emerging model. Wang et al. [34] found that, unlike real images, images generated by diffusion models can be reconstructed through pre-trained diffusion models. So they use the error between the reconstructed image and the input image to detect AI-generated images. However, this method mainly focuses on diffusion models. Ojha et al. [7] found that although detection methods trained on ProGAN [6] generalize well when tested on the same generation model family (GAN model family), their accuracy significantly drops when tested on different generative model family (diffusion model family). Previous methods [6] mainly relied on features of seen models to classify images. Therefore, Ojha et al. [7] proposed using untrained features to distinguish AI-generated images from real ones and using a frozen large pre-trained vision-language model for classification, thus enhancing the generalization of the detection model to the unknown generation models, but this leads to a slower inference speed. Zhong et al. [14] used the inconsistency between rich and poor texture regions in AI-generated images as a universal fingerprint. Chen et al. [35] proposed using the noise pattern of the simplest patch of the input image to identify AI-generated images. However, both approaches require selecting specific patches from a large number of patches through mathematical calculations before sending them into the neural network. For this reason, we hope that our IPD-Net to not only adapt to the detection tasks of the above generation models but also achieve ultra-fast forward inference speed to attain efficient scalability.

III. Our Method

A. Motivation

To ensure that a detector trained on a specific GAN-generated image training set can be generalized to other GAN-generated image detection, or even generalized to the detection task of images generated by different families of generative models, it is crucial to find common features of fake images. For example, Zhong et al. [14] found that AI-generated images processed with a carefully selected set of SRM filters [15] (a type of high-pass filter with fixed parameters) have inconsistencies in inter-pixel relations between the rich texture region and the poor texture region. Inspired by [14], we argue that there exists some kind of dependencies between different patches of AI-generated images processed by the SRM filter, which can be used as common features of the AI-generated images, and such dependencies are not limited to those between rich texture patches and poor texture patches. To extract these dependencies efficiently, we designed IPD-Net that enables the model to capture interdependencies from all patches. To avoid the huge computational overhead associated with actively selecting specific patches, we are inspired by Wang et al. [16], who proposed a self-attention mechanism that, in the process of computing the weight matrix, can be viewed as modeling dependencies between patches of the preprocessed image. Based on this process, we discarded the softmax operation and performed spatial transformations to avoid the step of actively selecting patches. In this way, we can obtain the dependencies between all patches we need. Next, we specifically designed a classification layer so that the obtained dependencies can be directly used for classification. This design enables the model to achieve end-to-end training, allowing it to self-learn how to extract suitable dependencies and perform classification, thus further improving detection efficiency. Through this method, our model can not only recognize AI-generated images generated by generative models seen in training data but also can be generalized to other unseen generative model image detection tasks, improving the generalization ability of the detector.

B. Inter-Patch Dependencies Extraction

As shown in Fig. 2, our network architecture is divided into two parts: Inter-Patch Dependencies Extraction and Inter-Patch Dependencies Classification. In the Inter-Patch Dependencies Extraction part, our neural network aims to extract dependencies between image patches processed by the SRM filter. Therefore, firstly the pre-processed input image needs to be processed using the SRM filters. This filter has been widely adopted in the field of fake image detection [12], [13]. To validate our IPD-Net of generality, we chose the same as the [12], [13], general SRM filter configuration. In terms of the computation of inter-patch dependencies, we are inspired by the self-attention computation method proposed by Wang et al. [16], where the computation process can be viewed as calculating a correlation score between each patch in the image and all other patches (including itself). Specifically, each patch is processed by the neural network to become a feature vector. We input the noise patterns processed by the SRM filter into the backbone to obtain a feature map of size $C \times H \times W$, where C, H, and W represent the number of channels, height, and width of the feature map, respectively. For each patch P_i, the corresponding feature vector extracted by the backbone is denoted as e_i, and its size is C. For the relationship between any two patches, such as P_i and P_j, we use their corresponding feature vectors e_i and e_j to calculate their dot product similarity to represent the dependencies between them, as described by the following equation:

$$\text{Dependency}(e_i, e_j) = f(e_i) \cdot f(e_j) \tag{1}$$

Where f represents a 1×1 convolution. We perform this operation for all feature vectors, i.e., calculating their dot product similarity with all other feature vectors, resulting in a dependencies matrix of size $(H \times W) \times H \times W$. This can be viewed as $H \times W$ two-dimensional dependencies matrices of size $H \times W$, where each point represents the dependency score between the feature vector e_i of a certain patch P_i and the feature vector of another patch. Through this step, we successfully extract the inter-patch dependencies matrix.

C. Inter-Patch Dependencies Classification

After extracting the inter-patch dependencies matrix for each input image, to enable end-to-end training of the model, we classify the inter-patch dependencies and use the classification loss to optimize the model training. However, directly flattening the dependencies matrix for linear classification would result in huge computational overhead. Convolution is also unsuitable because the dependencies matrix is not a traditional feature map, and direct convolution may destroy it. Therefore, we adopt a 2D AdaptiveAvgPool operation. For the dependencies matrix of size $(H \times W) \times H \times W$, we can regard it as the feature matrix of $C' \times H \times W$, where $C' = H \times W$, is regarded as the number of channels, and H and W can be regarded as the feature matrix height and width. At this point, any channel represents a two-dimensional matrix of dependencies between a particular feature vector and all other feature vectors (including itself). Given this, we perform a two-dimensional average pooling operation on the inter-patch dependencies matrices to scale the size to $(H \times W)$ to directly extract the average dependency scores between each patch and other patches. Subsequently, since the inter-patch dependencies matrix is processed into vectors of size $(H \times W)$, it can directly be input into the linear classification layer. Meanwhile, the pooling operation significantly reduces the number of parameters in the model, further improving the inference speed. To validate the effectiveness of our IPD-Net, our linear classification layer uses only one or two linear

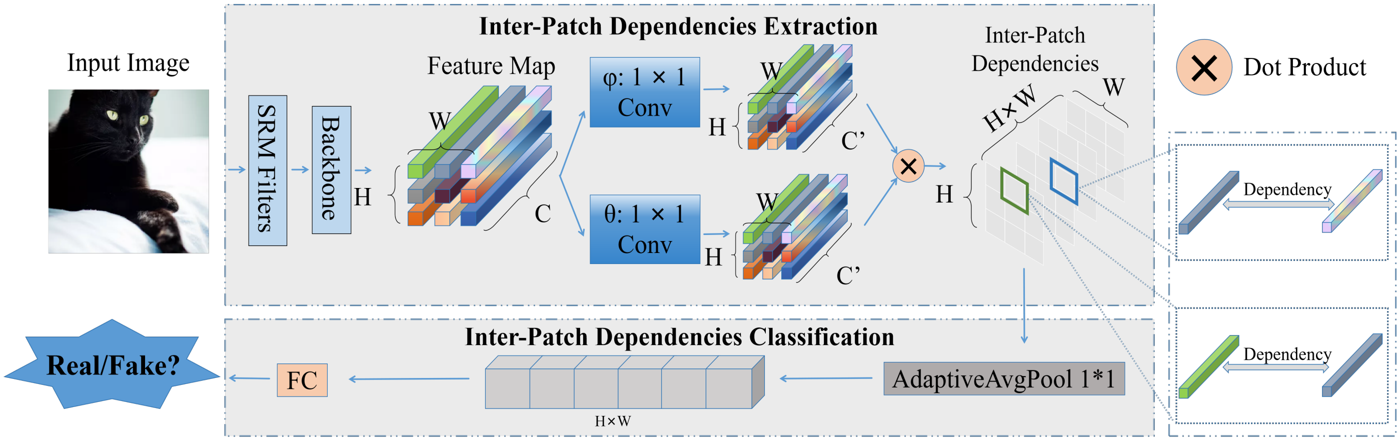

Fig. 2. Structure of IPD-Net. The preprocessed images are first processed by SRM filter and backbone to extract the dependencies between patches by a simple modified self-attention computation method. Subsequently, these dependencies are fed into a specially designed classification layer to determine whether the input image is an AI-generated image (Fake) or a real image (Real).

layers. The final output vector is processed with a sigmoid function to constrain the values to the $[0, 1]$, determining whether the input image is real or fake. We use Binary Cross Entropy Loss as the loss function, and our neural network is defined as $\mathrm{NN}(\cdot)$, formulated as follows:

$$\mathcal{L} = -\sum_{i=1}^{N} [y_i \log(\mathrm{NN}(x_i)) + (1 - y_i) \log(1 - \mathrm{NN}(x_i))] \quad (2)$$

Where x_i and y_i represent the input image and its corresponding label, respectively. The goal is to minimize this total loss during the training process to improve classification accuracy. Meanwhile, our network is more friendly to computation and memory due to the average pooling operation and simple linear classification operation.

IV. Experiment

A. Datasets

To fully evaluate the effectiveness of our proposed IPD-Net, we conducted experiments using the CNNSpot-DS [6] and GenImage dataset [11]. The AI-generated image in the former is mainly composed of the image generated by the GAN model, and the AI-generated image in the latter is mainly composed of the image generated by the diffusion model. We follow the same protocol as described in the baselines [6], [7], the training set we use for training is the training set of CNNSpot-DS [6]. The AI-generated images in the training set were generated by ProGAN [18], and the training set contains a total of 720k images, which contains 360k real images and 360k AI-generated images, where the real images are from LSUN [17] dataset of 20 categories. We only use it as the training set for all subsequent training, so our training and validation are restricted to only accessing the real/fake images of one generative model, and detecting other generative models that are not seen during training.

When evaluating the detector's ability, we considered various generative models. We tested the generative models on the test set of the CNNSpot-DS following the baselines [6], [7]: ProGAN [18], StyleGAN [19], BigGAN [20], CycleGAN [21], StarGAN [22], GauGAN [23], CRN [24], IMLE [25], SAN [26], SITD [27], and DeepFakes [28]. Additionally, we tested the test set of the GenImage dataset [11], which mainly contains many AI-generated images generated by diffusion models. Zhu et al. [11] used ImageNet [29] to generate 1.3 million AI-generated images. We tested the generation models in the GenImage dataset: Midjourney*, SDV1.4 [30], SDV1.5 [30], ADM [4], GLIDE [31], Wukong†, VQDM [32], and BigGAN [20].

B. Implementation Details

All training is implemented on an NVIDIA GeForce RTX 3090 GPU and an Intel Xeon Gold 6238R CPU. Our model is implemented using PyTorch [33] and the batch size was set to 32. We optimize using Adam with a learning rate of 0.0001. For the SRM filters [15], we follow the settings from [12], [13], adopting the three commonly used kernels from the original SRM filters [15]. To model the inter-patch dependencies of a feature map processed by the backbone, assuming the input feature map is $C \times H \times W$, we use two different 1×1 convolutions to process the feature map separately, reducing the number of channels to half of the original, and obtaining two different feature maps with sizes of $\left(\frac{C}{2}\right) \times H \times W$. We reshape them to $\left(\frac{C}{2}\right) \times (H \times W)$, converting them into two-dimensional matrices. We transpose one of the feature maps and then multiply it with another feature map to obtain a product f with a size of $(H \times W) \times (H \times W)$. After that, we transpose f once and reshape its size to $(H \times W) \times H \times W$ to perform the next step of the average pooling operation. We select a non-trained ResNet50 [5] as the backbone for feature extraction. In the design of the backbone, we consider three variants: ResNet50-Layer2, ResNet50-Layer3, and ResNet50-Layer4, where Layer2, Layer3, and Layer4 denote the layers after which truncation is applied. The input image can be of any size, we apply reflect padding to add 224 pixels on all sides of the image, then crop out 224 pixels and resize it to 256 pixels. During training, after resizing, we apply

Gaussian blur with $\sigma \sim \text{Uniform}[0, 3]$ with 10% probability, JPEG compression with quality $q \sim \text{Uniform}\{30, 31, \ldots, 100\}$ with 10% probability. In addition, we added random flip with 50% probability, and the above crop operations use random crop. During testing, our crop operations uniformly use center crop. For the classification part, we set up two linear layers for ResNet50-Layer2 and one linear layer for both ResNet50-Layer3 and ResNet50-Layer4.

For the baseline methods, we used CNNSpot [6], Fusing [10] and UnivFD [7]. For UnivFD [7], we tested using its publicly published training weights and open-source code. And for CNNSpot [6] and Fusing [10], we trained from scratch with the training dataset, following the settings in their open-source code. In evaluating our model and the baseline methods, we used Average Precision (AP) and Accuracy (ACC) to evaluate our model, which is consistent with recent related work [7]. We report the mean Average Precision (mAP) and Average Accuracy (Avg. acc) of each detector by averaging the AP scores and ACC scores obtained when each detector was tested against each test set of the generative model.

C. Evaluations

1) Combined dataset evaluation: Following the indicator setting of recent baselines [7], Table I and Table II present the average precision (AP) and accuracy (acc) of real/fake image detection by the baseline models and our IPD-Net (rows) for different generative models (columns). Following the training setting of recent baseline [6], [7], all our training is performed on the training set of CNNSpot-DS [6], the AI-generated images in the training set were all only generated by ProGAN. Therefore, models other than ProGAN can be considered as generalization domains. In the variant setting, Aug (0.1) and Aug (0.5) represent two training configurations of CNNSpot [6] open-source code, which apply JPEG compression and Gaussian blur with 10% or 50% probability, respectively. "Ours" represents our model's test results, and Layer2, Layer3, Layer4 correspond to the three backbone variants mentioned in Section IV-B, namely, ResNet50-Layer2, ResNet50-Layer3 and ResNet50-Layer4. The settings of the other two baseline methods [7], [10] are the same as those in the papers and open-source codes. Compared to the three baselines, all three variants of our proposed IPD-Net achieved better mAP and average accuracy. The mAP of our three variants improved by 1.47-2.6% over the best-performing baseline, and the average accuracy improved by 4.36-5.29% over the best baseline. Our model performs worse on Perceptual loss compared to other baseline models. We speculate that GAN models and Perceptual loss share some common features, which the baseline models may tend to fit. However, this common feature does not apply to diffusion models. In contrast, the common feature self-learned by our model is common to both the GANs model and the diffusion models, except that it is less general on Perceptual loss. Overall, our IPD-Net achieves the best performance in terms of mAP and average accuracy in combined dataset evaluation, indicating that our model has stronger generalization ability compared to the baseline models.

2) In-dataset and cross-dataset evaluation: To more effectively reflect the generalization ability of our proposed IPD-Net, we conducted in-dataset and cross-dataset evaluation. As shown in Table III, we analyzed the accuracy of the test set of CNNSpot-DS [6] and GenImage [11] datasets respectively. Among them, the accuracy of the CNNSpot-DS is an in-

TABLE III. Evaluation Results Accuracy of the CNNSpot-DS and GenImage Dataset. We Report Accuracy by Averaging the Accuracy Scores for Each Generative Model Detection in the Corresponding Dataset in Table II for Each Detector

Detection method	CNNSpot-DS [6]	GenImage [11]
	ACC	ACC
CNNSpot [6]	76.88	57.42
Fusing [10]	**82.21**	56.88
UnivFD [7]	80.59	69.96
Ours_Layer4	79.33	**82.71**

dataset evaluation, and the accuracy of the GenImage dataset is a cross-dataset evaluation. We report accuracy by averaging the accuracy scores for each generative model detection in the corresponding dataset in Table II for each detector. In the in-dataset evaluation, that is the evaluation on the test set of CNNSpot-DS. Because the AI-generated images in the training set are all generated by ProGAN, the trained baseline models still have high accuracy in detecting GAN variants. The CNNSpot-DS's test set is mainly generated by a large number of GAN-generated images, so all detectors achieved high accuracy. The in-dataset accuracy between all detectors ranged from 76-82%. In the cross-dataset evaluation, that is the evaluation on the test set of the GenImage dataset. When the baseline models are faced with the GenImage dataset's test set mainly containing a large number of images generated by the diffusion model, their detection accuracy drops significantly. Among them, the cross-dataset accuracy of CNNSpot [6] and Fusion [10] is even between 50-60%. In comparison, our IPD-Net's cross-dataset accuracy is 12.75% higher than the best baseline model. Overall, the results show that the generalization ability we demonstrated in the combined dataset evaluation is effective both within and across datasets, further demonstrating that our IPD-Net has a stronger generalization ability than other baseline models.

D. Effect of Different Backbone

When we design the IPD-Net backbone network, as the number of backbone network layers decreases, in the feature map extracted by the backbone network, the area corresponding to the original image for each feature vector becomes smaller. Therefore, we speculate that as the number of layers decreases, IPD-Net can learn to extract more detailed inter-patch dependencies, thereby achieving better results. In this section, we will study what happens when our proposed IPD-Net selects different backbone networks for feature extraction. We consider the three variants mentioned in Section IV-B: (i) ResNet-Layer2, (ii) ResNet-Layer3, and (iii) ResNet-Layer4. We trained each model again using the same ProGAN real/fake image training set as in the above experiments.

To better analyze these three different variants, we provide a visual analysis of these three variants. We saved the vectors obtained by average pooling and flattening of the inter-patch dependencies, tested them on the CNNSpot-DS and GenImage dataset respectively, and drew six t-SNE diagrams, as shown in Fig. 3, where the true/fake labels were marked in red/blue respectively. From top to bottom represent three variants: (i) ResNet-Layer2, (ii) ResNet-Layer3, and (iii) ResNet-Layer4. The left column (a) represents the three variants tested on the CNNSpot-DS test set, and the right column (b) represents the results of the three variants tested on the GenImage test set. However, it can be seen from the t-SNE visualization results that with the increase in the number of layers, the inter-patch dependencies after average pooling and flattening can be better divided into true/fake, and the features of the same class are more concentrated, even though the difference between these three variants in mean average precision and average accuracy indicators seems to be very small. This suggests that deeper model structures may still have better results, although they are less detailed in dividing patches than shallow backbone networks.

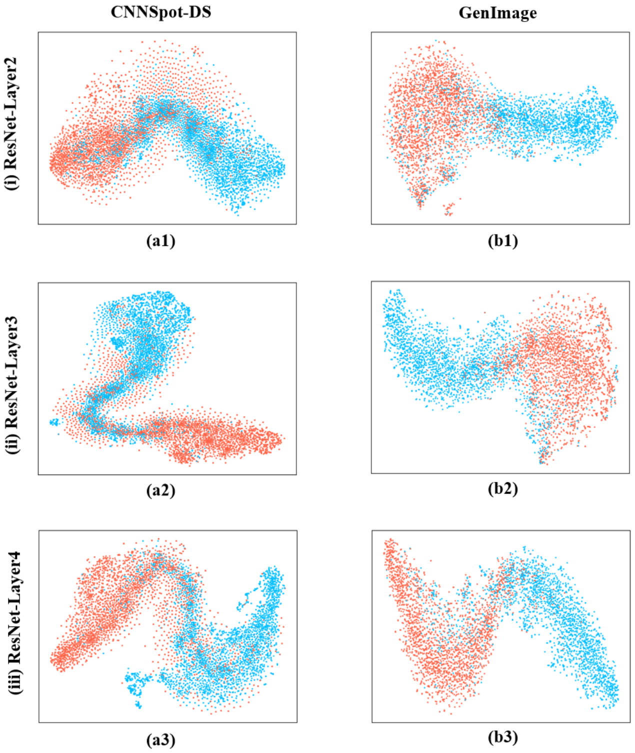

Fig. 3. Visualization results of three variants of t-SNE. True/fake labels are shown in red/blue, where the rows from top to bottom represent the three variants: (i) ResNet-Layer2, (ii) ResNet-Layer3, and (iii) ResNet-Layer4, left column (a) represents the results of the CNNSpot-DS test set, and the right column (b) represents the results of the GenImage test set.

E. Analysis of Limitations

We evaluated the robustness of our ResNet-Layer4 variant and the best-performing baseline model against jpeg compression and Gaussian blurring. Fig. 4 shows the mAP of both the ResNet-Layer4 variant and the best-performing baseline model under different post-processing configurations. Without any post-processing, the mAP of our method is significantly higher than that of the best-performing method. However, the robustness of our model to post-processing operations is significantly weaker than that of the best-performing baseline model, especially in the case of JPEG compression. We speculate that this may be because the way of extracting inter-patch dependencies in our IPD-Net is too simple, resulting in higher sensitivity to data changes and thus weaker robustness compared to the best-performing baseline model. We also

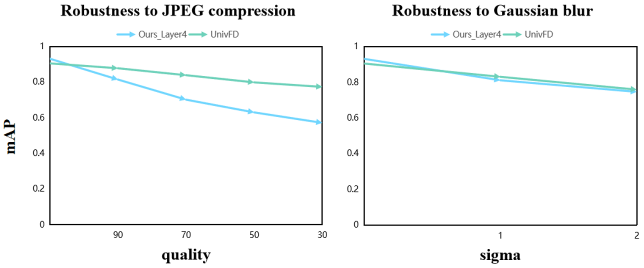

Fig. 4. Limitations analysis robustness analysis of different image post-processing operations.

analyzed the scalability issue. IPD-Net uses the self-attention calculation method proposed in [16]. To compare with the baseline models, the size of the input is only 256 × 256, and the training time per epoch is about 10-30 minutes slower than directly using ResNet50. However, because IPD-Net does not need to actively select specific patches, it is significantly faster than [14], [35]. If the input size increases, the calculation time of IPD-Net will significantly increase. Assume that when the height and width of the feature map to be multiplied both become n times larger, the number of dot products becomes n^4, while the number of channels remains the same. Therefore, optimizing the computation scheme for modeling the dependencies between patches is a problem for IPD-Net. For example, [36] proposed the Asymmetric Non-local Neural Network to improve Non-local Net. Therefore, reducing the number of steps in matrix multiplication, such as through dimensionality reduction or sampling before matrix multiplication, could potentially improve efficiency.

V. Conclusion

In this paper, we propose IPD-Net based on the existing inference that there is an inconsistency in the inter-pixels relation between the rich texture region and the poor texture region of AI-generated images. Firstly, we use a self-attention computation method and design a classification layer adapted to classification tasks, aiming to capture the interdependencies between patches of input images processed by the SRM filter. This enables the model to avoid the huge overhead caused by actively selecting specific patches and self-learn the common features of AI-generated images, thus improving computational efficiency. Secondly, we conduct extensive experiments on a test dataset containing 18 generative models, and the results show that our IPD-Net has high accuracy and good generalization ability. Thirdly, we conduct a comparison with several recent methods. IPD-Net outperforms the baseline models on multiple metrics. Regarding the future improvement of IPD-Net, we will focus on improving its network structure, especially the method of calculating the dependencies between patches to enhance its scalability and robustness. We hope that our work can provide some reference for future research.

***Abstract*—Network anomaly detection systems face challenges with imbalanced datasets, particularly in classifying underrepresented attack types. This study proposes a novel framework for improving F1-scores in multi-class imbalanced network attack detection using the UNSW-NB15 dataset, without resorting to resampling techniques. Our approach integrates Flower Pollination Algorithm-based hyperparameter tuning with an ensemble of XGBoost classifiers in a stacking configuration. Experimental results show that our FPA-XGBoost-Stacking model significantly outperforms individual XGBoost classifiers and existing ensemble models. The model achieved a higher overall weighted F1-score compare to the individual XGBoost classifier and Thockchom et al.'s heterogeneous stacking ensemble. Our approach demonstrated remarkable effectiveness across various levels of class imbalance, for example Analysis and Backdoor which is highly underrepresented classes, and DoS which is moderately underrepresented class. This research contributes to more effective network security systems by offering a solution for imbalanced classification without resampling techniques' drawbacks. It demonstrates that homogeneous stacking with XGBoost can outperform heterogeneous approaches for skewed class distributions. Future work will extend this approach to other cybersecurity datasets and explore its applicability in real-time network environments.**

***Keywords*—Intrusion detection; multi-class imbalanced classification; ensemble learning approaches**

I. Introduction

The proliferation of digital technology has led to a rise in cybersecurity concerns. The European Union Agency for Cybersecurity (ENISA) [1] reports that from the end of 2022 to the beginning of 2023, there was an increase in malware attack events. The increasing frequency of cyberattacks places sensitive data at danger of compromise. Researchers frequently use deep learning and machine learning algorithms to classify network traffic. The effectiveness of these algorithms in accurately classifying network traffic depends on the data used to train them. Typically, normal traffic constitutes the majority of training datasets, while abnormal traffic includes various potential attack types. Rare or unusual attacks are often underrepresented compared to regular or more common attacks, leading to an uneven class distribution. This imbalance can cause model bias towards the majority class [2], resulting in inaccurate predictions and difficulty in detecting rare network attacks.

Sampling approaches are commonly used to address data imbalance. Oversampling techniques, such as Random Oversampling [3] and SMOTE (Synthetic Minority Oversampling) [4], increase minority class samples to match the majority class. Conversely, undersampling methods, like Tomek-link [5] and Random Undersampling [3], reduce majority class samples to achieve a balanced distribution. Hybrid sampling combines both oversampling and undersampling techniques. However, oversampling can lead to overfitting [3], and undersampling may result in information loss.

Some researchers have proposed ensemble methods to address imbalanced datasets without resampling techniques [6], [7], [8]. However, these methods are typically applied only to binary classification. It is undeniable that some works involve ensemble approaches for multi-class imbalanced classification in network intrusion systems [9], [10], [11]. These works use a heterogeneous stacking ensemble approach, employing different algorithms as the base classifiers for the stacking model.

XGBoost model has shown superior ability to handle multi-class imbalanced classification [12] for network attack classification. It has also been widely used as a base learner in heterogeneous stacking models for multi-class imbalanced classification in network attack detection [13], [14], [15]. However, the use of XGBoost in homogeneous stacking ensemble approaches, where multiple instances of the same algorithm are used as base learners to solve imbalanced data, is limited and has not been applied to multi-class network attack detection [16]. The potential of homogeneous stacking with XGBoost, remains largely unexplored in the context of network attack classification. This gap in the literature is significant, as homogeneous stacking could potentially offer advantages in terms of model consistency and interpretability by leveraging the strength of XGBoost especially when dealing with the complex, multi-class nature of network attacks. Our work aims to address this research gap by investigating the effectiveness of homogeneous stacking with XGBoost for imbalanced multi-class network attack classification, without resorting to resampling techniques.

Although XGBoost has shown remarkable success compared to other machine learning algorithms [12], some researchers [17], [18], [19], [20], [21] have applied hyperparameter tuning techniques to further enhance its performance in network attack detection. Additionally, researchers such as [22], [23], [24] have involved hyperparameter tuning such as grid search and random search with heterogeneous stacking models that use XGBoost as one of the base classifiers for network anomaly detection. While meta-heuristic algorithms have shown promising results in optimizing machine learning hyperparameters across various domains, there remains a significant gap in their application to network attack classification, particularly in conjunction with XGBoost. However, the integration of the Flower Pollination Algorithm (FPA) with XGBoost for hyperparameter tuning in the context of network security remains largely unexplored. Existing studies utilizing FPA and XGBoost have primarily focused on regression models in fields such as civil engineering and environmental science, leaving a gap in their application to classification tasks in cybersecurity. Furthermore, the performance of meta-heuristic algorithms can vary significantly depending on the specific machine learning model and dataset characteristics.

Given that no single meta-heuristic algorithm consistently outperforms others across all tasks, there is a clear need to investigate the efficacy of FPA in optimizing XGBoost specifically for network attack classification. This study aims to address this research gap by exploring the potential of FPA-optimized XGBoost in the context of multi-class, imbalanced network attack detection, potentially offering new insights into improving the accuracy and robustness of intrusion detection systems.

In our approach, we first identify the optimal XGBoost models by optimizing the hyperparameters to maximise the base learner's performance on imbalanced datasets. The selection of these optimal models as the base learners are performed using hyperparameter tuning. Other than Flower Pollination Algorithm, four hyperparameter tuning techniques were investigated in this study: Random Search (RS), Bayesian Optimization (BO), Genetic Algorithms (GA), and Cuckoo Search Algorithms (CSA). Then, we integrate the hyperparameter tuning process with ensemble learning techniques to create a robust and effective ensemble classifier.

To summarize, the paper's contributions are as follows. First, the integration of FPA for optimization of XGBoost classifier in network security. Second, the paper shows that the proposed homogeneous stacking ensemble model with hyperparameter tuning, specifically the FPA-XGBoost-Stacking model, achieves better results than heterogeneous stacking model [11] for multi-class imbalanced network attack classification. The homogeneous FPA-XGBoost-Stacking model has proven effective by improving both overall detection performance and class-specific metrics compared to a standalone XGBoost model. These findings pave the way for addressing multi-class imbalanced classification issues using ensemble learning without the need for resampling techniques, with potential applications extending beyond network attack detection.

The structure of this paper is as follows: Section II reviews related work. Section III discusses XGBoost hyperparameters. Sections IV and V cover hyperparameter tuning and ensemble learning techniques. Section VI describes the datasets and experimental setup. Sections VII and VIII present the results of the optimized XGBoost models and ensemble models. Finally, Section IX provides the conclusions.

II. Related Works

Imbalanced classification presents a significant challenge in machine learning (ML), characterised by a notable difference in the number of instances between classes. This imbalance can lead to biased models that produce poor results for the minority class. Ensemble learning, a technique that combines multiple models to enhance performance, has been studied to tackle this problem. Ensemble ML techniques involve the combination of multiple base learners using a specific combination rule to create improved predictive models. Base learners may include a wide range of ML algorithms, such as decision trees, Naïve Bayes, K nearest neighbours, artificial neural networks, and logistic regression. The ensemble topology can range from a basic collaboration of individual learners combined through a majority vote to more sophisticated mechanisms. Research has indicated that incorporating multiple classification methods enhances performance scores [25], [26].

The Geometric Structural Ensemble (GSE) [27], Hybrid Data-Level Ensemble (HD-Ensemble) [28] and `sBal_IH` [6] applied both resampling and ensemble approaches in their works. The Geometric Structural Ensemble (GSE) learning framework effectively tackles imbalanced classification issues by leveraging geometric structures to partition and eliminate redundant majority samples. GSE uses the Euclidean metric to create hyper-spheres that contain minority samples, improving training efficiency and interoperability. The framework also incorporates relaxation techniques to improve generalization [27]. The Hybrid Data-Level Ensemble (HD-Ensemble) uses both undersampling on the margins and oversampling to improve diversity and balance the distribution of data in order to get the best ensemble properties [28]. The HD-Ensemble effectively rebalances data distribution and enhances performance in binary classification tasks. Kaixiang Yang et al. [29] introduced a hybrid optimal ensemble classifier framework that integrates density-based undersampling with cost-sensitive techniques to address class imbalances. This method employs a multi-objective optimisation algorithm to choose informative samples and adjust the weights of misclassified minority samples. The dual-ensemble class imbalance learning method integrates resampling techniques with multi-classifier models. It uses evolutionary algorithms to optimize the combination of base classifiers, achieving better accuracy and simpler ensemble structures. This method outperforms other ensemble classification methods on human activity recognition datasets [30]. A medical diagnosis system uses an ensemble learning approach that combines SMOTE with cross-validated committee filters and utilises ensemble support vector machines (SVM). This approach utilises a simulated annealing genetic algorithm to optimize the weight vector [31]. However, most of these methods modify the initial distribution of classes to achieve a more balanced dataset [30], [29], [27], [28]. This is done through techniques such as over-sampling or under-sampling. These techniques can result in overfitting or the removal of valuable data, which may eventually impede performance [6].

Without resampling, an ensemble method, `sBal_IH`, creates balanced splits of data based on instance hardness. This approach trains base learners on varied characteristics of the training data, significantly improving classification performance [6]. Chih-Fong Tsai et al. [7] and Hongle Du et al. [8] propose methods to solve imbalance class problems in network security. One-class classification (OCC) techniques, typically used for anomaly detection, are applied to two-class imbalanced datasets. Ensemble learning with OCC classifiers, both with and without feature selection, outperforms single OCC classifiers, demonstrating effectiveness in high imbalance ratio datasets [7]. An online ensemble learning algorithm for imbalanced data streams employs cost-sensitive techniques to dynamically adjust misclassification costs and sample weights. This method improves classification performance in imbalanced data streams, as demonstrated in network intrusion detection applications, reducing both false alarm and missing alarm rates [8]. These advancements highlight the potential of ensemble learning to address the challenges posed by imbalanced datasets effectively. However, these studies only applied to binary classification [6], [7], [8].

Recent research in network attack detection has explored ensemble methods to address imbalanced datasets in multi-class classification scenarios. Mansoor-ul-Haque et al. [9] proposed a heterogeneous stacking ensemble for multi-class network intrusion detection, utilizing resampling techniques with KNN, SVM, and RF as base learners and XGBoost as the meta-learner. Similarly, Thockchom et al. [11] developed a heterogeneous stacking ensemble model for multi-class intrusion detection, integrating Gaussian Naive Bayes, Logistic Regression, and Decision Tree as base classifiers with Stochastic Gradient Descent as the meta-classifier. Rajadurai and Gandhi [10] evaluated a stacked ensemble learning approach on the NSL-KDD dataset with four attack categories, employing Random Forest and Gradient Boosting. The majority of these approaches employ heterogeneous stacking ensembles. However, instead of using a variety of base learners as in [9], [10], [11], this study opts for using homogeneous learners by using XGBoost algorithm. This decision is based on the considering the ability of XGBoost in handling imbalanced multi-class classification effectively [12].

Meta-heuristic algorithms, which are optimisation techniques inspired by natural processes, have been increasingly used for ML parameter optimisation. Meta-heuristic algorithms have been successfully applied to optimize hyperparameters in diverse domains, including sentiment analysis, image reconstruction, and landslide susceptibility mapping [32], [33]. Meta-heuristic algorithms such as particle swarm optimisation (PSO), genetic algorithm (GA), and others have been shown to effectively optimize hyperparameters, leading to improved model performance across various ML tasks [32], [34], [33]. Meta-heuristics can outperform traditional methods like grid search and random search in terms of accuracy and computational efficiency [32], [34], [33]. The integration of meta-heuristics with ML models has led to significant improvements in predictive performance and robustness [35], [34], [33].

The integration of XGBoost and FPA algorithm for hyperparameter tuning has rarely been investigated. Flower Pollination Algorithm (FPA) has been used to optimize the regression XGBoost models in civil engineering [36], [37] and environmental science [38]. The existing models have mainly focused on building regression models. Studies indicate that no single meta-heuristic algorithm consistently outperforms others across all tasks. The performance can vary depending on the specific ML model and the nature of the dataset [34]. Hence, the current work attempts to fill these gaps in the literature by employing FPA in optimizing XGBoost for network attack classification.

III. XGBoost Hyperparameters

A. Overview of XGBoost

XGBoost (Extreme Gradient Boosting) is a powerful and widely-used machine learning algorithm under the Gradient Boosting framework. It combines multiple weak learners (decision trees) to create a strong learner by iteratively training on the residuals of previous trees, minimising the loss function, and enhancing overall performance. Known for its speed and efficiency, XGBoost is popular for various ML tasks, including classification and regression.

The XGBoost algorithm can be expressed using the following equation:

$$\hat{y}_i = \sum_{k=1} f_k(x_i), \quad f_k \in \mathcal{F} \tag{1}$$

where: $\hat{y}_i$ is the predicted value for the i-th instance, K is the total number of trees (iterations), f_k is the k-th tree (weak learner), x_i is the input feature vector for the i-th instance, and $\mathcal{F}$ is the space of possible trees (weak learners).

The objective function of XGBoost consists of two parts: the loss function and the regularization term.

$$\text{Obj}(\theta) = \sum_{i=1}^{n} l(y_i, \hat{y}_i) + \sum_{k=1}^{K} \Omega(f_k) \tag{2}$$

Where $\text{Obj}(\theta)$ is the objective function to be minimized, n is the total number of instances, $l(y_i, \hat{y}_i)$ is the loss function, such as squared error or log loss, and $\Omega(f_k)$ is the regularization term for the k-th tree, which penalizes the complexity of the model.

The gain function in XGBoost determines the optimal split point for a decision tree node by measuring the improvement in the loss function after splitting the node into two child nodes. The split with the highest gain is selected as the best split for the current node. The split with the highest gain is chosen as the best for the current node, and the process is recursively repeated for the child nodes until a stopping criterion is met, such as maximum depth or minimum number of instances in a leaf.

B. Hyperparameters

The performance of an XGBoost model can be improved by tuning various hyperparameters. Below are several critical hyperparameters and their influence on the model's performance:

1) Number of estimators: The number of estimators refers to the number of decision trees (also known as weak learners or base learners) that are built and combined to create the final ensemble model. A hyperparameter determines the total number of trees to be trained in the XGBoost model. Each estimator is a decision tree that is trained on a subset of the training data and contributes to the final prediction.

2) Learning Rate (eta): The learning rate determines the step size at which the model's weights are updated. A lower learning rate leads to slower convergence but can help reduce overfitting.

$$\hat{y}_i^{(t)} = \hat{y}_i^{(t-1)} + \eta \cdot f_t(x_i) \tag{3}$$

where $\hat{y}_i^{(t)}$ is the prediction for the i-th instance at iteration t, $\hat{y}_i^{(t-1)}$ is the prediction for the i-th instance at the previous iteration $t-1$, η is the learning rate, and $f_t(x_i)$ is the output of the t-th tree for the i-th instance.

3) Maximum depth (max_depth): The maximum depth of a tree controls the complexity and the ability of the model to capture interactions among features. Increasing the maximum depth can lead to overfitting while decreasing it can result in underfitting. A deeper tree can capture more complex patterns, but it may also overfit the training data.

4) Minimum child weight (min_child_weight): It defines the minimum sum of instance weights (hessian) needed in a child node. A higher value prevents overfitting by avoiding the creation of too many child nodes with low instance weights.

$$\sum_{i \in I_L} H_i \geq \texttt{min\_child\_weight} \tag{4}$$

where I_L is the set of instances in the left child node, and H_i is Hessian (second-order gradient) for instance i.

5) Subsample: Subsample is the fraction of observations to be randomly sampled for each tree. A value less than 1 introduces randomness and helps in reducing overfitting.

6) Colsample_bytree: It is the subsample ratio of columns (features) when constructing each tree. A value less than 1 introduces randomness and helps in reducing overfitting by considering only a subset of features for each tree.

7) Gamma: Gamma is the minimum loss reduction required to partition the leaf node of the tree further. Increasing gamma makes the model more conservative and can help reduce overfitting.

Tuning these hyperparameters can significantly impact the performance of an XGBoost model. The optimal values depend on the specific dataset and problem at hand. It is common to use techniques like grid search or random search to find the best combination of hyperparameters that maximize the model's performance on a validation set. Given the computational constraints and the exponential growth in possible parameter combinations, this investigation concentrates on a carefully selected subset of hyperparameters. The study emphasizes the optimization of four key parameters: the quantity of estimators, the rate of learning, the maximum depth of trees, and the minimum weight required for child nodes. These specific hyperparameters were chosen due to their substantial influence on both the model's efficacy and its capacity to generalize. Moreover, these parameters play a crucial role in determining the model's ability to learn from the data and in balancing the trade-off between bias and variance in its predictions.

IV. Hyperparameter Tuning

Hyperparameter tuning is a critical step in optimising the performance of ML models. Bayesian optimisation and Genetic Algorithm, have shown promising results in tuning support vector machines (SVM) and random forests (RF) [35], [33]. In this study, other than two commonly used hyperparameter tuning techniques: Random Search and Bayesian Optimization, we also applied three metaheuristics algorithms: Flower Pollination Algorithm (FPA), Cuckoo Search Algorithm (CSA), and Genetic Algorithm (GA), to tune the hyperparameters discussed in Section III-B.

A. Objective Function

In optimisation, an objective function is a mathematical function that needs to be minimised or maximised to find the optimal solution to a problem. In this study, the objective function is the weighted F1-score, a common metric for imbalanced classification problems. We focuses on the weighted F1-score rather than the macro-average F1-score because the weighted F1-score accounts for the imbalance in the dataset. It reflects the classifier's performance across all classes by considering the actual data distribution [39]. In contrast, the macro-average F1-score treats all classes equally [39], without accounting for class imbalance, which can be misleading for imbalanced datasets. Therefore, this study prioritises improving the weighted F1-score performance.

The F1-score (weighted) is calculated (see Eq. 5) as follows:

$$F1_{weighted} = \frac{\sum_{i=1}^{n} 2 \times \frac{precision_i \times recall_i}{precision_i + recall_i} \times w_i}{\sum_{i=1}^{n} w_i} \tag{5}$$

where: n is the number of classes, $precision_i$ is the precision for class i, $recall_i$ is the recall for class i, and w_i is the weight for class i, which is usually the number of instances in class i.

By using the weighted F1-score as the objective function, the hyperparameter optimisation ensures the resulting XGBoost model is optimized to perform well across all classes, considering the class imbalance in the dataset.

B. Random Search (RS)

Random search (RS) is a simple but effective method used for optimisation. In ML, random search is commonly used for hyperparameter tuning, which aims to find the best set of hyperparameters to maximize a model's performance [40]. With a set budget, random search randomly samples hyperparameters and assesses the model's performance for each hyperparameter combination. Unlike more complex methods such as grid search or Bayesian optimisation, random search involves randomly sampling points in the parameter space and evaluating the objective function at these points [32]. It is easy to implement and does not require any prior knowledge about the problem's structure.

C. Bayesian Optimisation (BO)

Bayesian optimisation (BO) is a highly effective and efficient method for hyperparameter tuning in ML [41], [32]. It consistently outperforms traditional methods and is applicable across a wide range of models. Advanced techniques and practical tools enhance its utility, making it a preferred choice for optimizing complex ML algorithms. It leverages probabilistic models to make informed decisions about where to evaluate the objective function next, aiming to find the global optimum with as few evaluations as possible. It is efficient in high-dimensional spaces and works well with expensive-to-evaluate functions.

D. Flower Polination Algorithm (FPA)

The Flower Pollination Algorithm (FPA) is a nature-inspired optimisation technique that mimics the pollination process of flowering plants. Introduced by Xin-She Yang [42], it leverages the principles of flower constancy and pollination to solve complex optimisation problems. The FPA is an attractive choice for optimisation due to its simplicity and ease of implementation, having only one main control parameter, which makes tuning straightforward and less sensitive to settings [42]. FPA effectively balances exploration and exploitation through global pollination (Lévy flights) for exploration and local pollination for exploitation. It has been successfully applied to various optimisation problems, including continuous, discrete, and multi-objective cases [43].

E. Genetic Algorithm (GAs)

Genetic Algorithms (GAs) are evolutionary algorithms inspired by natural selection and genetics. Introduced by John Holland in the 1970s, GAs solve optimisation problems by evolving a population of candidate solutions through selection, crossover, and mutation operators [44]. They have since been widely applied across various domains. GAs are effective for solving optimisation problems [45]. They can explore a wide range of solutions and escape local optima due to the stochastic nature of the operators. GAs handle complex, non-linear problems without needing gradient information and are flexible, easily adaptable to various domains with appropriate representation schemes and operators.

F. Cuckoo Search Algorithm (CSA)

The Cuckoo Search Algorithm (CSA) is a nature-inspired optimisation technique introduced by Xin-She Yang and Suash Deb in 2009 [46]. It mimics the brood parasitism behaviour of some cuckoo species, which lay their eggs in the nests of other birds. Host birds may discard these eggs or abandon their nests, a concept CSA uses to search for optimal solutions in a problem space. The CSA is simple to implement and balances exploration and exploitation effectively through Lévy flights [46]. It has demonstrated strong performance in various optimisation problems and has been successfully applied across different domains.

V. Ensemble Combination Techniques

Rather than relying on a single model, combining several models, known as the ensemble technique, leads to more accurate classification predictions [47]. This method aims to enhance classification performance by integrating multiple models and has been widely adopted in numerous studies. Ensemble learning involves using the output of base classifiers as input for a new classifier. In this research, the stacking and voting ensemble learning approach were employed.

Stacking, introduced by Wolpert in 1992 [48], is an ensemble technique that minimises generalisation error in ML. It commonly involves two layers: multiple base classifiers are trained in the first layer (level 0), and their predictions are fed into a meta-classifier in the second layer (level 1) for further training. The effectiveness of stacking depends on the selection of both base and meta-classifiers, better prediction results from the base classifiers improving overall predictions [49]. The meta-classifier combines these predictions to make the final decision, often using a simple model [47].

There are two types of voting techniques: hard voting and soft voting. Hard voting is an ensemble method where the predicted outcomes from different models are averaged based on the majority. Each model makes a prediction, and the instances are classified into the most frequently predicted class. In contrast, soft voting relies on the probabilities output by the base classifiers. It calculates the average probabilities for each class across the models and assigns the instance to the class with the highest average probability [50]. For example, if class 1 has a higher average probability than class 2, the instance is classified as class 1.

A. Optimized XGBoost Ensemble

This section details the generation of optimized XGBoost ensemble models, divided into two main phases as shown in Fig. 1. The first phase involves hyperparameter tuning to identify the best configurations for the XGBoost models. The second phase applies ensemble learning techniques, specifically stacking and voting, to enhance performance.

1) Phase 1 Hyperparameter tuning: Hyperparameter tuning is crucial for optimising ML models to achieve peak performance. In this research, it was used to refine XGBoost models for multi-class imbalanced classification in network attack detection. Initially, a broad range of hyperparameter combinations was set, as detailed in Section VI-B. This ensured a thorough search for optimal settings. XGBoost models were tuned using five techniques: RS, BO, CSA, FPA, and GA. Each aimed to identify the top five models with the best hyperparameters for maximising the weighted F1-score, crucial for handling the imbalanced dataset. This process produced 25 optimized models, five from each technique. To ensure robustness and generalisability, stratified k-fold cross-validation was employed, splitting the training dataset into three subsets. This approach mitigated overfitting and provided reliable performance metrics. After tuning, the top five models from each technique were evaluated based on their weighted F1-scores, as shown in Table I.

2) Phase 2 Ensemble learning: After obtaining 25 optimized XGBoost models, the subsets of these models were combined through stacking and voting (soft and hard) ensemble techniques. Models from each hyperparameter tuning technique were grouped by performance into top three, top four, top five, and top-performing categories. This combination resulted in 18 optimized stacking ensemble models, 18 optimized soft voting ensemble models, and 18 optimized hard voting ensemble models.

The top n category includes the first n optimized XGBoost models from each hyperparameter tuning technique that achieved the highest weighted F1-scores. The top-performing category selects the best model from each tuning technique. For example in the FPA-Stacking ensemble models as shown in Fig. 2, FPA-Stacking 3 uses FPA-XGBoost 1, FPA-XGBoost 2, and FPA-XGBoost 3 as the base classifiers. This approach is similarly applied to the soft and hard voting ensemble models.

TopP-Stacking ensemble model utilises the top optimized XGBoost models from each hyperparameter tuning technique. For instance, TopP-Stacking3 combines the top-performing individual optimized XGBoost models: CSA-XGBoost 1 (TopP1), GA-XGBoost 1 (TopP2), and FPA-XGBoost 1 (TopP3) as the base classifiers for the stacking ensemble model. This approach is similarly applied to the TopP-SoftVoting and TopP-HardVoting ensemble models, where the same top-performing classifiers are used as the base models.

VI. Experiment

The performance of these optimized stacking and voting XGBoost ensemble models was evaluated on the testing dataset to assess their generalisation capability and classification accuracy for unseen data. The default XGBoost model was used as the meta-classifier for all stacking ensembles.

A. Dataset Description

The dataset used in this experiment is the UNSW-NB15 dataset, which is publicly accessible from the University of New South Wales (UNSW). This dataset consists of 257,673 records of network traffic, primarily categorized as either normal or attack traffic. It includes a total of 43 features, along with two label features [51]. The attack traffic is further classified into nine different types based on their characteristics: analysis, backdoor, DoS, exploits, fuzzers, generic, reconnaissance, shellcode, and worms, as illustrated in Fig. 3. The dataset is stratified and split into a 70:30 ratio, with 70% used as the training set and 30% as the test set. As shown in Fig. 3, attack classes such as “Analysis,” “Backdoor,” “Reconnaissance,” “Shellcode,” and “Worms” constitute less than 6% of the total instances, thus being identified as minority classes in this study. This reflects the complexity of real-life scenarios, where certain network attacks, despite their rarity, are of significant concern.

B. Experimental Setup

The XGBoost models were implemented in a Python environment. This model is capable of utilising GPU acceleration, which enhances the efficiency of hyperparameter tuning. The experiments compared the proposed approach with baseline individual default XGBoost model which also serves as the meta-classifier in each ensemble.

The MEALPY Python package [52] was utilised for hyperparameter tuning using metaheuristic algorithms. Due to the extensive combinatorial optimisation search space, it is necessary to establish a specific range for each parameter. For the four critical parameters mentioned in Section III-B, the tuning ranges are specified as follows: Number of estimators = [100, 200, 300, 400, 500, 600, 700, 800, 900, 1000], eta = [0.001, 0.01, 0.05, 0.1, 0.2, 0.3], minimum child weight = [1, 2, 3, 4, 5, 6], maximum depth = [3, 4, 5, 6, 7, 8, 9, 10, 11,12,13,14,15]. The other parameters are set as follows: *booster*= “*gbtree*”, $gamma$ = 0, $subsample$ = 1, `colsample_bytree` = 1, `reg_lambda` = 1, `tree_method`=“*hist*”, and `random_state` = 42 *objective*=“*multi* : $softmax$.

VII. Hyperparameter Tuning Results

Table I demonstrates the performance of the top five XGBoost models from five different hyperparameter tuning techniques, resulting in a total of 25 optimized models. The primary focus is on their weighted F1-scores during training, which are crucial for evaluating performance on imbalanced datasets. All models demonstrate strong training performance, with weighted F1-scores above 0.8180. The table organizes the models according to their weighted F1-scores within each hyperparameter tuning technique, facilitating comparison. For example, RS-XGBoost 1 refers to the model with the highest weighted F1-score from Random Search (RS) tuning, while RS-XGBoost 5 denotes the model with the lowest weighted F1-score among the top five from the same technique. This arrangement allows for a clear comparison of the effectiveness of each tuning method based on weighted F1-scores.

VIII. Optimized XGBoost Ensemble Models Results

A. Comparison of Optimized XGBoost-Stacking Models

Table II compares the performance of 18 stacking ensemble models against a baseline individual XGBoost model. The results show that all stacking ensemble models outperform the individual XGBoost model with improvements in accuracy, macro-average F1-score, and weighted F1-score. The weighted F1-scores of the stacking models range from 0.8307 to 0.8367, significantly higher than the individual XGBoost model’s 0.8161. This highlights the effectiveness of the stacking ensemble approach in improving classification performance. Based on Table II, the FPA-stacking ensemble models outperform those using RS, BO, CSA, and GA-optimized models as

base classifiers. They also surpass the TopP-stacking ensemble models, which use the top-performing optimized classifiers as base classifiers. Among the FPA-stacking ensemble models, FPA-Stacking3 achieved the highest weighted F1-score of 0.8367, representing a 2.524% improvement over the individual XGBoost model's score of 0.8161. Beyond achieving the highest weighted F1-score, FPA-Stacking3 also emerged as the top-performing stacking ensemble model among all 18 models, with a macro-average F1-score of 0.6266 and the highest accuracy of 0.8450.

B. Comparison of Optimized XGBoost-Voting Models

Tables III and IV show the results for 18 models of soft voting and hard voting, respectively. The tables reveal that all voting ensemble models showed slight improvements over the individual XGBoost model, particularly in terms of weighted F1-score. Soft voting models had weighted F1-scores from 0.8197 to 0.8224, while hard voting models ranged from 0.8197 to 0.8235, compared to 0.8161 for the individual XGBoost model. This demonstrates the effectiveness of the voting ensemble approach in enhancing classification performance. Based on Table III, the TopP-SoftVoting ensemble models outperform other soft voting ensembles that use RS, BO, CSA, FPA, and GA-optimized models as base classifiers in terms of weighted F1-score, with the CSA-SoftVoting5 ensemble model (0.8220) also emerging as a strong contender. Among the TopP-SoftVoting models, TopP-SoftVoting3 stands out, achieving the highest weighted F1-score of 0.8224.

TABLE I. Hyperparameters and Weighted F1-Scores for 25 Optimized Classifier Models

Model	learning _rate	max_ depth	min_ depth	min_ child_ weight	Weighted F1- score (Train)
RS-XGBoost 1	**0.05**	**15**	**3**	**500**	**0.8196**

FPA-XGBoost 5	0.2263	10	2	347	0.8194
GA-XGBoost 1	**0.0898**	**12**	**2**	**727**	**0.8200**
GA-XGBoost 2	0.0898	11	3	660	0.8200
GA-XGBoost 3	0.1335	12	2	393	0.8198
GA-XGBoost 4	0.898	11	2	660	0.8198
GA-XGBoost 5	0.0898	12	2	660	0.8198

This represents a 0.7720% improvement over the individual XGBoost model's score of 0.8161. Additionally, Table III identifies FPA-XGBoost-SoftVoting3 as the ensemble model with the highest macro-average F1-score of 0.6010, while RS-XGBoost-SoftVoting3 stands out for achieving the highest accuracy of 0.8356.

Table IV shows that all hard voting ensemble models achieved a weighted F1-score above 0.8200, except for the BO-HardVoting3 ensemble model, which recorded a weighted F1-score of 0.8197. Among the 18 hard voting ensemble models, the FPA-HardVoting4 model stands out with the highest weighted F1-score of 0.8235, representing a 0.9068%

TopP-XGBoost-HardVoting4	0.8325	0.5952	0.8226
TopP-XGBoost-HardVoting5	0.8339	0.5952	0.8221

improvement over the individual XGBoost model's score of 0.8161. Additionally, Table IV indicates that the FPA-HardVoting3 model achieved the highest macro-average F1-score of 0.6010, while the RS-HardVoting3 model achieved the highest accuracy of 0.8356.

C. Per Class Comparison

We further perform a comparison of the proposed FPA-XGBoost-Stacking, focusing on performance improvements across classes achieved by the ensemble models compared to an individual XGBoost model. Considering FPA-XGBoost Stacking with three models performs the best, we compare the performance of the FPA-XGBoost Stacking with an individual XGBoost and another ensemble approach proposed by Thockchom et al. [11], This ensemble approach selected due to its relevance to the methods used in this research. Thockchom et al.'s [11] model is a heterogenous stacking ensemble involving Gaussian Naive Bayes, Logistic Regression, and Decision Tree as base classifiers, with Stochastic Gradient Descent as the meta-classifier, using the base classifiers' predictions as input.

TABLE V. F1-scores for Different Attack Classes Across Models

Attack class	Individual XGBoost (default)		FPA -XGBoost -Stacking		Thockchom et al. [11]	
Analysis	0.1861		0.2229	✓	0.0023	
Backdoor	0.1684		0.2085	✓	0.0336	
DoS	0.2041		0.4149	✓	0.1663	
Exploits	0.7420		0.7531	✓	0.7120	
Fuzzers	0.6395		0.6706	✓	0.6041	
Generic	0.9888		0.9894	*	0.9848	
Normal	0.9296		0.9350	✓	0.9135	
Reconnaissance	0.8384		0.8304		0.8114	
Shellcode	0.6763		0.6723		0.6099	
Worms	0.5714		0.5686		0.4296	
Weighted F1-score	0.8161		0.8367	✓	0.7934	
Accuracy	0.8343		0.8450	✓	0.8111	

(✓) Significant improvements, (*)Slight improvements

The results presented in Table V offer compelling evidence for the effectiveness of our proposed FPA-XGBoost-Stacking model in addressing the challenges of imbalanced network attack detection. One of the most striking findings is the model's performance on underrepresented attack classes. For instance, the F1-score for the DoS class improved dramatically from 0.2041 to 0.4149, a 103.3% increase. This is particularly significant given that DoS attacks comprise less than 2% of the samples compared to the majority class. Similarly, substantial improvements were observed for other rare attack types, with the Analysis class showing a 19.8% increase and the Backdoor class a 23.8% increase in F1-scores. The consistent improvements across almost all attack classes are noteworthy. Six out of ten classes showed significant enhancements, indicating that our model's performance boost is not limited to just a few categories. This broad-spectrum improvement suggests that the FPA-XGBoost-Stacking model has successfully captured a wide range of attack patterns and characteristics.

When comparing our model to both the individual XGBoost classifier and Thockchom et al.'s heterogeneous stacking ensemble, the advantages of our approach become clear. The overall weighted F1-score of 0.8367 represents a 2.52% improvement over individual XGBoost and a 5.46% improvement over Thockchom et al.'s model. This demonstrates that our homogeneous stacking approach with XGBoost, combined with FPA-based hyperparameter tuning, outperforms both simpler and more complex heterogeneous models.

It is worth noting that there were slight decreases in performance for the Reconnaissance, Shellcode, and Worms classes compared to the individual XGBoost model. However, these decreases were minimal, and our model still outperformed Thockchom et al.'s approach in these categories. This suggests that while our model excels in most areas, there may be room for further optimization in detecting these specific attack types. The improved accuracy (0.8450 compared to 0.8343 for individual XGBoost and 0.8111 for Thockchom et al.'s model) further corroborates the overall enhanced performance of our approach. This indicates that our model not only improves the detection of underrepresented classes but also maintains high performance on more common attack types and normal traffic.

IX. Conclusion

The experimental results highlight the effectiveness of ensemble learning techniques, particularly homogeneous stacking and voting, in addressing imbalanced datasets for network attack detection. Homogeneous stacking tends to produce more stable and consistent results because all base models in the ensemble use the same algorithm. In contrast, heterogeneous ensembles might be more volatile. Different algorithms can react very differently to changes in the data, potentially leading to less stable overall predictions. Key findings reveal that combining hyperparameter tuning, XGBoost, and homogeneous stacking, enhances detection performance and class-specific metrics compared to standalone classifiers. Our research has also demonstrates that FPA effectively improves XGBoost's performance in the context of multi-class, imbalanced network attack detection offering new insights into enhancing the accuracy and robustness of intrusion detection systems. These findings not only fill a gap in the literature but also provide practical implications for developing more effective network security solutions.

The FPA-XGBoost-Stacking model outperformed both individual XGBoost and Thockchom et al.'s ensemble model, significantly improving F1-scores for six classes and slightly improving one additional class. These results demonstrate that homogeneous stacking with XGBoost achieves better predictions than Thockchom et al.'s heterogeneous stacking. Additionally, our approach effectively addresses class imbalance without resorting to resampling techniques, avoiding overfitting or information loss.

In summary, this research contributes significantly to the field by introducing a novel ensemble learning approach that effectively addresses imbalanced classification without resampling. The combination of hyperparameter tuning, XGBoost, and stacking shows superior performance, greatly improving network attack detection and offering a robust solution for similar challenges across various domains. This methodology can be adapted to other areas with imbalanced multi-class datasets, paving the way for future research and the broader application of ensemble learning techniques, underscoring its impact in developing effective classification models.

Deep Learning and Web Applications Vulnerabilities Detection: An Approach Based on Large Language Models

Sidwendluian Romaric Nana, Didier Bassolé, Désiré Guel, Oumarou Sié
Laboratoire de Mathématiques et d'Informatique, Université Joseph KI-ZERBO,
Ouagadougou, Burkina Faso

***Abstract*—Web applications are part of the daily life of Internet users, who find services in all sectors of activity. Web applications have become the target of malicious users. They exploit web application vulnerabilities to gain access to unauthorized resources and sensitive data, with consequences for users and businesses alike. The growing complexity of web techniques makes traditional web vulnerability detection methods less effective. These methods tend to generate false positives, and their implementation requires cybersecurity expertise. As for Machine Learning/Deep Learning-based web vulnerability detection techniques, they require large datasets for model training. Unfortunately, the lack of data and its obsolescence make these models inoperable. The emergence of large language models and their success in natural language processing offers new prospects for web vulnerability detection. Large language models can be fine-tuned with little data to perform specific tasks. In this paper, we propose an approach based on large language models for web application vulnerability detection.**

Keywords*—*Deep learning; web application; vulnerability; detection; large language model

I. Introduction

Nowadays Information and Communication Technologies have facilitated business practices in all sectors of activity (finance, insurance, health, education, energy, etc.). Business processes are automated through the creation of software to improve the productivity of companies and administrations. In February 2024, the number of Internet users worldwide was estimated at over 5.4 billion[1]. Internet has become the ”crossroads” where all types of data are exchanged. This ever-increasing accessibility to web resources by internet users has led to the growth of online services via web or mobile applications. All of which increases the attack surface for malicious users exploiting web applications vulnerabilities. From January to December 2022, more than 60 million attacks were observed daily against web applications[2].

Web applications are designed on a client-server architecture. The server side generally includes an application server and a database server. The client (a computer with a web browser) sends an HTTP request to the application server, which queries the database server with an SQL query. The database server sends a response to the application server, which returns an HTTP response to the client. Fig. 1 gives an overview of web application architecture [1].

Different parts of this architecture may be subject to vulnerabilities: web application programming, interaction between client and server, server configuration, etc. In the literature, several approaches have been developed to detect vulnerabilities in applications and prevent web attacks:

- integrating a secure code approach into application development;
- manual code review;
- vulnerability testing (white box, black box and hybrid method);
- use of intrusion detection systems.

These approaches generally use a list of pre-written rules and vulnerability databases. They require cybersecurity expertise, are time-consuming and have a high False Positive Rate (FPR). In a recent study on the detection of malicious URLs [2], we showed the importance of using FPR as an evaluation metric. Our approach enabled us to build models with an FPR of 1.13%, compared with similar works that have a FPR of between 8.15% and 12.03%.

Recent advances in Machine Learning (ML) and Deep Learning (DL) especially offer interesting prospects for detecting vulnerabilities in web applications. Where resources are limited, the use of Large Language Models (LLMs) could be an excellent alternative for obtaining better results with little data. The main objective of this work is to present a review of the different DL approaches used in the literature to detect vulnerabilities in web applications, the difficulties encountered by researchers and how LLMs can contribute to better results.

The rest of this paper is organized as follows: Section II presents the background of study. In Section III, we define some concepts used in the study. Section IV deals with related works. In Section V, we present our approach for detecting web applications vulnerabilities using LLMs. We conclude this work in Section VI.

II. Background Study

A vulnerability is a flaw or weakness in an application's design or implementation. A vulnerability exploited by an attacker has consequences for the application, its owner and the

[1] https://www.wpbeginner.com/fr/research/internet-usage-statistics-and-latest-trends/

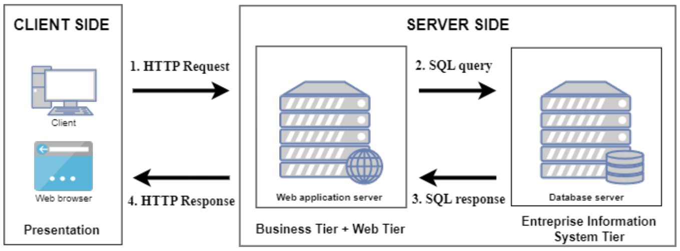

Fig. 1. Overview of web architecture.

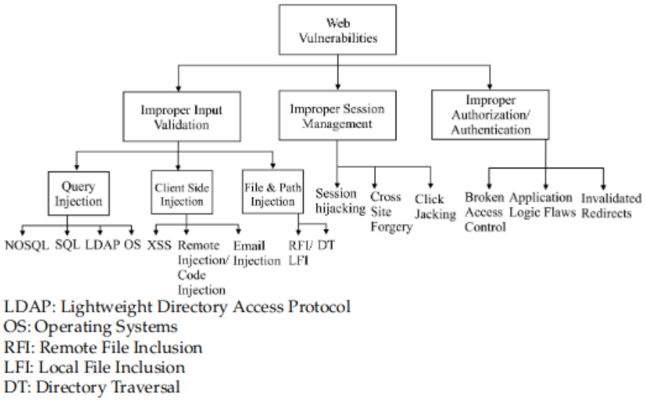

Fig. 2. Type of web vulnerabilities.

application's users[3]. In this section we present web application vulnerabilities, some countermeasures and DL approach in web vulnerabilities detection.

A. Vulnerabilities in Web Applications

OWASP (Open Web Application Security Project) regularly publishes the Top 10 web application security risks. The OWASP Top 10 is a standard awareness document for developers and web application security. It represents a broad consensus about the most critical security risks to web applications. The OWASP Top 10 for 2021[4] highlights the consolidation of certain vulnerabilities, such asInjection, Security Misconfiguration, and the emergence of others, such as Broken Access Control, Insecure Design, Vulnerable or Outdated Components.

Reference [3] classifies vulnerabilities into three main categories such as:

- Improper input validation: relates to an incorrect validation and sanitization of user input. Some examples of web attacks caused by this category of vulnerability are SQL injection and Cross-Site Scripting (XSS).
- Improper session management: relates to when the web session is insecured. Web requests could not be identified as malicious or not until these are linked with a proper valid session identifier. Some examples of web attacks caused by this category of vulnerability are Cross-Site Request Forgery (CSRF) and session highjacking.
- Improper authorization and authentication: involves a logic flaw in the implementation of access control rules and authentication functions. If web application does not correctly manage authentication and authorization procedures, broken access control is one of the web attacks likely to occur.

Fig. 2 shows a summary of web vulnerability types [3].

B. Existing Countermeasures

Numerous approaches are proposed in the literature for detecting and preventing vulnerabilities in web applications. However, no single approach can detect all vulnerabilities present in web applications. Existing approaches are complementary and can be integrated into all phases of the web application development cycle. Referring to research works [1], [3], existing approaches include secure programming, static, dynamic and hybrid analysis, black box testing, Intrusion Detection Systems (IDS). ML and DL techniques can be integrated into the above-mentioned approaches.

1) Secure programming: A survey conducted in 2019 found that 82 percent of vulnerabilities were located in application code and one in five vulnerabilities was high severity[5]. Secure programming is a set of best practice rules to help programmers develop secure web applications. Secure programming protects coding practices by coding properly, checks input data, encode correctly the user input, its type further by setting the query's parameter, also by bringing stored procedures to work [3]. Secure programming makes programmers aware of the security risks involved in writing code and using libraries and components. In fact, in the OWASP Top 10 for 2021, Vulnerable and Outdated Components is ranked 6th, whereas this vulnerability was ranked 9th in the previous ranking (OWASP Top 10 for 2017). ASVS (Application Security Verification Standard)[6], ESAPI (Enterprise Security API), SAMM (OWASP Software Assurance Maturity Model)[7] are different standard proposed by OWASP project to allow developers to code secure web applications.

2) Static analysis: Static analysis can be carried out at the implementation phase of web application, where it looks for vulnerabilities in source codes and trying to flag them without executing applications [4]. In the literature, several research works have focused on the detection of web application vulnerabilities using static analysis [5], [6], [7], [8]. Overall, static analysis-based tools detect web vulnerabilities despite their trend to generate false positives. Time required to use these tools increases with the size of the code to be scanned [1].

3) Dynamic analysis: It is the opposite approach to static analysis. Its aim is to identify security violations during web application execution. It is a useful technique to prevent web vulnerabilities. This technique incurs no false positives but is less effective for large code coverage. Some existing studies using Dynamic analysis [4], [9], [10], [11]

[6] https://www.owasp.org/index.php/ASVS
[7] https://www.owasp.org/index.php/SAMM

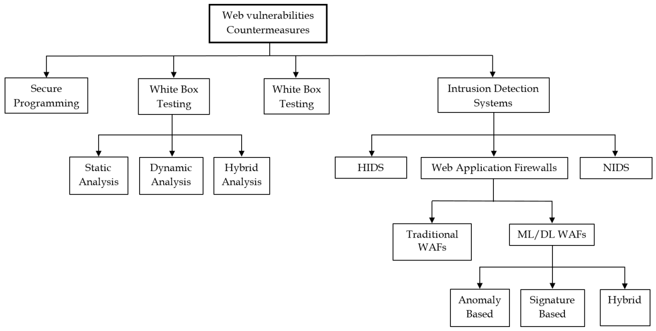

Fig. 3. Web vulnerabilities countermeasures.

4) Black Box testing: This method does not require source code information. It is done with no knowledge of the application's internals. This form of testing is carried out to evaluate the functionality, security, performance, and other aspects of an application. Details can be found in [12], [13]

5) Intrusion detection systems: An IDS is a mechanism designed to detect abnormal or suspicious activity on an analyzed target. It provides information on both successful and unsuccessful intrusion attempts. The target can be a host system (Host Intrusion Detection System (HIDS)) or Network communications (Network Intrusion Detection System (NIDS)) or Web Application (Web Application Firewall (WAF)). There are two main types of WAFs. Traditional WAFs and ML/DL based WAFs. Details can be found in [14], [15]

Fig. 3 shows a summary of web vulnerabilities countermeasures.

C. Deep Learning Approach in Web Vulnerabilities Detection

Alaoui et al. [1] conducted a Systematic Literature Review on the detection of vulnerabilities and attacks on web applications using DL techniques. The literature review covered 63 primary studies or articles on DL-based web application security published between 2010 and September 2021. The authors reviewed articles on various aspects and carried out a qualitative analysis of the results obtained. The qualitative analysis of the selected studies shows that the research area of DL-based web attack detection is yet to be properly explored, and that interest in web vulnerability detection using DL models is very recent. Since 2019, the number of papers published in this research area has increased significantly. Finally, authors noticed that CNN (Convolutional neural network), LSTM (Long short-term memory), and DFFN (Deep Feed Forward Network) are the most DL models used in the reviewed studies.

Dawadi et al. [15] focused on using DL techniques to improve performance of Web Application Firewall. Authors proposed a WAF layered architecture based on LSTM for DDoS (Distributed denial-of-service), SQL injection, and XSS detection in the web-based service system. The model achieved 97.57% accuracy for DDoS detection and 89.34% accuracy for XSS/SQL injection detection.

Alghazzawi et al. [16] conducted a Systematic Literature Review on the detection SQL Injection using ML/DL techniques. The literature review covered 36 articles published between 2012 and 2021. A large proportion of the reviewed studies (83%) used datasets collected from public repositories and HTTP requests. The remaining 17% of the reviewed studies used synthetic datasets created by the authors using deep learning models that can be trained to learn the semantic features of SQL attacks in order to generate new test cases from user inputs.

Maurel et al. [17] explored static approaches to detect XSS vulnerabilities using neural networks. Authors compared two different code representations: *word2vec* based on NLP (Natural Language Processing) and *code2vec* based on PLP (Programming Language Processing); and generate models using different neural network architectures for static analysis detection in PHP and Node.js. Model performed better with PLP approach (Accuracy 95.38%). As programs to be analyzed were run on the server side, authors were faced with the problem of data availability, so they opted for generated datasets (source code). The code generator of the NIST SAMATE project[8]. Authors improved this generator by correcting shortcomings and increasing the number of datasets generated by taking into account the rules announced by OWASP.

Alaoui et al. [18] proposed an approach to detect XSS attack. This approach based on LSTM Encoder-Decoder and Word Embeddings. Authors experiment different free context word embeddings (*Word2vec, Glove, FastText*) to transform HTTP requests to numerical vectors that can be processed by the classification models. Authors implement LSTM Encoder-Decoder and CNN Encoder-Decoder models. Overall LSTM Encoder-Decoder achieves the best classification results regardless of the word embedding technique used: 99.08% accuracy, 99,09% precision, and 99,08% Recall.

As stated above, research interest in web vulnerability detection using DL techniques has been growing in recent years. There are some interesting results in the literature. However, they face a number of limits. Thanks to the various systematic literature reviews, we can see that the majority of articles are oriented towards binary classification. However, it is important to evaluate how well DL models specifically detect different types of web vulnerabilities. Added to this is the availability of data. Indeed, the performance of DL models can be improved by the availability of sufficient quality data. Training a deep learning model requires large volumes of data. Unfortunately, data relating to the security of enterprise applications is sensitive and not always accessible to the general public. Most of the datasets used in the literature are available publicly. They are outdated and do not take into account new vulnerabilities or recent attack techniques [1]. These datasets no longer reflect the complexity of modern web applications. To address this shortcoming, several researchers have experimented with the data generation approach to train or test their models. But data is still synthetic, not real. It is therefore important for companies to contribute to research by making their application code and WAF logs available to the public, even anonymously. Another challenge is code representation. How to represent software programs so that they can be used by a DL model? Li et al. [19] gives some guide principle with VulDeePecker and proposed a framework called SySeVR (Syntax-based, Semantics-based, and Vector

[8] https://www.nist.gov/itl/ssd/software-quality-group/samate

Representations) [20]. This framework focuses on obtaining program representations that can contains syntax and semantic relevant information to vulnerabilities. SySeVR has been evaluated with dataset of open source C/C++ programs from the NVD[9] and from the SARD[10]. NLP and PLP approaches have been explored in literature but it's still an open question.

With reference to the limitations outlined above, we propose an approach based on LLMs. This approach will consist in fine-tuning LLMs for web vulnerability detection. This can be performed on small dataset. Indeed, the recent emergence of LLMs offers interesting prospects for detecting vulnerabilities in web applications. LLMs have been pre-trained on large datasets and succeed in a variety of NLP tasks for which they have not been specially trained [21]. In addition, LLMs represent an excellent advance in natural language processing, with a good representation of textual data. The proposed approach therefore addresses some limitations mentioned by Alaoui et al. in [1].

III. Concepts

In this section, we define some important concepts in the field of cybersecurity and artificial intelligence. This will help us to have a good comprehension of our approach.

A. Vulnerability

A vulnerability is a weakness in a computer system that allows an attacker to undermine the integrity of the system: its normal operation, the confidentiality or integrity of the data it contains. Vulnerabilities are the result of weaknesses in the design, implementation or use of a hardware or software component of the system.

Vulnerabilities can be intentional (backdoors) or accidental, resulting from a lack of knowledge on the part of developers of good security practices or due to the ever-increasing complexity of modern technologies, which increasingly require the adoption of new design and development methods in order to limit the risk of adding vulnerabilities. These vulnerabilities are generally corrected as they are discovered.

Once discovered, vulnerabilities can be the subject of an identification called a CVE[11](Common Vulnerabilities and Exposures). These are published by the Massachusetts Institute of Technology Research Establishment (MITRE[12]) at the request of researchers. This organization can also delegate its identification powers to a company or research center. The latter then becomes a CNA (CVE Numbering Authority)[13].

The CVE lists are brief and do not include technical data or information about risks, effects and patches. These details are recorded in other databases, such as the US National Vulnerability Database (NVD) or the CERT/CC Vulnerability Notes Database[14], etc.

B. Attack and Intrusion

An attack is any attempt to gain unauthorized access to a computer, computer system or computer network with the aim of causing damage. Computer attacks are aimed at disabling, disrupting, destroying or controlling computer systems or at modifying, blocking, deleting, manipulating or stealing data contained in these systems[15].

An intrusion is an internal malicious act, but of external origin, resulting from an attack that has succeeded in exploiting a vulnerability [22].

C. Large Language Models

LLMs are recent advances in deep learning models to work on human languages. LLMs refer to large general-purpose language models that can be pre-trained and then fine-tuned for specific purposes. LLMs are trained to solve common language problems, such as text classification, question answering, document summarization, and text generation[16]. The models can then be adapted to solve specific problems in different fields using a relatively small size of field datasets via fine-tuning. LLMs rely on substantively large datasets to perform those functions. These datasets can include 100 million or more parameters, each of which represents a variable that the language model uses to infer new content [23]. Understanding the importance of LLMs requires background knowledge of Deep Neural Networks (DNNs), Transformers, Attention mechanisms, etc. Indeed [24]:

- LLM is based on transformer architecture
- Attention mechanism allows LLMs to capture long-range dependencies between words, hence the model can understand context
- LLM generates text autoregressively based on previously generated tokens

Large Language Models have evolved rapidly. From 2018 to early 2024, hundreds of models have been created[17]. These models can be differentiated into 4 generations as of now, mainly separating model complexity, but also aspects such as model parameters (embedding encoding, activation functions), quantity and quality of input data, and additional fine-tuning steps. Fig. 4 shows the evolutionary tree of modern LLMs [25].

There are many LLMs developed: GPT-3 and GPT-4 from OpenAI[18],BERT, PaLM 2 and T5 from Google[19], RoBERTa and LLaMA 2 from Meta[20], etc. These are models that can understand language and can generate text.

IV. Related Works

In this section, we review previous work on using Large Language Models to detect software vulnerabilities.

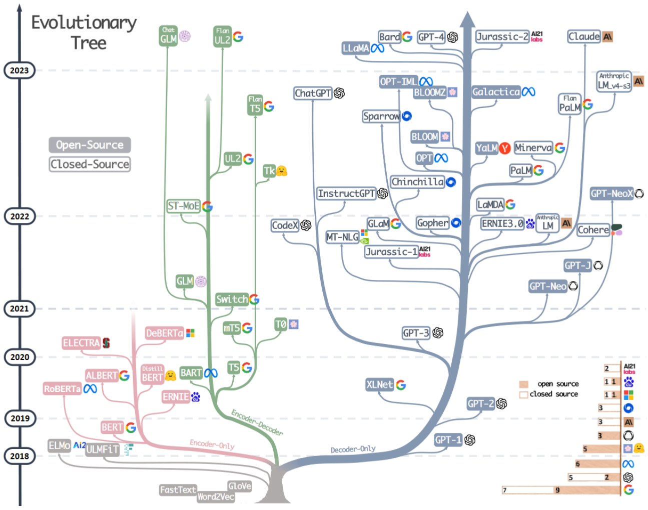

Fig. 4. The evolutionary tree of modern LLMs.

In 2021, Wu presented a literature review [26] on detection of software vulnerability using NLP technology. This paper that focused on static analysis, reviewed techniques to segment source code, extract features and modeling training. BERT [27], GPT [28] and their extended models have been presented as best models in NLP fields. Code being a kind of text, it is logic to think that these models can be used to detect software vulnerability.

Szabó and Bilicki [29] proposed a new approach to web application security using GPT language models for source code inspection. After showing the increasing use of AI in software development, authors formulated a categorization to determine the nature of the sensitive data and the application's vulnerability in a source code and then developed a method based on the GPT API. The targeted vulnerability in this study is CWE-653: Improper Isolation or Compartmentalization. The dataset used consisted of Angular projects collected from GitHub. The model trained on GPT-4 with an accuracy of 88.76% confirms the hypothesis that LLMs have the ability to analyse and interpret software source code. This study opens up prospects for research into the detection of other types of vulnerability using LLMs.

In 2021 Ranade et al. [30] developed CyBERT to represent textual data from the cyber security domain. CyBERT is a domain-specific BERT model. CyBERT is a BERT model fine-tuned with Masked Language Modeling (MLM) and an extended cybersecurity vocabulary. The model has been trained with a large corpus of text from Cyber Threat Intelligence. This model provides cyber security professionals the ability to perform tasks such as Named Entity Recognition (NER), multi-label classification of attacks based on a textual description of the vulnerability. CyBERT outperforms BERT-base model in these tasks. This demonstrates that fine-tuning has enabled the model to learn terms and concepts of cyber security, as well as the relationships between them.

Ameri et al. [31] also proposed CyBERT. In this paper, CyBERT stands for Cybersecurity Claim Classification by Fine-Tuning the BERT Language Model. This classification is based on sequences collected from the documentation of industrial control system devices. The experimental study carried out enabled the hyper-parameters to be optimised and led to a good choice of model architecture. This study led to the conclusion that fine-tuning a BERT model with 2 hidden dense layers and a classification layer achieves a greater accuracy. The resulting CyBERT model with an accuracy of 0.954 outperforms other language models (GPT-2, ULMFiT, ELMo+NN, ELMo+CNN, ELMo+BiLSTM, ELMo+LSTM) as well as other neural networks (CNN, LSTM, BiLSTM).

In 2022, Aghaei et al. [32] developed SecureBERT, a domain-specific language model for cybersecurity. SecureBERT is based on the architecture of RoBERTa (trained with RoBERTa-base) with weight adjustments of pre-trained model. SecureBERT has a good understanding of the semantics of words and phrases. In addition to the pre-trained tokenizer, authors have created a customized tokenizer specific to the cyber security domain, which preserves generic vocabulary while taking into account new tokens emerging from the cyber security domain. SecureBERT has been evaluated on several tasks such as cybersecurity masked word prediction, named entity recognition and sentiment analysis. Evaluation on this last task is proof that SecureBERT has a good understanding of generic language. SecureBERT outperforms others models (RoBERTa-base, RoBERTa-large, SciBERT).

Bokolo et al. [33] conducted a study on web attack detection using DistilBERT, RNN and LSTM. Using a dataset consisting of 33,000 http requests, several experiments were carried out: classification of attacks using URL, the content of the Body or the user data. RNN, with an accuracy of 94%, outperformed others models.

Gallus et al. [34] conducted an experimental penetration testing study on a web application. Thanks to its perfect understanding of web technologies and security principles, chatGPT was used as a penetration test guide. By following the procedures described by chatGPT, the authors were able to retrieve information about the targeted web application, such as the version of WordPress and the theme used. This information was used to discover vulnerabilities in the target application. Using chatGPT's instructions, the testers extracted the list of the application's user accounts as well as the administrator's account. This experiment shows that chatGPT can be used as a guide when testing vulnerabilities in web applications. However, malicious users, even with little technical knowledge, could reproduce chatGPT's instructions and perpetrate attacks on web applications.

Sakaoglu Sinan [35] presented KARTAL: Web Application Vulnerability Hunting Using Large Language Models; Novel method for detecting logical vulnerabilities in web applications with finetuned Large Language Models. The targeted vulnerability is Broken access control, more precisely:

- CWE-639 Authorization Bypass Through User-Controlled Key
- CWE-209: Generation of Error Message Containing Sensitive Information (Exposure of Sensitive Information)

GPT-3.5 was used to generate the dataset, followed by manual labelling for greater accuracy. A total of 1780 samples were annotated, containing at least 200 samples of each class (benign, CWE-639, CWE-209). The pre-trained models MPNet, DistillRoBerTa and MiniLM were used for fine-tuning. The best model (all-mpnet-base-v2) obtained an accuracy of 87.19%, F1-score of 0.82 and MCC (Matthew's correlation coefficient) of 0.7.

Hanif et al. [36] presented VulBERTa, a deep learning approach to detect security vulnerabilities in C/C++ source code at function-level granularity. This approach pre-trains a RoBERTa model with a custom tokenisation pipline of source code collected from open-source C/C++ projects. The pre-trained model was fine-tuned for vulnerability detection with alternatively a Multi-Layer Perceptron (VulBERTa-MLP) and a Convolutional Neural Network (VulBERT-CNN). The model outperforms existing approaches on binary and multi-class vulnerability classification across different datasets (Vuldeepecker [19], Draper [37], REVEAL [38] and muVuldeepecker [39]) and benchmarks (CodeXGLUE [40] and D2A [41])

Kim et al. [42] developped VulDeBERT, a vulnerability detection model for C/C++ source code by fine-tuning BERT model. VulDeBERT analyses code, extracts well-represented abstract code fragments and generates code gadgets that will be embedded to feed BERT model. VulDeBERT focuses on security vulnerabilities related to system function calls. it outperforms VulDeePecker [19] in detecting two vulnerability types (CWE-119 and CWE-399).

Table I summarizes related works, with an analysis of strengths and weaknesses. Overall, the current state of the literature shows interest in the detection of web application vulnerabilities using LLMs. However, we note that there is more research on adapting LLMs to the cybersecurity field [30], [31], [32]. These work show that, thanks to fine-tuning, LLMs are able to understand the semantics of words in a text dealing with cybersecurity. LLMs have shown excellent performance in NLP downstream tasks: cybersecurity NER, English sentiment analysis, etc. In addition, we note that some studies have used LLMs or deep neural networks to detect software vulnerabilities in C/C++ source code, with difficulties of generalization to other programming languages[36], [42]. However, a few studies have focused on detecting vulnerabilities in web applications [29], [35]. Finally, we also note that BERT and GPT remain the most widely used language models for cybersecurity adaptation and vulnerability detection [43]. It will be more useful to experiment with other types of LLMs and conduct a comparative study based on their architecture in order to address the weaknesses of existing works.

V. Methodology

Detecting software vulnerabilities by using LLMs has produced interesting results, despite the difficulties of generalising the models to other programming languages, particularly web languages. In order to fully exploit the potential of LLMs for detecting vulnerabilities in web applications, we propose a three-stage approach:

- Exploration
- Experimentation
- Evaluation

The exploration consists of a literature review on the use of LLMs in the field of cyber security, more specifically the detection of vulnerabilities in web applications. The literature review (summarised in the previous section) carried out using scientific publications (articles, web articles, dissertations, etc.) enabled us to identify the most widely used and best performing LLMs, types of data used and sources of data collection. Although our literature review revealed a predominance of the BERT and GPT models and their variants, our approach defines criteria for choosing LLMs. These criteria are based on the following points:

- Type of licence : open-source or closed-source
- LLM's architecture: encoder-decoder, encoder-only, decoder-only
- Publication's year
- Performance of models evaluated on the same datasets[21]

The Table II shows a short list of LLMs selected on the basis of the above criteria.

Experimentation consists of defining the neural network architecture and the network learning strategy, training the model and optimising it to obtain better performance. The experimentation stage is designed to be iterative, with the hyper-parameters of models being adjusted and the performance of models being continuously evaluated. Although the performance of NLP tasks is improved by pre-training the basic models, it is important to note that the process requires enormous hardware resources (computing power) and large corpus of text. The fine-tuning process, on the other hand, can be carried out on small datasets and does not require a large corpus of text [44]. In a context where hardware resources and training data are limited, it is advisable to adopt a fine-tuning strategy.

The evaluation stage enables a comparative analysis of the approach with the results of the state of the art; to identify the strengths and limitations of the proposed approach while studying the applicability of the model in a real environment.

Fig. 5 summarises the methodology described above.

VI. Conclusion and Future Works

As the number of Internet users increases, web applications are ubiquitous in all sectors of activity. Unfortunately, this proliferation of web platforms is accompanied by major security risks. Web applications are subject to numerous vulnerabilities reported in several vulnerability databases. Many approaches are proposed in the literature to detect these vulnerabilities. In this paper, after an overview of different approaches, we focus on DL techniques applicable to web vulnerability detection. We presented difficulties and challenges of these approaches to obtain better results and detect several types of vulnerabilities. Finally, we presented the potential of Large Language Models in the cybersecurity domain and proposed an approach for web vulnerabilities detection.

Application of this approach, subdivided into three stages (exploration, experimentation and evaluation), will enable researchers to carry out experimental studies, starting with the

constitution of the dataset, the choice of model architecture and culminating in performance evaluation. In terms of research perspectives, we will:

- Experiment with our LLM-based approach to detecting web attacks from a public dataset.
- Implement a data collection strategy to get malicious URLs from Burkinabe cyberspace in order to build a local dataset.
- Use LLMs to detect malicious URLs from the local dataset.
- Analyze and discuss results in terms of quality of the dataset and the performance of LLMs models in web attacks detection.

Exploring Effective Diagnostic and Therapeutic Strategies for Deep Vein Thrombosis in High-Risk Patients: A Study

Pavihaa Lakshmi B, Vidhya S
School of Electronics Engineering, Vellore Institute of Technology, Vellore, Tamilnadu, India 632014

***Abstract*—Blood clots formed in blood vessels are termed as Thrombus. The pivotal strategy in diagnosing the early-stage thrombus, plays a vital role. Most commonly, blood clot occurs in the calf muscles of the lower extremities which leads to Deep Vein Thrombosis (DVT). Vulnerable patients are those who are involved in prolonged bed rest post-surgery, and the patients who are already affected with stroke, acute ischemia, cerebral palsy, etc. According to a report by the World Health Organization (WHO), nearly 900,000 people are affected annually, with approximately 100,000 dies each year At present blood clots can be identified using blood tests such as D-dimer blood tests, Cardiac Biomarkers and some imaging modalities like Doppler ultrasound, venography, Magnetic resonance imaging (MRI), computed tomography (CT). We have elaborately discussed the importance of emphasizing diagnostic yield and incidence of DVT, focusing on the risk factors available for DVT diagnostic and therapeutic techniques. The research addresses DVT incidence, diagnostic strategies, and therapeutic interventions; the efficacy of VR rehabilitation and treatment modalities; challenges related to artificial intelligence (AI)-based treatments; and explores the potential benefits of different game types in DVT management. This study aims to bridge the gap between research and real-time application by providing a wide range of strategies that comprise both basic and state-of-the-art techniques. It is a vital source for researchers and experts, providing perceptions into the effective development of advanced medical devices. The study concludes with a summary of point-of-care diagnosis, rehab therapy, and an exploration of various game types, providing future insights.**

Keywords*—Diagnosis; DVT; game-based therapy; head-mounted display; rehabilitation therapy; virtual reality

I. Introduction

A condition of blood clot formation in a deep vein is termed as Deep Vein Thrombosis (DVT). These blood clots sometimes occur within the lower legs, thighs, or pelvis; however, they will also occur within the arms. The common causes of DVT are blood vessel or venous injury from surgery and trauma, or inflammation from infections and injuries. DVT may be terribly serious, which may often result in the breakage of blood clots within the veins that can pass through the bloodstream and eventually block the arteries and end up in Pulmonary embolism (PE). Embolism may be severe and require immediate treatment. Fig.1 illustrates the formation of DVT in the calf muscles of the lower extremities. It develops mainly in elderly patients and is very rare in adults whose age is less than 30. Incidence of DVT is higher in women during their post-pregnancy period. It can be sometimes asymptomatic and hence not suspected. High-risk patients vulnerable to DVT include those with paralyzed, immobilized patients, bedridden patients, whether due to illness, surgery, or injury, face a higher likelihood of developing DVT due to prolonged immobility. People with recent injuries or traumatic conditions, particularly those affecting the lower limbs, and patients who have suffered a stroke are at increased risk due to impaired mobility and possible changes in blood flow. Stroke patients are similarly at risk because of reduced mobility and potential changes in blood flow. Musculoskeletal injuries, particularly ankle injuries, can contribute to the development of DVT. Elderly patients, especially those with additional risk factors like immobility or comorbidities, are particularly susceptible to DVT. And also COVID-19 can increase clotting due to its infection or usage of drugs. Cancer patients are also at elevated risk due to malignancy-associated hypercoagulability. If it is not diagnosed properly on time, it can lead to chronic venous disease or recurrent Venous Thromboembolism (VTE) and long-term consequences such as post-thrombotic syndrome and chronic thromboembolic pulmonary hypertension and cause heart attack and even death. DVT/PE, affecting an unknown global population, presents a significant concern. In the United States, approximately 900,000 people, at a rate of 1 to 2 per 1,000, may experience this condition annually. Alarmingly, the National Center on Birth Defects and Developmental Disabilities reports that DVT/PE leads to 60,000-100,000 fatalities among Americans each year, highlighting the substantial impact and public health implications of these vascular disorders [1]. Fig.2 shows the comparative demographic information between the age group and gender for both males and females with the help of the Centers for Disease Control and Prevention. The primary objective is to investigate and advance the understanding of diagnosis and treatment of DVT. It focuses on innovative diagnostic sensors, explores therapeutic interventions, and integrates Virtual Reality (VR) tracking games for ankle rehabilitation.

Primary causes of DVT include:

- Prolonged bed rest after surgery or treatment.
- Prolonged travel.
- Mild protein C deficiency.
- Blood clots due to hormonal replacement therapy and birth control pills.
- Ankle sprain or injury due to any traumatic condition.
- Cigarette smoking and Obesity due to an increase in the pressure of veins.
- Pregnancy and the post-pregnancy period.

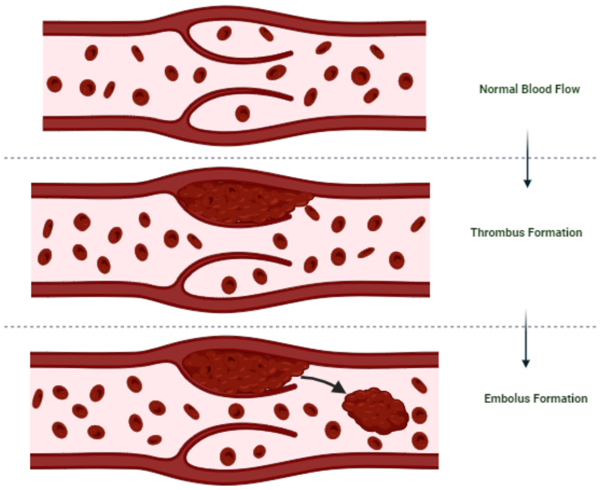

Fig. 1. Formation of DVT and PE.

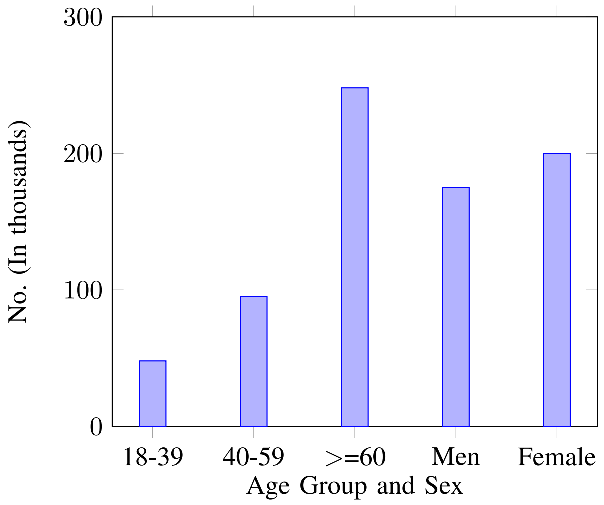

Fig. 2. DVT rate based on age and gender.

- General Anesthesia Surgery.
- Diabetes [2].

This study significantly contributes to understanding the progression of DVT through a comprehensive review of diagnosis and treatment strategies. It reviews existing invasive works, investigates survey findings, and gives an outline of a promising future scope. The discussion on DVT incidence and diagnostic yield, particularly emphasizing risk factors and clinical assessments of diagnostic sensors, enhances our knowledge in this critical medical area. The introduction of a VR tracking game for ankle rehabilitation devices provides an innovative approach to therapy engagement, addressing monotony issues in rehabilitation. Furthermore, the exploration of various game types (VR, augmented reality (AR), and artificial intelligence (AI)) and their benefits suggests a promising avenue for further investigation. The study highlights a gap in existing literature pertaining to the diagnostic aspects of invasive techniques and the specific integration of VR tracking games for ankle rehabilitation. Addressing these gaps, the study concludes with an endpoint summarizing the proposed advancements in understanding and addressing DVT, which may guide practical implementation and effectiveness of these proposed strategies.

The limitations and challenges in diagnosing and treating DVT conditions are significant:

- The existing system which involves detection of DVT using a light source is also an extra-corporeal technique.
- Early Detection: Identifying diseases early is challenging due to subtle or nonspecific symptoms.
- Imaging Accuracy: Variability in diagnostic imaging techniques.
- Accuracy of thrombolytic therapy diagnosis impacted by imaging methods, operator reliance, risks, and limited access to advanced technologies.
- Protocol Standardization: Lack of standardized diagnostic protocols across different healthcare facilities.
- Cost and Accessibility: Advanced imaging methods are expensive and less accessible in low-resource settings.
- Anticoagulation Management: Addressing difficulties in administering anticoagulant therapy effectively.
- Patient-related factors like immobility, body composition, prior medical conditions, anticoagulant therapy, and drug interactions also affect diagnostic accuracy.
- Individualized Treatment: Need for personalized treatment plans considering patient-specific factors.
- Resistance to Therapy: Managing cases where patients develop resistance to anticoagulant medications.
- Patient Compliance: Dealing with challenges related to patient adherence to long-term anticoagulation therapy.
- Complication Management: Difficulty in managing complications associated with DVT.
- Rehabilitation and Prevention: Improving rehabilitation strategies and preventive measures.
- Research and Development: Overcoming limitations due to limited clinical trials and slow adoption of innovative approaches.
- Technological Integration: Integrating new technologies into clinical practice effectively.
- Patient adherence, physical constraints, injury risk, resource demands, individual variations, costs, time limitations, limited long-term evidence, lack of standardization, and psychological factors.
- Consistent engagement in rehabilitation exercises is vital for severe DVT patients.
- Personalized treatment plans can be time-intensive and expensive.

Accurate diagnosis requires sequential clinical integration, functional assessment, pre-test clinical feasibility assessment, and confirmatory studies including D-dimer testing and diagnostic imaging [3]. Relapsed DVT is often suspected in patients who stop taking anticoagulants. Clinical symptoms can be confused with the development of post-thrombosis syndrome. Examining the direct imaging methods for thrombus formation using the ultrasound technique helps in the diagnosis of recurrent DVT and data monitoring [4]. According to the study by Tritschler, Tobias, et al. VTE management has improved significantly, enabling the diagnostic and therapeutic strategies tailored to the individual characteristics, preferences, and values of the patient who are prone to DVT [5]. Magnetic resonance direct thrombus imaging (MRDTI), which does not use intravenous contrast and has a 10-minute acquisition time, are used in distinguishing between acute recurrent DVT and chronic residual thrombotic DVT. The low incidence of VTE recurrence after negative MRDTI proves that MRDTI is a viable and reproducible diagnostic test [6].

Anticoagulants are medications used to treat DVT and PE, preventing clotting and thrombus growth. Heparin, low-molecular-weight heparin (LMWH), and warfarin are effective DVT reducers [7]. However, prolonged blood thinner usage can lead to risk factors such as bleeding susceptibility, menstrual bleeding, bowel movements, bleeding from the gums or nose, persistent bleeding, unusual bruising, and dizziness [8]. Despite various treatments, early identification of thrombus development is often lacking at the point of care. Increased awareness of risk factors and advancements in anticoagulant therapy have improved clinical evaluation and management of DVT patients. Direct oral anticoagulants (DOAC) are used to treat VTE and reduce bleeding factors. Increased use of agents like apixaban, rivaroxaban, dabigatran, and edoxaban also support the therapy [9] [10] [11]. Chopard et al. reported that DOAC are effective and reduces bleeding risk, but their high cost limits their use among some patients [12].

Adherence to Novel Oral Anti-Coagulants [NOAC dabigatran and rivaloxaban] on a large scale has an impact on Ischemic stroke (IS), major bleeding (MB), and DVT [13]. In multimodality therapy discussed by ZHAO, pharmacists addressed patients' drug treatment problems rationally, safely, and effectively. This study also showed that during pregnancy without thrombotic complications, the fetus was healthy and there was no recurrent thrombosis [14]. Atrial fibrillation (AF), DVT, and pulmonary embolism (PE) have been shown to be effective in the treatment of oral anticoagulant therapy and long-term persistence is highly associated with reduced adverse effects [15].

The quality of reports based on Randomized controlled trials (RCT) focusing on the use of anticoagulants rather than antiplatelet drugs for the prevention of venous thromboembolism remains inadequate [16]. Primary prophylaxis is the preferred mechanical method of using drugs to prevent DVT. Early detection with screening and treatment methods of asymptomatic DVT is a less commonly used approach. The study by Stubbs, M.J., Maria Mouyis, and Mari Thomas. outlines contraindications such as hemorrhage, coagulopathy patients, during surgery, thrombocytopenia and bleeding disorders, and discusses complications like renal failure and bleeding [17]. The systematic review summary provides basic results on the efficacy and safety of new direct oral anticoagulants (DOACs), thrombin inhibitors, and factor X inhibitors activated in DVT patients [18].

This work explores the diagnosis and therapy for early-stage DVT, with the thesis structured as follows: Section 1 provides a comprehensive introduction, delving into the strengths and objectives of our research about thrombus. Simultaneously, it reviews predominantly invasive pre-existing works, paving the way for a clear investigation into our survey and futurescope. In Section 2, the discussion shifts seamlessly to the incidence and diagnostic yield of DVT in patients with COVID-19, elaborating on associated risk factors. Moving to Section 4, we provide a brief description of the analysis and diagnosis of DVT, incorporating factors influencing both DVT and PE, as reviewed. Going on to Section 5, the focus is on clinical assessments of diagnostic sensors in DVT which are developed especially to perform conventional coagulation tests. Section 6 introduces dynamism, highlighting the creation of a VR tracking game for an ankle rehabilitation device to enhance therapy engagement and alleviate monotony from repetitive training. In Section 7, the study extends further, elucidating a list of screening and therapeutic interventions for DVT patients. Overall to AI-based Cogently guided treatment are discussed in Section 8. Section 9 will summarise our investigation about the point-of-care (diagnosis) and rehab therapy on the basis of the causes and signs, incidence and complication, rapid screening tests, designs, and evaluation, and furthermore, the types of games used and their benefits (VR, AR and AI). Section 10 discusses the future scope, discussing strategies to enhance non-invasive and non-contact therapeutic unit for early-stage DVT. Finally, Section 11 provides a conclusion to our work on DVT and its diagnosis and treatment approaches.

II. Point-of-Care Screening for DVT in Patients with COVID-19

A. DVT in Patients with COVID-19 and Methods of Diagonsis

The association between PE and DVT in patients with COVID-19 remains unclear, and the diagnostic accuracy of the PE D-dimer test is unknown. A study-level meta-analysis of PE and DVT incidence and an assessment of the diagnostic accuracy of the PE D-dimer test from multicentred individual patient data have been performed [19]. A single institutional study was conducted by Zhang, Li, et al. to assess prevalence, risk factors, prognosis, and potential thrombosis prophylaxis strategies at large referral and treatment centers. From January 29, 2020 to February 29, 2020, a total of 143 COVID-19 patients were tested. The prevalence of DVT is high and is associated with adverse outcomes in inpatients with COVID-19. Prevention of venous thromboembolism may protect patients with a Padua prediction score of 4 or higher after admission. The data presented indicate that COVID-19 is likely to be an additional risk factor for DVT among inpatients [20]. The prevalence of VTE in critically ill patients with COVID-19 is measured by venous ultrasound scanning of the lower extremities. A DVT screening on patients with five to ten days of admission revealed a 32% prevalence of VTE in critically ill patients with SARSCoV2 infection. 70% of the events occurred before the screening. Early screening may be effective in optimizing the care of ICU patients with COVID-19 [21].

Fig. 4. DVT in cancer patients: Comprehensive studies and insights.

Despite standard prophylactic anticoagulant treatment, patients with SARSCoV2 ventilators have a very high prevalence of DVT, including a high proportion of potentially life-threatening proximal DVT. This indicates the need for close monitoring of DVT and more intensive risk/benefit assessment of anticoagulant therapy in this population [22]. Cho et al. studied the clinical utility of D-dimer in diagnosing DVT in patients with COVID-19, potentially limiting the need for duplex venous ultrasound examination [23]. The predictive usefulness of the D-dimer assay in patients with coronavirus infection 2019 syndrome for DVT of the lower extremities has been demonstrated [24]. They have evaluated the applicability of bedside ultrasound in the diagnosis of DVT in COVID-19 patients treated with low molecular weight heparin (LMWH) [25]. Fig.3 and Fig.4 simplified block diagram outlines the major studies and their findings addressing the association between COVID-19, DVT, and PE, as well as studies related to DVT in cancer patients.

B. Diagnosis of DVT in Patients with Cancer

Patients with cancer are at a significantly higher risk of VTE. Hence, studies were conducted to evaluate the ability of FDG (Fluorodeoxyglucose) PET/CT to detect thrombosis in cancer patients. It shows that thrombi in cancer patients can be detected before clinical symptoms by FDG PET/CT [26] [27]. DVT is suspected based on pre-test probabilities, D-dimer, and ultrasound diagnosis [28]. Wang et al. analysed the clinical characteristics and prognosis of cancer patients with venous thromboembolism. Incidental pulmonary embolism (IPE) in cancer patients is not uncommon. Most VTE events occur within the first six months after the cancer diagnosis, and nearly half of the deaths occur within the first three months after VTE diagnosis [29]. Patients with residual vein obstruction (RVO) are at a higher risk of recurrent events [30]. DVT patients had lower adverse outcomes, while cancer-associated DVT had serious and comparable outcomes. Further, understanding the lower risk of cancer-associated DVT could aid in designing non-invasive devices [31].

C. Lower Extremity DVT in Bedridden Patients

Liu et al. studies showed that anticoagulation therapy improves and dehydration worsens lower extremity DVT; Vascular ultrasound can conveniently and flexibly monitor DVT in the lower extremity of bedridden patients [32]. Alaskar et al. conducted a study to determine the incidence and pathology that increased the risk of developing acute lower limb DVT in suspected bedridden patients for lower limb Doppler ultrasonography [33]. Cao et al. investigated whether risk factors for DVT were affected by resting periods and identified different risk factors in groups with different resting periods [34]. The various pneumatic treatment for DVT/PE involves initial management, primary treatment, and secondary prevention. Initial management occurs within 5-21 days, primary treatment lasts 3-6 months, and secondary prevention extends beyond 3-6 months. Wang et al. investigated the effect of various pneumatic treatment times on the prevention of DVT in patients with severe chronic bedridden. Compression stocking may significantly increase thigh deep vein blood flow velocity, reduce the incidence of DVT, and not increase the incidence of skin pressure injury in chronic bedridden patients [35]. Using orthopaedic therapy, researchers studied and analysed the risk factors for DVT. Two groups of patients were treated with orthopaedic treatment, with 232 not having DVT and 41 having DVT after minor and major surgery [36]. Narkhede and Nageswaran developed a system that electrically stimulates the nerves that connect to the calf muscles, which can cause the legs to contract and relax, which eventually implies pressure on the veins and keeps blood flowing and helps prevent DVT [37].

III. Analysis and Diagnosis of DVT

The coagulation in porcine blood by using a micro-optical sensor has been evaluated by Liu, Qiang, et al. [38]. They developed an artificial blood circulating apparatus and a miniature optical sensor to conduct blood clotting tests and oxygen saturation tests respectively. Work done in [39], effectively recognized blood vessels in the body using thermal and near-IR spectral bands. Also, the spatiotemporal steps of heating the skin surface to determine the location of blood vessels beneath the skin surface were detected. A magneto-elastic sensor has been utilized in monitoring the therapeutic anticoagulants of the blood clotting stage which emits magnetic flux and can be detected by the viscosity changes during the blood coagulation of the rat's blood sample. The magnetoelastic sensor (MES) strip oscillates at a wide frequency range when it vibrates with a certain applied magnetic field at resonance frequency of the blood sample [40]. The time-dependent mechanisms of thrombus formation were invented and the non-contacting blood visualization of thrombus formation was developed by Matsuhashi et al. The team devised an optical coherence tomography system with a wavelength of 1330 nm to reduce the attenuation of light intensity by erythrocytes. 3-D image of a thrombus was developed after capturing 2-D images of thrombi, using a stereo-OCT system [41]. Also light reflection rheography (LRR) method was revealed for screening patients with suspected DVT. LRR is a non-invasive method to examine the DVT with the help of an IR beam, which detects the number of backscattered rays by indirectly measuring the amount of blood present in a volume of the skin. It relates that an increase in the amount of reflected light is an indication to the presence of less blood to absorb the incoming IR light. The LRR probe is effective and accurately gives results; however, it is not suitable for bedridden patients because suffers ankle edema, pain of the foot and ankle [42].

Kim, Young-Hoo, et al. investigated factors influencing DVT and PE after mechanical compression devices, determined the occurrence of DVT, analysed relevant factors, and examined the development of DVT and PE [43]. Artificial neural networks have been used to develop a system in which patients would be able to self-diagnose themselves for blood clots and it's type. This persuades the patient to proceed with further diagnosis [44]. The development of DVT in patients taking low-dose anticoagulant therapy for ischemic stroke has been summarized by [44]. To ensure quality, screening methods such as study selection, data extraction methods, and bias risk assessment were carried out using predetermined criteria [45]. The study analyzed the effects of antiplatelet and anticoagulant agents on DVT in 272 patients undergoing rehabilitation. After physical examination, symptoms such as blockages, swelling, skin redness, discomfort and pigmentation. D-dimer assay and venous duplex ultrasonography were used to diagnose DVT [46]. Raskob et al. discussed the importance of enhancing patient adherence to successful VTE diagnosis and the need for comprehensive DVT and PE observation to provide data on the prevalence, incidence, benefits, drawbacks, and applicability of different techniques [47]. According to Ren et al., there are various detection techniques that have been developed for multiple research applications. They are as follows: Measurement of force, stress, and strain; monitoring of various chemical indices; consideration of different biomedical parameters such as the degradation rate and force conditions of artificial bone; multiple physiological indices such as ammonia level, glucose level, bacteria growing factors, and sometimes even coagulation factors [48].

A lab-on-a-chip (LoC) system has been employed to determine blood coagulation time. The first is a vibrating fibre embedded in the data that performs as a mechanical resonance employing distant magnetic actuation, and the second is a pick-up fibre that serves as a photodetector [49]. Llenas et al. and his team laid the technological groundwork for a diverse platform capable of recreating the specific characteristics found in vascular malignancies. Vessel-on-a-chip microfluidic technologies have been used less often to investigate the unique characteristics and physiological functions of the vascular networks. This technology might be used to study the dynamic processes associated with vascular disorders or to screen new pharmaceutical formulations, among other things [50]. Table I examines the outcomes and precision of the developed systems designed for thrombus assessment.

IV. Sensors for Thrombus Detection

Imaging techniques in light and electron microscopy allow for unprecedented perspectives on blood coagulation. The 3D structure of clots formed from reconstituted prelabelled blood components was determined, which provided new information on the effects of clot contraction on erythrocytes [51]. Images of fluorescently labelled platelets were obtained in real-time during whole blood perfusion, whereas the global electrical impedance of the sample of blood was monitored simultaneously between a pair of specially designed gold microelectrodes. Optical and electrical data techniques were combined to analyse the thrombus formation and identify weakening and detaching platelet aggregates [52]. Table II evaluates the outcomes and accuracy of the developed systems for thrombus detection. Blood coagulation is essential to predict the risk of hemorrhage and thrombosis during cardiac surgical procedures. The blood coagulation process under temperature and hematocrit variations using a microfluidic chip has been analyzed. An analysis of the impedance change of a blood sample during coagulation was conducted by Lei et al. to determine the starting time of blood coagulation. They focused on developing valuable clinical equipment for routine coagulation tests [53]. Blood coagulation monitoring was based on

TABLE I. Summary of Methodologies, Findings, Applications, Advantages, Limitations, and Other Details from Various Sources

Paper	Methodologies	Findings	Applications	Advantages	Limitations	Other Details
[38]	Light reflection rheography	Noninvasive DVT screening	Screening for DVT	Noninvasive, simple test using light reflection	Limited validation data, may require further clinical trials	Test based on light reflection, potential cost-effectiveness
[39]	Optical imaging and analysis	Optical clot detection	Blood clot detection	High-resolution imaging, potential for early detection	Limited experimental evidence, scalability challenges	Focus on optical imaging techniques for clot detection
[40]	Ultrasound imaging	Ultrasound for DVT diagnosis	DVT diagnosis	Widely available, real-time imaging	Operator-dependent, unable to assess clot age	Emphasizes ultrasound as a diagnostic tool for DVT
[41]	Photopl-ethysmography	Investigates the potential of photoplethysmography in detecting DVT	DVT detection	Noninvasive, cost-effective	Accuracy affected by skin pigmentation, limited depth penetration	Explores the use of photoplethysmography for DVT
[42]	Light reflection rheography	Noninvasive DVT screening	Screening for DVT	Easy to perform, potential for widespread use	Limited clinical validation, sensitivity concerns	Focuses on a noninvasive test using light reflection
[43]	Near-infrared spectroscopy	Explores near-infrared spectroscopy for DVT detection	DVT detection	Noninvasive, potentially sensitive to clot composition	Limited depth of penetration, variability in signal interpretation	Focuses on near-infrared spectroscopy for DVT
[44]	Machine learning and ultrasound	Uses machine learning with ultrasound for DVT detection	DVT detection	Potential for improved accuracy, automated analysis	Dependency on high-quality data, interpretability of models	Combines machine learning and ultrasound for DVT detection
[45]	Contrast-enhanced ultrasound	Discusses contrast-enhanced ultrasound for DVT diagnosis	DVT diagnosis	Enhanced visualization of vascular structures	Contrast agent-related risks, cost	Emphasizes the use of contrast-enhanced ultrasound
[46]	Neural networks for blood clot detection	Explores the use of neural networks for detecting blood clots	Blood clot detection	Potential for pattern recognition, adaptability	Dependence on training data, black-box nature	Focuses on neural network applications for clot detection
[47]	Magnetic resonance imaging (MRI)	Discusses MRI for DVT diagnosis	DVT diagnosis	High-resolution imaging, multiplanar views	Cost, limited access, contraindications (e.g., metal implants)	Emphasizes the use of MRI for DVT
[48]	Ultrasonography and compression sonography	Compares ultrasonography with compression sonography for DVT diagnosis	DVT diagnosis	Real-time imaging, compression helps detect flow abnormalities	Operator dependence, limited by obesity or anatomical factors	Compares two diagnostic methods for DVT
[49]	Duplex ultrasound	Evaluates the role of duplex ultrasound in diagnosing DVT	DVT diagnosis	Simultaneous imaging, assesses blood flow and structures	Operator-dependent, limited for obese patients	Focuses on the effectiveness of duplex ultrasound for DVT
[50]	Machine learning and ultrasonography	Investigates machine learning with ultrasonography for DVT detection	DVT detection	Potential for automated analysis, enhanced accuracy	Dependency on data quality, model interpretability	Combines machine learning and ultrasonography for DVT detection

a micro-electromechanical film bulk acoustic resonator. The coagulation stages were indicated by comparing the frequency responses. Glycerin solutions were used to map the frequency-viscosity relationship. A commercial coagulometer was used to compare the measured consistency with the co-efficient of variation [54].

A study on concepts for customizing biomaterials' blood responses included many ways to either entirely exclude interaction of the target surface with blood components or control the reaction of the blood clots, platelets, and leukocytes. Antioxidative surfaces have been created with the goal of essentially mimicking the anticoagulant capabilities of epithelium by immobilizing heparin, which reflects some of these cells' anticoagulant properties, and coating surfaces with them to form the optimum blood compatibility of the device [55]. Ultrasonography (USG) with color doppler imaging can detect DVT. The risk factors, such as arterial hypertension, congestive heart failure, stroke severity, and level of consciousness were examined using USG by Bembenek et al. Their research revealed that DVT occurs most often in acute mild-to-severe stroke patients in medical environments. Patients with pre-stroke dependency and an elevated serum C-reactive protein (CRP) level are more likely to develop DVT, regardless of stroke severity. According to their research, it may be reasonable to give such patients extra attention and proper DVT prophylaxis to avoid thrombotic complications of life-threatening potential [56]. The color Doppler and pulse wave Doppler machines were used to examine DVT in patients with acute stroke, hemorrhagic stroke subtype, old age, severe stroke, and severe lower limb disability. This will aid in the early detection and intervention of silent DVT as well as the prevention of Pulmonary thromboendarterectomy (PTE) [57]. D-dimer cross-sectional studies were performed to estimate sensitivity and specificity using ventilation/perfusion (V/Q) scintigraphy, computerized tomography pulmonary angiography (CTPA), selective pulmonary angiography, and magnetic resonance pulmonary angiography (MRPA) [58]. Stephens has developed a contrast agent to identify clots in the AF of patients, which could be used to find thrombus in other parts of the body [59]. Pre and post-blood clot conditions by evaluating the actuation of the helical microrobot at a distance were analysed [60]. Fig.5 shows a schematic representation of thrombus visualization techniques. magnetomotive optical coherence tomography (MMOCT) is a new method for contrasting magnetic agents with high magnetic permeability to human tissue [61].

The magnetic actuation along with phase-sensitive optical monitoring of nanoscale displacements, mostly through MMOCT, was employed by Oldenburg et al. Their results proved that the MMOCT platform has applications for fundamental approaches to thrombus formation dynamics, which can be used to correlate clot viscoelastic behavior with erythrocyte activity and evaluate platelet efficacy as a hemostatic therapeutic intervention. Detection and assessment of blood clot elastic modulus using superparamagnetic iron oxides (SPIO-RL platelets) were major challenges [62]. Li et al. integrated coagulation factors, residence duration, and shear stress to enhance a thrombosis model. Simulation results, aligning closely with testing and observational data, identified vulnerable areas for thrombus development. This approach contributes to establishing effective therapeutic strategies [63].

V. AR, VR and Robotics in DVT Therapy

The functions and angles of the major human body joints are tracked and evaluated. Simple rotation movements around each joint's degree of freedom (DOFs) and the joint angles could be monitored. The angle of the upper limb and lower limb relative to the vertical direction has been determined by calculating absolute and relative angles [64]. A rotating position sensor and a min-max scaling (MMS) filter were utilised to analyse the finger isometric contraction and adduction/abduction movements. This helped to make the VR interaction possible. The position sensors were placed on the metacarpophalangeal (MCP) joints to control and enable hand motion-tracking. The performance is evaluated in terms of accuracy, latency, and finger length variations, and compared to existing method with immersive VR interaction methods [65]. Shin et al. investigated the incidence and risk factors for VTE in hip fracture patients with a delay of greater than 24 hours before surgery. The overall VTE risk and the median time from injury to CT scan were determined [66]. The effectiveness of a modular impedance controlled lower leg device in the rehabilitation of post-stroke hemiparesis was proven to be beneficial by enabling ankle robotic feedback training. This enhances chronic hemiparetic gait velocity and proprioceptive ankle impulse control. In addition to walking speed, accuracy, and smoothness, the effects of various types of feedback and reward on motor and cognitive performance

TABLE II. Comparison Table of Results and Accuracy of Developed Systems

Reference	Method	Patients involved	Sensitivity	Positive predictive value	Negative predictive value	Accuracy	Result
[42]	light reflection rheography (LRR)	61	96.4 %	79 %	97.1 %	98.8 %	Simple 10 minutes diagnostic method with high sensitivity and negative predictive value.
[43]	mechanical compression device	874 patients (1434 knees)	93.2%	77%	88.2%	94.6%	No thrombi and PE after 6 months of treatment.
[44]	'nftool' software system	360 samples	96.7%	89.4%	96.7%	99.99 %	Type of blood clot disease identified .

were explored [67]. Monaco et al. developed the robotics NEUROBike for neurorehabilitation to assist bedridden post-stroke patients to recover their walking abilities, particularly by observing the mechanical structure, control architecture, and kinematic models implemented in the control algorithm [68]. Ahn and Hogan performed the realistic analysis of a robot-assisted motion that utilised the spontaneous kinetics of walking while simultaneously facilitating the patient's performance rehabilitation [69].

Low et al. developed a robotic ankle exercise support (robotic arm sock) for stroke patients at high risk of developing DVT. In stroke patients, the device was tested with traditional treatments, an intermittent pneumatic calf pump, and ultrasound Doppler. Investigation revealed that the soft extension actuators in our soft robotic sock could provide enough tensile force for ankle actuation. The robotic sock device was also shown to improve femoral venous blood flow in the ipsilateral limb [70]. After total knee arthroplasty (TKA), the incidence of thromboembolic and hemorrhagic disorders were analysed by Hamilton et al., while employing mechanical prophylaxis and preoperative risk evaluation. Mechanical prophylaxis, was effective for low-risk patients. This includes audio/video (AV) impulse lower extremity, compressive stockings, and early ankle mobility. Medications were only given to the patients who were at high risk. The mechanical treatments based on risk stratification were evaluated to ensure that they are both safe and effective after TKA [71]. Silva et al. evaluated the state-of-the-art ankle-foot orthoses utilising additive manufacturing. Their work suggested that evaluating the employed production techniques, customisation phases, mechanical qualities, and bio-mechanical aspects in humans would give vital insights for future study [72].

A. *Proprioceptive Home Rehab*

Ren et al. designed and developed a prototype for intensive passive and active movement training in acute or haemorrhagic stroke patients. Early in-bed rehabilitation improved neuroplasticity and helped patients develop motor controllability to enhance dorsiflexion motion, according to their studies [73]. Pasqual et al. proposed the gaming environment for ankle movement in two DOFs. The game is similar to classic Pong with slight changes. The two-player options are also given. The game was tested on healthy subjects and showed that it helps in ankle rehabilitation therapy. It is critical to recognize the calibration of dorsiflexion new ankle movement and to improve the low impact on the control factors [74].

Researchers investigated the viability of framework rehabilitation robots. According to their research, platform-based robots used in rehabilitation have some promising outcomes. Of all the types of these robots, the immersive VR-based Rutgers Ankle and the Hunova were identified as the most effective ones for the therapy of individuals with neuropsychological issues and certain other musculoskeletal ankle injuries. However, the challenge lies in accurately assessing the efficacy of platform based robotic rehabilitation systems [75]. Developing a VR tracking game for an ankle rehabilitation device make the therapy more engaging and to remove the monotony from the repetitive training. This game was tested on five healthy volunteers, providing two DOF. It was a simple game that has proven to be very effective in ankle rehabilitation [76]. Agyeman and Al-Mahmood developed wearable technology for patients with limb disabilities. The design focuses on three attributes: ensuring proper device connection, managing the connection status for server communication, and generating a server ID or IP address. A microcontroller processes sensor data transmitted via Wi-Fi to the server using web applications. The server imports data into its database, facilitating management of the gaming environment [77]. Table III scrutinizes remote assistance and its impact on enhancing the quality of patients' lives.

A new rehabilitation method created by J. A. Garcia and K. F. Navarro to improve the effectiveness of three games to promote ankle rehabilitation has been described. The provisioning and ongoing real-time monitoring of the mobile augmented reality (MAR) reinforcement networks, which aid in enhancing motion range during the training phase, are observed. These games are reported to improve overall balance restoration, mobility, and muscle strength [78]. Burdea et al. conducted a case study on the effectiveness of game-based lower leg rehab for children with cerebral palsy (CP). They found that robotic ankle training games improved gait by triggering specific gaming sequences for patients' ankle motions, thereby enabling the development of smart gaming structures for rehabilitative devices [79].

Rugsters ankle CP has been shown to be effective in providing ankle strengthening treatment and increased control for children suffering from CP. A significant improvement in ankle kinetics, efficiency, and persistence has also been observed in gait performance [80]. The task based VR gaming simulations are used to assess a rehabilitation approach that simultaneously exercised the upper extremities. They are developed with virtual targets in interactive entertainment by neural control mechanisms [81]. Alexandre and Postolache created a set of artificial smart gloves that allow for real-world interactions with therapeutic gamification for upper extremity rehabilitation. Using the Bluetooth wireless communication protocol, the processor of the Arduino Nano embedded platform is interconnected to the sensing part [82]. The quality of motor rehabilitation by involving patients in their training schedule was reported to be improved. An intuitive user interface based on the Leap Motion Controller was uesd to operate a 3D gaming engine. By using real data from neuromuscular rehab, it could allow therapists and patients to determine the proper motions. Moreover, VR offers patients an easy-to-use and customizable way to analyse data, which may be used for brain stimulation or treatment [83]. Do et al. designed a soft pneumatic robotic glove to assist stroke patients. Silicone platinum is used to create the soft actuator material. By controlling the air pressure inside the fingers, it can handle the force, bending angle, and fast response time [84].

B. Immersive VR-based Ankle Rehab

Borghese et al. designed a video game to adhere to clinical requirements and meet the doctors' and patients' expectations by monitoring patients at various stages with therapists' support [85]. An SVM classifier and pressure distribution data have been used to analyze compensatory pattern recognition in stroke patients during robotic neurological rehabilitation. Real-time observation using pressure data aims to minimize torso compensation. Analysis of data from robot-assisted stroke patients determines the effectiveness of haptic feedback in reducing compensation during tasks [86]. An interactive home-based rehabilitation system for patients who recover from knee replacement surgeries has been developed and tested. The patients' progression with the help of wireless inertial sensors was examined by the therapist, using triple axial magnetometer, and accelerometer [87]. Kyto et al. developed the supportive haptic device for providing the therapy for the stroke patients in a household environment and customising and motivating their activities [88]. The joint movements in both forward and inverse kinematic models at different angles are evaluated as motion controls. Measurements and recordings are made in real-time for rehabilitation training and assessment of haptic interactive tasks, aiding in the design and proposal of rehabilitative devices [89].

C. Immersive AR-based Ankle Rehab

An intelligent user interface has been developed that enables people to perform rehabilitation exercises on their own while being supervised offline by a therapist and healthcare providers. A sleeve AR is a novel approach to real-time, active feedback that employs multiple projection surfaces to provide effective visualizations. It provides patients with appropriate guidance and enables them to implement their rehabilitation training autonomously and is capable of recreating simple arm movements easily by mimicking the therapist's movement patterns [90]. Condino et al. developed the first wearable AR and was introduced in an application for shoulder rehabilitation based on Microsoft HoloLens and highlighting real-time markerless tracking of the user's hand. WiFi802.11ac and Bluetooth 4.1 LE wireless technology was applied in providing network connectivity. The Virtual Magnetic 3D Cursor is a custom script that was created to provide a hand-controlled cursor for our AR rehab gaming app [91]. Park et al. in their research proved that the following two factors have to be ensured for effective implementation of AR innovation for telemonitoring-remote assist guidance;improving patient's health [92].

D. Other Modalities to Sense and Rehabilitate with DVT Rehabilitation

Rehabilitation therapy is provided to patients with hemiparetic CP by combining physical exercises with a variety of video games. The information is evaluated and analysed based on the performance and progress of the collection of the data [93]. Sadihov et al. developed a technique for immersive rehabilitation with haptic feedback in VR. They introduced a system combining Kinect and a haptic glove, designed using

Unity3D and OpenN. The interactive haptic rendering algorithm enhances integration, offering patients motion-dependent haptic feedback during rehabilitation exercises [94]. Weber et al. developed a humanoid robot to showcase human-robot interaction. The sensor glove uses an inertial measurement unit (IMU) to measure movements and orientation, which will aid in the design and proposal of rehabilitative devices [95].

In the rehabilitation process, 3D motion capture sensors were used to analyse clinical parameters such as the angle of inclination of the neck, arm, forearm, posture, pushing force at the foot, and so on [96]. Ambient Assistance Living (AAL) refers to a set of intelligent environmental techniques, methods, and technologies that enable the elderly to live independently without being bothered by intrusive behavioural patterns [97]. Rego et al. designed a serious gaming platform that includes features such as natural and multimodal user interfaces, competent. This was implemented to boost patients during cognitive rehabilitation. Motion capture systems, haptic technology, and a biofeedback network was used to track and measure the DOF [98]. To improve motor learning and generalization to other tasks, as well as promote occupational practice in a more contextually relevant environment, there has been some controversy between VR and AR [99]. Mekbib et al. showed that VR-based therapeutic systems could enhance motor functions in stroke patients during physical therapy. This technology has been an ideal technique for contributing to the design and development of rehabilitative devices, ultimately assisting in the formulation of rehabilitation strategies [100]. Clothing-based rehabilitation and assistive devices can achieve high DOF and complex movements, benefiting from the direct guidance and attachment to human bodies. Flexible piezoelectric materials (polyvinylidene difluoride (PVDF)) are successfully used as sensing elements in rehabilitation and assistive devices [101]. Wang, Yanzhuo, et al. introduced an innovative cable-driven lower limb rehabilitation robot (CDLLRR). This advanced system was capable of effectively assessing the characteristics of gait movement, system stability, position tracking, and feasibility, thereby significantly contributing to the improvement of rehabilitation strategies [102].

E. Performance Measures for Rehabilitative Devices

The performance measures in stroke rehabilitation are primarily concerned with the process of care, specifically prevention, assessment, education, treatment (setting selection, and treatment standards) [103]. Fig.6 shows that comparative diagram of observation and screening methods used for DVT patients. Using different sensors, therapists accurately estimated patients' rehabilitation status, enabling them to create a follow-up treatment plan. This allows them to control location and movements in a virtual space, improving mobility and rehabilitation strategies [104]. The fuzzy control algorithm is capable of detecting an emergency, such as a rapid muscle spasm or twitch, and stop the robot immediately to prevent further harm to the impaired limb in case of emergency [105]. A multistage rehabilitation robot, specifically designed for hemiplegic lower limbs, has been developed to augment both tracking performance and motion control, thereby playing a significant role in the advancement of rehabilitation strategies [106]. Khalid et al. designed a simple and light rehabilitation device with low inertia and a less threatening design to enhance its mobility. Motor learning and ankle plasticity in patients with dropped ankles were promoted using such systems [107].

Zhou et al. developed a robot-assisted gait training platform with a human-computer interaction interface, where electromyography signal, joint torque, and joint angle were acquired. The effects of the robotic system's neuromuscular facilitation rehabilitation technique were investigated [108]. The patient's participation during rehabilitation training was encouraged [109], where a fuzzy algorithm was employed to change the impedance factors that influenced the human exoskeleton interface torques. For the swing phase of the training, an adaptive impedance control-based patient cooperative rehabilitation training strategy was used. Niikura et al. reported the prevalence of VTE being followed by complex lower-limb fracture surgery without pharmacological prophylaxis. Contrast-enhanced imaging can detect PE and is thus routinely used in high-risk patients with significant injuries or pelvic and acetabular fractures [110]. Dao and Yamamoto examined the safety of AIRGAIT, a gait-training robotic orthosis. They categorized frequent system issues into sensor failures, actuator malfunctions, and power supply interruptions. Their proposed control system identifies failures and applies techniques to reduce accident risks [111].

Ultrasonography is used to assess the effects of Electrical muscle stimulation (EMS) on venous blood flow in the lower extremity of ICU patients. Each method of prophylaxis has drawbacks, and none of them completely prevents DVT. EMS may be a new and effective method of preventing DVT in in-patients [112].

A modified computed torque controller has been proposed to improve the tracking performance based on a mathematical model with two DOF. The use of actuator configurations based on the human musculoskeletal system provided the system with more power and redundancy [113]. Robot-administered therapy, including classroom therapy, back-drivable robots, and sensorimotor training, are key technologies for reducing impairment and facilitating the development of rehabilitative devices [114].

It is highly effective to restore joint range of motion, mus-

cular strength, neuromuscular coordination, and gait analysis in patients suffering from various foot and ankle problems [115]. Ren et al. addressed the implementation of a wearable ankle robotic platform for intensive active and passive gait analysis for acute stroke patients. To assist the patients with motor relearning, the isometric torque generation mode with real-time feedback was used. Here the wearable robotic device extended the ankle efficiently and safely throughout its range of motion, all the way to the extreme of dorsiflexion [116]. Table IV illustrates the comparative methodologies utilized in different techniques. The patient transmits control signals to the device and the exoskeleton provides the majority of the mechanical power required to complete each task. The decrease in mid-lateral forces could indicate the capacity to improve a much more physiological gait while trying to prevent lateral movement [117].

F. Cogently Guided Treatment for Recovery

Roy et al. investigated the ankle stiffness, ankle sprains, and plantar fasciitis estimation which served as valuable asset for locomotors rehabilitation to improve ambulatory performance. The characteristics of sensorimotor function, gait analysis, stability, and motor function were evaluated by providing a customizable, adaptive, and quantitative assessment and rehabilitative tool [118]. The centrosymmetric analysis also showed that the hip and knee joints were affected by the illness in terms of interlimb coordination, but the ankle joint appeared to be largely unaffected from this perspective. The current study assessed healthy volunteers who were age and gender matched, and also utilized 3D computerized gait analysis to do point-by-point assessments of thigh and ankle joint angle changes [119].

Logistic regression analysis was used to investigate the various causes of postoperative PE, to identify perioperative risk factors associated with them, and to examine the effect of combining fondaparinux with mechanical prophylaxis on the prevalence of PE following total hip and knee arthroplasty [120]. An optoelectronic monitoring system is used for measuring thrombus formation, contraction, and size. These are computationally converted into a kinematic contraction gradient that can be evaluated [121]. A model for game generation was created for ankle rehabilitation that effectively addressed gamification, how the patient feels about the game, and visual observation of lower extremity practices that have already evolved, and adapts the game using a statistical methodology [122].

The study analyzed user performance and system usability in a 3D game-based rehabilitation system, aiding in the design and development of rehabilitation devices.

[123]. The ankle joint mechanism and control system using a series of elastic actuators based on the double tendon sheath transmission mechanism and torsion spring has been described by [124]. Girone et al. developed the World Tool Kit for deformities in lower limb rehabilitation, which is run on a computer system. This controls the device's gestures and output forces through the use of an RS232. The diagnostic functions such as evaluating the ankle's range of motion, effectively forcing exertion capabilities, and synchronization were performed [125].

VI. Comparative Summary

The aetiology of DVT is asymptomatic, and its major causes are high morbidity and mortality. The paper summarizes the techniques based on randomised controlled trials (RCT) focusing on the use of anticoagulant therapy, a D-dimer blood test, duplex ultrasound, venography, an MRI scan, compression stockings, prophylaxis strategies, and an optical coherence tomography system. A scalable technique to access the efficacy of evidence-based vulnerable therapy.

The main intention is to compare the existing works on the basis of causes and signs, screening tests, designs, and evaluation. Furthermore, the types of games used and their benefits (VR, AR, AI, robotics, assistive and wearable devices). Several research articles have been pubished so far on the diagnosis of DVT in the medical field, mostly invasive and also as an extra-corporeal technique. To evaluate the approach's

TABLE IV. Comparison Table of Methodology Involved in Various Rehabilitation Therapy

Reference	Method	Result /Values	Method involved
[65]	Low-latency haptic open glove (LLHOG)- Immersive VR interaction.	For flexion/extension, the average mean Absolute error (MAE) was 3.091; for adduction/abduction, it was 2.068.	Diagnostic techniques.
[76]	Game developed for ankle rehabilitation.	More intuitive movements of patients.	Rehabilitation therapy.
[77]	Wearable devices, games, IOT.	Stroke patients are assisted by gaming and wearable technology.	Rehabilitation therapy.
[78]	Mobile RehApp	Assisted physiotherapists and patients on ankle sprain rehabilitation.	AR Rehabilitation therapy.
[79]	Rutgers Ankle CP system.	A game-based robotic ankle training can enhance walking in children with CP.	VR Rehabilitation therapy.
[81]	Robotic-assisted arm training devices.	Upper extremity function of post-stroke patients is improved.	Robotically-assisted therapy.
[82]	Fabrication of a soft pneumatic finger- 3D model in CAD software.	Stroke patients supported by the fabrication.	Rehabilitation equipment.
[91]	Wearable AR application for shoulder rehabilitation, based on Microsoft HoloLens, with real-time markerless tracking of the user's hand.	20 healthy subjects were involved rehabilitation was provided by head-mounted displays (HMDs).	AR Rehabilitation therapy.
[94]	Expandable immersive VR platform -gesture based tactile rendering algorithm.	Interactive vibration patterns focused on the user's movement that improve immersion and generate sensory perception during rehabilitation therapy.	VR Rehabilitation therapy.
[100]	VR-based therapy systems.	Motor function of stroke patients is improved.	VR Rehabilitation therapy.
[116]	Wearable robotic device.	The patient is guided and inspired to participate actively in movement (extreme dorsiflexion training via game play).	VR based bed rehabilitation therapy.

feasibility, game-specific performance data from patients is collected and utilised to build a trained machine learning algorithm. The designed games allow for the unhindered evaluation of a patient's performance in a therapeutic environment. The proposed system permits remote follow-up assessments to be performed in a more convenient and user-friendly way.

Due to our consistent hypothetical and problem identification, the diagnostic techniques available for DVT in the medical field are mostly invasive. The existing system, which involves detection of DVT using a light source, is also an extra-corporeal technique. There are lots of therapy techniques available for DVT to ensure constant movement of the lower limb for a particular time period. However, these methods are monotonous and stressful.

VII. Discussion and Future Directions

Directions to advance the field of DVT diagnosis and improve patient rehabilitation: The current methods for diagnosing and treating DVT have limitations such as compatibility, accessibility, reliability, and accuracy. Advances in imaging modalities offer the potential for early detection. Combining these with new diagnostic tests and point-of-care techniques could lead to a more effective and accessible diagnosis. A new strategy emphasizes early identification and detection to improve patient outcomes and timely intervention. Future directions include advanced imaging practices, machine learning frameworks, long-term studies, IoT integration, early identification frameworks, real-time data, and rehabilitation through games. These developments aim to improve patient healthcare.

VIII. Conclusions

This review summarises our investigation of the diagnosis and rehabilitation therapy of DVT: causes and signs; incidence and complication; interpretation and prediction; rapid screening tests and designs; observations and evaluation; and furthermore, vulnerable and scalable therapy. This study focuses on DVT and its diagnosis and treatment methods; several research articles have diagnosed DVT on the basis of extra-corporeal techniques, which involve the use of anticoagulant therapy, a D-dimer blood test, duplex ultrasound, venography, an MRI scan, compression stockings, prophylaxis strategies, and an optical coherence tomography system. Current methods for diagnosing and treating DVT have limitations, but advances in imaging modalities and new diagnostic tests could improve early detection and patient outcomes. Future directions include advanced imaging practices, machine learning, long-term studies, IoT integration, early identification frameworks, real-time application, and rehabilitation through VR and AR games.

Declarations

Research funding: No funding was received for this manuscript.

Author Contributions: Conceptualization, all authors; methodology, all authors; writing - original draft preparation, L.B.; writing - review and editing, all authors. All authors have read and agreed to the published version of the manuscript.

Consent for publication: Not applicable.

Conflict of Interest Statement The authors declare no conflict of interest.

Informed consent: Not applicable.

Ethical approval: Not applicable.

Availability of data and materials: All data analysed for this review are included in this published article.The data used and/or analysed in the manuscript are available from the corresponding author on reasonable request.

Abstract—**In this digital era, social media is one of the key platforms for collecting customer feedback and reflecting their views on various aspects, including products, services, brands, events, and other topics of interest. However, there is a rise of sarcastic memes on social media, which often convey contrary meaning to the implied sentiments and challenge traditional machine learning identification techniques. The memes, blending text and visuals on social media, are difficult to discern solely from the captions or images, as their humor often relies on subtle contextual cues requiring a nuanced understanding for accurate interpretation. Our study introduces Offensive Images and Sarcastic Memes Detection to address this problem. Our model employs various techniques to identify sarcastic memes and offensive images. The model uses Optical Character Recognition (OCR) and bidirectional long-short term memory (Bi-LSTM) for sarcastic meme detection. For offensive image detection, the model employs Autoencoder LSTM, deep learning models such as Densenet and mobilenet, and computer vision techniques like Feature Fusion Process (FFP) based on Transfer Learning (TL) with Image Augmentation. The study showcases the effectiveness of the proposed methods in achieving high accuracy in detecting offensive content across different modalities, such as text, memes, and images. Based on tests conducted on real-world datasets, our model has demonstrated an accuracy rate of 92% on the Hateful Memes Challenge dataset. The proposed methodology has also achieved a Testing Accuracy (TA) of 95.7% for Densenet with transfer learning on the NPDI dataset and 95.12% on the Pornography dataset. Moreover, implementing Transfer Learning with a Feature Fusion Process (FFP) has resulted in a TA of 99.45% for the NPDI dataset and 98.5% for the Pornography dataset.**

Keywords*—*Deep learning; natural language processing; offensive images; sarcastic memes; toxic content detection

I. Introduction

Nowadays, most companies use social media to communicate with customers, understand customer needs, and promote their goods and services. A positive review can significantly influence consumer behavior and decision-making, whether it praises a product's quality, applauds exceptional customer service, or lauds the overall brand experience. Consequently, information about any company's success and failure spreads rapidly and extensively through social media. Individuals may express their opinions and thoughts in various ways, occasionally using sarcasm, especially when conveying solid emotions. Sarcasm involves using an apparent positive phrase with a hidden negative sentiment. Additionally, text data is often associated with offensive images, leading to hostile intentions. There is a growing demand for practical computational tools that automatically identify and censor undesirable or offensive information on social media.

Researchers have previously employed several neural network - based models to address challenges ranging from sentiment analysis in social media data to object recognition in computer vision tasks. According to [1], a mixed neural network design using an attention mechanism should focus on delivering various components that reveal the aspects making a statement sardonic in reality.[2] created a supervised learning model to identify sarcasm on Facebook, marking a significant achievement in sarcasm detection. Another approach considering user interaction is using convolutional neural networks (CNN) and long short-term memory (LSTM) to implement an advanced neural network-based method for sarcasm detection in newspaper headlines. However, this requires additional LSTM training time and CNN text tagging, as mentioned in [3], which can be challenging because of potential lacuna in connections between adjacent words. [4] uses an LSTM-based SenticNet-based graph neural system, incorporating additional graph structures specific to sentences. The dependence graph for words in sentences can be improved through a graph-network-based approach [5], integrating emotions of words retrieved from the SenticNet Common Knowledge Database. A hybrid neural network, comprising a Graph Convolutional Network (GCN) for gathering global information from sentences and a bidirectional LSTM (BiLSTM) network for capturing feature sequences, has also been recommended [6]. The feature sequence is combined and then sent to an existing classifier for prediction.

In a study, Bidirectional Encoder Representations from Transformers (BERT) [7], along with GCN [8], are employed to enhance humor recognition in a text. SenticNet creates dependency and adjacency graphs, and BERT improves text characteristics. Later, BERT sends the graph structures it generates to a GCN. ”The classification algorithm employs softmax to determine whether to accept or reject a given claim based on the context representations, which it updates according to the outputs of GCN algorithms.” Research conducted by Poria et al. [9] introduced CASCADE (ContextuAl SarCasm Detector), a model designed to detect sarcasm in social media forums and chat conversations. This model has achieved successful sarcasm detection by integrating contextual and content-based models, demonstrating its effectiveness in discerning sarcastic expressions within social media forums and chat conversations. We design a sequencing model to identify sentences that express humor or not, depending on the context. Simple Exponential Smoothing (SES) is employed to determine if a sentence might have a sarcastic meaning. SES is an approach to predicting information from time series data that remains constant regardless of the season or trend. We incorporate it into the system to determine whether a sentence could convey sarcasm.

A. Contributions and Paper Organization

To effectively process sarcastic text, memes, and offensive images, researchers have leveraged the benefits of Long Short-Term Memory (LSTM) networks. To tackle snarky text, a bidirectional encoder has been employed to enhance the understanding of contextual nuances. This algorithm seamlessly integrates robust vision and language fusion capabilities. Furthermore, implementing Optical Character Recognition (OCR) technology enables the detection of sarcasm within memes. Lastly, we will implement a Transfer Learning (TL) - based Feature Fusion Process (FFP) customized to the data's characteristics to address offensive images. Section II presents a concise overview covering an analysis of current research methods, including CASCADE, SCUBA, and BossaNova. Section III addresses our models for written sarcasm, memes, and offensive images. Section IV introduces the datasets central to our study. We provide a detailed description of the datasets and discuss the rationale for their selection. Section V presents the performance assessment parameters and the results of testing the proposed model. Section VI delves into the implications of our findings, the limitations of the work, and potential avenues for future research. As Section VII concludes, our study adds meaningful value to the ongoing discourse in the field, setting the stage for future investigations and advancements.

II. Related Works

Researchers have studied sarcastic language in the realm of social media for years. However, the research method to detect sarcasm within text is an emerging subject. Recently, researchers working in emerging areas of artificial intelligence and NLP, which refers to natural language processing, have been fascinated by the automatic detection of sarcasm [10]. NLP techniques use corpora, which are linguistic and characteristic of a language, to comprehend qualitative data. In contrast, ML algorithms use unsupervised and supervised instruction methods based on unlabeled or labeled material to understand sarcastic language. A study by Poria et al. [9] introduces CASCADE (ContextuAl SarCasm Detector) to identify the sarcasm prevalent in social media forums and chats by combining contextual and content-based models. We design a sequencing model to determine whether sentences express humor, depending on the context. Within the integration layer, we use Simple Exponential Smoothing (SES), an approach for predicting information from a time series that remains constant regardless of season or trend, to assess if the sentence might convey a sarcastic meaning. The SCUBA method (Sarcasm classification based on a Behavioral Modelling Approach) [11] can identify differences in emotions and evaluate present and past tense, readability, status grammar, vocabulary, structure, and message position to ensure clear differentiation. The technique relies on the interaction model for users as a crucial element in discovering the inherent contradictions of their tweets than focusing solely on tweet's content and setting. However, the authors in [12] developed an online codebook employing a random sampling technique to identify naked spaces using time space-interest points and a traditional Bag of Words (BoW) method. In [13], researchers employed BossaNova and local binary descriptors to detect videos and photos containing obscene content. BossaNova surpasses the conventional BoW-based approach by integrating color information and shape description. Researchers used the SURF technique to blend the algorithm for audio codebooks with an algorithm for visual codes to detect the process. Effectiveness of these methods relies on selecting an appropriate codebook size, employing an optimal pooling technique, and determining a suitable threshold. The author in [14] propose an approach that examines periodicity in audio frames and saliency in visual frames. Considering valuable findings from the previous studies, we designed multimodal co-occurrence semantics that outperform state-of-the-art methods in preventing explicit content dissemination. In [15], the authors propose a method named Deep One-Class with Attention for Pornography (DOCAPorn) to recognize pornographic images through a one-class classification model based on neural networks and a visual attention mechanism. In the study presented in [16], researchers used the Caffenet method to accurately classify 97.2 percent of pornographic images posted on social networks. Additionally, in [17], authors utilized a mid-level feature combination approach to develop a more detailed model, having initially collected temporal and spatial features of a video stream using Google. The SVM classifier utilized these attributes to determine if the video contained sexually explicit content. To achieve an accuracy of 97.9 percent, the GoogleNet models were pre-trained using images from both the Pornography-2k database and the ImageNet dataset.

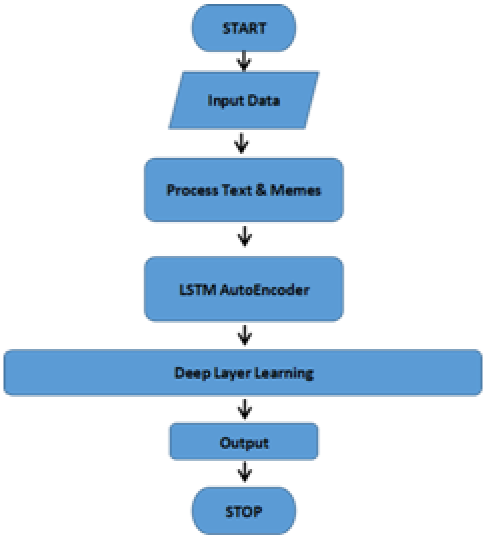

Fig. 1. Flowchart of the proposed model.

III. Proposed Methods

A. Sarcasm Text and Meme Detection

We present the flowchart of the proposed model in Fig. 1.

The proposed model involves a mixture of methods that utilize sentence-based techniques for offensive detection. The process employs a bidirectional encoder with an extended long short-term memory to detect sarcasm in the text. The thick layers learn embeddings that concatenate sentences to enhance categorization probabilities after receiving results from previous methods. Subsequently, the resulting vectors combine with the inputs and are sent to Softmax to decide whether the input is offensive. Initially, the preprocessing layer receives the text input and gets preprocessed. The optical character recognition (OCR) API Pytesseract retrieves text from the meme picture. Google's OCR API is called Tesseract. Pytesseract is the Python version of the tesseract API. We then consider the representation vector for the pre-training output. The embedded values are fused and transmitted to dense layers to learn features. Softmax processes the output from the thick layer and determines whether it contains sarcasm.

B. AutoEncoder

An autoencoder is a network of neurons with identical values in both the input and output layers. The significance of autoencoders lies in the rapidly expanding field of unsupervised learning techniques, where they find several applications. Its simplest form consists of a decoder and encoding units buried behind a layer. The encoder's objective is to transform input data into a code, a lower-dimensional representation.

The decoding part learns how to decrease prediction error in conjunction with the dimensionality reduction. Despite its design, it functions as an ordinary feedforward neural network that calculates gradients of the loss function through the backpropagation technique. An alternative method for employing an autoencoder in a multi-class classification scenario involves training multiple autoencoders and consolidating them at the conclusion. After completing the initial training step, we build a second classification on top of the previous one using prediction errors as input and accurate labels as output.

The autoencoder comprises two main components: an encoder and a decoder. The encoder initially comprehends the input before compressing it into an internal representation determined by the bottleneck layer. Subsequently, the decoder replicates the output of the encoder. Once the autoencoder has undergone training, we retain only the encoder, utilizing it to compress input samples into vectors generated by the bottleneck layer. The initial autoencoder decides to forego compressing the input. Instead, we use a bottleneck layer of the same size as the input.

C. Loss Function

The combination of the frameworks enables the secondary task to guide the training on the main job by calculating the model's loss using Eq. 1.

$$L_i = \sum_{(x,y)\in\Omega_1} L_1(x,y) + \sum_{(x,y)\in\Omega_2} L_2(x,y) \tag{1}$$

$$CategoricalCrossEntropy = -\sum_{j=1}^{c} t_i \log(f(\text{Softmax})_i) \tag{2}$$

$$BinaryCrossEntropy = -t_i \log(s_1) - (1-t_i)\log(1-s_1) \tag{3}$$

t_i represents the true label or target for the ith sample or data point. s_i represents the output of the sigmoid function for the ith sample. c represents the number of classes in the classification problem, i.e., 2. L_i is the proposed model's overall loss, and L_1 and L_2 are the losses for the primary and secondary tasks. We compute the complete loss for each phrase in the dataset Ω_i using L_i. Eq. 2 and 3 provide the cross-entropy loss for sentiment and sarcasm classification, respectively. In our framework, the RMSprop optimizer enhances the model's performance. The suggested approach calculates the gradient of L_i for each batch at each epoch to optimize the parameters.

D. LSTM

Traditional RNNs, due to the vanishing gradient issue, struggle with problems that require understanding long-term temporal connections, such as sentences or text data. However, our proposed model, which employs LSTM networks, overcomes this limitation. The duo of LSTMs, with one handling input in the forward direction and the other processing it backward, allows the network to store information from both the present and the past, thereby capturing long-term dependencies in data more effectively than traditional RNNs.

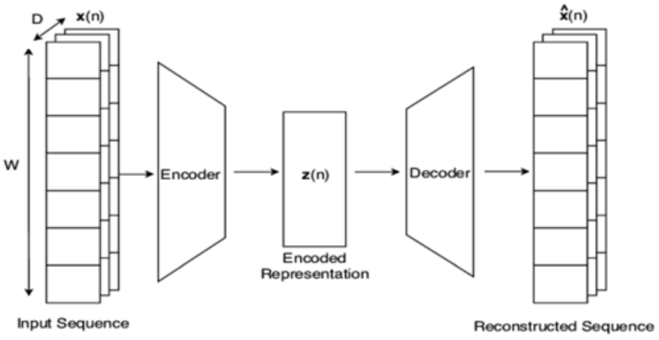

Fig. 2. Architecture LSTM-based autoencoder [17].

Fig. 2 depicts the LSTM network's fundamental design. To address the vanishing gradient issue, the LSTM network, a specific type of RNN, employs both specialized units known as memory cells and additional conventional units. A cell state comprises three distinct gates: the forget gate, the input gate, and the output gate, which can be incorporated into an LSTM network to enhance Performance. Using the explicit gating mechanism, the cell can decide whether to read from, write to, or delete the state vectors at each step. The input gate grants the cell the option of updating its state. In contrast, the forget gate enables the cell to decide whether to make the results accessible at the output gate, facilitating memory clearance. LSTM is a valuable approach for sentiment and sarcasm models, as every word in a phrase holds significance, and the ability to "memorize" and forget enhances model capabilities. When evaluating the characters of a phrase, preserving bidirectional information flow is also crucial.

The autoencoder, illustrated in Fig. 3, applies text conversion into high-dimensional vectors, facilitating tasks such as text categorization, semantic similarity in clustering, and other applications within the natural language processing domain. The autoencoder, developed by researchers, processes text with more than one word, including sentences, phrases, and short paragraphs, facilitating comprehensive text analysis. It can quickly respond to various tasks related to natural language comprehension and activities. The output is an adjustable-length English sentence, while the input data consists of a sizable 512-dimensional array. Notebook examples demonstrate the application of this format in the STS standard for assessing semantic similarity. We train the universal sentence encoder model using a deep average network (DAN) encoder. Iyyer et al. [18] inspired the encoder model. We calculate phrase embeddings by averaging across the bi-grams of words. Then, we feed the embedded information to the feedforward structure of a four-layer DNN, producing an embedding that spans 512 dimensions. Learning the embedding form of bi-grams and words mirrors human learning.

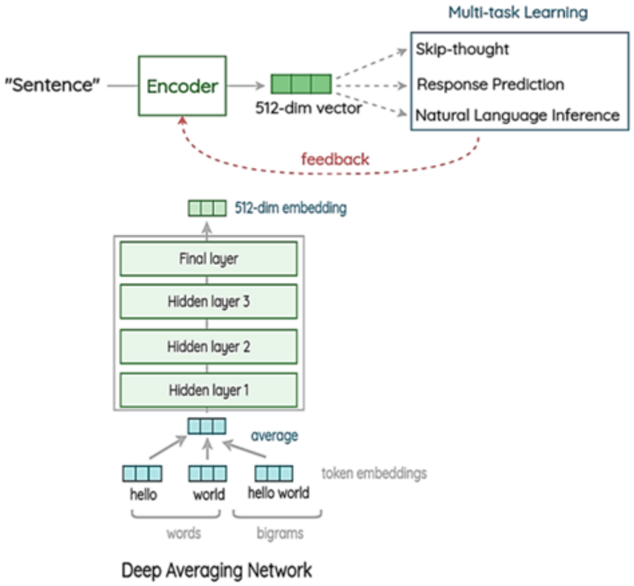

Fig. 3. Autoencoder method[19].

1) Memes detection: Individuals transmit memes, which are integral components of behavioral and cultural patterns, among themselves through imitation or other non-genetic activities. They have gained increasing popularity on social media, manifesting in various designs and formats such as images, videos, and posts. One noteworthy concern is the abundance of memes on the internet. Not only can memes express people's inherent emotions, but they also have the potential to cause harm to someone's feelings. Consequently, hateful memes have begun to emerge, posing a severe threat to contemporary civilization. Since a meme typically combines neutral text with a provocative visual, or vice versa, individuals might perceive it as implicitly harmful. Including unrelated words, or vice versa, sometimes obscures the underlying content of a pejorative picture. We have provided several instances of offensive and non-offensive memes, as the opaque nature of memes has led to disagreements among annotators.

Memes of this nature often comprise false information, derogatory language, and potentially harmful images. Individuals with malicious intentions employ them to target or attack others. To ensure a balanced consideration of individual information needs across different modalities, we conceived the idea of identifying harmful memes through a multi-task learning approach. Our strategy involved leveraging the autoencoder LSTM model for multimodal information processing. We refrained from manually introducing any extra information or labels, minimizing the risk of generalization errors.

We propose a model for identifying hostile memes. Our model outperforms contrasting methods and significantly improves the accuracy of detecting offensive memes. The multi-task approach and adaptive LSTM model used in our framework quantitatively enhance the generalization and resilience of the model, capturing consistency and variability across various modalities. In the absence of additional information or labels generated by humans, our supplementary tasks, which utilize a self-supervised label generator module, further enhance the capabilities of feature learning for the accessory.

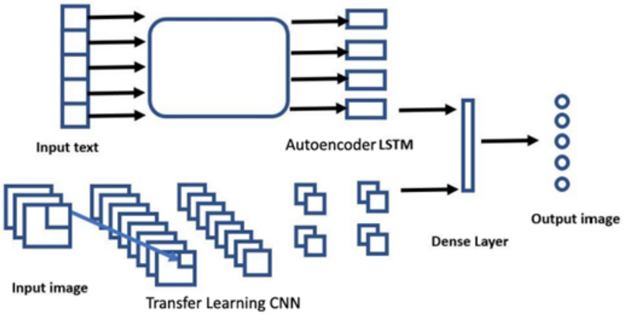

Fig. 4. Model for combining visual and textual data associated with the meme [20].

We load the meme into the OCR module. Then, all caption content from the memes is extracted [19]. In the subsequent step, both the text captions taken by OCR and the textual object tags generated by the model will be fed into the LSTM autoencoder model for further processing in terms of extracting sarcasm from the meme. We obtain the image for offensive detection using the Transfer Learning model. Fig. 4 is a multimodal meme model that combines visual features through a Convolutional Neural Network (CNN) and textual features using an autoencoder LSTM. The CNN processes image content, extracting high-level features, while the autoencoder LSTM captures sequential patterns in the textual data. The fused representations contribute to a joint model, enhancing meme analysis for tasks such as sentiment analysis or meme classification.

E. Offensive Image Detection

We propose a computer vision-powered framework for Transfer Learning with Image Augmentation and Feature Extraction, aiming to identify offensive content in an image. Researchers have presented several studies employing CNNs to distinguish between appropriate and inappropriate images.

1) Transfer learning: With the current volume of data, training a neural network from scratch is not feasible. Consequently, we opt for pre-trained networks and refine them with limited yet meticulously constructed training data. Given our initial constraint of a few photos, our application needs to revise traditional image data augmentation methods such as translation, flip, rotation, color/contrast correction, and noise integration. While we employ the mentioned controlled alterations, we also leverage other cutting-edge picture enhancement and discovery methods, including the Feature Fusion Process (FFP) based on Transfer Learning (TL). The FFP amalgamates low-level and mid-level attributes from models that surpass pre-trained ones to maintain deep characteristics of the training samples. We retrained the final layers of the combined model to construct the desired categorization models. More visual details are preserved throughout the feature fusion process grounded in transfer learning, leading to increased classification accuracy.

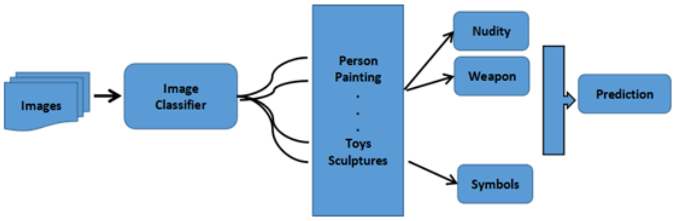

Fig. 5. Model for the offensive image classifier [20].

Fig. 5 elucidates a transfer learning model for offensive image classification constructed using a pre-trained image classifier, such as ResNet50. The model is fine-tuned on a dataset specific to offensive content, leveraging the learned features from the base model. After training, the model can predict whether an input image contains offensive content, providing a binary classification output.

The existing neural network models such as MobileNet, ResNet 101, DenseNet 169, Xception, ResNet 50, AlexNet, VGG16, ResNet 152, and VGG19 learn from Transfer Learning through training on images. Our suggested model, incorporates a unique Feature Fusion Process (FFP) based on Transfer Learning (TL). To maintain the deep characteristics of the training samples, we utilize FFP to fuse both low-level and middle-level features from the superior models we have trained. We then retrain the layers comprising the fused model to construct the desired categorization models. The feature fusion process based on transfer learning preserves more visual details, thereby increasing classification accuracy.

We enhance the primary network architectures of deep learning models by incorporating sequential normalization alongside mixed pooling strategies. This modification aims to attain training stability and mitigate the overfitting issue. The benchmark data design mirrors NPDI or Pornography 2k, which relies on an obscene recognition system utilizing the deep feature fusion method in developed models. We then compare the performance of the superior fused model to cutting-edge CNN-based techniques, considering both quantitative and qualitative perspectives.

2) Selection of outperforming pre-trained models for feature fusion: Our present research has utilized ten deep learning architectures, including MobileNet, ResNet 101, DenseNet 169, Xception, ResNet 50, AlexNet, VGG16, ResNet 152, and VGG19. The number of layers varies in each deep learning model. Each model employs input photographs of varying sizes based on its specific requirements, and we resize all images before they enter the model architecture. We have implemented several modifications to enhance training stability, such as including Batch Normalization (BN) layer and incorporating mixed pooling in the fundamental network design of each deep learning model. The term “optimized deep neural model” denotes more efficient models. These models evaluate and verify photos from the NPDI and Pornographic 2k datasets, utilizing information acquired during training. We apply various parameters to both the Pix-2Pix GAN model and the testing and training of enhanced deep-learning models. This study has selected numerous optimal parameters for improving the proposed model’s classification performance. Specifically, we employ a learning rate of 0.001 during the deep learning model training, and 0.002 serves as a parameter value for GAN optimization. Lower learning rates prevent optimization algorithms from getting trapped in local minima.

We utilize a two-class categorization technique to determine the obscenity of unseen pictures. Consequently, each model’s output layer incorporates a sigmoid activation function and binary cross-entropy (BC) as loss functions. We apply the Adam optimizer to optimize the BC loss function, combining the advantages of gradient descent with root mean square propagation. Furthermore, we leverage sparse properties to expedite convergence, performing well with substantial datasets. We employ the Sigmoid activation function in our categorization method. by limiting the reduction of the loss function after 50 iterations. We use various batch sizes (16, 32, and 64) in the categorization method, maintaining a balance between computational burden and precision, significantly when batch sizes exceed 32. We employ testing accuracy as a quantifiable measure in detection to assess algorithm performance.

F. Batch Normalization (BN)

To ensure the incorporation of inputs within each mini-batch into the network before progressing to the subsequent layer, we utilize Batch Normalization (BN) to normalize each input. We standardize the activation layers throughout the process to maintain consistent values and variances. Limiting the number of epochs used for model learning is crucial, as an excessive number can decelerate the learning process. Reducing internal covariance shifts accelerates the network training procedure, decreasing errors and enhancing stability of the training process.

After training our model for 50 epochs with a batch size of 200, we calculate each μ_{batch} and σ^2_{batch} for all batches using Eq. 4 and 5. Subsequently, we perform batch normalization by subtracting the mean from each batch and dividing by the variance using Eq. 6. This standardizes each mini-batch to have a zero average and one variance. In summary, the batch normalization procedure introduces its regularization effects while enabling stochastic descent to carry out the denormalization process, thereby reducing overfitting.

$$\mu_{\text{batch}} = \frac{1}{n}\sum_{i=1}^{n}\text{batch}_i \tag{4}$$

$$\sigma^2_{\text{batch}} = \frac{1}{n}\sum_{i=1}^{n}(\text{batch}_i - \mu_{\text{batch}})^2 \tag{5}$$

$$\hat{x}_i = \frac{x_i - \mu_{\text{batch}}}{\sqrt{\sigma^2_{\text{batch}} + \epsilon}} \tag{6}$$

µbatch: µcalculates the mean of the batch by averaging all samples within the batch.

i: i is an index representing each sample in the batch.

n: n is the total number of samples in the batch.

batch$_i$: Denotes the value of the ith sample in the batch.

$(x)_i^\wedge$: Represents the normalized value of the ith sample in the batch.

x_i: Denotes the original value of the ith sample in the batch.

ϵ: This is a small constant (epsilon) added to the denominator to avoid division by zero and stabilize the computation, especially when the variance is close to zero.

G. Mixed Pooling

Maximum-average pooling, commonly referred to as mixed pooling, combines maximum with average pooling. The mixed pooling's stochastic nature helps to avoid over-fitting. Eq. 7 provides a mathematical equation for mixed pooling.

$$f_{\text{min}}(x) = a \cdot f_{\text{max}}(x) + (1 - a) \cdot f_{\text{avg}} \tag{7}$$

$f_{\text{min}}(x)$: This represents the result of the mixed pooling operation for the input x, which combines both max pooling ($f_{\text{max}}(x)$) and average pooling ($f_{\text{avg}}(x)$).

a: The pooling result ranges between 0 and 1, with 0 indicating consideration solely of the average pooling result and 1 indicating consideration solely of the max pooling result.

$f_{\text{max}}(x)$: This represents the result of the max pooling operation for the input x, which selects the maximum value from a set of values within a specified window or kernel.

$f_{\text{avg}}(x)$: This represents the result of the average pooling operation for the input x, which calculates the average value from a set of values within a specified window or kernel.

The equation for mixed pooling combines the results of max pooling and average pooling using a parameter aa, allowing for a flexible combination of these two pooling techniques to extract features from the input data. Adjusting the value of aa allows for controlling the balance between preserving the maximum activations and considering the average activations within the pooling window.

The mixed pooling technique is superior to max pooling and average pooling in classification performance. Due to its fixed mixing proportion, it is insensitive to the essential features in the pooled area [21].

A dropout layer, also known as a regularization technique, limits the integration of embedded input. We have assumed that the dropout rate is 50%.

Researchers frequently use the Rectified Linear Unit, or ReLU, as the activation function due to its faster performance and lower computational costs. When a deep learning algorithm's output represents a probability value, researchers can apply the sigmoid activation method to generate the output. For the final classification in production, we used the sigmoid function at the output layer. Its values range from 0 to 1, with Class 0 indicating non-obscene and Class 1 indicating obscene. The sigmoid function is denoted by

$$S(x) = \frac{1}{1 + e^{-x}} \tag{8}$$

x is input vector.

H. Feature Fusion and Transfer Learning

This section aims to efficiently derive the most highly trained models from those mentioned in 3.2 to perform a feature-level fusion of characteristics. The initial stages of these models encompass lower and mid-level characteristics. Within the FCL, we identify distinct and different characteristic descriptors at the first level of every model. Subsequently, we integrate the feature extractions from the two models exhibiting superior performance, enhancing deeper characteristics. In this stage, we can execute an inverted process of feature fusion, wherein the feature descriptors from two different models are combined into a single descriptor, thereby enhancing the overall feature representation. In Eq. 9, model M1 contains feature descriptors f1 of dimensions (1 x m1), and Model M2 is a feature descriptor f2 with dimensions (1 x m2). Following fusion, we define F$_f$ as the concatenation of features:

$$[F_f]_{(1\times m_1 + 1\times m_2)} = \text{Concatenate}(f_{1,1\times m_1}, f_{2,1\times m_2}) \tag{9}$$

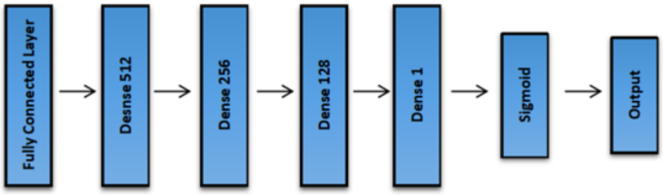

Fig. 6. Retrained module.

After feature fusion, researchers utilize the integrated network for the Transfer Learning Process (TLP). As depicted in Fig. 6, we combine the retrained module into the transfer learning process. In subsequent stages, the Final Classification Process (FCL) retrains, incorporating fused deep features, before directing the data to a sigmoid classifier for ultimate classification. The retaining module is visibly evident during this process. An output layer, fully connected, spans across three layers (512-¿256-¿128-¿64-¿32-¿1) before undergoing classification using a sigmoid classifier, with an average dropout rate of 0.5. Feature fusion, rooted in the transfer learning procedure, preserves more intricate details from the image, enhancing classification accuracy. Fig. 7 illustrates the framework designed for obscene image detection. An overview of the layers with a focus on their relevance to this specific task is as follows. The input image, containing visual information, undergoes analysis to identify obscene content. Image Augmentation augments the input image to improve the model's ability to generalize and detect obscene content under various conditions. Batch Normalization normalizes the activations in intermediate layers, helping the model converge faster during training and improving the overall performance of obscene image detection. Mixed Pooling technique combines pooling operations to down-sample the input's spatial dimensions, aiding in feature extraction and reducing computational complexity. Fully Connected Layer learns high-level features from the processed image data, essential for identifying patterns associated with obscene content. Dropout + Batch Normalization applies dropout for

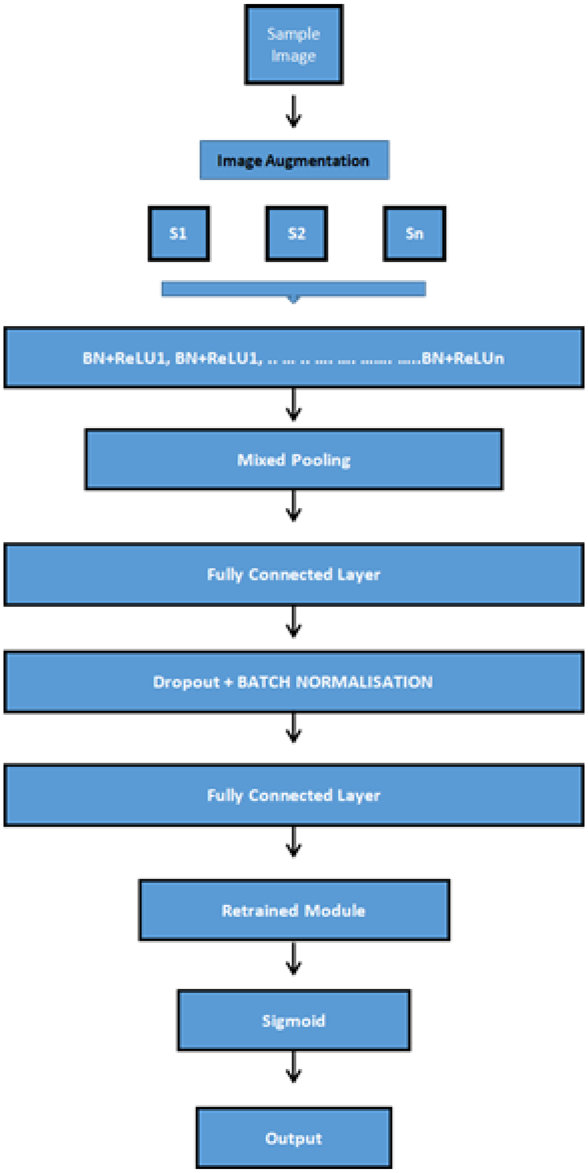

Fig. 7. Framework for obscene image detection.

regularization to prevent over-fitting and combines it with batch normalization for stable training.

The retrieval module integrates a pre-trained module, potentially trained on a diverse dataset, to capture general visual features relevant to explicit content detection. Sigmoid activation function at the output layer for binary classification, indicating the probability of the input image containing obscene content.The final layer provides the model's output, classifying the input image as either obscene or not based on the threshold set by the sigmoid activation function. We implement this framework to leverage various techniques, including data augmentation, normalization, dropout, and pre-training, to enhance the model's ability to detect obscene image content.

IV. Datasets

In this section, we have covered the datasets obtained from various sources.

3:15 AM - 8 Aug 2015

276 310

Fig. 8. Sample of Sarcasam text data.

A. SARC Dataset

Reddit forum comments have been integrated into the self-annotated Reddit corpus, widely recognized as SARC 2.0. The tokens, employed by users to express the tone of their comments, can be utilized to identify and filter out sarcastic posts. Fig. 8 shows one of the records from the SARC dataset. Our study will exclusively focus on the original posts, excluding child and parent comments. Specifically, we analyze the "Main Equal" and "Political" versions of the database, as outlined in our study. Both versions exclusively contain responses related to discussions on politics [22].

B. Headline Dataset

Two news sources, Onion and HuffPost, have released headlines related to this information. While HuffPost presents authentic headlines, The Onion provides satirical viewpoints on current news. The news item is a background piece, whereas the headlines contribute substance. There are 27,709 headlines, of which 11,725 are humorous, while 14,984 are not.

C. Memes Dataset

For our experimental dataset, we employed hateful memes dataset sourced from the "Hateful Memes Challenge" [2], generously provided by Facebook AI. This collection comprises over 10,000 memes meticulously classified as hateful or not, employing precise criteria. Fig. 9 shows a sample from the memes dataset. The researchers thoughtfully created each meme, employing techniques such as "benign confounders" to blend harmful and benign memes. These memes possess subtle features, making it challenging for unimodal detection systems to identify them accurately. To accomplish this, we use a combination of textual and visual reasoning.

D. Offensive Images

We conducted several tests to evaluate the effectiveness of our proposed model in detecting inappropriate content. To do this, we used benchmarks that include explicit content data, such as Pornography 2k [23] and the NPDI Dataset [24]. Fig. 10 shows sample images from the dataset. We can benchmark our proposed model's performance against several advanced deep-learning models.

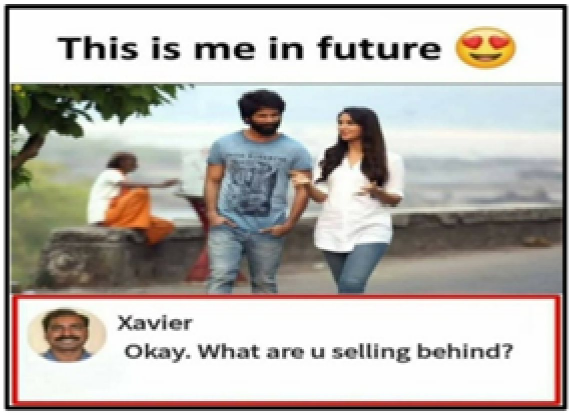

Fig. 9. Sample of sarcastic memes.

Fig. 10. Sample images from the pornography dataset.

V. Experiments and Evaluation

The experiments utilized a computer with an Intel Core™ i5-10500 CPU running at 3.10 GHz, 16 GB of RAM, the 64-bit Windows 10 operating system, and 2TB of hard disk space. The Keras deep learning system constructs deep learning models. This system leverages the capabilities of TensorFlow as its backend, which Google Colab provides. Colab provides approximately 25 GB of memory and a reversible graphics processing unit, depending on volume of data.

We utilize various statistical metrics to evaluate the classification performance, including precision, accuracy, recall, and F1 score.

$$\text{Accuracy} = \frac{TP + TN}{TP + FN + TN + FP} \tag{10}$$

$$\text{Precision} = \frac{TP}{TP + FP} \tag{11}$$

$$Recall = TP/(TP + FN) \tag{12}$$

$$\text{F1 score} = 2 \cdot \frac{\text{precision} \cdot \text{recall}}{\text{precision} + \text{recall}} \tag{13}$$

Accuracy measures the correctness of the model's predictions, while precision focuses on proportion of accurate optimistic predictions among all positive predictions. Recall, also known as sensitivity, assesses the model's ability to capture all positive instances. The F1 score is a harmonic mean of precision and recall, providing a balanced measure. These metrics collectively offer a comprehensive evaluation of our model's performance in various classification and localization tasks.

TABLE I. Comparison of Models and their Results on SARC Dataset

Model	Accuracy(%)	Precision(%)	Recall(%)	F1(%)
CASCADE [9]	75.00	-	-	0.75
SARC [19]	76.92	-	-	-
CSDM [26]	83	-	-	-
MHA-BiLSTM [27]	86	80	73	75
MHA-BILSTM [28]	-	72	83	77
Elmo-BiLSTM [29]	78.98	-	-	-
Multi-Head Attn [30]	82.01	0.79	0.81	0.89
Proposed Model	92.92	0.89	0.89	0.88

The SARC dataset, the largest of the three datasets, includes comments from the Reddit website. Previous studies primarily utilized attention processes and LSTM/Bi-LSTM as their primary tools, and Table I illustrates their results. On the other hand, the Bi-LSTM Encoder can learn from past and present sequences [25]. The Bi-LSTM encoder accurately grasps the context, ensuring precise classification. The Bi-LSTM is similar to a transformer, and the encoding stack performs better in context and is bidirectional. Our model, based on a large corpus from various domains, outperforms previous LSTM models. As a result, the recommended method generally classifies data efficiently, depending on the dataset's criteria, epoch, and training rate. In analyzing a dataset containing hostile memes, we compared the output of our model with that of various unimodal and multimodal models. Our model employs a sigmoid activation function, and the cut-off point for classifying as hateful or not is set at 0.5. Table II illustrates the validation and testing accuracies on the Hateful Memes dataset. The table provides a detailed comparison of different models and their performance, showcasing how each model's accuracy varies between the validation and testing phases. These results are crucial in understanding the effectiveness and reliability of the models in detecting and classifying hateful memes.

We observed that unimodal models often need to perform more satisfactorily. Furthermore, the unimodal text model outperforms the unimodal picture model, emphasizing the potential for including additional information in text characteristics. The pre-trained multimodal model does not show significant differences in the pre-training process for multimodal data.

The study presents the results in two ways: (i) by testing the performance of deep-learning models trained to identify superior performance and (ii) by evaluating the performance of transfer learning (TL) through the fusion of features and practical models. The testing accuracy (TA) and validation accuracy (VA) of each optimized deep learning model improve compared to models built using traditional methods by incorporating the Batch Normalization (BN) layer with a mixed pooling method. However, optimized deep-learning models consume significant resources compared to their standard counterparts. As the number of epochs increases, the TA and VA graphs depict variations in model outputs for the improved ResNet 101 model, VGG 19, AlexNet, and Xception models, as demonstrated in Fig. 11.

Table III presents the accuracies of optimized models on the NPDI Dataset and the pornography dataset.The DenseNet 169 model gives a TA of 95.71 percent on the NPDI dataset and

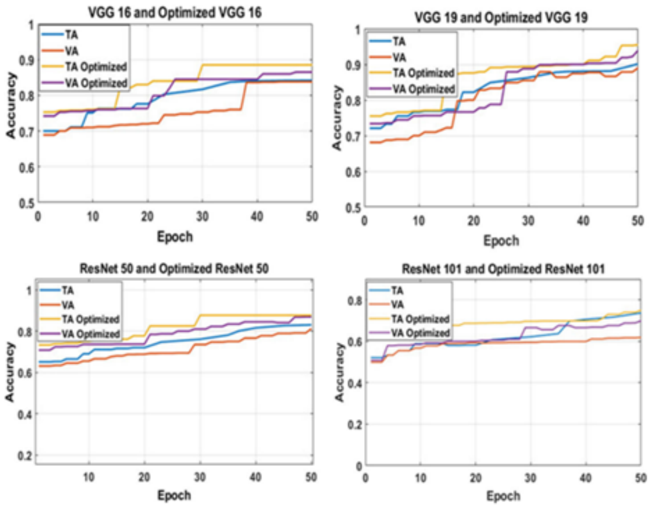

Fig. 11. TA of deep learning models on the NPDI Dataset and Pornography 2k dataset.

TABLE II. The Accuracy of Prediction for Different Models based on Hateful Memes Dataset.

Model	Validation	Test
Image-Grid	52.73	52.00
Image-Region	52.66	52.13
Visual BERT	62.10	63.10
Proposed Model	83.10	80.20

95.12 on the Pornography dataset, outperforming other models. The MobileNet V2 model followed closely, with 95.22 percent accuracy on the NPDI dataset and 95.31 on the Pornography dataset, and MobileNet V1 with 94.55 percent accuracy on the NPDI dataset and 92.65 on the Pornography 2k dataset. We selected the optimized versions of DenseNet 169, MobileNet V1, and MobileNet V2 as the most effective models.

After evaluating multiple pre-trained models, we chose the Optimized DenseNet and MobileNet V2 models as the best options for combining features. Fig. 12 and 13 display the results of utilizing fused functions with various models, such as MobileNet V1, MobileNet V2, DenseNet 169, and combinations thereof, for the classification task. We performed the classification using a fully connected TLP layer that fused functions and trained it using a newly trained module. Combined with the MobileNet V2 and TLP, the suggested model proves computationally less complicated and significantly improves testing accuracy over other examined techniques.

TABLE III. Testing Accuracy of Comparative Optimized Models on Various Datasets

Models	NPDI Dataset (%)	Pornography 2k dataset(%)
VGG16	91.60	91.70
VGG19	92.30	91.95
AlexNet	92.45	90.50
ResNet50	86.65	84.35
ResNet 101	74.45	72.65
ResNet 152	69.05	66.65
Xception	72.70	65.00
DenseNet 169	95.71	95.12
MobileNet V1	94.55	92.65
MobileNet V2	95.22	95.31

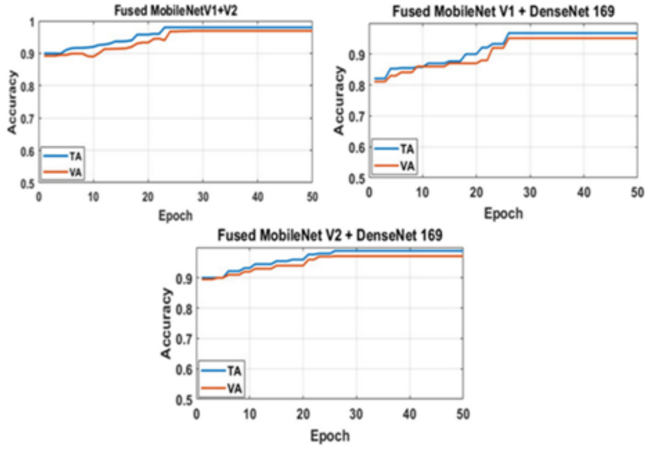

Fig. 13. TA of the proposed method with TL and feature fusion.

VI. Discussion

Several studies have explored the effectiveness of different models in detecting and classifying content across various modalities. For instance, modality [30] employed LSTM and GRU models to analyze text data, achieving a notable accuracy of 73% on tweets from Twitter and Reddit comments. In contrast, [31] utilized a multilayer perceptron model to analyze memes, incorporating both image and text modalities, and achieved an impressive accuracy of 87% on the MemeBank dataset. Moving to image-based detection, [32] employed an

RCNN model to analyze images and achieved high accuracies of 92% on the Pornography-800 dataset and 90% on the Pornography-2K dataset. Additionally, [33] focused on the YCBCr modality for image analysis and obtained a respectable accuracy of 76% on a random dataset of pornographic images. The proposed study emphasizes the importance of leveraging deep learning techniques to identify offensive content on social media platforms automatically. Additionally, the model utilizes TL with MobileNet V2 and DenseNet169 to enhance the identification of undesirable information on social media, surpassing existing models in performance.

VII. Conclusion

Our study demonstrates the potential and necessity of advanced automated systems to manage the growing influx of harmful content online. Our research has focused on developing models that can effectively identify offensive images and detect the nuanced nature of sarcasm in memes. The proposed model employs a bidirectional long short-term memory encoder to detect sarcastic memes and transfer learning for feature fusion to detect offensive images. The study presents the results of testing the proposed model on real-world datasets like The Hateful Memes Challenge, headlines database, and the Self-Annotated Reddit Corpus (SARC) and benchmark tests on NPDI and Pornography 2k. The model achieved high accuracies on these datasets, and the proposed transfer learning model incorporating MobileNet V2 and DenseNet169 was superior to existing models.

Log-Driven Conformance Checking Approximation Method Based on Machine Learning Model

Huan Fang, Sichen Zhang, Zhenhui Mei
School of Mathematics and Big Data, Anhui University of Science and Technology, Huainan, China, 232001

***Abstract*—Conformance checking techniques are usually used to determine to what degree a process model and real execution trace correspond to each other. Most of the state-of-the-art techniques to calculate conformance value provide an exact value under the circumstance that the reference model of a business system is known. However, in many real applications, the reference model is unknown or changed for various reasons, so the initial known reference model is no longer feasible, and only some historical event execution traces with its corresponding conformance value are retained. This paper proposes a log drivened conformance checking method, which tackles two perspective issues, the first is presenting an approach to calculate the approximate conformance checking value much faster than the existing methods using machine learning method. The second is presenting an approach to conduct conformance checking in probabilistic circumstances. Both kinds of approaches are from the perspective of no reference model is known and only historical event traces and their corresponding fitness can be used as train data. Specifically, for large event data, the computing time of the proposed methods is shorter than those align-based methods, and the baseling methods includes k-nearest neighboring, random forest, quadratic discriminant analysis, linear discriminant analysis, gated recurrent unit and long short-term memory. Experimental results show that adding a machine learning classification vector in the training set as preprocessing for train data can obtain a higher conformance checking value compared with the training sample without increasing the classification vector. Simultaneously, when conducted in processes with probabilities, the proposed log-log conformance checking approach can detect more inconsistent behaviors. The proposed method provides a new approach to improve the efficiency and accuracy of conformance checking. It enhances the management efficiency of business processes, potentially reducing costs and risks, and can be applied to conformance checking of complex processes in the future.**

***Keywords*—Conformance checking; fitness; log driven; machine learning; deep learning; probabilities**

I. Introduction

Process mining mainly extracts valuable process information from events. It is a supplement and innovation to business process management methods. Process mining is mainly composed of three parts, namely, discovery, conformance checking, and enhancement [1]. Conformance checking is designed to check the conformity of discovered process model with the event executions, so conformance checking value or fitness is used to describe the degree that the event execution conforms to the process model.

Two problems and two major challenges are encountered in conformance checking studies [2]. The two problems are described as follows: (1) Does the process execute the process model in the manner recorded in the model? (2) How much flexibility does the log trace allow in the execution of the process in the case of violation of the rules? The two challenges are described as follows: (1) How to improve the performance of conformance checking when the models and logs become larger? (2) How to balance between precision and deliberate vagueness?

For the two challenges, we do not need to obtain a specific value for conformance checking in several cases as long as we can acquire an approximate value to meet our needs. Therefore, studying efficient approximate consistency methods is important for large-scale log situations or situations where the reference model is unknown.

The state-of-the-art studies on conformance checking methods are mostly based on rule checking [20], token-based replay [7], and alignment [9]. The main starting points of these existing methods are based on the assumption that the process reference model is known. However, in some real cases, the process reference model is unknown for some reasons, such as some changing operations are introduced as software maintenance and business integrations. In such cases, the initial reference model is no longer suitable for current use, and the process reference model is not saved for further use in some other situations. Thus, considering how to efficiently measure conformance checking value only on the basis of historical event execution traces with the absence of the process reference model is crucial.

This paper proposes a new approach to calculate the conformance checking value through machine learning method from event logs. The designed method uses some machine learning and deep learning algorithms to calculate the approximate conformance checking value, and a collection of experiments is implemented. The results show two fold conclusions. On the one hand, our method provides an approximate one but quicker, specifically in large event data for the reason of introducing machine learning algorithm compared with the alignment method that usually provides a precise conformance value and takes long computation time. On the other hand, adding a machine learning classification vector in the training set can obtain an approximate conformance checking value with higher precision compared with the training sample without introducing the classification vector obtained by machine learning. Furthermore, a series of experiments were also conducted in probabilistic processes. A stochastic process miner was used to mine models from real event logs, and the generated stochastic process model was used to simulate event logs, which were then subjected to a series of variations. The real logs were compared with the simulated logs through a conformance check to obtain a conformance score, which was then compared with alignment methods. This approach does not require maintaining organizational process models but instead detects noncompliant process traces based on historical data. The results indicate that when considering probabilities, the conformance checking technique detects more inconsistent behaviors.

The remainder of this paper is structured as follows. Section II discusses related work. Section III reviews some basic concepts and notations. Section IV introduces the proposed method. Section V conducts experiments and analyzes the results. Section VI provides the conclusions and presents some future work.

II. Related Work

For the first question posed in the previous section of the conformance checking study is as follows: are the logs executed in the manner the model records it? The state-of-the-art research has provided relatively complete methods and conclusions. The early research of conformance checking is dedicated to determining whether a given process instance conforms to a given process model [3], [4], [5], that is, whether the process log conforms to the model is quantified through discrete values 0 and 1, where 0 indicates that the log does not conform to the process model, and 1 indicates that the log fully conforms to the process model. In [6], a recurrent neural network (RNN) is used to classify the traces in the log, where the discrete values 0 and 1 are used for classification. Some scholars aimed to provide diagnosis at the event log level, that is, to observe the extent to which the log instance violates the process model rather than simply providing a simple yes/no answer. This type of method usually assigns a value between 0 and 1 to quantify the degree to which the process log conforms to the process model. The larger the value, the higher the degree to which the process log conforms to the model, thereby solving the second problem of the conformance checking research. The method proposed in [7] can accurately point out where the deviations occur more frequently and the severity of process instances that do not conform to the process model. The early work of conformance checking is mostly based on token-based replay [8]. This technology replays each trace of the event log in the process model by executing tasks in accordance with the sequence of each event and by observing the process during the replay. The final state of the model can determine whether and to what extent the tracking actually corresponds to the effective execution sequence of the model. However, this method may be constrained by its dependence on the final model state, which might not capture all the subtle nuances of process deviations. Alignment was introduced in [9] and quickly developed into the mainstream of conformance checking technology, and many alignment-based extension methods were developed. The work in [10] proposed an incremental method to check the consistency of the process model and the event log. It may still face challenges when dealing with extremely large datasets. The work in [11] presented a conformance checking method based on multiperspective declarative, adding other perspectives, such as data or time for consistency testing, such as describing process behavior. Most conformance checking techniques using alignments provide an exact solution for fitness values. However, in many applications, having an approximation of the conformance value is sufficient. Specifically, for large event data, the computing time for alignments is considerably long by using current techniques, making them inapplicable in reality [12].

Some studies have investigated approximate consistency calculation methods. The work in [12] used subset selection and edit distance for conformance checking, thereby improving the performance of the conformance checking method compared with alignment. But the selection of subsets may ignore some key process behaviors. The work in [13] applied bound approximation guides for the selection of the relevant subsets of the process model behavior, further improving the approximate accuracy of the consistency calculation value. The work in [14] presented a statistical approach to ground conformance checking in trace sampling and conformance approximation. This type of method significantly reduces the running time while still ensuring the accuracy of the estimated conformance checking results, And the author has improved it in the latest work [15]. The work in [16] used the simulation behavior of the process model to approximate the conformance checking value. The simulation method generates a trace that is more similar to the behavior recorded in the event log and uses these simulated traces and edit distance functions to approximate the conformance checking value. The work in [17] developed an approximation method for calculating the fitness value by applying the relaxation labeling to the process partial order representation of the model. The work in [18] proposes a method to compute the alignment of logs to a reference process using trie data structures to improve efficiency through compact representation of process proxy behavior and attempts to reduce the search space. The work in [19] proposes an online approximate consistency detection method that clusters event logs and selects representative traces to construct support sets for consistency detection. However, the clustering quality directly affects the detection accuracy.

III. Preliminaries

In this section, we give a brief introduction to basic process mining, especially the conformance checking terminology and notation that can improve the readability of this paper.

A. Log Trace and Log

An event trace (or event executions) over an alphabet of activity names $\varSigma$ is a finite word $\sigma \in \varSigma^*$ that corresponds to an event sequence. A log is a collection of log traces.

Denoting $L = \{\tau_0, \tau_1, \tau_2, \cdots, \tau_n, \}$ as an event log, and τ_i as a log trace. Each event in the process is recorded in a trace, that is, $\tau = \{e_1 e_2 e_3 \cdots e_n\}$. $len(\tau)$ indicates the number of cases recorded in the trace, and $\tau(j)$ indicates the $j-th$ event in τ.

As shown in Table I, 6676 event traces constitute log L, $\langle A, C, G^7, H, D, F, I\rangle$is an event trace in L, and $\varSigma = \{A, B, C, D, E, F, G, H, I\}$ is the set of activities corresponding to events. The labels 0 and 1 denote the a binary output.

B. Classification Learning Method

1) Quadratic Discriminant Analysis (QDA): The idea of QDA classification is to first construct a discriminant function F and use it to determine the decision boundary between classes. The discriminant function F is used to establish the

TABLE I. AN EVENT LOG EXAMPLE

ID	Event sequence	label
1	$\langle D, B, D, E, I \rangle$	0
2	$\langle A, C, D, A, C, F, I \rangle$	0
3	$\langle A, C, B, H, F, I \rangle$	0
4	$\langle A, C^4, D, G, F, I \rangle$	0
......	......	......
6673	$\langle A, C, G^7, H, D, F, I \rangle$	1
6674	$\langle A, C, G^7, D, H, F, I \rangle$	1
6675	$\langle A, C, G^7, D, G, F, I \rangle$	1
6676	$\langle A, C, G^8, D, F, I \rangle$	1

decision boundary for distinguishing different categories into different regions [21].

Assuming that the data follow the Gaussian mixture model, the observations in the category conform to the multivariate Gaussian distribution of mean and covariance, that is,

$$x \in C_i \Leftrightarrow x = \mu_i + \textstyle\sum_i^{1/2} z,\ with\ z \sim N(0, I_p) \tag{1}$$

where I_p represents the size of the $p \times p$ unit matrix.

Let $\pi_i,\ i \in \{0, 1\}$ denote the prior probability that x belongs to class C_i. The classification rules related to QDA classifier are given as (Eq. 2).

$$W^{QDA}(x) = -\frac{1}{2}log\frac{|\Sigma_0|}{|\Sigma_1|} - \frac{1}{2}x^T(\sum_0^{-1} - \sum_1^{-1})x + x^T\sum_0^{-1}\mu_0$$
$$-x^T\textstyle\sum_1^{-1}\mu_1 - \frac{1}{2}\mu_0^T\sum_0^{-1}\mu_0 + \frac{1}{2}\mu_1^T\sum_1^{-1}\mu_1 - log\frac{\pi_1}{\pi_0} \tag{2}$$

The number of training observations for each class $C_i,\ i \in \{0, 1\}$ is denoted as $n_i,\ i \in \{0, 1\}$, and $T_0 = \{x_l \in C_0\}_{l=1}^{n_0}$ and $T_1 = \{x_l \in C_1\}_{l=n_0+1}^{n_0+n_1}$ are used to represent their respective samples.

$$\widehat{\mu_i} = \frac{1}{n_i}\textstyle\sum_{l \in T_i} x_l,\ i \in \{0, 1\} \tag{3}$$

$$\widehat{\Sigma_i} = \frac{1}{n_i - 1}(x_l - \widehat{\mu_i})(x_l - \widehat{\mu_i})^T,\ i \in \{0, 1\} \tag{4}$$

$$\begin{cases} x \in C_0, if\ W^{QDA} > 0 \\ x \in C_1,\ otherwise \end{cases} \tag{5}$$

2) AdaBoost: AdaBoost [22] is a popular integrated learning technology due to its adaptability and simplicity. AdaBoost has been successfully extended to the field of pattern recognition, computer vision, and has been used in many fields, such as two class and multiclass scenes. The main idea of AdaBoost is to build a series of weak learners by using different training sets, which are obtained by resampling the original data. These learners are combined through weighted voting to predict the class label of the new test instance.

3) Long Short-term Network (LSTM) network: LSTM network is an improvement of RNN [23], which effectively solves the gradient disappearance and gradient explosion of RNN by adding a gate structure. The LSTM network is widely used in time series forecasting and has been utilized in process monitoring and forecasting in recent years.

4) Gated Recurrent Unit (GRU): The GRU network is a variant of the LSTM network [24], which combines the forget gate and the input gate in the LSTM network into one gate, which is called the update gate. It has two door structures, the update door and the reset door. The update gate is used to determine the degree of retention of the state information at the previous moment in the current moment of learning. The larger the update gate value, the greater the degree of retention. The reset gate is used to control the degree of combination between the state information at the previous moment and the state information at the current moment. The larger the reset gate value, the greater the degree of combination. A simplified GRU network maintains the LSTM effect, has a simpler structure, fewer parameters, and a better convergence model.

C. Regression Learning Method

1) Light Gradient Boosting Machine (LGBM): Light GBM is a gradient boosting framework originally developed by Microsoft and uses a tree-based learning algorithm. Its main idea is to use weak classifiers (decision trees) for obtaining the optimal model through iterative training. This framework has good training effect, difficult overfitting, and is widely used to solve regression problems.

2) Random forest: Random forest is an ensemble learning method for classification and regression [25]. It runs by constructing a large number of decision trees during training. The random forest regression model is a model obtained by synthesizing the results obtained from several established decision tree models, and the final prediction result is obtained by averaging the prediction results of all decision tree models.

D. One-hot Encoding Method

One-Hot encoding, also known as one-bit effective encoding, mainly uses N-bit status registers to encode N states. Each state has its own independent register bit, and only one bit is valid at any time. One-hot coding represents the categorical variables as binary vectors.

IV. LOG-DRIVEN APPROXIMATE CONFORMANCE CHECKING VALUE CALCULATION METHOD

A. Method Framework

The method proposed in literature [6] has some commonalities with this paper in that they are based on classifying logs and error logs to obtain the conformance checking values. The difference is that the values in literature [6] use RNN methods for classification to obtain global accuracy and recall between logs and models, whereas our proposed method obtains the approximate conformance checking values for each trace in the logs. In this paper, we propose a method to approximate the conformance checking values by using machine learning. The results are improved by adding an intermediate vector for the classification to the original data's method for fitting.

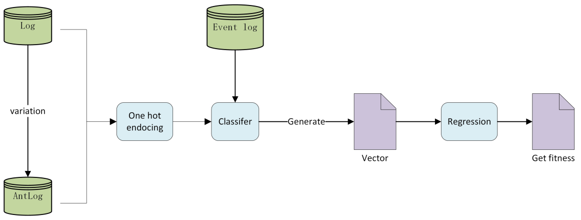

Fig. 1. Overall implementation framework of the proposed method.

Fig. 1 shows the overall framework of the proposed method proposed. In accordance with the existing event log and its consistency training samples, the traces in the log are divided into "correct traces" and "error traces," and label values of 1 and 0 are assigned, respectively. The two types of trace data are preprocessed. For simplicity of expression, the set of "correct traces" is recorded as Log, and the set of "error traces" is recorded as Antilog. To better maintain the order relationship of the traces in the log, this article uses one-hot encoding to process all the traces. The use of GRU, LSTM, k nearest neighbor, Gaussian process, decision tree, random forest, AdaBoost, and QDA learning with algorithms, such as LDA, can obtain the classification accuracy of the "correct trace" and "wrong trace" in the log. On the basis of the classifier, the approximate value of the consistency is further obtained.

Let all gather event executions as set $L = \{L_T, L_X\}$, where L_T denotes the trace set that all event execution trace in it have conformance checking value between 0 and 1, and L_X denotes the trace set that all event trace in it have no conformance checking value.

B. Metric Method

In this paper, the accuracy [26] is used to evaluate the classification algorithm, and the conformance checking value of fitting is measured in terms of mean absolute error (MAE), mean square error (MSE), and R-squared [27]. The related evaluation index calculation methods are expressed as Eq. (6), (7), (8) and (9).

For binary classification problems, the samples can be divided into true positive (TP) in accordance with their true categories and the predicted categories of the classifier. The true category and the predicted category are positive examples. False positive (FP): The true category is negative, and the predicted category is positive. False negative (FN): The true category is positive, and the predicted category is negative. True negative (TN): The true category is a negative case, and the predicted category is a negative case. The accuracy rate is calculated, as shown in Eq. (6).

$$accuracy = \frac{TP + NP}{TP + TN + FP + FN} \tag{6}$$

y_i is the true value of the $i-th$ sample, and $\widehat{y_i}$ is the observed value of the $i-th$ sample.

The MAE is used to measure the average value of the absolute difference between the predicted value and the true value. The smaller the MAE, the better the model. The calculation method is shown in Eq. (7).

Algorithm 1: Conformance checking value approximate calculation method

```
Input: log $L = \{L_T, L_X\}$, $Fit = \{c_i \mid c_i \in [0,1] \wedge$
        $c_i = fitness(\pi_i) \wedge \pi_i \in L_T\}$
Output: the fitness value of each trace in the trace set
        $L_x$.
Procedures:
Step 1: In accordance with the fitness value in $Fit$, if
  the fitness value of a trace is less than 1, then mark
  its classification label as 0, else if the fitness value
  equals 1, then set its classification label to 1.
Step 2: The traces in $L$ are processed by using
  one-hot encoding and machine learning algorithms. k
  nearest neighbor, decision tree, random forest, and
  QDA are used to classify the traces in accordance
  with the labels in step 1.
Step 3: Perform one-hot encoding on the trajectory in
  $L$, and use the LSTM and GRU deep learning
  algorithms to classify in accordance with the label in
  step 1, where the coding of each activity is inputted
  into each time step.
Step 4: Use the classification model with the highest
  score in Steps 2 and 3 (known as the QDA
  algorithm), and apply the classification model to all
  the trajectories in L to obtain the classification
  vector.
Step 5: Add the classification vector to the original
  data.
Step 6: Use regression algorithm to fit and obtain the
  fitness value of each trace.
```

$$MAE = \frac{1}{n}\sum_{i=1}^{n} |(y_i - \widehat{y_i})| \tag{7}$$

The MSE represents the average of the squared difference between the original value and the predicted value in the data set. It measures the variance of the residuals. The smaller the value, the better. The calculation method is shown in Eq. (8).

$$MSE = \frac{1}{n}\sum_{i=1}^{n} (y_i - \widehat{y_i})^2 \tag{8}$$

R-squared represents the coefficient of the degree of fit between the predicted value and the original value. The larger the value, the better the model. The calculation method is shown in Eq. (9).

$$R^2 = 1 - \frac{\sum_{i=1}^{n} (\widehat{y_i} - y_i)^2}{\sum_{i=1}^{n} (\bar{y} - y_i)^2} \tag{9}$$

C. Probabilistic Log-Driven Stochastic Process Conformance Checking

First, using the stochastic process miner from the [34] and the Prom tool, a probabilistic stochastic process model was mined from the real event log L. Then, the generated model was simulated using Pm4py to produce event logs, which underwent a series of variations to obtain the simulated event log $L^{'}$. The real event log L and the simulated event log $L^{'}$

were then subjected to a Log-Log conformance check using the method from the [35] to obtain the conformance value. The specific steps are as follows:

```
Algorithm 2: Probabilistic log-driven stochastic process conformance checking

Input: Event log $L$, $L'$
Output: $L - L'$ conformance score
Procedures:
Step 1: Mine a probabilistic stochastic process model
    $M$ from the real event log $L$.
Step 2: Use the Pm4py tool to simulate event logs
    using $M$, and apply a series of variations (including
    some traces that do not conform to the model) to
    obtain the log $L'$.
Step 3: Compute the reallocation matrix for $L$ and $L'$.
Step 4: Compute the distance matrix for $L$ and $L'$.
Step 5: Calculate the $L - L'$ conformance score
    based on the reallocation matrix and distance matrix
    of $L$ and $L'$.
```

V. Evaluation

A. Artificial Log Acquisition and Preprocessing

No benchmark case library can be used for the calculation and evaluation method of the approximate conformance checking value based only on logs. Therefore, this paper adopts the following methods to generate the associated manual integration log. A process is customized by using the Petri net model SN, and then the token replay technology in pm4py library [28] is used to generate the "correct traces" set (Log) that conforms to the process model for the process model SN. We then mutate these traces to make them noncompliant with the process model "error traces" set ($Antilog$) and use the alignment technology in pm4py to calculate the consistency value of each trace with respect to the model. These traces and their fitness are used as the data set of the experimental work in this paper.

This paper obtains two real event case datasets from the public datasets, a real event log of a sepsis case [29] and a real event log of the information system for managing road traffic fines [30]. No traces in these real logs that do not conform to the real process model. Therefore, we first use the mining algorithm to obtain a model of real logs and then use the real model to simulate real logs as the dataset for the experimental work.

Fig. 2, 3 and 4 show the three Petri net models used in this paper, respectively. This paper uses the models in Fig. 2, 3 and 4 to generate $Log1$, $Log2$, and $Log3$, respectively. The three models contain different loops and concurrent behavior that can be used to test the applicability of the proposed method to various behavior. As shown in Table I, the set of "correct trace" and "error trace" is generated by model 1. Given that cycles are found in the model and generating all traces is impossible, we categorize the log into two disjoint parts, which are $L_{=K}$ and $L_{<K}$, where $L_{<K}$ denotes the completeness log set under the k constraint, that is, the trace length is k, and $L_{<K}$ contains all traces of the model that have length less than k.

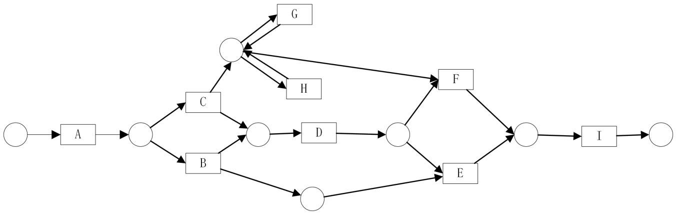

Fig. 2. Petrinet model SN1.

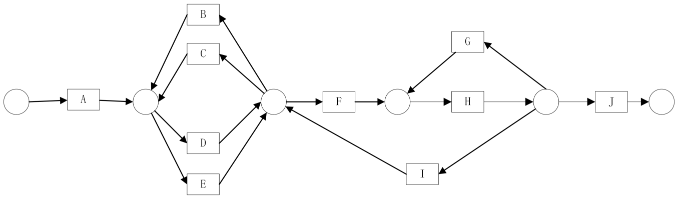

Fig. 3. Petrinet model SN2.

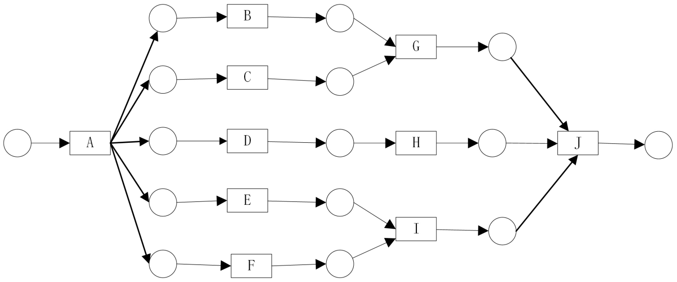

Fig. 4. Petrinet model SN3.

B. Practical Logs

The experiments implemented here uses five different types of event logs, three of which are manually generated logs (named Log1, Log2 ,and Log3 produced in last section), and the other two are real event logs (named sepsis and road fine). The data presented in this study are openly available in at https://pan.baidu.com/s/1TFEobiqrXTWjQF4R-cLHwQ (extract code: aidw).

Taking $Log1$ for an example. As shown in Table I, the first log contains 6667 different traces. Its consistency is marked as 1 and 0 in accordance with whether the trace conforms to the process in the data. The detailed information of the five logs is shown in Table II.

C. Classification Result Analysis

We selected two types of learning algorithms for classification experiments, which are deep learning algorithm and machine learning algorithm. The use of machine learning and deep learning methods require different processing of the generated logs. To better preserve the sequence relationship in the logs, we perform one-hot encoding on the log.

The traces in $Log1$ (Table I) are taken as an example. $Log1$ has a total of nine activities, and the longest trace length is 18. The length of trace $\langle D, B, D, E, I \rangle$ is 5. In the procedure of one-hot encoding, the character "0" is filled to make the trace with a length of

TABLE II. Information about the Five Logs

Log	Completeness	Num. activities	Max. case length	Min. case length	cases Normal	cases Deviant
Log1	true	9	18	1	4098	2578
Log2	true	10	20	1	4862	4005
Log3	true	10	15	1	2240	2025
Sepsis	false	16	14	3	41143	17397
Road fine	false	11	14	3	21868	11378

18, that is, $\langle D, B, D, E, I, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0\rangle$ after filling. One-hot encoding is performed for each activity of the trace. Given that 10 elements are found in the activity table $[A, B, C, D, E, F, G, H, I, 0]$, each element of the activity table can be represented by 10 bits. For example, A is represented by $[1, 0, 0, 0, 0, 0, 0, 0, 0, 0]$, and B is represented by $[0, 1, 0, 0, 0, 0, 0, 0, 0, 0]$, and similar means for other elements. Therefore, each trace is filled as a vector of 180 dimensions. The trace $\langle D, B, D, E, I, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0\rangle$ is represented by a 180 bit as $[0, 0, 0, 1, 0, 0, 0, 0, 0, 0, 0, 1, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 1, 0, 0, 0, 0, 0, 0 \ldots\ldots\ldots\ldots 0, 0, 0, 0, 0, 0, 0, 0, 0, 1]$.

For deep learning, we directly use the encoded vector, each trace has a label, and each activity is inputted into the LSTM and GRU as an event step. We use LSTM and GRU for classification experiments, which are different from [6]. Our training data have more variables than [6], and the length of the trace is longer than that used in [6]. RNN specializes in processing time series data. The disadvantage of RNN is that it cannot handle long-term dependencies, whereas LSTM and GRU can handle long-term dependencies well. We use the LSTM and GRU network in Pytorch library [31] for training. For machine learning, we use the PCA dimensionality reduction algorithm to reduce the dimensionality of the data after one-hot encoding and then we use several typical methods, such as random forest, secondary discrimination, decision tree, and k nearest neighbors. These algorithms are integrated into the sklearn library [32] in Python and can be easily used. The supposed framework is shown in Fig. 5.

In this paper, we conduct two type of experiments. In the first experiment, we perform a classification experiment on three different logs. These logs are divided into two categories. The first category is in line with the process model and is marked as 1. Another type of log that does not conform to the process model is marked as 0. We use machine learning and deep learning methods to classify these data, so we can obtain a classification method with a higher accuracy score.

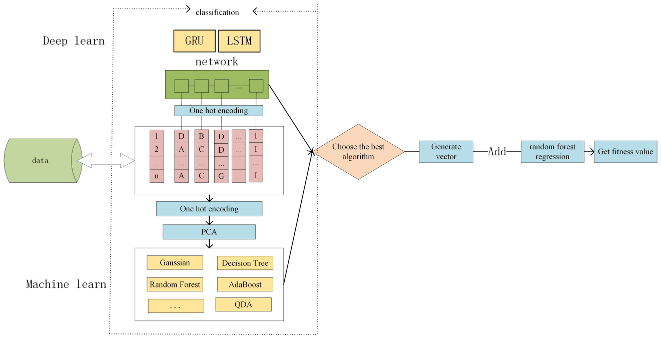

Fig. 5. Supposed framework.

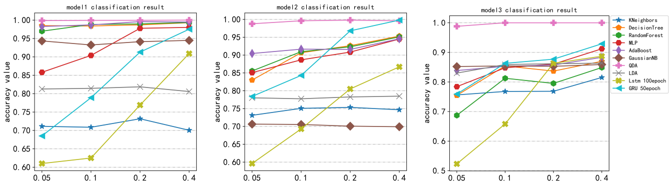

Fig. 6. Comparison of the classification accuracy of various methods.

In the second experiment, we use the method with the best classification effect in experiment 1 to process the log and obtain the classification vector of each trace in the log. The classification vector and the original trace vector are used to fit the fitness, so that we can obtain a good fitting effect.

In the classification experiment of different labels, for three different logs, we divided the training set of 5%, 10%, 20%, and 40%, and the rest is the test set. Fig. 6 shows the classification results under 5%of the training set. We use a line chart to easily observe the effect of the classification model. The QDA classification method has the highest accuracy by observing the different classification methods in Fig. 6 for the three different log classification results. It can obtain 99% accuracy under 5%of the training set, and the QDA method is better than the method ranked as second. The classification accuracy is higher, indicating that the QDA method can better classify the logs generated by the Petri net structure. Therefore, we use the QDA classifier to generate a classification vector for the classification to fit the conformance checking value. The vector is added to the PCA dimensionality reduction vector, and then the fit method is used to fit the fitness value, as shown in the next section.

The experimental results in Fig. 6 show that using QDA to classify data can obtain higher classification accuracy. Therefore, the probability generated by the decision function of QDA classification is added to the data as a classification vector for fitting.

D. Analysis of Fitting Experiment Results

This experiment is divided into two groups. The experimental results of fitting the data without the classification vector are used as a control, and the consistency calculation of data after adding the classification vector is analyzed specifically. In the experiment, 60% of the three artificial log samples are used as the training set, and the remaining 40% are used as the test set. To evaluate the fitting effect, we use three fitting metrics: MSE, MAE, and coefficient of determination (R^2).

The experimental results of the three different logs are shown in Fig. 7, 8 and 9. In the three different logs, the fitting effect of the various measurement methods after adding the classification vector is significantly improved than the one without adding the classification vector. The R^2 score of log1 added to the classification vector is 2 percentage points higher than that of the unadded vector, and log2 is 4 percentage points higher. The other two measurement methods have different degrees of improvement, showing the superiority of the proposed methods.

This work compares the conformance checking technology based on token replay in [33] and the proposed method to evaluate their differences. We still use MAE, MSE, and R^2 metrics to evaluate and calculate the difference between the proposed method and the alignment, and the difference between [33] and the alignment separately. We can obtain a better approximation effect than the consistency of [33] when we use the proposed method to train the training set of 5% manual logs. The comparison between the proposed method and the method in [33] on the synthetic log results is shown in Fig. 10. The comparison between the proposed method and the method in [33] on the real log is shown in Fig. 11. The proposed method is found to obtain lower MAE and MSE than the method in [33] on real and synthetic logs for 5% of the training set and obtain higher R^2 scores. Our method is slightly less effective than the artificial logs for real logs because the artificial logs are complete logs and the real logs are noncomplete logs. Our method cannot learn more behavior from fewer training logs. After evaluating different artificially generated and real event logs, we verify that the proposed method can be used to evaluate the consistency of other traces in the logs when the consistency of some traces in the logs is known and can be closer to the consistency with the real ones than other methods.

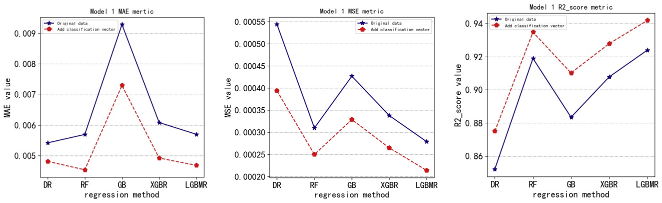

Fig. 7. Fitness for Model 1, PCA=40.

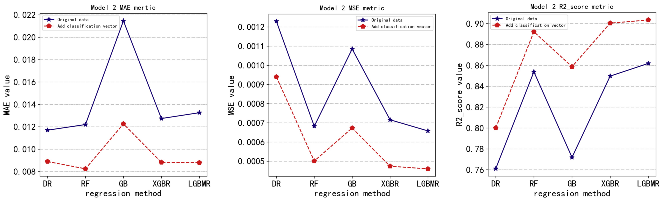

Fig. 8. Fitness for Model 2, PCA=40.

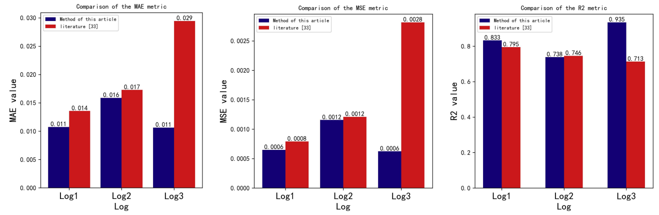

Fig. 10. Comparison of manual event log results.

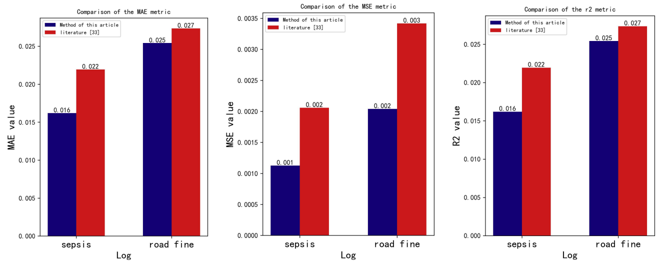

Fig. 11. Comparison of real event log results.

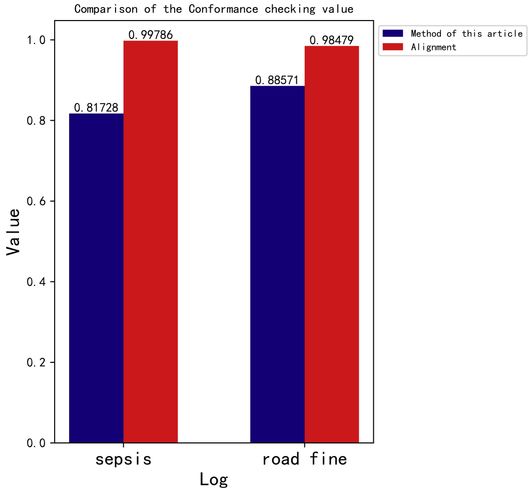

Fig. 12. Comparison of real event log Conformance checking results.

Probabilistic log-driven stochastic process conformance checking results are shown in Fig. 12. As seen in the figure, the results calculated using the probabilistic conformance checking technique may detect more inconsistent behaviors, resulting in a lower conformance score.

VI. Conclusion and Future Work

In this paper, we propose a novel method to calculate the trace approximate conformance checking value based on logs The proposed method integrates traditional machine learning in obtaining conformance checking, thereby enabling the calculation of the trace conformance checking value without a systematic reference model and extending the breadth of existing studies. It provides a new approach to improve the efficiency and accuracy of conformance checking, reducing the difficulty of conformance verification in complex processes, enhancing the management efficiency of business processes, and potentially lowering costs and risks. However, this method has some limitations. The proposed method belongs to supervised learning. The fitness of the training samples must be determined in advance to perform related machine learning and fitting operations. Therefore, the format of the data set has certain requirements. No enterprise-level, large-scale benchmark case library is used at present.

The proposed machine learning calculation method for the approximate conformance checking value can be further applied to change mining and business process prediction and monitoring. As the business system progresses over time, many changes, such as software maintenance, business fusion, and other factors, are inevitably introduced. Detection of log behavior deviation and verification through machine learning and deep learning without a reference model are necessary. Therefore, machine learning and deep learning will be used to detect the behavior changes of logs in future studies. Related analysis and discussion are important branches in the study of process mining, and they are future extension of the work in this paper.

ACKNOWLEDGMENT

This work was supported by the National Nature Science Foundation of China (No.61902002), and the National Key R&D Program of China (Nos. 2023YFC3807500 and 2023YFC3807501).

We also gratefully acknowledge the helpful comments and suggestions of the reviewers, which have improved the presentation.

***Abstract*—This paper is focusing on the problem of the time taken by different algorithms to search data in a large database. The execution time of these algorithms becomes high, in the case of searching data in a non-redundant data, distributed in different database sites where the research consists of reading on each site for finding data. The main purpose is to establish adapted models to represent data in order to facilitate data research. This paper describes a classification of spatial data using a combination of k-means algorithm and voronoï diagram to determine different clusters, representing different group of database sites. The advantages of classification is made through the k-means algorithm that defines the best number and the centers of required clusters and voronoï diagram which gives definitely the delineation of the area with margins, representing the model of organizing data. A composition of K-mean algorithm followed by voronoï diagram has been implemented on simulation data in order to get the clusters, where future parallel research can be realized on different cluster to improve the execution time. In application to e-health in GIS, a best distribution of medical center and available services, will contribute strongly to facilitate population well-being.**

Keywords*—*Classification; K-means; voronoï diagram; GIS; big data; data research

I. Introduction

Data research is often made through different requests submitted to the database. The problem of data research become complex in the context of multi database not-connected, distributed in several sites, having big data. For instance, in the structure of a spatial database, where each GIS position corresponds the localization of a database site with big data, the execution time of data research will depend on the number of database site.

Classification is necessary to organize data in order to facilitate data research. The criteria of classification define requirements that must be respected to put together the data in the same cluster. The application of criteria could lead to have partitions, called clusters to store data. Each cluster contains similar elements regarding to criteria definition. Many techniques of Classification have been proposed by different scientists. For instance, Koperski et al. in [8] have proposed an efficient two-step method for classification of spatial data.

There are also supervised classification and unsupervised classification. Supervised classification consists of labeling the dataset and assigning a new data to a pre-existing class. K-nearest neighbors (KNN), decision trees, neural networks, support vector machines(SVN) and Bayes classifiers are supervised classification. For. Instance, Karem et al. in [2] used a supervised classification to study the theory of believing fonction. Kessler et al. in [6] applied neural network to classifier mails.

Unsupervised classification consists of finding a group in unlabeled dataset for a new observation. K–means, K–meloïd, hierarchical classification are unsupervised classification. For instance Kodinarya et al. in [4] have realised a review on determining number of cluster in k–means clustering. Sinaga et al. in [5] proposed unsupervised k–means clustering algorithm.

Meshing space could lead to supervised classification or unsupervised classification. Regular grid or irregular grid are meshing technique. Bottela et al. in [7] generated a mesh for modeling simulation for physique phenomene. Duchaine in [9] also generated a structured mesh kriging with local elliptical refinement. Antoine Vacavant in his thesis, proposed a survey on regular and irregular grids that could be considered as supervised classification.

The initial works of Sere et al. in [1] impose artificial meshing on data that leads to empty clusters used for the map-reduce algorithm. The size of clusters does not take into account the number of data inside.

Our purpose is to reduce the execution time of data research algorithms, in building a model of data structure with relevant clusters. The achievement of this purpose will lead to avoid many artificial clusters and to remove empty clusters.

Our hypothesis is that an adequate model of data structure will contribute to reduce the execution time of data research.

This paper follows and extends the initial works in [1], to explore the combination of k-means clustering and voronoï diagram successively on simulation data, as an alternative to create a model for data structure : the outputs of k–means clustering with different centers are the inputs of voronoï diagram algorithm to get definitely clusters.

The proposed method could be applied to the data set in e-health, representing data related to the sites of pharmacies with drugs characteristics or medical centers. More others fields are concerned with applications, as to find the nearest vehicle seller, the nearest security station in a region.

This paper is organized as follows: Section 2 presents the state of art with classification techniques. Section 3 describes the method while Section 4 shows the results of implementation.

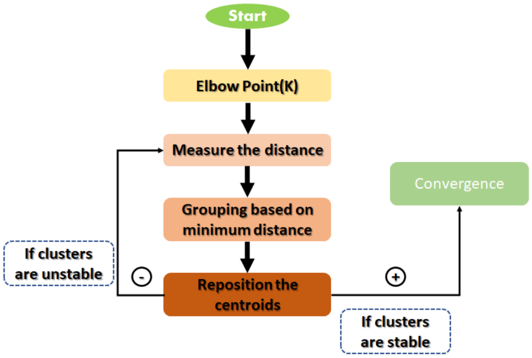

Fig. 1. K-means algorithm.

II. Preliminary

A. Problem Statement

The pharmacies of the city of Ouagadougou have databases within their premises which store the name, the quantity of stock and the price of each product. They are located in different districts. We do not know in its various pharmacies which ones have more influxes. The establishment of a new pharmacy is done without optimization. The acquisition of products is still archaic because the user must always go to a pharmacy before obtaining information on the stock of the product he is looking for. We have developed in our master's thesis and in the article SERE and Al [1], the parallel search for a datum d in several spatial databases by prioritizing the closest database. If we assume B the set of databases of all pharmacies in Ouagadougou and B_i the database associated with each pharmacy with B= $\{B_1, B_2, ..., B_n\}$; we are dealing with a large volume of data commonly called big data.

Our study consists in optimizing the classification of the different cluster pharmacies and the meshing of the clusters obtained for a better spatial distribution of the pharmaceutical sites and better search results.

B. K—means

The k-means algorithm, proposed by MacQueen (1967), is an aggregation technique around mobile centers [10]. The principle in [11] is to place the k chosen points in the space represented by the individuals to be classified. These k points go formerly the first centers of the different clusters. In addition, the barycenter of each cluster is calculated. Finally, the individuals are reassigned according to the proximity to the new center Fig. 1.

C. Mesh Techniques

A mesh is a partition of space or a domain into a set of elementary cells that have coordinates, dimensions and information on the connectivity relationship between its cells (vertices, edges, faces, volume). Bastian and al in [17] used the connectivities for the implementation of a c++ algorithm that generates quadrilateral meshes. Consider a bounded domain noted D of $\mathbb{R}^2$ and $\mathbb{R}^3$, P_h is a mesh of D if:

- $D = U_{K \in P_h} K$
- The interior of any element K of P_h is no empty
- The intersection of the interior of two elements is empty.

There are tree types of mesh as structured, unstructured and hybrid presented in [9].

1) Structured Meshes: Consider any bounded domain noted Q to which a mesh has been applied. The mesh of the domain Q is said to be structured if and only if from a single one of its meshes it is possible to reconstruct the whole identical mesh. It is characterized by a cell that repeats itself identically and ordered in [3], [9].

2) 1D mesh: The mesh is carried out on the right of the abscissa whose domain is a segment [AB] in Fig. 2. This segment is partitioned into m cells with a constant pitch C which is equal to $\frac{B-A}{m}$. Then $X_1 = A, X_{i+1} = X_i + C$ and $X_m = B$ with $i = 1, 2 \ldots m$.

The relationship $X_{i+1} = X_i + C$ expresses the connectivity link between two cells.

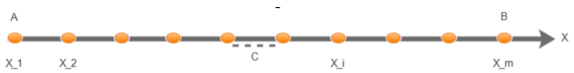

Fig. 2. 1D mesh.

3) 2D mesh: For a rectangular domain (a, b) x (c, d) we have:

- $X_1 = a, X_i + 1 = X_i + C$ with C the pitch of the mesh in the direction X; $C = \frac{b-a}{m}$ and $i = 1, 2...m$
- $Y_1 = a, Y_j + 1 = Y_J + K$ with K the pitch of the mesh in the Y direction; $K = \frac{b-a}{m}$ and $j = 1, 2 \ldots m$
- Cartesian and polar mesh (cylindrical and spherical in 3D)

This mesh is composed of pairs of transverse lines which intersect at the nodes of the mesh and a cell which is repeated with the same number of nodes around a vertex. Each node is obtained thanks to the coordinates (i, j) formed by the indices of the transverse lines. The decrementation and/or the incrementation of the coordinates (i, j) of a node makes it possible to locate its neighbors. Then the incrementation and the decrementation constitute the relations of connectivities between the different cells.

The structured mesh reveals its weaknesses when it comes to the meshing of a domain and its borders. Moreover one cannot control neither the form nor the distribution of the cells in the field, one cannot either mesh according to the simulated phenomenon. To make up for this shortcoming, we are going to switch to the unstructured mesh.

4) Unstructured meshes: The mesh of an unstructured bounded domain Q is characterized by unordered cells and all its cells are not identical [9]. Owen described the majority of unstructured meshes which we summarize in [3].

After the generation of the mesh algorithms necessarily comes the step of improving the overall quality of the elements.

The two types of mesh enhancement smoothing and cleaning developed by Owen in [3].

- Smoothing is the adjustment of nodes without any change in connectivity between elements.
- Cleaning is the adjustment that modifies the connectivity of the elements.

Bastian and al in [17] presents an unstructured quadrilateral meshing algorithm that generates the mesh by recursively subdividing domains.

5) Hybrid meshes: it is a mesh that combines both structured and unstructured elements. source [9]

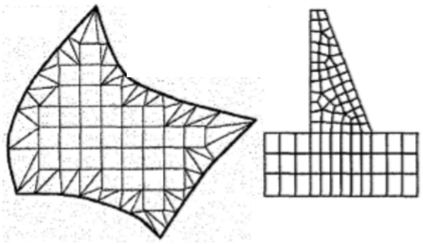

Fig. 3. Hybrid mesh.

6) Description of the Voronoï-Delaunay mesh: Johann Peter Gustav Lejeune Dirichlet in [13] introduced the Voronoï diagram in 1850, which is how a given domain could be systematically decomposed into a set of compact convex polygons. Georgy Voronoï in [16] formalized this notion in the general case in 1908.

Definition 1: Voronoï diagram [12], [14], [15]: Let P be a set of points p$_i$ such that $1 \leq i \leq n$. Let E be a Euclidean vector space such that $P \in E$. Consider a point among the n points of P and denote the p$_i$. Let us delimit the space which gathers all the points of E which are closer to p$_i$ than the rest of the points of P. This delimitation forms a cell called the Voronoï cell of the point p$_i$ and is denoted C$_i$. In the cell C$_i$ all the points of E are closer to p$_i$ than the rest of the points of P. Let p$_i$ be the set of points of P except p$_i$ and q the set of points of C$_i$ we have: $d(q, p_i) \leq d(q, p_j)$; the point p$_i$ is called the germ of the cell C$_i$.
Next, take another point of P and delimit its corresponding Voronoï cell. Let us do the same for all the points of P. We note that the space E is subdivided into cells C$_i$ associated with the points p_i with $1 \leq i \leq n$. This subdivision of space E into cells C$_i$ associated with points p$_i$ with $1 \leq i \leq n$ is called Voronoï diagram and is denoted Vor(P). Note that the union of cells C$_i$ is equivalent to the Voronoï diagram of P: $Vor(P) = U_{pi \in P} C_i$ The boundary between two cells is called the Voronoï edge and is halfway between the two seeds corresponding to the two cells in 2D, it is a segment of the perpendicular bisector of the line joining these two seeds.
Drawing:
Case 1: two cinemas A and B are at different positions. From my position, if I want to go to the nearest cinema, it is in my interest to head towards a Fig. 4.

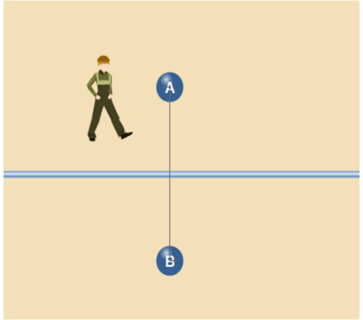

Fig. 4. Closest distance between two sites.

If all the pairs of points that have an edge in common are connected by straight lines, the result is a triangulation within the convex hull of the set of points $\{Pi\}$. This tessellation is known as the Delaunay triangulation in [12], [14], [15].

There is a particular similarity between the k-means classification and the space mesh with the voronoï diagram. The synthesis of the two methods could be a basis for the grouping and distribution of sites in clusters in order to organize the distribution of data in space and to facilitate their search.

III. Method Description

Pharmacies in Ouagadougou are located in the different districts with the aim of bringing their services closer to beneficiaries. This requires a good distribution or network of sites in the locality while projecting the coverage of users by each pharmacy. Pharmaceuticals are widely diversified. Thus it is difficult or even impossible for a pharmacy to have all types of products in stock. Consequently, users must go to other pharmacies for cases of missing product. To do this, we are going to classify the pharmacies into clusters to guide users to search for products first in the cluster in which they are housed, then in the nearest neighboring cluster in the event that they have not obtained all of their products within their cluster.

Our objective is to optimize the distribution or meshing of sites in space, to classify them into groups or clusters in order to facilitate the search for a service according to the position of the user in relation to the different groups of sites. To do this we will make a synergy between the k-means algorithm and the voronoï diagram.

We will first form the clusters. Each cluster consists of a set of pharmacy databases. It occupies a well-defined space that we call a cell. When a new pharmacy is created, it is assigned to the nearest cell. We will then look for the cluster closest to the position of the user who is looking for information on the disposal of a pharmaceutical product.

A. Cluster Creation

Let k $\in \mathbb{N}$ and k less than the pharmacy numbers. We will use the k–means algorithm to group database sites into k-clusters. The centroids of the different clusters are called seeds. We will then use the seeds to build the Voronoï diagram. We get k-cells. We've just applied the function kmeans∘Voronoï or f∘g if we consider that kmeans is the function f and

Voronoï is the function g. Each cell houses a cluster and each cluster groups pharmaceutical database sites. The GPS(x,y) coordinates of each seed and all of its database sites are collected. The following algorithm makes it possible to create the k-clusters and to accommodate them in cells thanks to the Voronoï diagram.

1) Cluster creation algorithm: Cluster creation is define by the procedure:

- Group objects into k-clusters using the k-means algorithm.
- Using the centroids of the different clusters as seeds, separate the locality into k-cells using the Voronoï diagram. Each cell gathers the sites of the cluster and the barycenter becomes the seed of the cell.
- Locate the GPS coordinates (x, y) of the seed of each cell and all of its sites.

Note: This algorithm is called kmeans$\circ$Voronoï.

2) Nearest cell search algorithm: The following algorithm determines the cell closest to any point. The coordinates of this point are determined using GPS. The distance used is the Euclidean distance.

- Locate the GPS(x,y) coordinates of the person concerned.
- Calculate the Euclidean distance between the position of interest and the different seeds of the cells $d(i,j) = \sqrt{(x_{i1} - x_{j1})^2 + (x_{i2} - x_{j2})^2}$.
- Compare distances.
- Choose the minimum distance as the nearest cell.

Given a set S composed of n points $(y_1......y_n)$ in a space E, k an integer less than n and x another point not belonging to the set S. We are looking for the k nearest neighbor of x. The neighborhood problem first involves knowing the distance between x and the different points of S. The algorithm below calculates and displays the Euclidean distance between two points A and B.

For k=1 the nearest neighbor search is limited to the single nearest neighbor of x. We are looking for the smallest distance between x and y_i for i ranging from 1 to n. Let d$_i$=d(x,y$_i$) then the nearest neighbor algorithm amounts to finding the smallest d_i for i ranging from 1 to n. Let d$_i$=d(x,y$_i$) then the nearest neighbor algorithm amounts to finding the smallest d_i for i ranging from 1 to n.

Algorithm 1 NearestNeighbor

```
Variable i, n, index: integer
procedure $index \longleftarrow 1$
    for i ranging from 2 to n do
        if D[index] ¿ D[i] then index =i
        end if
    end for
    Display D[index] is the smallest distance
    Show y[index] is nearest cell
end procedure
```

We can use the two previous algorithms to determine the nearest neighbors to the farthest neighbors. For k=1, it is the nearest neighbors algorithm. We will rank the nearest neighbors to the farthest neighbors. So we're going to sort the distances from the smallest to the largest.

Algorithm 2 RankNearestNeighbor

```
variable $i, j, integer$
procedure
    for i going from n to 1 do
        for j ranging from 2 to i do
            if D[j-1] ¡ D[j] then
                Exchange (D[j-1],D[j])
            end if
        end for
    end for
end procedure
```

IV. Experimental Result

The choices of tools used to implement k–means and Voronoï diagram are based on reliability, flexibility and concordance with the method description.

- R software: It is a programming language and a free open source software environment mainly dedicated to statistical analyses, data science and graphical representations.
- RStudio is an interface facilitating the use of R. It is also free and freely distributed. The RStudio interface is divided into four windows: the console where you can execute commands; the environment where we can view the constructed objects; files and plots where you can install packages and view graphics; R script where you can keep the command lines as well as the comments.
- Installation of packages and import of libraries required.

We will first create a "mydata" data table which contains the x and y coordinates expressing the spatial position of the pharmaceutical sites.

Algorithm 3 Algorithm for creating a data table

```
Xvalue ¡- c(4, 1, 0, 20, 7, 7, 3, 10, 16, 1, 2, 11, 25, 1, 6, 1)
Yvalue ¡- c(7, 9, 20, 11, 8, 10, 40, 25, 33, 21, 11, 8, 13, 13, 12, 16)
mydata ¡-data.frame(x = Xvalue, y = Yvalue)
```

Consider the x and y coordinates of the following 16 sites below. We calculate the barycenters of the x and y coordinates for each cluster. We will first choose the number of cluster k using the curve we generate with the tools.

TABLE I. ¡X AND Y COORDINATES¿

Order	X	Y
1	4	7
2	1	9
3	0	20
4	20	11
5	7	8
6	7	10
7	3	40
8	10	25
9	16	33
10	1	21
11	2	11
12	11	8
13	25	13
14	1	13
15	6	12
16	1	16

To classify sites into groups we need to know the number of groups k. The best choice of this number k makes it possible to obtain very homogeneous groups. The R software allows us to draw a curve with elbows. The numerical value of the elbow with the greatest inflection corresponds to the best k. Algorithm 4 allows to draw the curve in Fig. 5.

Algorithm 4 Algorithm for determining best k

```
{plot(1:10, t, type = ”b”, pch = 19, frame= FALSE, xlab = ”Number of clusters (k)”, ylab = ”Intra-cluster sum of squares (wss)”, main = ”Optimal number of clusters k”)}{}
```

We obtain the curve in Fig. 5 that presents the choice of the number of clusters.

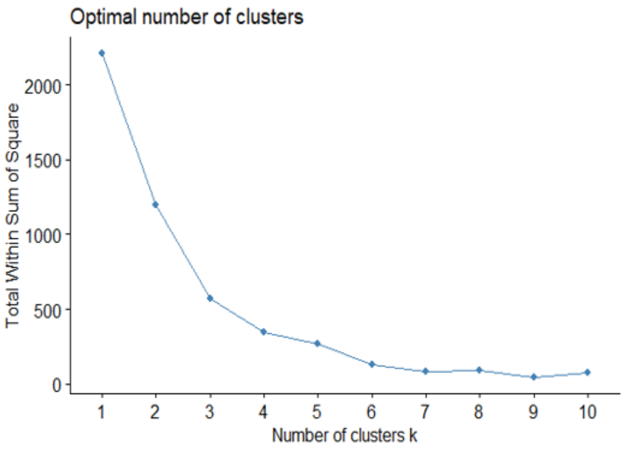

Fig. 5. Choice of the number of clusters.

The best number of clusters is obtained by choosing the elbow which presents an inflection. By observing we notice that k=3 and k=4 present inflections. We will work with his two cases and choose the best one in the end.

We will calculate the coordinates of the different centers of the k groups using the Algorithm 5.

Algorithm 5 Cluster center calculation algorithm

```
for (k in 1:10) {
kmeans_result ¡- kmeans(data, centers = k)
t[k] ¡- sum(kmeans_result$tot.withinss) }
k=3
kmeans_result¡- kmeans(data, centers = k)
cat(” Clusters centers : \n”)
print(kmeans_result$centers)
```

For k=3 the centroids of the clusters obtained have x and y coordinates in the Table II:

TABLE II. ¡X AND Y COORDINATES¿

Order	X	Y
1	3.72	12.27
2	9.66	32.66
3	22.50	12.00

Algorithm 6 shows the representation of three groups.

Algorithm 6 Cluster graphing algorithm

```
fviz_cluster(kmeans_result, data = mydata, geom = ”point”, ellipse.type = ”convex”) + labs(x = ”X-axes”, y = ”Y-axes”, title = ” K-means analysis”)
```

We obtain three clusters grouped together in space as shown in Fig. 6:

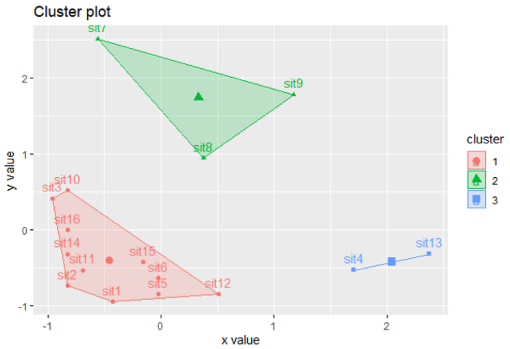

Fig. 6. Grouping into three kmeans clusters.

To finish with the classification of the three groups, Algorithm 7 allows us to display a Table III which indicates the coordinates of each site and its group to which it belongs.

Algorithm 7 Cluster membership table algorithm

```
r¡- data
r$cluster < -as.factor(kmeans - result$cluster)
print(r)
```

TABLE III. ¡X, Y COORDINATES AND THEIR CLUSTER ¿

Order	X	Y	cluster
1	4	7	1
2	1	9	1
3	0	20	1
4	20	11	3
5	7	8	1
6	7	10	1
7	3	40	2
8	10	25	2
9	16	33	2
10	1	21	1
11	2	11	1
12	11	8	1
13	25	13	3
14	1	13	1
15	6	12	1
16	1	16	1

We will now apply the voronoï diagram to these three clusters. We manage to separate them into three cells. Each cluster covers its corresponding cell. We get Fig. 7 and 8.

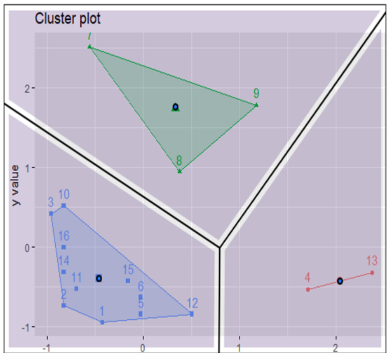

Fig. 7. Delineation of the area of each cluster with the voronoï diagram.

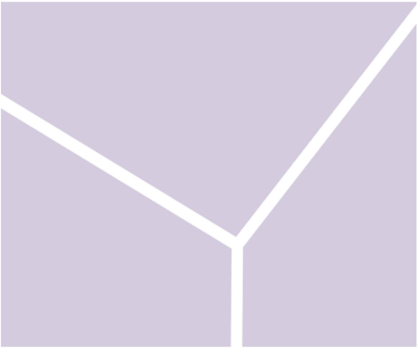

Fig. 8. Representation of each voronoï cell of each cluster.

For k=4 the centroids of the clusters obtained have x and y coordinates in the Table IV below:

TABLE IV. ¡X AND Y COORDINATES FOR K=4¿

Order	X	Y
1	5.42	9.28
2	9.66	32.66
3	22.50	12.00
4	0.75	17.50

We obtain four clusters grouped in space as shown in Fig. 9.

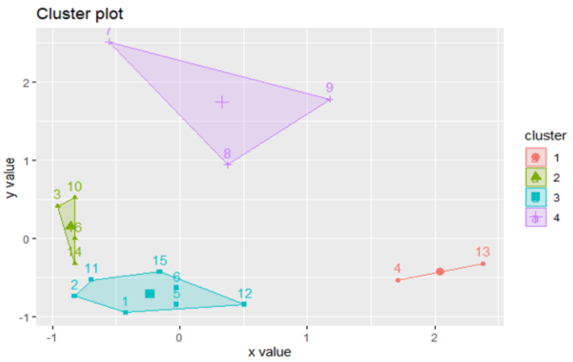

Fig. 9. Grouping into four k–means clusters.

We will now apply the voronoï diagram to these four clusters. We manage to separate them into four cells. Each cluster covers its corresponding cell. We get Fig. 10 and 11.

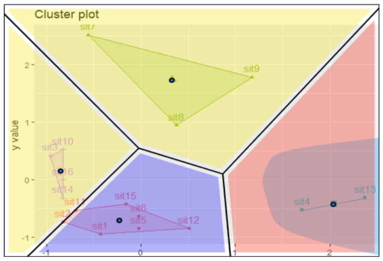

Fig. 10. Delineation of the area of each cluster with the voronoï diagram.

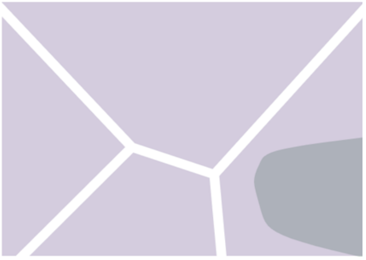

Fig. 11. Representation of each voronoï cell with its corresponding cluster.

V. Description of the Process with the Case of Pharmacies

When a user searches for a pharmaceutical product, he can launch the search from his position. The platform retrieves its position and its product then searches in the cluster closest to its position, if no pharmacy contains the product then the search continues to the next cluster. When the product is found, the pharmacy containing the product is indicated.

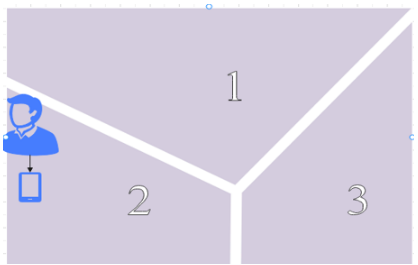

Fig. 12. Search for a pharmaceutical product.

In Fig. 12, the user using his telephone searches for doliprane. With regard to its position, the search begins in cluster 2 and ends if cluster 2 contains doliprane, otherwise the search continues in cluster 1 and ends if the latter contains doliprane, otherwise the search continues and ends in cluster 3. When the product is found, the platform returns the name of the pharmacy that contains it and its cluster.

VI. Conclusion and Perspectives

This paper carried out an unsupervised classification as k-means clustering of pharmaceutical sites in space to obtain different groups. Border Delimitation of each group has been done by voronoï diagram, to obtain definitely clusters. In this classification, data research could be firstly done with the closest cluster in serial case or in parallel on several clusters, simultaneously with map-reduce framework.

The future works will concern with analysis of new site insertion in the area that could change data structure, to lead to new clusters creation and to complete implementation of proposed algorithms in a software. Moreover, each database site or cluster will be also associated to a probability as Bayesian probability in order to start data research with cluster having the best probability.

Analysis could consider others criteria, as open sites in the schedule, the less expensive products in the sites, the existence of a path to connect the sites according to the initial position of users.

Abstract—**Due to the efficiency and reliability of delivering goods by ships, maritime transport has been the backbone of global trade. In normal circumstances, a ship's voyage is expected to assure the safety of life at sea, efficient and safe navigation, and protection of the maritime environment. However, ships may demonstrate unexpected behavior due to certain situations, such as machinery malfunction, unexpected bad weather, and other emergencies, as well as involvement in illicit activities. These situations pose threats to the safety and security of maritime transport. The expansion of the threats makes manual surveillance inefficient, which involves extensive labor and is prone to oversight. Thus, automated surveillance systems are required. This paper proposes a method to detect the unexpected behavior of ships based on the Automatic Identification System (AIS) data. The method exploits the geometrical features of AIS-generated trajectories to identify *unexpected trajectory*, which could be a deviation from the common routes, loitering, or both deviating and loitering. It introduces novel formulas for calculating trajectory redundancy and curvature features. The DBSCAN clustering is applied based on the features to classify trajectories as *expected* or *unexpected*. Unlike existing methods, the proposed technique does not require trajectory-to-image conversion or training of labeled datasets. The technique was tested on real-world AIS data from the South China Sea, Western Indonesia, Singapore, and Malaysian waters between July 2021 and February 2022. The experimental results demonstrate the method's feasibility in detecting deviating and loitering behaviors. Evaluation on a labeled dataset shows superior performance compared to existing loitering detection methods across multiple metrics, with 99% accuracy and 100% precision in identifying loitering trajectories. The proposed method aims to provide maritime authorities and fleet owners with an efficient tool for monitoring ship behaviors in real time regarding safety, security, and economic concerns.**

Keywords*—*Automatic identification system; vessel trajectory classification; unexpected behavior detection; data mining; data-driven decision support

I. Introduction

Global trade has been heavily reliant on maritime transport. More than 80 percent of the worldwide merchandise trade volume is delivered by ships, which are considered an economical, energy-efficient, and reliable long-distance means of transportation [1]. To ensure its economic and energy-efficient advantages, the voyage of a ship needs to be carefully planned.

According to the Guideline of Voyage Planning mandated by the International Maritime Organization (IMO), the voyage of a ship is a deliberately planned event that should assure the safety of life at sea, efficient and safe navigation, and protection of the marine environment [2]. For the sake of simplicity, this paper uses the term expected voyage to refer to such a voyage that is compliant with the guideline.

In normal circumstances, any ship will not make any maneuver that endangers people's lives at sea. They will navigate as efficiently as possible in a safe manner, which means that they are to take the shortest and fastest route whenever it is safe to do so. They will not deliberately conduct any activity that causes pollution or damage to the marine environment. Particularly for vessels of types of cargo and tanker, constrained by strict regulations, economic, and safety requirements, they should be the most likely to perform the expected voyage. However, ships might not follow the expected voyage due to certain situations, such as machinery malfunction, unexpected bad weather, and other emergencies, as well as involvement in illicit activities. These situations pose threats to maritime security, and the threats are continuously expanding, making automated surveillance systems critically required in the maritime domain [3]. In addition, the 12-month ship anomaly data provided by the Indonesian Coast Guard consists of nearly 400 ships that demonstrate anomalous behaviors such as loitering, deviation from common routes, and AIS on/off[1]. Roughly 97% of the ships are of types cargo and tanker, which are the core of the international maritime transport. The anomalous behaviors were identified manually by experts, which means the actual number of the anomalous ships could be higher due to the possibility of oversight. Thus, an automated means of monitoring and examining ship voyages is necessary to confirm compliance with the expected voyage and preserve the benefits of maritime transport.

Meanwhile, due to the worldwide adoption of the sea-borne Automatic Identification System (AIS) on seagoing vessels, AIS has emerged as a potential leading source of ship voyage data. AIS shares navigational data among vessels, terrestrial base stations, and/or satellites. The data consists of static, dynamic, and voyage-related information. The static information includes ship name, type, and MMSI. Ship position, position timestamp, speed over ground (SOG), course over ground (COG), heading, and navigational status are the dynamic information, while destination, estimated time of arrival, and draught are voyage-related. MMSI stands for Maritime Mobile Service Identity, a unique nine-digit number to uniquely identify a ship or a coast radio station [4]. AIS device transmits messages containing the information every 2 to 10 seconds for ships moving faster than 3 knots and every 3 minutes when they are at anchor or moored and not moving faster than 3 knots [5].

[1] The data were granted upon a formal request from the authors.

The real-time feature of AIS has made it possible for maritime stakeholders to utilize AIS as a monitoring tool. The abundant availability and straightforward accessibility of AIS data have facilitated researchers to develop methods for analyzing ships' tracks and trajectories to comprehend ship behavior. The methods are designated for various tasks, such as anomalous behavior detection [6], trajectory classification [7][8][9], construction of port performance indicators [10][11], and building real-time indicators of world seaborne trade [12].

In this paper, a method to detect ships that do not follow the expected voyage is proposed. The method exploits the geometrical features of the AIS-generated trajectories to identify unexpected trajectories, representing the routes of ships that do not comply with the expected voyage. Specifically, the unexpected trajectory could be a trajectory that deviates from the common routes, a loitering trajectory, or a trajectory that is both loitering and deviates from the common navigation routes.

Existing studies take two approaches to classifying vessels' trajectories based on AIS data: analyzing the spatiotemporal characteristics of the AIS tracks and finding patterns by studying the geometrical features of the AIS-generated trajectories. Although tankers and cargo vessels are the core of international maritime transport [13], few studies address these types of ships for trajectory classification [9]. Most works put their attention on the trajectory of fishing vessels, such as the works of references [14] and [15]. Furthermore, the approaches that examine the geometrical features of the AIS-generated vessels' trajectories often involve the conversion of trajectory data into digital images and rely on the trajectory classification on manually labeled datasets [7], [16], [17].

This study takes the geometrical approach to classify ships trajectories. The approach calculates the rate of redundancy and curvature of all trajectories of interest. It proposes novel formulas for the calculation. Next, a weighted DBSCAN (Density-based Spatial Clustering of Application with Noise) clustering [18] is applied to the trajectories to classify trajectories that belong to the common voyages and those of the unexpected trajectory. The proposed method does not involve the conversion of trajectories into images and does not require any labeled datasets.

The purpose of this work is to provide a straightforward unexpected trajectory detection technique suitable to real-time surveillance systems for a designated maritime area.

It is intended to contribute in two ways: 1) help maritime authorities to efficiently identify unexpected behavior of vessels within their surveillance area, and 2) support merchant fleet owners with online monitoring tools to ensure that all of their ships are following the known efficient and safe voyage routes.

The remainder of this paper is organized as follows. Section II reviews relevant literature. Then, the proposed method is described in Section III followed by the presentation of the experiment results and evaluation in Section IV. Finally, Section V concludes this article and specifies the future tasks to further improve this work.

II. Related Works

Luo et al. classify ship trajectories into five types: 1) normal navigation trajectory, 2) anchoring or mooring trajectory, 3) navigation trajectory with deviation, 4) trajectory of missing AIS signal, and 5) irregular trajectory [9]. The normal navigation trajectory is defined as the trajectory of a ship traveling from the departure point to the destination port without redundancy, deviation of course, or loss of AIS transmission. In other words, any trajectories with redundancy, deviation, or loss of AIS transmission are deemed as not normal. Anchoring and mooring trajectories belonging to the ship-stopping behavior are discussed comprehensively in the work of Yan et al. [19]. In this paper, these stopping trajectories are removed by employing the method proposed in reference [11], [20], and only the trajectory between the start and end of a ship voyage is processed to identify unexpected trajectory. Navigation trajectory with deviation and trajectory of missing AIS signal refers to the types of anomalies in maritime traffic proposed by Lane et al. [21], whereas the irregular trajectory corresponds to the loitering trajectory discussed in references [16] and [22]. In this paper, any trajectories with loitering, or deviation, or having both of them are determined as unexpected trajectory.

Luo et al. employ an ensemble classifier, a combination of Naive Bayes and Random Forest classifiers, to classify the five types of vessel trajectories. The approach adopts the feature-extraction submodule of the Tsfresh package to automatically extract spatiotemporal features from vessel trajectories [23]. In their experiment, they rely on a labeled dataset to conduct the trajectory classification. However, their work does not provide the information on how and by who the dataset was labeled. In addition, each trajectory is given one label and grouped into one type of trajectory. In the real world, a trajectory may belong to more than one category, such as one that both deviates from the common routes and loiters. Thus, in this study, the unsupervised learning approach is selected, and each input trajectory is classified into an expected trajectory or an unexpected trajectory, where the unexpected trajectory may be deviating or loitering, or exhibiting both behaviors. In other words, this study does not involve the labor of dataset labeling and does not force the classification into the provided labels.

A technique to specifically detect loitering trajectory was proposed by Zhang et al. which introduce the concept of trajectory redundancy [16]. The formula to calculate the redundancy is as defined in Eq. 1. However, the method is designated to classify the trajectories belonging to the types of vessels that consider loitering a normal behavior in their nature of operation. These types of vessels include fishing ships, Search and Rescue (SAR) vessels, tug boats, survey ships, patrol boats, and ships of military operations. The method does not recognize loitering as an abnormal or unexpected behavior.

Identifying the gap, Wijaya and Nakamura proposed a loitering detection method targeting vessels that do not normally engage in loitering movement, such as tankers and cargo ships [22]. They define loitering as a type of anomaly in maritime traffic. The method exploits the spatiotemporal features of the AIS tracks, such as speed, course change, heading change, and the geodesic distance between two consecutive tracks. It identifies the loitering trajectory along with its score, which determines how severe the loitering is. The method's implementation in the maritime surveillance system will facilitate the operators to sort the detected loitering vessels based on their priority (loitering score). The evaluation experiment proves that the method outperforms the loitering detection technique proposed by Zhang et al. in all metrics (Table I). However, the method is specifically designated to detect loitering trajectory while the unexpected trajectory defined in this paper is not only about loitering. It has a wider scope to include loitering and deviating trakcs.

III. Proposed Methods

This study defines *unexpected trajectory* as a trajectory constructed with the AIS tracks of a ship voyage that does not follow the IMO's Guideline of Voyage Planning.

According to the guideline, the voyage of a ship should assure: 1) the safety of life at sea, 2) efficient and safe navigation, and 3) protection of the marine environment [2].

Considering the efficiency and safety of navigation, ships should take the most straightforward, shortest, and fastest route whenever it is safe to do so. This ensures efficiency in both cost and time. Thus, any ship trajectory that is not straightforward or demonstrates redundancy is considered an unexpected trajectory. It could be a trajectory that deviates from the common routes, a loitering trajectory, or a trajectory that is both loitering and deviates from the common navigation routes.

Zhang et al. introduce the concept of trajectory redundancy(TR) as a formula for detecting loitering trajectories from AIS tracks [16]. Eq. (1) represents the formula, where TR is denoted by ψ, D is the length of ship trajectory, and P is the perimeter of the minimum bounding rectangle of ship trajectory. The larger ψ is the greater the possibility of loitering, and the threshold is $\psi_{min} = 1$.

Fig. 1 shows three different trajectories in the same size of the spatial range (all have the same P) with $\psi < 1$, $\psi \approx 1$, and $\psi > 1$.

$$\psi = D/P \tag{1}$$

Since the TR calculates redundancy by comparing the length of trajectory with the perimeter of the trajectory's bounding box, a redundant trajectory along the diagonal of the bounding box may result in $\psi < 1$. In other words, it may not be considered as redundant or loitering.

Thus, in this paper, the trajectory redundancy is calculated by comparing the length of trajectory, denoted by D, with the length of the diagonal of the trajectory's bounding box, denoted by L. Eq. 2 represents the comparison.

$$R = D/L \tag{2}$$

However, this study considers that merely calculating the redundancy of ship trajectory is not enough to detect unexpected trajectory of the ship's voyage. Hence, a formula to measure the curvature of vessel trajectory is proposed as in Eq. 4.

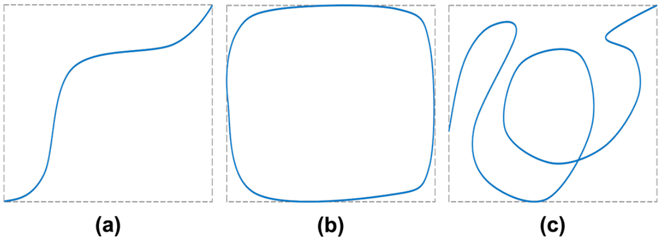

Fig. 1. Three different trajectories with the equivalent TR (ψ) values. The grey dashed lines represent the minimum bounding rectangle of each trajectory, while the blue solid lines depict vessel trajectories: (a), (b), and (c) are the trajectory with $\psi < 1$, $\psi \approx 1$, and $\psi > 1$, respectively.

For every voyage's trajectory $M = \{m_0, m_1, m_2, \ldots, m_n\}$ where $0 \leq i \leq n$, $T = \{t_0, t_1, t_2, \ldots, t_n\}$ is the corresponding timestamps of the trajectory M as to m_i is the track position at timestamp t_i. In other words, m_0 is the starting track, and m_n is the last track position of a ship's voyage. The trajectory curvature is defined as inversely proportional to the average Cartesian distance from the starting track position m_0 to each track position $m_1, m_2, m_3, \ldots, m_n$. Eq. 3 yields the average Cartesian distance $\overline{d}$, where $d(m_0, m_i)$ is the Cartesian distance between m_0 and m_i.

$$\overline{d} = \frac{1}{(n+1)} \sum_{i=1}^{n} d(m_0, m_i) \tag{3}$$

$$C = \frac{1}{\overline{d}} \tag{4}$$

The variables used in Eq. 2 and 4 indicate that this paper utilizes the geometrical features of vessels' trajectories to detect unexpected trajectories instead of exploiting the spatiotemporal characteristics as in the existing work of Wijaya and Nakamura [22].

The overall process of the unexpected trajectory detection method proposed in this paper is conducted in three steps: 1) AIS data preprocessing, 2) trajectory segmentation to split the stopping and underway trajectories of every ship's voyage, and 3) the implementation of Eq. 2 and 4 to detect unexpected trajectories. This paper employs the AIS data preprocessing and trajectory segmentation methods described in [20]. The preprocessing removes all invalid data, while the segmentation separates the stopping and underway segments of each trajectory representing a ship voyage. The validated underway segments are the input for the unexpected trajectory detection computation technique proposed in this paper.

Eq. 2 and 4 are applied to each underway segment of all trajectories of the ships of interest to calculate the rate of redundancy and curvature. Every ship's trajectory represents a ship's voyage from one endpoint to another. The starting point and the destination can be a port or a water area. For example, a container's voyage from Singapore port to the port of Jakarta, a tanker's voyage from the South China Sea to the Indian Ocean, and a cargo coming from the Indian Ocean to Singapore port. Due to the constraints of the geographical features, the typical characteristics of the waters, and the weather patterns between the two endpoints, voyages of the same ends should have at least one commonly traveled route, which has been proven to be efficient and safe for a known period of time. Normally, most ships are expected to follow the commonly known route(s) rather than taking the risk of navigating the unknown passage. However, under certain situations, a ship may take an unexpected path indicated by her trajectory.

To identify the unexpected trajectory(s) of the ships' trajectories belonging to voyages between the same endpoints, this paper applies the DBSCAN clustering algorithm to classify the trajectories by using the rate of redundancy (Eq. 2) and the trajectory curvature (Eq. 4) as the clustering features. Since the rate of redundancy R is the main parameter to detect loitering, and the curvature C is the extension, R is weighted twice the weight of C in the implementation of DBSCAN.

The DBSCAN algorithm is selected because it can detect noises, the ones whose features cannot be associated with any clusters. The noises are labeled '-1', which means they do not belong to any clusters. They are different and few in number. When there is no noise detected, none of the data will be labeled '-1'. Thus, if the unexpected trajectory exists, it should be classified as noise since it must have different features from the common trajectories and be much fewer in number.

For every voyage's trajectory $M = \{m_0, m_1, m_2, \dots, m_n\}$ with timestamps $T = \{t_0, t_1, t_2, \dots, t_n\}$, W is defined as a time window with an arbitrary duration k hours, where $W \subseteq T$ and the duration of W is less than the duration of T. The time window W is sliding from the start to the end of T while executing the calculation of the rate of redundancy R and the curvature C. The calculation results are compared and each maximum value of R and C is returned as in Eq. 5 and 6.

$$R_w = Max(R_{(t_0,t_k)}, R_{(t_{0+1},t_{k+1})}, \dots, R_{(t_{n-k},t_n)}) \qquad (5)$$

$$C_w = Max(C_{(t_0,t_k)}, C_{(t_{0+1},t_{k+1})}, \dots, C_{(t_{n-k},t_n)}) \qquad (6)$$

This process is to excerpt the segment of a voyage's trajectory with the maximum redundancy and curvature. To further precisely locate the segment, multiple time windows with different durations are applied. In this case, three time-windows, $W1 = 6$ hours, $W2 = 24$ hours, and $W3 = 48$ hours, are determined. The maximum R and C of each time window are compared to select the one final maximum R and C as expressed in Eq. 7 and 8.

$$R_{max} = Max(R_{w1}, R_{w2}, R_{w3}) \qquad (7)$$

$$C_{max} = Max(C_{w1}, C_{w2}, C_{w3}) \qquad (8)$$

The calculation of R and C with the sliding time windows is executed on every underway trajectory belonging to the voyages of the same endpoints. The computation results in a set of trajectory excerpts $E = \{e_0, e_1, e_2, \dots, e_m\}$ having the R_{max} and C_{max} as their attributes, where $m+1$ is the number of trajectories belonging to the voyages of the same origin and destination. Thus, each trajectory excerpt e_j, for $0 \leq j \leq m$, can be expressed as a position on a two-dimensional space $e_j(x_j, y_j)$, where $x = R_{max}$ and $y = C_{max}$. Here, the DBSCAN algorithm is implemented to classify the set of trajectory excerpts E by taking R_{max} and C_{max} as the clustering features. The Euclidean distances amongst the set of E are calculated to determine the epsilon ε parameter of the DBSCAN algorithm. Every trajectory excerpt e_j with -1 label is classified as an excerpt of an unexpected trajectory, while the rest belong to the trajectories of the common routes. The whole process of the unexpected trajectory detection workflow is summarized in Fig. 2.

IV. Experiment and Evaluation

The proposed unexpected trajectory detection technique is implemented on real-world historical AIS data of vessels navigating through the southern part of the South China Sea, western Indonesia, Singapore, and Malaysian waters. The area is roughly 3,230,663.98 km^2 depicted in Fig. 3. They were recorded between 1st July 2021 and 28th February 2022 within the area. The dataset is the same as the one used in [11].

A. AIS Data Preprocessing and Trajectory Segmentation

A one-month subset (1st - 31st July 2021) of the dataset is cleaned with the following filters:

1) $length(MMSI) = 9$,
2) $-90 \leq Latitude \leq 90$,
3) $-180 \leq Longitude \leq 180$, and
4) $70 \leq vesselTypeCode \leq 89$

to retrieve all MMSIs of valid AIS messages of tankers and cargo ships. The $70 \leq vesselTypeCode \leq 89$ refers to the vessels of types cargo and tanker [24].

The filtering collects 6,950 unique MMSIs, of which 4,182 MMSIs are used as the keys to fetch one-month historical AIS data of 1st - 31st July 2021. It consists of 3,514,126 AIS records. The remaining 2,768 MMSIs are the keys to retrieve eight-month historical AIS data between 1st July 2021 and 28th February 2022 that contains 15,955,795 recorded AIS transmissions. Thus, this experiment processes 19,469,921 AIS messages in total.

Following the AIS data preprocessing, the trajectory segmentation procedure is executed on the one-month and eight-month AIS datasets to separate the stopping and underway segments of each ship's trajectory. This process adopts the trajectory segmentation technique presented in [20]. This paper's unexpected trajectory detection algorithm takes only the underway segments of each ship's trajectory as the input. The trajectories of the underway segments are grouped into four types of voyages as follows:

1) Voyages between two different ports: the voyages between the port of Jakarta and Singapore port, and between Port Klang and Singapore.
2) Voyages between a port and sea area: the voyages between Singapore port and the South China Sea.
3) Voyages between a sea area to another sea area: the voyages between the South China Sea and the Indian Ocean.
4) Voyages within a relatively wide area of the sea without stopping at any ports: the voyages within the western part of Indonesian archipelagic waters (Natuna Sea and Java Sea).

B. Detecting the Unexpected Trajectory

Before calculating the trajectory redundancy R and curvature C for the trajectories of the underway segments of each voyage group, the two endpoints (origin and destination point/area) of each voyage group need to be determined. The polygon defining the area of the Singapore Port is publicly available by the Maritime and Port Authority of Singapore [25], while the geometrical boundaries of the port of Jakarta and the Port Klang are defined in reference [11]. In the case of sea area, this experiment uses the geographic boundaries provided by MarineRegions.org [26].

For the first voyage group, the trajectories are filtered to select those that start and end at either the Jakarta or Singapore ports, and those that start and end either at Port Klang or Singapore port. Further, this experiment selects only the trajectories whose track interval $\leq$ 6 hours to avoid processing truncated trajectories. This filter is applied to all voyage groups. The rate of redundancy R and curvature C are calculated within three time-windows W on every trajectory. The time windows are $W1 = 6$ hours, $W2 = 24$ hours, and $W3 = 48$ hours. This process returns a set of trajectory excerpts E of which each excerpt has two attributes: R_{max} and C_{max}. The DBSCAN clustering algorithm is applied to the set of excerpts E. The result is visualized as depicted in Fig. 4 and 5. The experiment produces two unexpected trajectories from the voyages between Jakarta and Singapore ports. The trajectory's excerpt near Singapore Port, labeled Ship-AL, belongs to a container ship with a gross tonnage of 66,280 tons and a dimension of 276 x 40 meters, while the excerpt near the port of Jakarta is of a container ship measuring 161.85 x 25.6 meters.

The same processing procedure is applied to the remaining three voyage groups. The results are visualized in Fig. 6, 7, and 8.

This experiment confirms that DBSCAN clustering does not forcibly classify the dataset into cluster and noise. When noise does not exist, none would be labeled as one. It is observable in the visualization of the trajectories between the South China Sea and the Indian Ocean (Fig. 7). None of the trajectories is classified as noise as all of them seem to follow the common routes.

The implementation of the unexpected trajectory detection algorithm reveals the same ship, labeled Ship-AL, shows unexpected movement on the voyage between Jakarta and Singapore port and the voyage within the Western part of Indonesian archipelagic waters. When the unexpected trajectory algorithm is applied to the ship trajectories individually, it confirms that Ship-AL frequently demonstrates unexpected behaviors during her voyages between July 1st, 2021 to February 28th, 2022. Fig. 9 depicts Ship-AL's trajectories with excerpts indicating the unexpected behaviors. Ship-AL is a container ship of Portuguese nationality measuring 66,280 tons of gross tonnage and 275 x 40 (meters) in dimension. Considering the type and size of the ship, her behavior is definitely not normal. Another finding is the trajectory labeled Ship-MA in the voyage within the Western Indonesian Archipelagic waters. The ship, a crude oil tanker of 105,484 tons (deadweight), was loitering at sea for

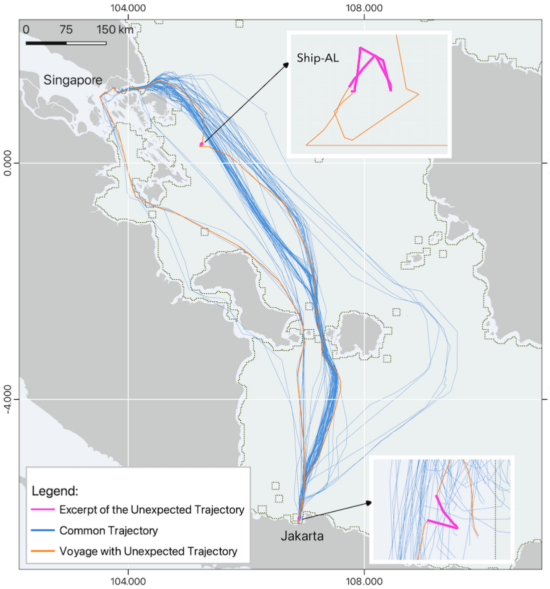

Fig. 4. The trajectories of voyages between Jakarta and Singapore Port. The orange lines illustrate voyages with *unexpected trajectory* whose excerpts are depicted by the magenta lines. The common trajectories of the voyages are indicated with blue lines. The trajectory excerpt labeled Ship-AL belongs to a container ship with a gross tonnage of 66,280 tons measuring 276 x 40 meters in length and width.
Basemap adopts geoBoundaries by D. Runfola et al. [27]

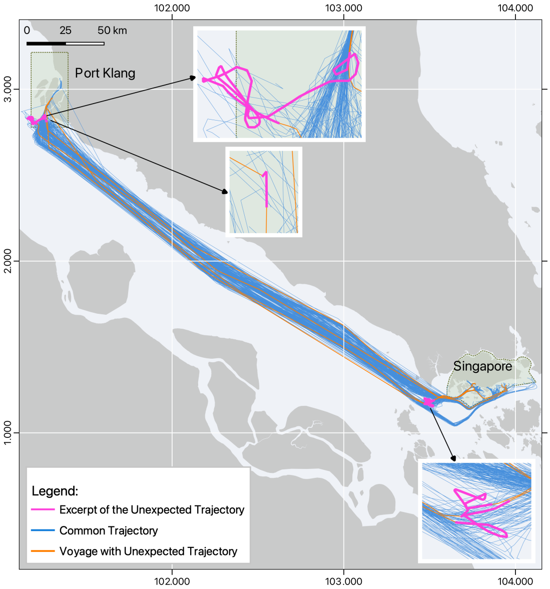

Fig. 5. The trajectories of voyages between Port Klang and Singapore Port. The orange lines illustrate voyages with *unexpected trajectory* whose excerpts are depicted by the magenta lines. The common trajectories are drawn in blue lines.
Basemap adopts geoBoundaries by D. Runfola et al. [27]

155 hours. This type of ship, with a size of 243 x 42 (meters), is not normally engaged in loitering movement [22], which is normal for other types of vessels such as fishing boats, patrol vessels, and SAR (Search and Rescue) ships[16].

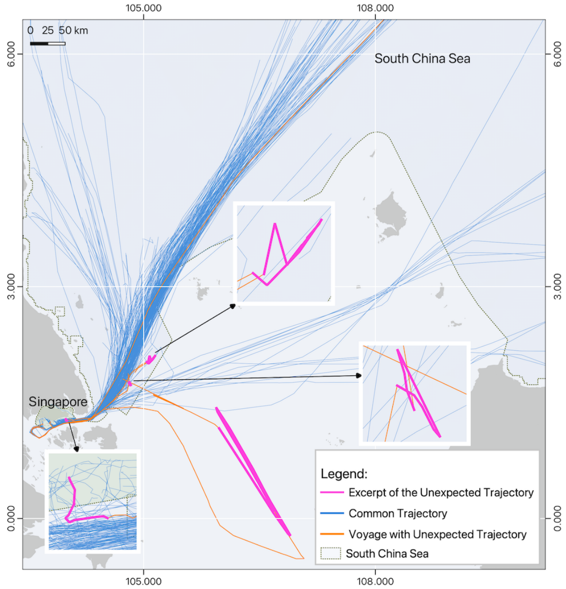

Fig. 6. The trajectories of voyages between the South China Sea and Singapore Port. The orange lines indicate voyages with *unexpected trajectory* whose excerpts are colored magenta. The common trajectories are drawn in blue lines.
Basemap adopts geoBoundaries by D. Runfola et al. [27]

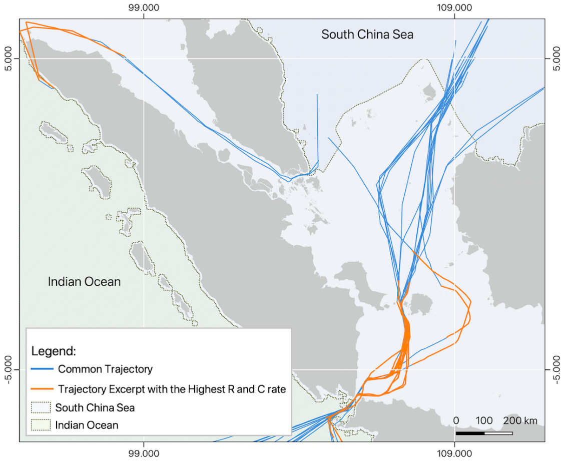

Fig. 7. The trajectories of voyages between the South China Sea and the Indian Ocean. The common trajectories are depicted with blue lines, while the orange lines indicate the excerpt of the trajectories with the highest rate of redundancy R and curvature C. In this case, the DBSCAN clustering returns no trajectory excerpt with a -1 label, meaning that the dataset has no *unexpected trajectory*. The visualization confirms that all voyages seem to follow the common routes.
Basemap adopts geoBoundaries by D. Runfola et al. [27]

C. Evaluation

The experiment results prove the capability of the proposed method to detect unexpected trajectories of vessels navigating through the sea area of interest. To measure the efficacy of the technique, an evaluation is conducted on the same dataset as the evaluation section of reference [22]. The dataset consists of 137 labeled trajectories of vessels navigating through the West Coast of North America. It comprises 24 loitering (anomalous) and 113 normal trajectories. Since the unexpected trajectory

TABLE I. Evaluation Metrics Comparison with Existing Methods

Method	*Accuracy*	*Specificity*	*Precision*	*F-score*	*Undetected***	*False Negative*
TR	0.87	0.84	0.60	0.70	4	14
$F(c)$	0.95	1.0	0.78	0.88	0	7
$F(c,h,d)$	0.93	0.96	0.75	0.84	1	8
$Integrated^{*}$	0.97	0.96	0.89	0.92	1	3
$ProposedMethod$	0.99	0.92	1.00	0.96	2	0

*Weighted integration of $F(c)$ and $F(c,h,d)$.
**The number of undetected loitering ships.

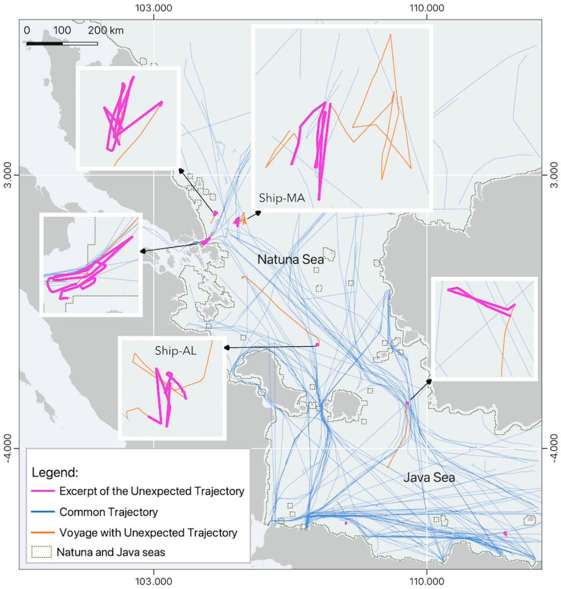

Fig. 8. The trajectories of voyages within the Western Indonesian Archipelagic Waters. The blue lines indicate the common trajectories, while those in orange are the *unexpected trajectories* whose excerpt is in magenta. The ship with an *unexpected trajectory* labeled Ship-AL is also revealed in the voyages between Jakarta and Singapore port. The trajectory labeled Ship-MA is a crude oil tanker loitering for 155 hours.
Basemap adopts geoBoundaries by D. Runfola et al. [27]

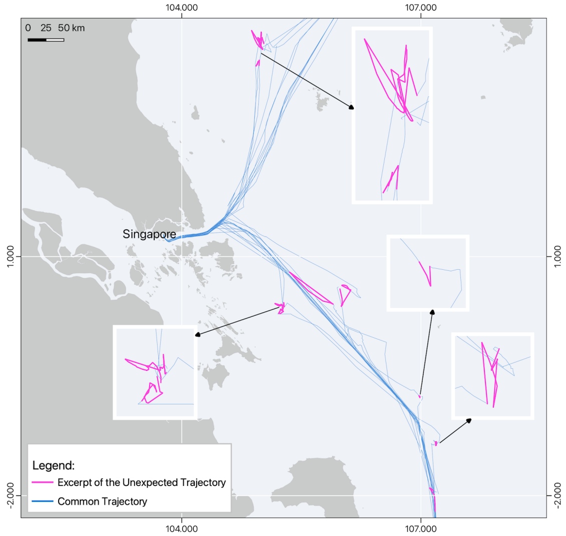

Fig. 9. The trajectories of the Ship-AL between 1st July 2021 and 28th February 2022 that are revealed in the Jakarta-Singapore voyages and the voyages within the Western Indonesian Archipelagic Waters. It is a Portuguese container ship measuring 66,280 tons of gross tonnage and 275 x 40 (meters) dimension.
Basemap adopts geoBoundaries by D. Runfola et al. [27]

could be a trajectory that deviates from the standard routes or that of a loitering behavior, the dataset is valid for this evaluation. The results are compared with the Trajectory Redundancy (TR) calculation formula proposed by Zhang et al. [16] and the loitering detection method of Wijaya and Nakamura [22]. Table I presents the comparison. The proposed unexpected trajectory detection technique outperforms all of the existing methods with 0.99 accuracies, 0.92 specificities, 1.00 precision, and 0.96 F-score. The technique produces no false negatives and merely two undetected loitering trajectories. The prediction results are visualized in Fig. 10. The undetected loitering trajectories possess loitering movements that last less than an hour. It seems that the detection fails because the duration of the loitering movement is too short.

The proposed unexpected trajectory detection technique performs remarkably better in all measurement metrics compared with the existing loitering detection methods. However, the approaches with $F(c)$ and $F(c,h,d)$ formulas return loitering scores. Each detected loitering trajectory is given a loitering score that indicates the severity of the loitering movement. The approach is intended to help maritime authorities to achieve better efficiency in conducting maritime surveillance. It does not only automatically detect loitering ships but also suggests their priority so that the officer in charge can decide which ship to handle first, second, and soon. On the other hand, the unexpected trajectory detection approach proposed in this paper is intended to provide a high-accuracy detection tool without considering the priority of the detected vessels. The result is binary, either normal or unexpected trajectory.

V. Conclusion

This paper presents a novel method for detecting unexpected trajectories of vessels based on AIS tracks. The proposed approach leverages the geometrical features of ship trajectories, specifically the rate of redundancy and curvature. It is to identify voyages that deviate from the expected voyage. By applying DBSCAN clustering based on these geometrical features, the method can effectively distinguish between trajectories that follow the common routes and that of the unexpected trajectory. The classification is accomplished without relying on labeled training data or image conversion techniques.

The experimental results demonstrate the efficacy of the proposed method across various types of maritime voyages,

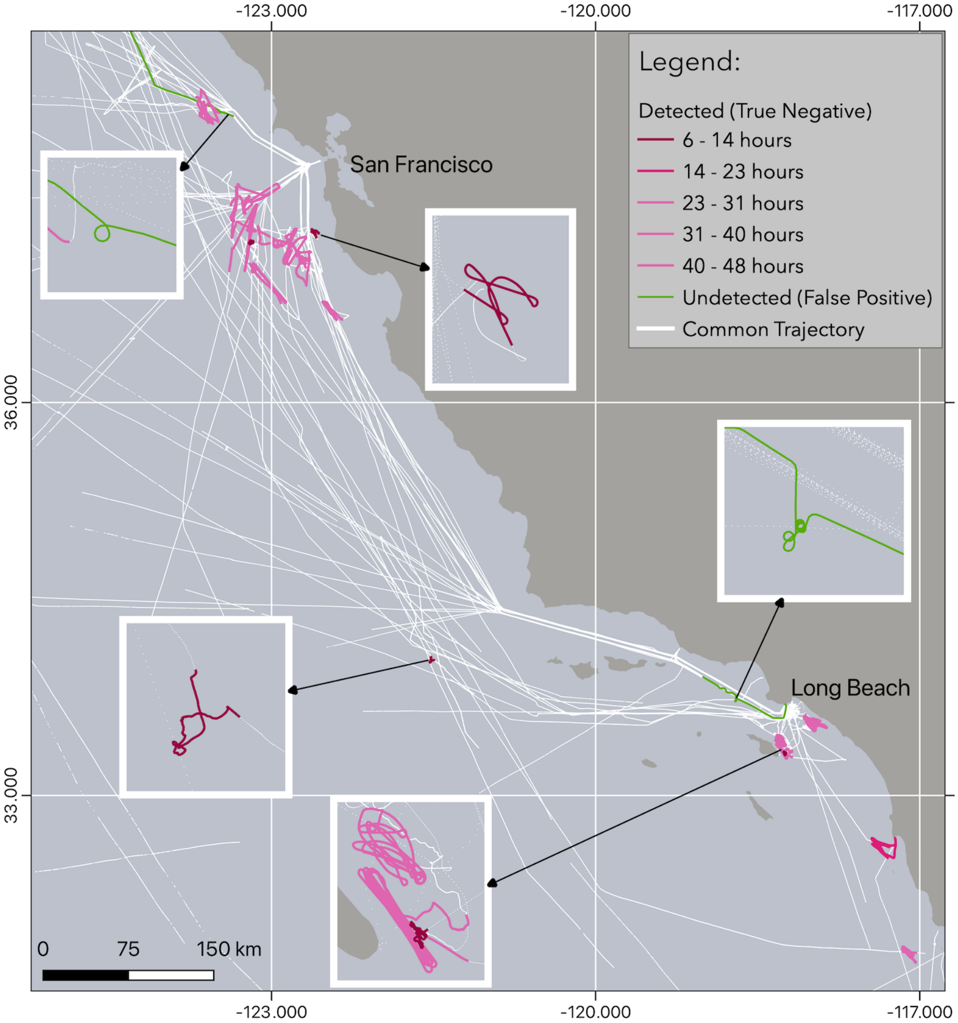

Fig. 10. The purple-red lines indicate the prediction of loitering that matched the actual loitering trajectories (true negative), while the green lines represent the undetected loiterings (false positive). The white lines illustrate the trajectories of the common routes. The prediction achieves 0.99 accuracy, 1.00 precision, and 0.96 F-score with two false positives and zero false negatives.
Basemap adopts geoBoundaries by D. Runfola et al. [27]

including port-to-port, port-to-sea area, and open-water routes. The technique successfully identified several instances of unexpected behavior, including a container ship exhibiting frequent unexpected trajectory and a large oil tanker engaged in prolonged loitering. These findings highlight the method's potential to detect behaviors that may need further investigation by maritime authorities.

The Comparative evaluation against existing approaches shows that the proposed method achieves superior performance across multiple metrics, including accuracy, precision, and F-score. This indicates that the technique offers a robust and reliable means of identifying unexpected trajectory in maritime traffic. The evaluation result confirms that the proposed method is not region-dependent. The evaluation dataset is of the West Coast of North America, while the experiment dataset covers the archipelagos of Indonesia, Malaysia, and Singapore. Despite the proven performance and versatility, the proposed unexpected trajectory detection method possesses several limitations. When it is applied to detect loitering movement, the detection fails if the loitering duration is too short, such as less than an hour. The method is also unable to determine the magnitude of the detected unexpected trajectory, whether it is a slight track deviation due to an instantaneous unplanned maneuver to evade danger or a redundant deviation because of a deliberately planned maneuver.

To further enhance and extend the proposed approach, this study considers the following future works: 1) combining both geometrical and spatiotemporal features to potentially improve detection accuracy and provide a more nuanced characterization of unexpected behaviors, 2) integrating the unexpected trajectory detection method into real-time maritime surveillance systems to evaluate its performance in operational scenarios, and 3) investigating the potential of the approach to detect other types of maritime anomalies.

In conclusion, this study offers a feasible approach for maritime authorities and fleet operators to efficiently monitor vessel voyages and identify potential security, safety, or efficiency concerns. It is the answer to the need for automated surveillance systems because of the increasing threats to maritime security. The technique could substantially contribute to the overall safety and efficiency of maritime transportation.

SecureTransfer: A Transfer Learning Based Poison Attack Detection in ML Systems

Archa A T, K.Kartheeban
Computer Science and Engineering
Kalasalingam Academy of Research and Education
Krishnankoil, TamilNadu, India

***Abstract*—Critical systems are increasingly being integrated with machine learning (ML) models, which exposes them to a range of adversarial attacks.The vulnerability of machine learning systems to hostile attacks has drawn a lot of attention in recent years. When harmful input is added to the training set, it can lead to poison attacks, which can seriously impair model performance and threaten system security. Poison attacks pose a serious risk since they involve the injection of malicious data into the training set by adversaries, which influences the model's performance during inference. It's necessary to identify these poison attacks in order to preserve the reliability and security of machine learning systems. A novel method based on transfer learning is proposed to identify poisoning attacks in machine learning systems.The methodology for generating poison data is initially created and later implemented using transfer learning techniques. Here, the poisonous data is detected using the pre-trained VGG16 model. This method can also be used in distributed Machine learning systems with scattered data and computation across several nodes. Benchmark datasets are used to evaluate this strategy in order to prove the effectiveness of proposed method.Some real-time applications,advantages,limitations and future work are also discussed here.**

***Keywords*—Poison attacks; machine learning security; transfer learning; generative adversarial networks; convolutional neural networks; VGG16**

I. Introduction

Nowadays, machine learning techniques have been used across various domains such as healthcare, finance, and autonomous systems. However, the applications of machine learning models in real-world systems has also raised concerns about their vulnerability to adversarial attacks [5]. Among these attacks, poison attacks stand out as a particularly critical threat, where adversaries inject subtle but malicious perturbations into the training data to undermine the integrity and performance of the models. Detecting and mitigating poison attacks [20][23] in machine learning systems is a critical challenge that requires innovative solutions to safeguard the reliability and trustworthiness of deployed models. Traditional defense mechanisms, such as input sanitization [30] and robust training [10] have shown limited effectiveness against sophisticated poison attacks that exploit vulnerabilities in the training process.

Security is paramount in distributed settings [14] due to the decentralized nature of data and computation. In distributed systems, sensitive information is often spread across multiple nodes or devices.So, various security threats such as unauthorized access, data breaches, and malicious attacks affects the the confidentiality, integrity, and availability of data [3] and resources in distributed environments.So,it is essential for maintaining trust, protecting privacy, and upholding regulatory compliance. Moreover, the interconnected nature of distributed systems amplify the impact of security breaches, potentially leading to widespread disruption and financial loss. Therefore, implementing robust security measures is critical to safeguarding distributed settings against emerging threats and preserving the trust of users and stakeholders.

In this context, utilizing advanced techniques from the fields of GAN's and CNN's holds great promise for enhancing the security of distributed machine learning systems. GANs [10] are a type of deep learning models that is made of two neural networks, a generator and a discriminator, trained simultaneously. GANs is useful for generating realistic synthetic data, which can be leveraged to augment the training dataset and improve model robustness against poison attacks in federated learning Systems [17]. On the other hand, CNNs have emerged as a cornerstone in computer vision tasks, owing to their capacity to learn hierarchical representations of data automatically. CNNs excel at extracting discriminative features from images, making them wellsuited for detecting subtle patterns indicative of poison attacks. By combining the generative power of GANs [31] with the discriminative capabilities of CNNs, a comprehensive defense mechanism can be developed for poison attack detection in distributed machine learning systems.Poisoning attacks affect the wrong prediction of system.It is very crucial in health care,self driving vehicles and many other applications.So,in order to improve machine learning systems' ability to resist poison attacks.

This paper proposed an innovative approach that uses GANs to create threat model and VGG16 for transfer learning techniques to identify poisonous and nonpoisonous data. Some widely used datasets such as CIFAR10, CIFAR-100 are used to illustrate the effectiveness of this method in detecting poison attacks.

A. Research Motivation

The necessity for strong security measures has been highlighted by the incorporation of machine learning into critical systems. An adversarial approach known as "poisoning" can seriously impair model performance by contaminating the training set. It is frequently not possible for traditional defense measures to identify and prevent these highly trained attackers. Since transfer learning may make use of pre-trained model knowledge, it presents a viable path toward a more precise and efficient defense against poison attacks. The goal of this study is to investigate and validate the application of transfer learning to improve ML system security against these kinds of attacks.

II. Related Works

Several studies have explored various techniques for defending against poison attacks [3] [15] in machine learning systems. Modern Deep learning techniques such as auto encoder [4] are also used to detect poisoning attacks. Early approaches focused on input sanitization and outlier detection, which proved insufficient against sophisticated adversaries [6]. Recent research has shifted towards more advanced defense mechanisms leveraging techniques such as robust training, model verification, and adversarial training.

Advanced advancements in adversarial attacks and defence strategies in vision applications were covered by [1]. This article discusses several kinds of adversarial attacks on realtime applications. This paper formulates many types of attacks, including white box, black box, and real-world attacks. This survey also mentions a few defensive techniques, including randomised smoothing, regularisation schemes for ReLU networks, ensemble generative cleaning with a feedback loop, and the usage of variational auto-encoders (VAEs). This study also discusses how detecting attacks in language models and vision is becoming a tedious tasks.

Chen, Xiaolin, et al. [8] discussed a data poisoning framework based on Gan against anomaly detection.Here, the poisoning model is based on a generative adversarial network.Perturbations are added for poisoning some inputs. They also developed a a serverside algorithm based on a deep autoencoder in order to defend against such attacks. When the number of labelled datasets increases, its performance decreases slowly.

Psychogyios, Konstantinos [17] discussed generating images using GAN. Here, label flipping attacks are generated and tested based on an aggregation algorithm. This method is also examined in the FL system using secure aggregation methods. Accuracy issues still pose a major challenge in this area. This paper also suggested adding additional datasets and hyperparameters to improve accuracy.

The primary machine learning (ML) concerns for an AI system are the data, model, training, testing, and validation procedures. However, AI also uses a number of knowledge-based techniques, which presents particular security challenges [19] both in the testing and training stages. Although this assumption isn't always accurate, machine learning approaches operate under an assumption that their environment is benign. One of these security issues is the potential for training data manipulation and the exploitation of model sensitivity to reduce the effectiveness of ML classification and regression [27].

Convolutional Neural Networks are extensively used in the computer vision field for the detection of poisoning attacks due to their ability to extract toxic characteristics from images [1] Here, pre-trained CNN models are refined on poisoned data using transfer learning approaches, and the result is highly effective poisonous data detection. Tolpegin et al. [21] used the CIFAR-10 and Fashion MNIST datasets to investigate label flipping based attacks within a distributed system. They used these datasets to evaluate different labelflipping scenarios. In Federated Systems, these techniques yield better results.

TABLE I. Summarizing Existing Recent Surveys

Literature	Methods used	Challenges
Jonnalagadda et al.(2024)	CNN method of poisoning using MNIST	Data leakage issue
Lahe, A.D et al.(2023)	Different stages of ML pipelining and their vulnerabilities	Not efficient to detect attacks in real-time scenarios
Bovenzi et al.(2022)	Shallow autoencoder, deep autoencoder, and ensemble-based encoder for anomaly detection	Less effectiveness of countermeasures against Data Poisoning Attacks in real-time.
Anisetti et al.(2022)	Random Forest method	Label flipping degrading the performance of plain random forests
Raghavan et al.(2022)	Real-Time Poisoning attacks detection using Model Verification in deep computer vision	Method works on neural networks only
Altoub et al.(2022)	convex polytope method	Ensemble method can be used to improve transferability
Liu, I-Hsien, et al.(2022)	Data Washing and IDA Algorithm for detecting poisoned datasets	Not suitable for detecting poisoning attacks on non-DNN models

Table I summarizes the approaches used in a few recent articles along with the difficulties they faced. While these approaches have made significant strides in mitigating poison attacks, there remains a need for more robust and comprehensive defense mechanisms.

III. Poisoning Attack Model

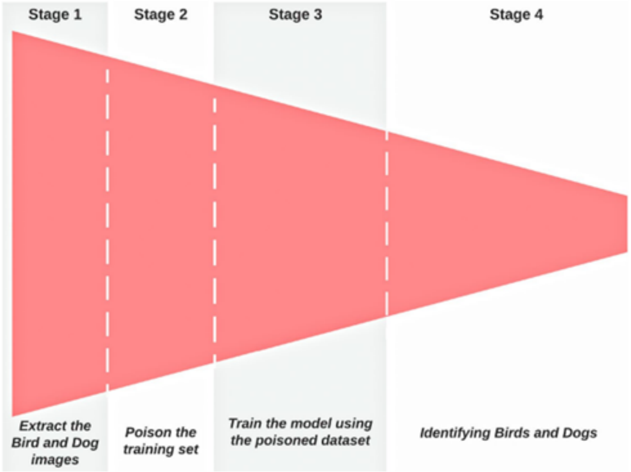
A. Generation of Threats

In order to identify impure images, a threat model is simulated. Generative networks are used here to develop such threat model creation. It is created by injecting poisons into different types of labelled images with the help of Generative Adversarial Networks.

1) Training circumstance: Here, the primary goal is to classify the poisonous and nonpoisonous images using CIFAR10 datasets. A certain amount of data was trained by several clients. Assume a global CNN is trained in a distributed fashion, with each client having access to a subset of the entire dataset. Clients have access to images for every class, and each local data distribution roughly resembles the distribution of the whole dataset.

B. Attacker's Goal

The main goal of attacker is to add malicious behaviour to training datasets. Here, the attacker targets on specific labels which causes manipulation of global model's prediction.GAN is used to misclassify poisonous and nonpoisonous images.Attacker also focusses on degrading the accuracy of global model by adding poison to local datasets. Hence, it creates GAN generated images and assigns some labels to them.The model is trained locally utilising poisoned samples once the resultant images have been combined with each malicious node dataset.



Stage 1
Stage 2
Stage 3
Stage 4
Extract the Bird and Dog images
Poison the training set
Train the model using the poisoned dataset
Identifying Birds and Dogs

Fig. 1. Steps of image poisoning.

C. The Capability of the Adversary

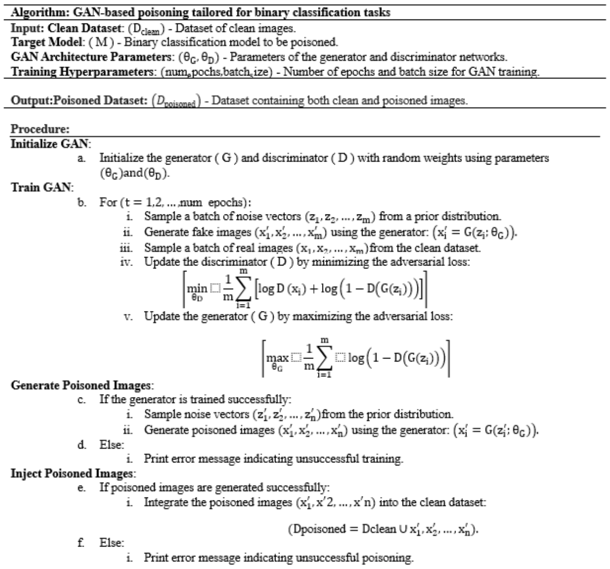
The global aggregation mechanism used by the server is unknown to the attacker.It can only influence learning by means of poisoned model updates. Here, the datasets of the benign customers are unknown to the attacker. But we assume that they are aware that all of the classes accessible in the federated system are also contain the poisoned dataset. Adversary can only increase the compromised client's private collection by adding more generated images, rather than altering it. Finally, it is assumed that the attacker cannot directly access or modify the weights of the local model or affect the local training method.

IV. Proposed Methods

In this paper, Generative Adversarial Networks and transfer learning approaches are used inorder to detect poisoning attacks in machine learning systems. Fig. 1 illustrates the stages of poisoning image.

A. Generating Poisons

To generate poisons in the training data, the GAN approach is employed as an improved technique. By training a generative model to produce images that are perceptually similar to real data, but can trick the classifier into making false predictions, poisoning with a GAN is accomplished. It first retrieves the global parameters from the parameter server in order to update the local model. It then employs a GAN, which consists of a discriminator and a generator, to generate samples of target labels through local training. The generator's goal is to mislead the discriminator into assuming that the generated samples are obtained from the target; the discriminator's role is to identify if the samples are fake and to classify the genuine samples as precisely as possible.The downloaded model acts as the discriminator, while the attacker defines the generator. Once the current round of GAN training is finished, the attacker will intentionally mislabeled the samples that the generator generates. The binary cross entropy loss function and the Adam optimizer are used in the compilation of the generators. Fig. 2 describes The Attack-Poison GAN algorithm.



```
Algorithm: GAN-based poisoning tailored for binary classification tasks
Input: Clean Dataset: ($D_{clean}$) - Dataset of clean images.
Target Model: ( M ) - Binary classification model to be poisoned.
GAN Architecture Parameters: ($\theta_G, \theta_D$) - Parameters of the generator and discriminator networks.
Training Hyperparameters: ($num_epochs,batch_size$) - Number of epochs and batch size for GAN training.

Output:Poisoned Dataset: ($D_{poisoned}$) - Dataset containing both clean and poisoned images.

Procedure:
Initialize GAN:
    a. Initialize the generator ( G ) and discriminator ( D ) with random weights using parameters
       ($\theta_G$)and($\theta_D$).
Train GAN:
    b. For ($t = 1,2, \ldots ,num\ \ epochs$):
        i. Sample a batch of noise vectors ($z_1, z_2, \ldots, z_m$) from a prior distribution.
        ii. Generate fake images ($x'_1, x'_2, \ldots, x'_m$) using the generator: $\left(x'_i = G(z_i; \theta_G)\right)$.
        iii. Sample a batch of real images ($x_1, x_2, \ldots, x_m$)from the clean dataset.
        iv. Update the discriminator ( D ) by minimizing the adversarial loss:
                $\left[\min_{\theta_D} \square \frac{1}{m} \sum_{i=1}^{m} \left[\log D\,(x_i) + \log\left(1 - D\left(G(z_i)\right)\right)\right]\right]$
        v. Update the generator ( G ) by maximizing the adversarial loss:
                $\left[\max_{\theta_G} \square \frac{1}{m} \sum_{i=1}^{m} \square \log\left(1 - D\left(G(z_i)\right)\right)\right]$
Generate Poisoned Images:
    c. If the generator is trained successfully:
        i. Sample noise vectors ($z'_1, z'_2, \ldots, z'_n$)from the prior distribution.
        ii. Generate poisoned images ($x'_1, x'_2, \ldots, x'_n$) using the generator: $\left(x'_i = G(z'_i; \theta_G)\right)$.
    d. Else:
        i. Print error message indicating unsuccessful training.
Inject Poisoned Images:
    e. If poisoned images are generated successfully:
        i. Integrate the poisoned images ($x'_1, x'2, \ldots, x'n$) into the clean dataset:
                ($Dpoisoned = Dclean \cup x'_1, x'_2, \ldots, x'_n$).
    f. Else:
        i. Print error message indicating unsuccessful poisoning.
```

Fig. 2. Attack-Poison GAN algorithm.

In the context of Generative Adversarial Networks (GANs), both the generator and discriminator have specific loss functions that drive their training process. These loss functions are fundamental in guiding each network to improve its performance in the adversarial setup. The objective of the generator in a GAN is to generate synthetic data that resembles the real data well enough to fool the discriminator. The loss function for the generator typically aims to minimize the discrepancy between the generated data distribution and the real data distribution.Binary CrossEntropy Loss and Minimax Loss are used as loss function: Minimax Loss reflects the original adversarial nature of GANs where the generator aims to minimize the probability that the discriminator correctly classifies generated data as fake.

Binary Cross-Entropy Loss can be expressed as:

$$\mathcal{L}\text{gen} = -E_{z\sim p(z)}[\log D(G(z))] \tag{1}$$

where
z is the random noise vector input to the generator
G(z) is the generated output
D(G(z)) is the discriminator's output probability on the generated data.

Minimax Loss can be expressed as

$$\mathcal{L}\text{gen} = \log(1 - D(G(z))) \tag{2}$$

where
$\mathcal{L}_{\text{gen}}$ represents the generator loss function
log is the logarithm function.
D is the discriminator network.
G(z) is the generated output from the generator G.
z is the random noise vector input to the generator G.

B. Convolutional Layers [22]

An image's features are extracted and learned using a convolutional layer [2]. An image passes through or slides through a convolutional filter or kernel based on its size or stride.

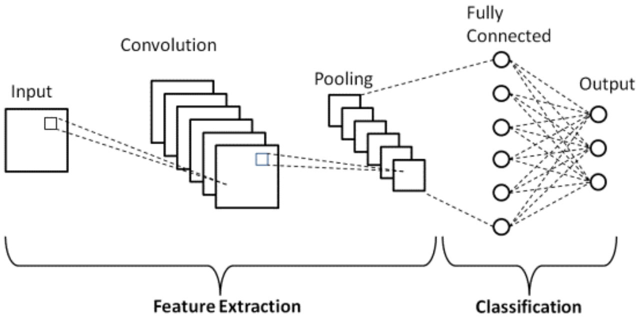


Fig. 3. CNN Architecture[28].

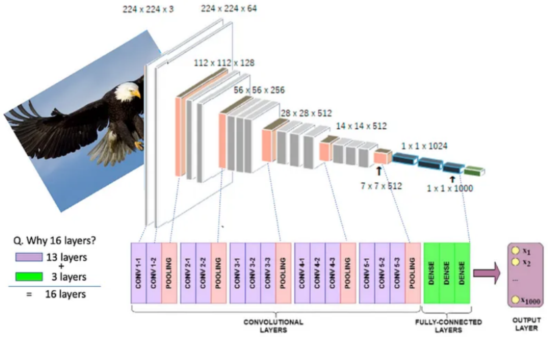

Fig. 4. VGG16 Architecture[9].

Using the kernel's sliding movement as a feature detector, the convolutional layer maps out the features in the image. The convolutional layer maps features from the image using the kernel, a feature detector, and its sliding action. Translational invariance is present in these convolutional filters.Multiple feature learning is possible with more filters. RGB colour images have three channels as well as a depth component. The network breaks these features with the help of the convolution layer. Deeper convolutional layers improve feature detection from a low to a high level, which helps in image detection.

C. Pooling Layer

By reducing the dimensionality of the image without losing its features, the pooling layer compresses the picture layer's dimensions. As a result, overfitting is minimised.Maxpooling, which includes extracting the largest value from a kernel window, is a technique used by CNNs [18].

D. Fully Connected Layer

In the fully linked layer, all neurons are linked to all other neurons. This layer is in control of classification and prediction. The neural network's weights are then modified using back propagation in accordance with the results of a comparison between these predictions and the labels. In the model, a pooling layer is placed after each convolutional layer. Two completely linked layers that come after these layers and meet the output predictions. Three convolutional layers and two fully linked layers constitute the model. Three input channels and sixteen output channels make up the first convolutional layer. The second convolutional layer has 16 input channels and 32 output channels, while the third convolutional layer has 32 input channels and 64 output channels.The 3x3 kernel size is the default. There are 500 output channels and 4*4*64 input channels in the first completely connected layer. The second completely connected layer receives these 500 output channels, which are divided into 10 output channels apiece. Add 0.25 dropout to lessen overfitting.The ADAM optimizer is used, and the learning rate is set to 0.0001. The flattening method and the Relu activation function aid in avoiding the vanishing gradient problem. The CNN workflow is shown in Fig. 3.

E. Transfer Learning with VGG16

When setting up the models for dogs and birds classification using transfer learning with VGG16 [9], we begin by leveraging the pre-trained VGG16 [29] model.This pre-trained model is highly effective at extracting meaningful features from images. By utilizing VGG16 [13] as a base, it has gained knowledge from learning to recognize a wide range of objects and features in images. To ensure that the features learned by VGG16 are preserved and effectively utilized for our classification task, we freeze the convolutional layers of the model. Freezing these layers prevents their weights from being updated during training, preserving the representations learned from ImageNet. This step is crucial for preventing the model from overfitting to the relatively small CIFAR-10 dataset and allows us to leverage the generalization power of the pre-trained model. In the next step,custom classifier layers are build on top of VGG16's frozen convolutional basis. These extra layers are in control of modifying the high-level characteristics that VGG16 extracted for the particular purpose of differentiating between dog and bird images. To transform the 3D feature maps the convolutional layers produced into a 1D feature vector, Flatten layer is added. One or more Dense layers process the flattened representation by applying nonlinear transformations to further process the features. The basic architecture of VGG16 is shown in Fig. 4.

In order to avoid overfitting, dropout layers are frequently placed in between Dense layers and randomly remove a portion of the input units during training. The final layer of the model is an output layer with softmax activation, which produces class probabilities for the categories of interest—in this case, dogs and birds. By compiling the model with appropriate loss and optimization functions,prepare it for training on the dataset. This typically involves using categorical crossentropy loss as the loss function and the Adam optimizer for gradient descent. Before training the model, it's beneficial to inspect the architecture of the model using the summary method.This method gives you information about the model's general structure and the number of trainable parameters. This step helps ensure that the model is configured correctly and ready for training.

Federated systems [24][25] are vulnerable to attacks due to their attacking nature. Malicious clients frequently appear with the intention of interfering with the federated system's training process by directly or indirectly altering the model's weights using data.In such scenario, a malevolent client might add new data or modify the already existing data to suit their needs.At such times, adversaries damage machine learning systems by inserting fake data points or altering already-existing data. One or more opposing nodes within the federated framework may seek to disrupt the federated process in order to carry out model performance collapse or pattern injection. In order to predict this, various experiments helps to look into the effects of the dataset generation based on GAN [8] for the synthesis of attacks known as data poisoning, which can lead to the degradation of a FL model [26]. In order to increase accuracy of detection, the proposed transfer learning method is used. Assume that one attacker is in control of every wild node and can process all of their datasets simultaneously. First, targeted label attack model is generated in which a GAN is trained on a single class, poisoned bird and dog images in this case using CIFAR-10 datasets, and then generate samples of that class. After that the created samples are given the label "Clean" and sent to the malicious clients. As a result, both the benign dataset and the contaminated samples make up the enhanced dataset that each malicious client possesses. The attacks are detected using VGG16.

V. Experimental Evaluation

A. Dataset

CIFAR-10 [11] [16]and CIFAR-100 image datasets are used for experimental evaluation. CIFAR-10 images has over 60,000 colour, low-resolution images in a 32 by 32 format. The photos are separated into ten sections, with roughly 6000 images in each class. Here, GAN is used to create poisoned images of dogs and birds. Subsequently, the contaminated dataset used as a training set for the development of an image classification algorithm. Then,VGG16 is used to extract the characteristics from the manipulated images. Train the model using its features, then assess the model's performance.The dataset undergone preprocessing procedures to get it ready for training and evaluation. Normalization: By dividing each pixel value by 255.0, the image pixel values were scaled to the range [0, 1]. This ensures that the input data falls within a similar numerical range, which can help improve the convergence of optimization algorithms during training. Data Augmentation: To boost the models' capacity for generalisation and to broaden the dataset. This techniques were applied to the training images.The steps contain rotation, width shift, height shift, and horizontal flipping. Data augmentation helps prevent overfitting by providing the model with variations of the training data. Resizing: The poisoned images generated by the GANs were resized to match the dimensions of the CIFAR-10 images, which are 32x32 pixels in size. This resizing step ensures that the poisoned images are compatible with the input size expected by the classification models.

B. Experimental Procedures

Here,both CIFAR-10 datasets and CIFAR-100 datasets are for the proposed work. There are several key steps to build and evaluate models for classifying and detecting poisonous images incorporating transfer learning with VGG16 and addressing the presence of poisoned images. Firstly, it loads the CIFAR-10 dataset, a collection of 60,000 labeled images in 10 classes, and normalizes the pixel values to a range between 0 and 1. This dataset serves as the foundation for training and evaluating the models. Next,by utilizing Generative Adversarial Networks (GANs) to generate poisoned images. It defines and compiles two GAN architectures, one for generating images of dogs and the other for birds. These GANs are trained to produce synthetic images that may potentially disrupt the performance of the subsequent classification models. After the generation of the poisoned images, the algorithm uses VGG16, a pre-trained convolutional neural network (CNN) known for its efficiency in image identification applications, to build up the models for the classification of dogs and birds via transfer learning. The convolutional layers of the VGG16 model are frozen to preserve their learnt features, and the model is loaded without its top classification layers.

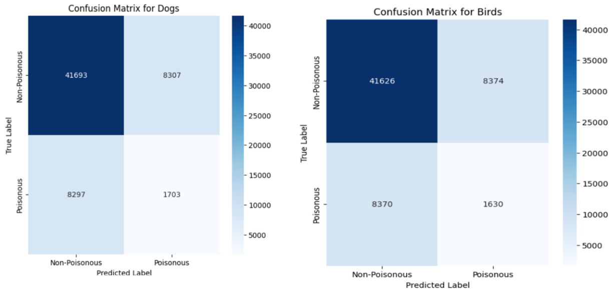

Fig. 5. Confusion matrix using CIFAR-10 datasets.

After that, further layers of custom classifiers are added to the model to modify it for the particular goal of classifying among dogs and birds. The combined dataset—which is divided into training and validation sets—contains both original and polluted images. This data is used to train the models. To enhance model generalisation, data augmentation methods including rotation, width/height shift, and horizontal flip are utilised in addition to the training set. Finally,model is able to detect poisoned images by predicting labels for all images, including both original and poisoned ones. It calculates the percentage of poisoned images correctly identified by each model, shedding light on their robustness in the face of adversarial attacks. This comprehensive evaluation process ensures a thorough understanding of the models' performance and their resilience to potential threats posed by poisoned data.The models' performance is assessed on the validation sets, and the training process is monitored over several epochs. To assess the models' effectiveness,the confusion matrix is shown in Fig. 5. Here,there are two classes such as class0 and class1. Class0 represents images of dogs and the images of bird comes under class1. The model effectiveness can be evaluated by plotting the training and validation loss curves as well as the accuracy curves are plotted which are shown in Fig. 6 and Fig. 7.

C. Experimental Results

The summary of the performance of a classification model on a set of test data is described on the classification report which is shown in Fig. 8.

Inorder to effectively improve F1 score, CIFAR-100 image datasets are also used.CIFAR-100 offers a wider range of classes and images, making it appropriate for a wider range of challenging and complex recognition tasks. The CIFAR-100 dataset is a collection of 60,000 32x32 color images in 100 classes, with 600 images per class. It serves as a

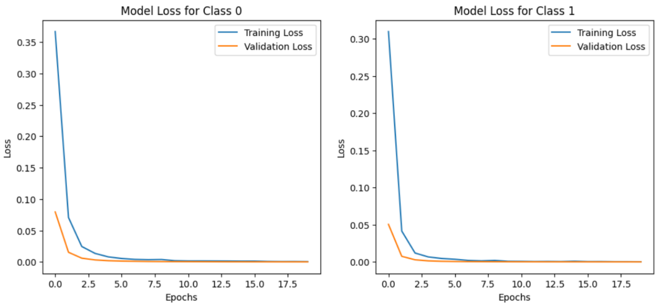

Fig. 6. Model loss curve using CIFAR-10 datasets.

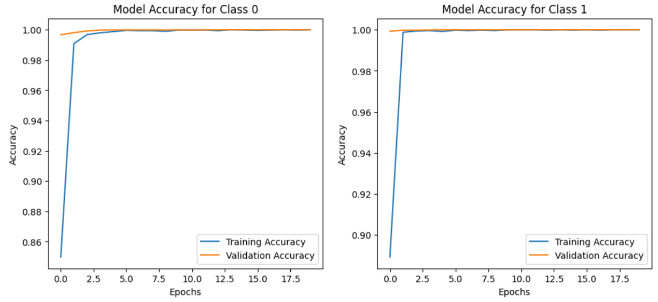

Fig. 7. Accuracy curve using CIFAR-10 datasets.

benchmark dataset for image classification tasks, particularly for multiclass classification.Initially load such datasets,then normalized and resize, and select a subset of classes (select classes 0 (apple) and (aquarium fish) for poisoning. Creates a Generative Adversarial Network to generate poisoned images for selected classes,trains two separate models (one for each class) using transfer learning, evaluates the models' performance by plotting the training loss and accuracy which is shown in Fig. 9 and Fig. 10. It also generates confusion matrices shown in Fig. 11, and assessing its performance on both original and poisoned data using classification report for both classes which is shown in Fig. 12.

Federated settings can be implemented using Keras having 20 clients and the no.of poisoned points can be detected which is shown in the Fig. 13. This novel approach can be applied in distributed ML systems also.

VI. Discussion

The results indicate that the proposed method using transfer learning and a pre-trained VGG16 model is effective in detecting poisoned images in the CIFAR-10 and CIFAR-100 dataset. Both models (for classes 0 and 1) showed high training and validation accuracy, along with strong precision, recall, and F1 scores.

VII. Real World Applications

The proposed framework for poison attack detection in distributed machine learning systems offers tangible benefits across diverse sectors, as corroborated by existing research findings. In the cybersecurity domain, where data integrity is paramount, advanced detection mechanisms are imperative. By integrating the framework into intrusion detection systems, organizations can fortify their capabilities against malicious activities.

Autonomous vehicles, reliant on machine learning algorithms for safe navigation, stand to gain significantly from the framework's implementation. The potential risks posed by poison attacks targeting distributed learning systems within autonomous vehicles. By deploying the framework, automotive manufacturers and transportation authorities can augment their vehicles' defenses against adversarial manipulation, bolstering passenger safety and public trust, as evidenced by studies conducted by [7].

In healthcare, where accurate diagnoses are critical, safeguarding distributed machine learning systems is essential. Poison attacks on these systems can compromise patient confidentiality and introduce diagnostic errors. By adopting the framework, healthcare providers can fortify their defenses against adversarial threats, ensuring the integrity of medical data and the reliability of clinical decision-making processes. Financial institutions face significant risks from poison attacks targeting distributed machine learning systems used in fraud detection and algorithmic trading. The author in [8], underscore the potential impact of adversarial manipulation on financial markets and investor confidence. By integrating the framework into their security protocols, financial institutions can mitigate these risks, protect customer assets, and uphold the integrity of financial transactions.

The main advantages of using this method include:

1) Enhanced detection accuracy: SecureTransfer improves the accuracy of poison attack detection by using pre-trained models that recognise tiny abnormalities in the training set.

2) Scalability: SecureTransfer is a scalable solution for diverse machine learning applications because it utilises transfer learning, which enables it to be applied across several datasets and domains without requiring a significant amount of retraining.

3) Efficiency: By using pre-trained models, the method saves time and resources by reducing the computational overhead often involved with anomaly recognition.

4) Robustness: By offering an extra line of defence against complex poison attacks, SecureTransfer strengthens the resilience of machine learning systems and guarantees dependable model performance.

5) Adaptability: The technique can be applied in a variety of contexts since it can be tailored to various data kinds and attack circumstances.

VIII. Limitations and Future Work

While SecureTransfer demonstrates promising results, it is essential to acknowledge certain limitations. The reliance on pre-trained models may not always guarantee optimal performance, especially when the target task significantly deviates from the original training context. Additionally, the approach's effectiveness may vary based on the nature and sophistication of the poison attack, necessitating ongoing research to refine the model.

Furthermore, the flexibility and adaptability of transfer learning enable the integration of additional defense mechanisms to mitigate the impact of poison attacks [12] on ML systems. Future research directions may explore the combination of transfer learning with other anomaly detection techniques and investigate the robustness of the proposed method against sophisticated poisoning strategies.The findings and methodologies can inspire further studies into the application of transfer learning for other types of adversarial attacks. Future research could explore the integration of SecureTransfer with other ML security techniques to develop comprehensive, multilayered defense strategies.It will also focus on improving the scalability and applicability of SecureTransfer to a broader range of ML tasks.

IX. Conclusion

In conclusion, the use of transfer learning methods for poison attack detection in machine learning systems presents a promising approach to enhance the security and robustness of ML models. Through the integration of pre-trained models such as VGG16, the proposed method leverages the knowledge learned from large-scale datasets to detect anomalies introduced by poisoned data.The experimental results demonstrate the effectiveness of the transfer learning-based approach in accurately identifying poisoned instances across different datasets and scenarios. By combining the feature extraction capabilities of pre-trained models, the proposed method achieves high detection accuracy while maintaining computational efficiency.

Overall, the findings suggest that transfer learning-based approaches hold significant potential for enhancing the security and reliability of ML systems in real-world applications,paving the way for more resilient defense mechanisms against adversarial attacks.

Overview of the Complex Landscape and Future Directions of Ethics in Light of Emerging Technologies

Marianne A. Azer[1],[2], Rasha Samir[2]
School of Information Technology and Computer Science, Nile University[1]
Department of Computers and Systems, National Telecommunications Institute, Egypt[2]

Abstract*—In today's rapidly evolving technological landscape, the ethical dimensions of information technology (IT) have become increasingly prominent, influencing everything from algorithmic decision-making to data privacy and cybersecurity. This paper offers a thorough examination of the multifaceted ethical considerations inherent in information Technology, spanning various domains such as artificial intelligence (AI), big data analytics, cybersecurity practices, quantum computing, human behavior, environmental impact, and more. Through an in-depth analysis of real-world cases and existing research literature, this paper explores the ethical dilemmas and challenges encountered by stakeholders across the IT ecosystem. Central to the discussion are themes of transparency, accountability, fairness, and privacy protection, which are crucial for fostering trust and ethical behavior in the design, deployment, and governance of IT systems. The paper underscores the importance of integrating ethical principles into the technological innovation, emphasizing the need for proactive measures to mitigate biases, uphold individual rights, and promote equitable outcomes. It also explores the ethical implications of emerging technologies such as AI, quantum computing, and the Internet of Things (IoT), shedding light on the potential risks and benefits they entail. Furthermore, the paper outlines future directions and strategies for advancing ethical practices in IT, advocating for multidisciplinary collaboration, global regulatory frameworks, corporate social responsibility initiatives, and continuous ethical inquiry. By providing a comprehensive roadmap for navigating ethical considerations in IT, this paper aims to empower policymakers, industry professionals, researchers, and educators to make informed decisions and promote a more ethical and sustainable digital future.

Keywords*—*Artificial intelligence; cybersecurity; data privacy; digital ethics; ethical considerations; information security; machine learning; technology ethics; transparency

I. Introduction

In recent years, the rapid advancement of technology has revolutionized various aspects of society, from communication and commerce to healthcare and governance. However, this rapid progress has also brought forth complex ethical dilemmas and challenges, particularly in the realm of Information Technology (IT) and cybersecurity. As Artificial Intelligence (AI), big data analytics, and quantum computing continue to permeate every aspect of our lives, ensuring that these technologies are developed and deployed ethically has become a pressing concern. Ethical decision-making in IT involves navigating complex situations where choices impact stakeholders' privacy, security, and overall well-being [1]. This requires adhering to principles like honesty, integrity, fairness, and respect for user rights. For instance, in data privacy, a social media company has access to vast amounts of user data, including personal messages and location information. An ethical decision would be ensuring that this data is not shared with third parties without explicit user consent and implementing robust security measures to protect this information from breaches. In the context of artificial intelligence and bias, for a company developing an AI algorithm for job recruitment, which screens resumes and ranks candidates. An ethical decision involves regularly auditing the algorithm for biases to ensure it does not discriminate against candidates based on race, gender, or age. Amazon abandoned an AI recruiting tool that showed bias against women. The ethical decision would be to correct the biases or halt the tool's use until fairness could be ensured. Regarding security vulnerabilities, for a software company discovering a critical vulnerability in their widely-used application. An ethical decision is to promptly notify users about the vulnerability and release a patch to fix it, rather than concealing the issue to avoid bad publicity. In terms of intellectual property and open source, an IT company using open-source code in their proprietary software must comply with the licensing terms of the open-source software, credit the original authors, and contribute back to the community where possible. Google, Microsoft, and other technology giants contribute to open-source projects like Kubernetes, benefiting the broader technology community while respecting intellectual property rights. In the context of user consent and transparency, mobile applications request access to various phone features, such as the camera, microphone, and contacts. An ethical decision involves clearly explaining why each permission is needed and allowing users to opt-out of non-essential permissions. Applications that provide detailed privacy policies and granular control over permissions, like the Signal messaging app, are known for their strong privacy stance. Regarding environmental impact, for an IT company setting up a new data center. An ethical decision would be implementing energy-efficient technologies and renewable energy sources to minimize environmental impact. Google's commitment to carbon neutrality and using renewable energy for their data centers sets a standard for environmentally responsible operations in the IT industry. Ethical decision-making in IT is crucial for fostering trust, ensuring compliance with legal standards, and promoting social responsibility. By prioritizing ethical considerations, IT professionals can create technology that not only serves business objectives but also contributes positively to society.

This paper aims to comprehensively explore and address ethical considerations within the context of Information Technology (IT). By identifying and presenting various ethical challenges in different IT domains, including artificial intelligence, cybersecurity, big data analytics, and quantum computing, the paper seeks to provide a nuanced understanding of the ethical dilemmas faced by stakeholders. Through the analysis of real-world cases and examples, it aims to offer concrete illustrations of ethical issues encountered in IT practice [3]. Furthermore, the paper endeavors to examine existing ethical frameworks and guidelines applicable to IT, emphasizing principles such as transparency, accountability, fairness, and privacy protection. In addition it highlights the ethical implications of emerging technologies and proposes future directions for ethical practice in order to empower policymakers, industry professionals, researchers, educators, and other stakeholders to navigate ethical challenges effectively and promote a more ethical and sustainable digital future [4], [5].

The contributions of this paper are as follows:

1) A comprehensive coverage of ethical considerations, the paper extensively covers a wide range of ethical considerations within information technology, including AI, cybersecurity, big data analytics, quantum computing, and more. By addressing various domains, it provides a holistic view of the ethical challenges facing the IT sector.
2) In-depth Analysis of Real-world Cases: Through the examination of real-world cases and examples, the paper offers insights into emerging ethical dilemmas encountered in IT practice. This analysis helps stakeholders understand the complexities of ethical decision-making in technology-related contexts.
3) Exploration of the multifaceted landscape of ethical considerations in information security and IT, shedding light on key challenges, strategies, and future directions.
4) Drawing on insights from interdisciplinary research and real-world case studies, this paper offers a comprehensive overview of the ethical dimensions inherent in IT and information security. By synthesizing existing literature and research findings, it identifies key ethical challenges, proposes strategies for addressing them, and highlights the importance of proactive ethical decision-making in technology development and deployment. Moreover, the paper outlines a roadmap for future research and collaboration, emphasizing the need for continuous evaluation, adaptation, and education in the ever-evolving field of information technology ethics.
5) Proposal of Ethical Frameworks and Solutions: Drawing from existing research and ethical principles, the paper proposes practical frameworks and solutions to address identified challenges. These frameworks emphasize transparency, accountability, fairness, and privacy protection, offering actionable guidance for ethical decision-making.
6) Guidance for Policymakers and Industry Professionals: By presenting ethical considerations and suggesting solutions, the paper provides valuable guidance for policymakers, industry professionals, researchers, and educators. It informs the development of policies, regulations, best practices, and educational initiatives aimed at promoting ethical behavior and responsible innovation in IT.
7) Stimulation of Ethical Awareness and Dialogue: Through its thorough analysis and discussion of ethical issues, the paper aims to raise awareness and stimulate dialogue on ethical considerations in IT. By fostering a deeper understanding of ethical implications, it encourages stakeholders to critically reflect on practices and engage in constructive discourse.

The remainder of the paper is organized as follows: Section II represents the Historical Ethical Dilemmas, Section III represents the related work and the ethics in emerging technologies, Section IV illustrates the cybersecurity workforce ethics, Section V shows the future considerations in ethical information technology roadmap, and finally the paper is concluded in Section VI.

II. Historical Ethical Dilemmas

Ethical decision-making in IT encompasses a wide array of domains, including AI and autonomous systems, big data analytics, cybersecurity workforce ethics, environmental impact, bias and fairness in security AI, information warfare, incident response and recovery, privacy-preserving machine learning, and more. Each domain presents unique ethical challenges that demand careful examination and consideration [2]. For instance, the deployment of AI systems raises concerns about transparency, accountability, and algorithmic bias, while cybersecurity practitioners grapple with ethical dilemmas related to whistleblowing and balancing loyalty with ethical responsibilities. Moreover, the environmental impact of data centers and electronic waste disposal underscores the need for sustainable practices in information security. In the following, we mention some technology-related ethical dilemmas that have gained attention in recent history:

1) Facebook-Cambridge Analytica (2018): This case involved the unauthorized harvesting of personal data from millions of Facebook users by the political consulting firm Cambridge Analytica. The data was allegedly used to influence voter behavior in various elections, raising concerns about privacy, data security, and the ethical responsibilities of tech companies. [The Guardian. (2018). Cambridge Analytica: how did it turn clicks into votes? Retrieved from https://www.theguardian.com/news/2018/mar/17/cambridge-analytica-deleted-linkedin-profiles-data-/scraping.]
2) mazon's Facial Recognition (Ongoing): Amazon's facial recognition technology, known as Rekognition, has raised concerns about privacy, surveillance, and potential bias. Critics argue that the technology could be misused by law enforcement or government agencies for mass surveillance and racial profiling, leading to calls for regulation and oversight. [ACLU. (n.d.). Amazon's Face Recognition Falsely Matched 28 Members of Congress With Mugshots. Retrieved from https://www.aclu.org/blog/privacy-technology/surveillance-technologies/amazons-face-recognition-falsely-matched-28.]

3) Tesla Autopilot Crashes (Ongoing): Tesla's Autopilot, an advanced driver-assistance system, has been involved in several accidents, some of them fatal, raising questions about the safety and ethical implications of autonomous driving technology. Critics argue that Tesla may be overpromising the capabilities of its Autopilot system and not doing enough to ensure user safety. [The Verge. (2021). Tesla with Autopilot hits cop car—driver admits he was watching a movie when it happened. Retrieved from https://www.theverge.com/2021/6/2/22465423/tesla-autopilot-crash-texas-cop-car-driver-movie.]
4) Amazon's Working Conditions (Ongoing): Amazon has faced criticism for its working conditions in fulfillment centers, including reports of long hours, low pay, and inadequate breaks. Concerns have been raised about the impact on employee health and well-being, as well as questions about the ethical treatment of workers by one of the world's largest companies. [The New York Times. (2019). How Amazon automatically tracks and fires warehouse workers for 'productivity'. Retrieved from https://www.nytimes.com/2019/04/25/technology/amazon-warehouse-robots.html.]
5) Deepfakes and Misinformation (Ongoing): The rise of deepfake technology, which uses artificial intelligence to create realistic but fake videos or audio recordings, has raised concerns about the spread of misinformation and the potential for misuse in areas such as politics and social media. The ethical implications of deepfakes include issues of consent, privacy, and trust in digital media. [Brookings. (2020). Deepfakes and national security: Getting ahead of the technology. Retrieved from https://www.brookings.edu/research/deepfakes-and-national-security-getting-ahead-of-the-/technology.]
6) SolarWinds Cyberattack (Ongoing): The SolarWinds cyberattack was a supply chain attack that targeted SolarWinds' Orion software, compromising numerous government agencies and private organizations worldwide. It raised concerns about cybersecurity vulnerabilities in software supply chains and the potential for large-scale espionage. [CNN Business. (2020). The SolarWinds hack: How it happened, who was affected, and what comes next. Retrieved from https://www.cnn.com/2020/12/22/tech/solarwinds-hack-explainer/index.html.]
7) WhatsApp-Pegasus Spyware (2019): WhatsApp users were targeted by sophisticated spyware known as Pegasus, developed by the Israeli surveillance company NSO Group. The spyware exploited vulnerabilities in WhatsApp to remotely access users' devices and monitor their communications, raising concerns about privacy and surveillance. [The Washington Post. (2019). WhatsApp sues Israeli surveillance firm, accusing it of hacking activists' phones. Retrieved from https://www.washingtonpost.com/technology/2019/10/29/whatsapp-sues-israeli-surveillance-firm-accusing-it-/hacking-activists-phones.]
8) Clearview AI Facial Recognition (Ongoing): Clearview AI, a facial recognition company, scraped billions of images from social media platforms to create a vast database for law enforcement agencies. This raised concerns about privacy, surveillance, and potential misuse of facial recognition technology. [The New York Times. (2020). The secretive company that might end privacy as we know it. Retrieved from https://www.nytimes.com/2020/01/18/technology/clearview-privacy-facial-recognition.html.]
9) COVID-19 Contact Tracing Apps (Ongoing): Contact tracing apps were developed and deployed worldwide to track and contain the spread of COVID-19. However, they raised concerns about privacy, data security, and potential surveillance, prompting debates over the balance between public health and individual privacy rights. [The Guardian. (2020). Contact-tracing apps help fight Covid-19, but are they worth the privacy loss? Retrieved from https://www.theguardian.com/technology/2020/may/05/contact-tracing-apps-covid-19-worth-privacy-loss.]
10) The Facebook Oversight Board:, established in 2020, serves as an independent body tasked with making binding decisions on content moderation issues on Facebook and Instagram. Comprising experts from various fields, including law, journalism, and human rights, the board provides an avenue for users to appeal decisions made by Facebook regarding the removal or retention of content. This case marks a significant development in addressing concerns about transparency and accountability in content moderation practices on social media platforms. However, the board's decisions have faced scrutiny over their consistency and effectiveness in upholding free speech while combating harmful content. [The New York Times. (2020). Facebook's Oversight Board Is a Deciding Factor in Trump's Case. Retrieved from https://www.nytimes.com/2020/11/14/technology/facebook-oversight-board-trump.html.]
11) Google's Project Dragonfly (Ongoing): Project Dragonfly was a secretive Google project to develop a censored search engine for the Chinese market. It sparked controversy over censorship, human rights, and Google's ethical responsibilities, leading to internal protests and public scrutiny. [The Intercept. (2018). Google plans to launch censored search engine in China, leaked documents reveal. Retrieved from https://theintercept.com/2018/08/01/google-china-search-engine-censorship/.]
12) Reddit GameStop Stock Trading Fiasco (2021): The GameStop stock trading frenzy on Reddit's WallStreetBets subreddit led to significant market volatility and raised questions about market manipulation and the power of online communities to influence financial markets. [The Wall Street Journal. (2021). Reddit's Profane, Greedy Traders Are Shaking Up the Stock Market. Retrieved from https://www.wsj.com/articles/reddits-profane-greedy-traders-are-shaking-up-the/-stock-market-11611517203.]

13) Google's Tracking of Android Phones (2020): Google faced criticism for tracking the location of Android phone users even when location services were disabled, raising concerns about privacy and data collection practices. [Reuters. (2020). Google tracked his bike ride past a burglarized home. That made him a suspect. Retrieved from https://www.reuters.com/article/us-alphabet-google-lawsuit/google-tracked-his-bike-ride-past-a-burglarized-home-/that-made-him-a-suspect-idUSKBN20Y2DO.]
14) Zoom's Security and Privacy Issues (2020): Zoom faced scrutiny over security and privacy issues, including concerns about data encryption, unauthorized access to meetings ("Zoombombing"), and sharing user data with third parties like Facebook. [NPR. (2020). Zoom Faces Scrutiny Over Privacy, Security Practices Amid Increased Use. Retrieved from https://www.npr.org/2020/04/03/826129520/zoom-faces-scrutiny-over-privacy-security-practices-/amid-increased-use.]
15) Capital One Data Breach (2019): Capital One experienced a data breach that compromised the personal information of over 100 million customers, highlighting concerns about data security and the vulnerability of financial institutions to cyberattacks. [The New York Times. (2019). Capital One Data Breach Affects 100 Million; Woman Charged as Hacker. Retrieved from https://www.nytimes.com/2019/07/29/business/capital-one-data-breach-hacked.html.]
16) Huawei Security Concerns (Ongoing): Huawei, a Chinese telecommunications company, has faced allegations of posing national security risks due to its close ties with the Chinese government. Concerns include potential surveillance capabilities and the security of Huawei's products in global telecommunications networks. [BBC News. (2021). Why is Huawei still in the UK despite security concerns? Retrieved from https://www.bbc.com/news/business-56993145.]
17) Google+ Data Breach (2018): Google announced a data breach on its social networking platform Google+ that exposed the private information of up to 500,000 users. The incident raised questions about Google's data protection practices and led to the eventual shutdown of Google+. [The Verge. (2018). Google exposed user data, chose not to tell public. Retrieved from https://www.theverge.com/2018/10/8/17951890/google-plus-data-breach-exposed-user-profile-information-/privacy-notification.]
18) Edward Snowden's NSA Leaks (2013): Edward Snowden, a former contractor for the National Security Agency (NSA), leaked classified documents revealing the extent of government surveillance programs, including the collection of mass data on citizens' communications. His actions sparked a global debate on privacy, government surveillance, and whistleblowing. [The Guardian. (2013). Edward Snowden: the whistleblower behind the NSA surveillance revelations. Retrieved from https://www.theguardian.com/world/2013/jun/09/edward-snowden-nsa-whistleblower-surveillance.]
19) Apple-FBI Dispute (2016): The dispute between Apple and the FBI highlighted the ethical dilemma of enabling access to private data versus safeguarding user privacy. This case underscored the responsibility of technology companies to balance law enforcement's needs with users' fundamental rights to privacy and security. The disagreement centered around the FBI's request for Apple to unlock an iPhone used by a perpetrator in a terrorist attack, raising concerns about the potential creation of a backdoor that could compromise the security and privacy of all users. [The New York Times. (2016). Why Apple is fighting the FBI over iPhone privacy. Retrieved from https://www.nytimes.com/2016/02/18/technology/apple-fbi-san-bernardino-iphone.html.]
20) Whistleblower Chelsea Manning (2010): Chelsea Manning's leak of classified documents shed light on the ethical quandary of exposing classified information to reveal possible wrongdoing. The case ignited debates about the moral responsibility of individuals to expose misconduct in the name of transparency and accountability. Manning's actions raised ethical questions about the balance between loyalty to one's organization and the broader societal duty to expose potential abuses of power. [The Guardian. (2013). Chelsea Manning: the whistleblower behind the biggest leak in US history. Retrieved from https://www.theguardian.com/world/2013/jul/30/bradley-manning-wikileaks-revealed-true.]
21) Equifax Data Breach (2017): The Equifax breach highlighted the ethical obligation of organizations to secure sensitive user data. It brought attention to the consequences of inadequate cybersecurity measures and the potential impact on individuals' financial well-being. The breach exposed the personal information of millions of people and emphasized the need for organizations to prioritize cybersecurity to protect individuals' privacy and prevent potential harm. [The New York Times. (2017). Equifax data breach may affect up to 143 million Americans. Retrieved from https://www.nytimes.com/2017/09/07/business/equifax-cyberattack.html.]
22) AI and Bias (ongoing): The emergence of artificial intelligence systems has unveiled the ethical challenge of algorithmic bias, which can lead to discriminatory outcomes. The ongoing discourse emphasizes the importance of addressing bias to ensure fairness, especially in areas like hiring, lending, and criminal justice. The ethical dilemma arises from the potential amplification of societal biases by AI systems, which may disproportionately affect marginalized communities and perpetuate systemic inequalities. [Nature. (2016). Ethical pitfalls in the automation of criminal justice. Retrieved from https://www.nature.com/news/ethics-of-machine-learning-in-criminal-justice-1.22993.]
23) Biased Algorithms in Criminal Justice (2023): Recent research has highlighted the ethical concerns surrounding the use of biased algorithms in criminal justice. Algorithms used in predicting recidivism

and parole decisions have been found to perpetuate racial and socioeconomic biases, raising questions about the fairness and justice of such systems. [The Atlantic. (2023). Biased algorithms are everywhere, and no one seems to care. Retrieved from https://www.theatlantic.com/technology/archive/2023/09/biased-algorithms-are-everywhere-and-no-one-seems-care/619209/.]

24) Ethics of Social Media Manipulation (2022): The ethical implications of social media manipulation have gained prominence, as platforms are increasingly scrutinized for their role in disseminating misinformation and facilitating polarization. The consequences of algorithmic content curation on user behavior and democratic processes are central to these discussions. [The New York Times. (2022). The rise of social media manipulation. Retrieved from https://www.nytimes.com/2022/05/17/technology/social-media-manipulation.html.]

Table I presents a comparative analysis of ethical dilemmas encountered in the realm of information technology across various years. Each case highlights distinct challenges and considerations pertaining to transparency, accountability, privacy, security, and the ethical responsibilities of both technology companies and individuals. Through this comparative examination, we aim to identify recurring themes, lessons learned, and evolving ethical standards in the rapidly evolving landscape of technology. The table offers insights into how these cases have shaped ethical discourse and influenced decision-making processes in the field of information technology.

III. Related Work

In this section, we explore the different ethical guidelines and frameworks related to technology and overview the efforts done in the literature to investigate the ethics in technology

A. *Ethical Frameworks and Guidelines*

The ethical frameworks and guidelines discussed in the literature, particularly concerning Information Technology (IT), include:

1) ACM Code of Ethics [6]: A set of guidelines developed by the Association for Computing Machinery to ensure professional conduct among IT professionals, emphasizing societal contributions, avoidance of harm, honesty, and fairness.
2) IEEE Code of Ethics [7]: Developed by the Institute of Electrical and Electronics Engineers, this code outlines ethical principles for engineers, focusing on responsibility, honesty, public welfare, and confidentiality.
3) General Data Protection Regulation(GDPR) [8]: A comprehensive regulation enacted by the European Union to protect personal data and privacy, emphasizing lawfulness, fairness, transparency, data minimization, and security.
4) The Belmont Report [9]: A foundational document in research ethics that outlines principles of respect for persons, beneficence, and justice, particularly relevant for IT in the context of human subjects research.
5) Utilitarianism [10]: An ethical theory that advocates for actions that maximize overall happiness and well-being, often applied in IT to make decisions that benefit the majority of users.
6) Deontological Ethics [11]: An ethical approach that focuses on following universal moral rules and duties, respecting individual rights, and ensuring ethical actions regardless of outcomes.
7) Virtue Ethics [12]: This framework emphasizes the development of moral character and virtuous behavior, encouraging IT professionals to cultivate qualities like honesty, integrity, and responsibility.
8) Principlism [13]: An approach that balances multiple ethical principles, including autonomy, beneficence, non-maleficence, and justice, to guide decision-making, often used in healthcare IT.
9) Ethics of Care [14]: A framework that prioritizes relationships, empathy, and context-specific decision-making, ensuring technology meets the needs and concerns of users, particularly vulnerable groups.
10) Sustainable Development Goals (SDGs) [15]: A set of global goals established by the United Nations to promote sustainability and social impact, guiding IT projects to contribute to issues like poverty alleviation, health, education, and environmental protection.

These frameworks provide a broad spectrum of ethical guidelines that help IT professionals navigate complex ethical dilemmas, ensuring that their work promotes trust, integrity, and positive societal impact. Comparing various ethical frameworks and guidelines is crucial for understanding the diverse approaches available for ethical decision-making in Information Technology (IT). Each framework offers unique principles and focus areas that address different ethical challenges, such as privacy, data security, transparency, and social responsibility. By examining these frameworks side-by-side, IT professionals can better appreciate their strengths and limitations, allowing them to select the most appropriate principles for specific situations. This comparative analysis helps ensure that ethical considerations are comprehensively integrated into IT practices, promoting trust, integrity, and positive societal impact across various technological domains. The following table provides a comparative overview of various ethical frameworks and guidelines pertinent to decision-making in the field of Information Technology (IT). Each framework presents a set of principles designed to guide IT professionals in making ethically sound decisions, addressing key areas such as privacy, data protection, transparency, and social responsibility. The frameworks include professional codes like the ACM and IEEE codes of ethics, regulatory standards such as the General Data Protection Regulation (GDPR), and broader ethical theories including utilitarianism and deontological ethics. Additionally, Table II highlights the application of these principles in real-world scenarios, illustrating how ethical considerations can be integrated into IT practices to promote trust, integrity, and positive societal impact.

Prior research has extensively explored the ethical implications of information security across various domains. In the realm of AI and autonomous systems, the authors in [16]–[18] conducted a comprehensive survey of the ethical challenges arising from biases in AI algorithms. Their work highlighted the need for fair and unbiased AI models to

TABLE I. A Comparative Overview of Key Ethical Cases in Information Technology

Case	**Time Period**	**Nature of Ethical Concern**	**Impact on Individuals/Consumers**	**Legal Ramifications**	**Industry Response/Company Actions**	**Public Perception /Trust in Companies**
Facebook-Cambridge Analytica	2018	Data Privacy, Misuse of Data	Data Misuse, Privacy Invasion	Fines, Investigations	Apologies, Policy Changes	Decreased Trust
Amazon's Facial Recognition	Ongoing	Surveillance, Privacy	Privacy Concerns	Potential Regulation	Policy Changes	Decreased Trust
Tesla Autopilot Crashes	Ongoing	Safety, Overpromising	Safety Risks	Investigations	Safety Improvements	Varied
Amazon's Working Conditions	Ongoing	Working Conditions	Work Conditions	Labor Disputes	Policy Changes	Varied
Deepfakes and Misinformation	Ongoing	Misinformation Spread	Misinformation Spread	Potential Regulation	Content Moderation Efforts	Varied
SolarWinds Cyberattack	Ongoing	Cybersecurity	Data Breach	Legal Actions	Security Measures	Decreased Trust
WhatsApp-Pegasus Spyware	2019	Privacy Invasion	Privacy Breach	Legal Actions	Security Patches	Decreased Trust
Clearview AI Facial Recognition	Ongoing	Privacy, Surveillance	Privacy Concerns	Legal Challenges	Policy Changes	Decreased Trust
COVID-19 Contact Tracing Apps	Ongoing	Privacy, Surveillance	Privacy Concerns	Legal Compliance	Policy Changes	Varied
Google's Project Dragonfly	Ongoing	Censorship, Human Rights	Censorship	Employee Protests	Project Cancellation, Policy Changes	Decreased Trust
Facebook Oversight Board	Ongoing	Content Moderation, Free Speech	Content Moderation Policies	Policy Compliance	Content Decisions	Varied
Reddit GameStop Stock Trading Fiasco	2021	Market Manipulation, Free Speech	Financial Losses, Investor Trust	Legal Inquiries	Policy Changes	Varied
Google's Tracking of Android Phones	2020	Privacy, Data Collection	Privacy Invasion	Legal Investigations	Privacy Settings Updates	Decreased Trust
Zoom's Security and Privacy Issues	2020	Privacy, Data Security	Privacy Breaches, Unauthorized Access	Legal Settlements	Security Updates	Decreased Trust
Capital One Data Breach	2019	Data Security	Identity Theft	Legal Settlements	Security Improvements	Decreased Trust
Huawei Security Concerns	Ongoing	National Security, Data Privacy	Data Security, Surveillance Risks	Regulatory Restrictions	Security Measures	Varied
Google+ Data Breach	2018	Data Security	Privacy Breach	Legal Investigations	Service Shutdown, Legal Settlements	Decreased Trust
Edward Snowden's NSA Leaks	2013	Government Surveillance, Whistleblowing	Privacy Violations	Legal Charges, Asylum	N/A	Varied
Apple-FBI Dispute	2016	Privacy, Law Enforcement	Privacy Concerns, Legal Implications	Legal Disputes, Public Debate	Policy Changes	Varied
Whistleblower Chelsea Manning	2010	Transparency, Government Accountability	Legal Consequences	Public Debate, Media Coverage	Varied	
Equifax Data Breach	2017	Data Security	Identity Theft, Financial Loss	Legal Settlements	Security Improvements	Decreased Trust
AI and Bias	Ongoing	Algorithmic Bias	Discriminatory Outcomes	Research, Public Awareness	Algorithm Audits, Bias Mitigation	Varied
Biased Algorithms in Criminal Justice	2023	Algorithmic Bias	Racial and Socioeconomic Biases	Legal Scrutiny	Bias Awareness Campaigns	Varied
Ethics of Social Media Manipulation	2022	Misinformation, Polarization	Impact on Democracy, User Behavior	Public Scrutiny	Content Moderation Efforts	Varied

TABLE II. Comparative Overview of Ethical Frameworks and Guidelines in Information Technology

Ethical Framework/Guideline	Principles/Guidelines	Key Focus Areas	Examples/Applications
ACM Code of Ethics	1) Contribute to society and human well-being 2) Avoid harm 3) Be honest and trustworthy 4) Be fair and take action not to discriminate	Professional conduct, societal impact	Encourages transparency and integrity in software development, emphasizing user privacy and non-discrimination in algorithms.
IEEE Code of Ethics	1) Accept responsibility in making decisions 2) Improve understanding of technology 3) Be honest and realistic 4) Maintain confidentiality	Responsibility, honesty, confidentiality	Guides engineers to prioritize safety, public welfare, and honest disclosure of potential risks, applicable in scenarios like security vulnerability reporting.
General Data Protection Regulation(GDPR)	1) Lawfulness, fairness, and transparency 2) Purpose limitation 3) Data minimization 4) Accuracy 5) Storage limitation 6) Integrity and confidentiality	Data protection, privacy	Requires organizations to obtain explicit consent for data collection, ensure data accuracy, and protect user data, with applications in social media and e-commerce data handling.
The Belmont Report	1) Respect for persons 2) Beneficence 3) Justice	Human subjects research ethics	Applicable in IT for ensuring ethical treatment in user studies and experiments, ensuring informed consent, and equitable treatment of research participants.
Utilitarianism	1) Maximize overall happiness 2) Consider the consequences of actions	Outcome-based decision-making	Used in IT for decisions that impact large user bases, like implementing features that benefit the majority, such as accessibility enhancements in software platforms.
Deontological Ethics	1) Follow universal moral rules 2) Respect individual rights	Duty-based ethics, respect for rules	Applied in scenarios like respecting user privacy and data protection regardless of potential benefits of data exploitation, such as in healthcare IT systems.
Virtue Ethics	1) Focus on moral character 2) Encourage virtuous behavior	Personal integrity, character development	Emphasizes the cultivation of professional virtues like honesty and integrity among IT professionals, promoting ethical behavior in coding practices and team collaborations.
Principlism	1) Autonomy 2) Beneficence 3) Non-maleficence 4) Justice	Balanced ethical decision-making	Often used in healthcare IT, balancing different ethical principles to make decisions about patient data usage, ensuring privacy while enabling beneficial research.
Ethics of Care	1) Emphasize relationships and care 2) Context-specific decision-making	Empathy, relational context	Relevant in IT for developing user-centric designs and empathetic AI, ensuring technology meets the genuine needs and concerns of users, particularly vulnerable groups.
Sustainable Development Goals (SDGs)	1) No poverty 2) Zero hunger 3) Good health and well-being 4) Quality education 5) Gender equality	Global sustainability, social impact.	Guides IT projects towards contributing to global goals, such as using technology for education (e-learning platforms) or healthcare improvements (telemedicine) in underserved communities.

avoid discriminatory outcomes. In [19] different approaches to address bias in AI were analyzed and the importance of algorithmic fairness methods and diverse training data was emphasized. In the field of big data analytics, the challenges of privacy preservation when collecting and analyzing large volumes of data were discussed in [20]. The research focused on data anonymization techniques and the implementation of data protection regulations like the General Data Protection Regulation (GDPR). The authors in [21] explored the ethical implications of big data analytics in cybersecurity, particularly addressing concerns related to data minimization and purpose limitation. Their research proposed methods to protect individual privacy while still allowing valuable data insights. In the context of quantum computing, the potential ethical consequences of quantum-enabled cyber attacks was investigated in [22]. The work highlighted the importance of understanding the implications of using quantum algorithms for offensive cybersecurity strategies. The authors in [23] focused on the ethical considerations of using quantum computing in national security and critical infrastructure protection. Their research emphasized the need for responsible deployment and regulation of quantum computing in the context of information security. Regarding cyber threat intelligence sharing, the ethical challenges of sharing sensitive information between organizations were examined in [24]. The research highlighted the importance of trust, data anonymization, and encryption techniques in promoting ethical and secure cyber threat intelligence sharing. The impact of data privacy regulations on threat intelligence exchange was explored in [25] and the authors emphasized the role of ethical guidelines in shaping responsible sharing practices. In the domain of human behavior in security, the authors in [26]investigated the ethical implications of using social engineering tactics for defensive cybersecurity strategies. Their research discussed the ethical boundaries of manipulating individuals for cybersecurity purposes and proposed guidelines for responsible use. The role of organizational culture in promoting a security-conscious mindset among employees was discussed in [27]. The research emphasized the significance of fostering an ethical security culture that balances security awareness and employee privacy rights. The impact of responsible vulnerability disclosure on user safety and security was discussed in [28] to explore the field of security research and disclosure. The research provided insights into the ethical considerations of bug bounty programs and their role in encouraging responsible disclosure. The authors in [29] discussed the challenges of attributing cyber-attacks to specific actors or entities and discussed the ethical implications of accurate attribution in shared threat intelligence. Concerning the domain of cyber warfare, the ethical implications of using cyber capabilities in geopolitical conflicts were examined in [30]. The authors emphasized the need for international treaties and agreements to regulate cyber warfare and establish rules of engagement. The ethical dimensions of quantum-enabled attacks in the context of cyber warfare were discussed in [31], [32]. The potential consequences of using quantum algorithms for offensive cyber operations and proposed ethical guidelines for responsible conduct were presented. Regarding IoT security, Brown and Lee [33] examined the ethical considerations of data collection and sharing by IoT devices. Their research highlighted the importance of user consent and data protection in IoT design and implementation. Wilson and Kim [34] focused on the challenges of securing IoT devices and preventing large-scale botnet attacks. Their research proposed strategies to ensure ethical IoT security practices among manufacturers, regulators, and users. In the context of biometrics, Chen and Johnson [35] explored the ethical implications of using biometrics for surveillance and law enforcement. Their research discussed the potential impact on privacy and civil liberties and emphasized the role of informed consent in ethical biometric practices. Martinez and Brown [36] investigated the challenges of biometric data storage and proposed secure encryption and access control mechanisms to protect sensitive information. Regarding the cybersecurity workforce, the ethical challenges faced by cybersecurity professionals in balancing loyalty and ethical responsibilities were studies in [37]. The research provided insights into decision-making models used by practitioners and the impact of organizational culture on ethical behavior. The authors in [38] explored the role of professional codes of conduct and certifications in promoting ethical behavior in the cybersecurity workforce. Their research discussed the significance of policies that protect whistleblowers and foster a culture of accountability. In the domain of environmental impact, the carbon footprint of data centers and explored strategies for reducing their environmental impact was examined in [39]. The role of energy-efficient data centers and renewable energy sources in promoting green computing practices was emphasized. The authors in [40] investigated the challenges of e-waste disposal in the information security industry and proposed environmentally responsible solutions to address electronic waste. Regarding the ethics of Artificial General Intelligence (AGI), the potential societal impact of AGI deployment and proposed strategies for mitigating negative consequences was explored in [41]. The need for transparency, fairness, and human control over AGI systems was mentioned. The ethical implications of using AGI in cybersecurity and the risks of autonomous cyber attacks were addressed in [42]. The research recommended international collaboration to establish guidelines for responsible AGI development and deployment. In the context of security AI, the ethical implications of bias in security AI and its impact on decision-making were examined in [43]. The authors discussed the challenges of identifying and mitigating bias in AI models used for security tasks. The role of interpretability and explainability in ensuring transparent and fair security AI systems was discussed in [44]. The authors emphasized the significance of AI models that can be audited and understood to address bias. To address information warfare, the ethical implications of using information warfare as a geopolitical tool were investigated in [45]. The research discussed the potential consequences of disinformation and propaganda dissemination on individuals and societies. The authors in [46] explored the challenges of defining the boundaries of ethical conduct in information warfare and emphasized the role of international collaboration and multilateral agreements in establishing ethical guidelines. In the context of incident response and recovery, frameworks for balancing transparency and confidentiality during incident response efforts were examined in [47], [48]. The authors discussed the importance of clear incident response policies and communication plans to respond ethically to security incidents. The ethical implications of incident response decision-making and information disclosure were investigated in [49]. The research explored the challenges of balancing transparency and confidentiality to protect sensitive information. Regarding privacy-preserving machine learning, the ethical implications of using machine learning for security applications and data privacy concerns were explored in [50]. The research discussed the challenges of preserving user privacy while maintaining model accuracy in security AI. The authors in [51] investigated the role of privacy-preserving techniques in promoting responsible and ethical machine learning for security. Their research explored techniques like federated learning and differential privacy to protect user data while deriving valuable insights. It is important to build upon the existing research in these areas, to advance ethically sound practices, address emerging challenges, and create a secure and trustworthy information security ecosystem.

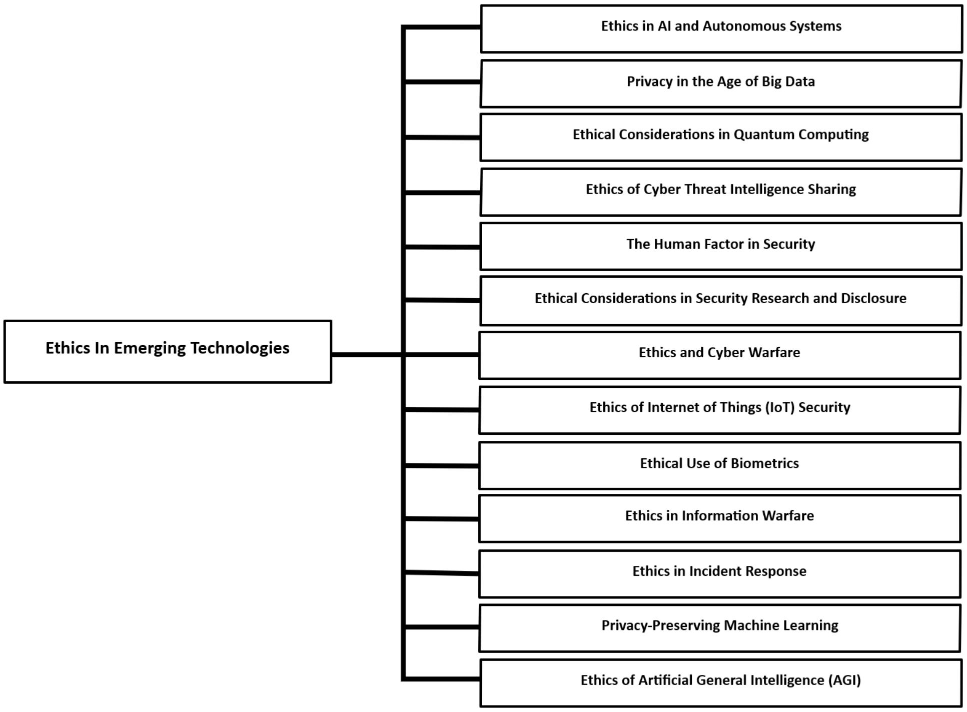
B. Ethics in Emerging Technologies

In this section, we explore various ethical considerations spanning across different domains within information security as shown in Fig. 1. These ethical considerations are vital as technology continues to advance and reshape our digital landscape. From the ethical implications of AI and autonomous systems to the challenges posed by big data analytics, quantum computing, and cybersecurity workforce ethics, each topic addresses critical issues that require thoughtful examination and ethical guidance. We explore the challenges, proposed solutions, real-life cases, and example research focuses for each area, providing a comprehensive overview of the multifaceted ethical landscape in information security. Through interdisciplinary collaboration and a commitment to ethical principles, we aim to foster a secure and trustworthy digital ecosystem that upholds individual rights and promotes responsible innovation.

1) Ethics in AI and Autonomous Systems: Ethical considerations surrounding AI and autonomous systems are critical as they become increasingly integrated into information security. AI systems, driven by machine learning algorithms, are now being used for a wide range of security applications, such as threat detection, anomaly detection, and incident response. However, one major concern is the potential for bias in AI algorithms, leading to discriminatory outcomes [52]. Biases in AI algorithms can arise from the data used to train them. For example, if historical data used to train a facial recognition system is biased towards a certain demographic, the system may exhibit higher error rates for other demographics. This can lead to unjust profiling or discrimination, especially when deployed in law enforcement or security applications. Another challenge is the accountability of AI-driven actions. As AI systems make autonomous decisions, it becomes difficult to attribute responsibility in case of harm. In high-stakes applications like autonomous vehicles, determining who is responsible for accidents becomes a complex ethical question [53]. There are many real life cases that happened in this domain. In 2018, a study revealed that some facial recognition algorithms exhibited higher error rates for women and people of color, leading to concerns about unjust profiling and discrimination. In 2020, an autonomous vehicle involved in a fatal accident raised questions about accountability and responsibility in cases of harm caused by AI-driven systems. Ethical research in AI and autonomous systems should focus on developing fair and unbiased AI algorithms [54], [55]. Researchers should explore techniques to identify and mitigate bias in AI models, such as algorithmic fairness methods and diverse training data. Additionally, transparent and interpretable AI models can help in understanding the decision-making process and attributing accountability. Developing ethical guidelines for AI deployment and regulation can also provide a framework for responsible use. The research can focus on the following: Investigating the impact of biased AI algorithms on vulnerable populations, analyzing the role of human biases in shaping AI training data, and exploring the ethical implications of AI deployment in security-critical applications.

2) Privacy in the Age of Big Data: Big data analytics offer significant advantages in information security, enabling organizations to identify patterns and trends that may indicate cyber threats. However, the use of big data raises ethical concerns related to privacy. Striking a balance between leveraging data for security purposes and safeguarding individual privacy rights is crucial. Collecting and analyzing large volumes of data can lead to unintended privacy breaches [56]. For example, when aggregating data for analysis, there is a risk of re-identifying individuals from supposedly anonymized data. Additionally, organizations must consider the principles of data minimization and purpose limitation to avoid excessive data collection and use. Another challenge is the Cambridge Analytica scandal, which highlighted how personal data from millions of Facebook users was accessed and used without their consent for targeted political advertising [57]. This raises concerns about data privacy and ethical data practices in the context of big data analytics. In healthcare, the use of big data analytics on patient data raises ethical concerns about the privacy and confidentiality of sensitive medical information. Ethical research in big data analytics should focus on developing methods for data anonymization, secure data sharing, and privacy-preserving analytics. Techniques such as differential privacy can help protect individual privacy while still allowing for valuable data insights. Implementing data protection regulations, such as the General Data Protection Regulation (GDPR), can also provide a legal framework for ethical data practices. There are many openings for research in this domain: Investigating the impact of data breaches on individual privacy and security, analyzing the effectiveness of privacy-enhancing technologies in big data analytics, and exploring the ethical implications of using personal data for targeted marketing and surveillance.

3) Ethical Considerations in Quantum Computing: The emergence of practical quantum computing presents both opportunities and ethical challenges in information security. Quantum computers have the potential to break classical cryptographic systems, leading to data breaches and unauthorized access. Quantum computers can factor large numbers exponentially faster than classical computers, posing a significant threat to current public-key encryption systems [58]. This raises concerns about data security in a post-quantum world and the need to develop quantum-resistant cryptographic algorithms. Another challenge is the ethical implications of using quantum-enabled attacks. For instance, quantum algorithms can be used to efficiently break encryption keys, but their deployment could have serious consequences for data privacy and confidentiality. In 2019, Google claimed ”quantum supremacy” when its quantum processor performed a task faster than the most advanced supercomputer, raising concerns about the implications of quantum computing for data security [59]. Another current issue is the development of quantum-resistant cryptographic algorithms, it has become



Ethics In Emerging Technologies

Ethical Use of Biometrics
Ethics in Information Warfare
Ethics in Incident Response
Privacy-Preserving Machine Learning
Ethics of Artificial General Intelligence (AGI)

Fig. 1. Ethics in emerging technologies.

a pressing research focus in the field of information security to protect data from future quantum threats. Ethical research in quantum computing should focus on developing quantum-resistant cryptographic algorithms and assessing the ethical consequences of quantum-enabled attacks. Quantum-safe encryption schemes, such as lattice-based cryptography or hash-based signatures, are some of the proposed solutions in the literature. Additionally, educating policymakers and the public about the potential impact of quantum computing on data security can promote informed decision-making. There are many possible directions for research: Investigating the ethical dimensions of quantum-enabled attacks, analyzing the vulnerabilities of current cryptographic systems to quantum attacks [60]. This is in addition to exploring the ethical implications of quantum computing in national security and critical infrastructure protection.

4) *Ethics of Cyber Threat Intelligence Sharing:* Effective cyber threat intelligence sharing is essential for collective defense against cyber threats. However, ethical challenges arise concerning data privacy and data ownership when sharing sensitive information between organizations. Sharing threat intelligence requires trust between organizations, but concerns about data privacy and liability hinder some from sharing critical information. Organizations may fear that sharing threat intelligence could expose them to legal or reputational risks if the information is mishandled. Additionally, sharing threat intelligence can raise ethical questions about data ownership. While organizations should contribute to collective defense efforts, they also need to ensure that their proprietary information remains protected. In 2017, the WannaCry ransomware attack affected organizations worldwide, and timely sharing of threat intelligence could have helped prevent or mitigate its impact. However, concerns about data privacy and liability hindered some organizations from sharing critical information. In the financial sector, the sharing of cyber threat intelligence among banks has been limited due to competitive concerns and questions about data ownership, leaving institutions potentially vulnerable to coordinated attacks. Ethical research should focus on developing frameworks for responsible and secure cyber threat intelligence sharing that strike a balance between collective defense and safeguarding individual and organizational rights. Encouraging data anonymization and adopting encryption techniques can protect sensitive information while allowing for valuable intelligence sharing. The establishment of public-private partnerships and Information Sharing and Analysis Centers (ISACs) can also facilitate ethical threat intelligence sharing. Research should investigate the barriers to effective threat intelligence sharing, analyze the impact of data privacy regulations on threat intelligence exchange, and explore the ethical implications of attribution and information accuracy in shared threat intelligence.

5) *The Human Factor in Security:* Human behavior plays a pivotal role in information security, and ethical considerations are essential in shaping security culture within organizations. Employees' actions and decisions can significantly impact an organization's security posture. Human vulnerabilities, such as social engineering, remain a significant challenge for information security. Attackers exploit human psychology to manipulate employees into disclosing sensitive information or performing actions that compromise security. Another challenge is the ethical dimension of security awareness and training programs. Organizations must strike a balance between fostering a security-conscious mindset and avoiding intrusive surveillance or violating employees' privacy rights. Ethical research should explore the design of security awareness and training programs that consider the impact of security policies on employees.

Organizations can implement security training that educates employees about potential risks without compromising their privacy. Moreover, fostering a culture of open communication and encouraging employees to report security incidents can help in mitigating security risks. Research should focus on investigating the effectiveness of security awareness training in reducing human-related security breaches, analyzing the ethical implications of using social engineering tactics in defensive or offensive cybersecurity strategies, and exploring the role of organizational culture in promoting a security-conscious mindset among employees.

6) Ethical Considerations in Security Research and Disclosure: Security researchers play a critical role in identifying vulnerabilities and helping organizations improve their security. However, ethical dilemmas arise when disclosing vulnerabilities responsibly. Responsible vulnerability disclosure involves striking a balance between timely informing affected parties and giving them sufficient time to develop and release patches. Coordinating the disclosure process can be challenging, especially when multiple stakeholders are involved. Another challenge is determining the severity of a vulnerability and the likelihood of exploitation. Researchers must assess the potential risks and impact on users and organizations before publicly disclosing the vulnerability. Ethical research should examine different approaches to vulnerability disclosure, considering factors such as severity, likelihood of exploitation, and the impact on users and organizations. Collaboration between researchers, vendors, and relevant authorities can lead to coordinated and effective disclosure processes. It is important to investigate the impact of responsible vulnerability disclosure on user safety and security, analyze the ethical implications of bug bounty programs and their role in encouraging responsible disclosure, and explore the role of ethical guidelines and best practices in shaping responsible disclosure policies.

7) Ethics and Cyber Warfare: The use of cyber capabilities in warfare raises ethical concerns about the potential for harm to civilian infrastructure, critical services, and innocent individuals. Ethical principles must guide the development and use of offensive cyber capabilities. Attribution in cyber warfare remains a significant challenge, making it difficult to hold perpetrators accountable. The use of proxy servers and advanced evasion techniques can obfuscate the true source of cyber attacks. Another challenge is determining the proportionality of cyber responses during times of conflict. Unlike traditional warfare, cyber attacks can have far-reaching and unpredictable consequences, and measuring the appropriate response can be complex. Ethical research should explore the development of international norms and guidelines for responsible conduct in cyberspace during times of conflict. Engaging with policymakers, international organizations, and legal experts can help establish ethical frameworks for cyber warfare. More research should include investigating the ethical implications of using cyber capabilities in geopolitical conflicts, analyzing the challenges of attributing cyber attacks to specific actors or entities, and exploring the development of international treaties and agreements to regulate cyber warfare and establish rules of engagement.

8) Ethics of Internet of Things (IoT) Security: The proliferation of IoT devices introduces unique ethical considerations. Researchers must address issues of data protection, user consent, and potential vulnerabilities that could be exploited by malicious actors. Challenges: IoT devices often collect and transmit vast amounts of data, raising concerns about user consent and data ownership. Users may not be fully aware of the data collected and shared by IoT devices, leading to potential privacy violations. Another challenge is the security of IoT devices themselves. Many IoT devices lack proper security mechanisms, making them susceptible to exploitation by malicious actors. Compromised IoT devices can be used in large-scale botnet attacks, leading to significant security risks. Ethical research should investigate design principles for IoT devices, emphasizing security and privacy-by-design. Implementing industry standards for IoT security can help ensure that devices are resistant to attacks. Additionally, educating users about the data collected by IoT devices and obtaining explicit consent for data sharing are essential for protecting user privacy. Research can tackle the following issues: The ethical implications of data collection and sharing by IoT devices, the challenges of securing IoT devices and preventing large-scale botnet attacks, and the role of manufacturers, regulators, and users in ensuring ethical IoT security practices.

9) Ethical Use of Biometrics: Biometric technologies, such as fingerprint or facial recognition, are increasingly used for authentication and identification. Ethical concerns arise regarding user consent, data storage, and the potential for misuse of biometric data. Biometric data is sensitive and unique to each individual, raising concerns about the secure storage and use of such data. Unauthorized access to biometric databases can lead to identity theft and potential misuse of biometric information. Another challenge is obtaining informed consent from individuals for biometric data collection and usage. Users may not fully understand the implications of sharing their biometric information, and obtaining explicit consent becomes critical to ensure ethical use. Ethical research should propose guidelines for the transparent and ethical use of biometric data, emphasizing user consent and data protection. Implementing strong encryption and access controls for biometric databases can help safeguard the data from unauthorized access. There are important issues that need to be considered in research: The ethical implications of using biometrics in authentication and identification systems, the challenges of securing biometric data and preventing unauthorized access, and the role of regulations and user education in promoting ethical biometric practices.

10) Ethics in Information Warfare: Information warfare involves the use of information and misinformation as a strategic tool in conflicts. It raises ethical concerns about the dissemination of false information, propaganda, and attacks on public trust. The anonymity and ease of spreading information on the internet make it challenging to control the spread of false or harmful information. Information warfare can exploit existing societal divisions, leading to the erosion of trust and social cohesion. Another challenge is the use of social media platforms to amplify misinformation. The use of bots and fake accounts to spread propaganda can manipulate public opinion and influence democratic processes. Ethical research should focus on countering misinformation and propaganda through media literacy programs and fact-checking initiatives. Strengthening social media platforms' policies and algorithms to detect and remove false information can also be instrumental in combating information warfare. The following issues should be investigated. The ethical implications of information warfare in destabilizing societies and democracies, the role of social media platforms in amplifying misinformation and propaganda, and the effectiveness of media literacy programs in empowering individuals to critically evaluate information.

11)Ethics in Incident Response: Incident response involves reacting to and mitigating cyber incidents promptly. Ethical considerations are essential in balancing effective response actions and preserving evidence for investigation. Incident response teams face the challenge of rapidly containing cyber incidents to prevent further damage. In urgent situations, there may be pressure to take immediate actions that could inadvertently destroy crucial evidence. Another challenge is the ethical handling of sensitive data during incident response. Incident responders must ensure that confidential information is adequately protected and not exposed to unauthorized individuals. Ethical research should explore best practices for incident response, emphasizing the preservation of evidence and the responsible handling of data. Incident response teams should be trained in ethical decision-making during high-stress situations. It is important to explore the ethical challenges in balancing rapid response actions with preserving evidence during cyber incidents, analyze the role of incident response policies and guidelines in guiding ethical decision-making, and explore the role of cybersecurity certifications and training in promoting ethical incident response practices.

12)Privacy-Preserving Machine Learning: Machine learning techniques offer valuable insights but can also involve the use of personal data. Privacy-preserving machine learning techniques aim to protect individual privacy while still enabling valuable analysis. Traditional machine learning models often require centralized data collection, which raises privacy concerns. Sharing sensitive data between organizations or with third parties can result in privacy breaches. Another challenge is the potential for model inversion attacks, where attackers can infer sensitive information from a trained machine learning model [61]. Privacy-preserving techniques must protect against such attacks. Ethical research should focus on developing privacy-preserving machine learning techniques, such as federated learning and secure multi-party computation. These techniques allow data analysis without the need for centralized data collection, thereby reducing privacy risks [62]. More research should be directed to investigating the privacy implications of traditional machine learning models and centralized data collection, analyzing the effectiveness of privacy-preserving machine learning techniques in protecting against model inversion attacks, and exploring the adoption of privacy-preserving machine learning in various domains to protect sensitive data.

13) Ethics of Artificial General Intelligence (AGI): AGI refers to highly autonomous systems capable of outperforming humans in most economically valuable work. Ethical considerations become paramount as AGI development progresses. AGI can have far-reaching societal impacts, including automation of various jobs and ethical concerns surrounding control and accountability. Ensuring that AGI systems act ethically and align with human values is critical. Another challenge is the potential for AGI to concentrate power and resources, leading to economic disparities and exacerbating existing societal inequalities. Ethical research should explore the development of AI systems that are transparent, interpretable, and capable of aligning with human values. Implementing frameworks for value alignment and AI safety can help ensure that AGI systems are developed and deployed responsibly. Other important research areas are: The ethical implications of AGI deployment on the job market and workforce, the challenges of value alignment in AGI systems to ensure ethical decision-making, and the role of AGI in addressing or exacerbating societal inequalities and ethical considerations in AGI governance. Ethical considerations in information security are multidimensional and continue to evolve with technological advancements. An ethical framework that guides the responsible use of technology and address potential harms should be developed. By integrating ethics into information security practices, a safer and more trustworthy digital ecosystem can be built for the future.

IV. Cybersecurity Workforce Ethics

Ethical considerations play a crucial role in shaping the behavior and decisions of cybersecurity professionals. Conflicts of interest, whistleblowing, and adherence to ethical guidelines are some of the challenges faced by cybersecurity practitioners. Cybersecurity professionals may face conflicts of interest, such as protecting their employer's interests versus disclosing vulnerabilities publicly. Balancing loyalty to the employer and ethical responsibilities can be a complex ethical dilemma. Another challenge is the role of cybersecurity professionals in whistleblowing. When encountering unethical practices within their organizations, cybersecurity professionals may struggle with the decision to report the misconduct. Ethical research could investigate decision-making models for cybersecurity professionals and explore the role of organizational culture in promoting ethical behavior [63]. Organizations can implement policies that encourage ethical conduct, protect whistleblowers from retaliation, and foster a culture of accountability. Important issues that need further investigations are: The ethical challenges faced by cybersecurity professionals in balancing loyalty and ethical responsibilities, the impact of organizational culture on ethical decision-making among cybersecurity practitioners, and the role of professional codes of conduct and certifications in promoting ethical behavior in the cybersecurity workforce.

1) Environmental Impact of Information Security: The rapid growth of digital infrastructure has environmental consequences, and ethical research should examine the carbon footprint and environmental impact of information security practices. The energy consumption of data centers, particularly those powering cloud services and cryptocurrency mining, contributes significantly to carbon emissions. Reducing the environmental impact of data centers is a challenging task. Another challenge is the responsible disposal of electronic waste generated from outdated or malfunctioning hardware. Improper e-waste disposal can lead to environmental pollution and health hazards. Ethical research could explore ways to minimize the carbon footprint of information security practices. Promoting energy-efficient data centers, renewable energy sources for powering data centers, and virtualization technologies can help reduce energy consumption. More research should be directed to investigating the environmental impact of data centers and exploring strategies for reducing their carbon footprint, analyzing the challenges of e-waste disposal in the information security industry and proposing environmentally responsible solutions, and exploring the role of green computing and sustainable practices in information security [64].

2) Bias and Fairness in Security AI: AI systems used in information security may inadvertently perpetuate biases, leading to unfair outcomes in threat detection or decision-making processes. AI algorithms can inherit biases from biased training data, leading to discriminatory outcomes in security-related tasks. Another challenge is the lack of transparency in some AI models, making it challenging to identify and mitigate bias effectively. Ethical research could explore methods to identify and mitigate bias in security AI models, ensuring equitable and unbiased security practices. Implementing fairness-aware AI models and auditability mechanisms can help enhance transparency and address bias in security AI. The ethical implications of bias in security AI and its impact on decision-making, the challenges of identifying and mitigating bias in AI models used for security tasks, and the role of interpretability and explainability in ensuring transparent and fair security AI systems should be explored.

3) Ethical Implications of Information Warfare: As information warfare becomes a potent tool in geopolitical conflicts, ethical research should examine the implications of using information as a weapon. Information warfare blurs the lines between traditional warfare and cyber operations, making it difficult to define the boundaries of ethical conduct. Another challenge is the potential for psychological harm to individuals and societies targeted by disinformation and propaganda. Ethical research could assess the impact of information warfare on individuals and societies and propose ethical guidelines for responsible use. Developing international norms and agreements for responsible conduct in information warfare can help mitigate potential harm. The ethical implications of using information warfare as a geopolitical tool should be investigated as well as the challenges of defining the boundaries of ethical conduct in information warfare. In addition, the role of international collaboration and multilateral agreements in establishing ethical guidelines for information warfare should be explored.

4) Ethics in Incident Response and Recovery: Ethical decision-making is vital in incident response and recovery efforts. Incident response teams must balance transparency with confidentiality to mitigate damage effectively. Incident response teams may face ethical dilemmas when deciding how much information to disclose to the public and affected parties. Balancing transparency with the protection of sensitive information is a complex challenge. The ethical responsibility of organizations to inform affected individuals about data breaches promptly is also very important. Ethical research could investigate frameworks for incident response that consider the implications of transparency and confidentiality. Implementing clear incident response policies and communication plans can help organizations respond ethically and responsibly to security incidents. The following issues should be explored: The ethical implications of incident response decision-making and information disclosure, the challenges of balancing transparency and confidentiality in incident response efforts, and the role of ethical guidelines and best practices in shaping incident response and recovery policies.

5) Privacy-Preserving Machine Learning for Security: As machine learning is increasingly employed in security applications, preserving user privacy while benefiting from data-driven insights is a critical ethical challenge. Security applications often require analyzing sensitive data, raising concerns about preserving user privacy and data protection. Another challenge is the trade-off between data privacy and model accuracy. Applying privacy-preserving techniques can reduce model performance, making it challenging to strike the right balance. Ethical research could explore privacy-preserving machine learning techniques, such as federated learning, that enable collaborative analysis without sharing raw data [65]. Implementing differential privacy and homomorphic encryption can help protect user data while still allowing valuable insights to be derived. More research should be directed to: The ethical implications of using machine learning for security applications and data privacy concerns, the challenges of preserving user privacy while maintaining model accuracy in security AI, and the role of privacy-preserving techniques in promoting responsible and ethical machine learning for security [66].

By addressing these directions through rigorous ethical research and considerations, the information security community can enhance its practices, protect individual rights, and promote a secure and ethical cyberspace for all stakeholders. Interdisciplinary collaboration, engagement with policymakers, and the application of ethical principles are crucial for building a sustainable and trustworthy information security ecosystem.

Table III provides an overview of key ethical considerations spanning various domains within information security, including AI and autonomous systems, big data analytics, quantum computing, cyber threat intelligence sharing, the human factor in security, incident response, and more. Each topic is accompanied by a description of its ethical implications, challenges faced, proposed solutions, example research focuses, and real-life cases. By addressing these ethical dimensions through interdisciplinary collaboration and a commitment to ethical principles, stakeholders can foster a secure and trustworthy digital ecosystem that upholds individual rights and promotes responsible innovation.

V. Future Considerations in Ethical Information Technology Roadmap

Analyzing the ethical dilemmas presented by various cases in information technology brings to light several crucial lessons for both individuals and institutions:

1) Transparency and Accountability: The cases examined highlight the paramount importance of transparency and accountability in the deployment and management of technology. The lack of transparency can lead to public mistrust, while accountability ensures that those responsible for technology-related decisions are held answerable for their actions. Clear guidelines for data collection, usage, and sharing are essential to maintain integrity.

2) Balancing Rights and Security: The delicate balance between individual rights and national security emerges as a recurring theme. The cases emphasize the need to navigate this balance cautiously, considering the potential consequences of compromising civil liberties in the name of security. A nuanced

TABLE III. Ethical Considerations in Information Security

Topic	Description	Challenges	Proposed Solutions	Example Research Focus
Ethics in AI and Autonomous Systems	Ethical considerations in AI and autonomous systems.	Biases in AI algorithms, accountability of AI-driven actions.	Developing fair and unbiased AI algorithms, transparent models, ethical deployment guidelines.	Biased AI algorithms on vulnerable populations.
Privacy in the Age of Big Data	Ethical concerns related to privacy in big data analytics.	Re-identifying individuals from anonymized data, data breaches.	Data anonymization, secure data sharing, privacy-preserving analytics.	The impact of data breaches on individual privacy and security.
Ethical Considerations in Quantum Computing	Ethical challenges in practical quantum computing.	Threats to classical cryptographic systems, ethical implications of quantum-enabled attacks.	Developing quantum-resistant cryptographic algorithms, assessing ethical consequences.	The ethical dimensions of quantum-enabled attacks.
Ethics of Cyber Threat Intelligence Sharing	Ethical challenges in sharing cyber threat intelligence.	Data privacy, data ownership, barriers to sharing.	Secure sharing frameworks, data anonymization, public-private partnerships.	The barriers to effective threat intelligence sharing.
The Human Factor in Security	Ethical considerations regarding human behavior in security.	Human vulnerabilities, ethical dimensions of security awareness training.	Ethical security training, open communication, organizational culture.	The effectiveness of security awareness training in reducing human-related security breaches.
Ethical Considerations in Security Research and Disclosure	Ethical dilemmas in vulnerability disclosure.	Responsible vulnerability disclosure, severity assessment.	Coordinated disclosure processes, ethical guidelines.	The impact of responsible vulnerability disclosure on user safety and security.
Ethics and Cyber Warfare	Ethical implications of using cyber capabilities in warfare.	Attribution, proportionality of cyber responses.	International norms, engagement with policymakers.	The ethical implications of using cyber capabilities in geopolitical conflicts.
Ethics of Internet of Things (IoT) Security	Ethical considerations in IoT security.	Data protection, device vulnerabilities.	Privacy-by-design principles, industry standards.	The ethical implications of data collection and sharing by IoT devices.
Ethical Use of Biometrics	Ethical concerns regarding biometric technologies.	Data storage, informed consent.	Encryption, access controls.	The ethical implications of using biometrics in authentication and identification systems.
Ethics in Information Warfare	Ethical concerns surrounding information warfare.	Dissemination of misinformation, social media manipulation.	Media literacy programs, platform policies.	The ethical implications of information warfare in destabilizing societies and democracies.
Ethics in Incident Response	Ethical considerations in incident response efforts.	Balancing transparency with confidentiality, sensitive data handling.	Ethical frameworks, incident response policies.	The ethical implications of incident response decision-making and information disclosure.
Privacy-Preserving Machine Learning	Ethical challenges in maintaining user privacy while using machine learning techniques.	Data privacy, model accuracy.	Federated learning, differential privacy.	The ethical implications of using machine learning for security applications and data privacy concerns.
Ethics of Artificial General Intelligence (AGI)	Ethical considerations in the development and deployment of AGI systems.	Societal impacts, value alignment.	Transparent, interpretable AI, value alignment frameworks.	The ethical implications of AGI deployment on the job market and workforce.

TABLE III. Ethical Considerations in Information Security (continued)

Topic	Description	Challenges	Proposed Solutions	Example Research Focus
Cybersecurity Workforce Ethics	Ethical considerations in the behavior and decisions of cybersecurity professionals.	Conflicts of interest, whistleblowing.	Organizational policies, whistleblower protection.	The ethical challenges faced by cybersecurity professionals in balancing loyalty and ethical responsibilities.
Environmental Impact of Information Security	Ethical concerns regarding the environmental impact of information security practices.	Carbon footprint, e-waste disposal.	Energy-efficient data centers, sustainable practices.	The environmental impact of data centers and exploring strategies for reducing their carbon footprint.
Bias and Fairness in Security AI	Ethical considerations in addressing biases and ensuring fairness in security AI systems.	Inherited biases, lack of transparency.	Fairness-aware AI, auditability mechanisms.	The ethical implications of bias in security AI and its impact on decision-making.
Ethical Implications of Information Warfare	Ethical considerations in using information as a weapon in conflicts.	Defining ethical conduct, psychological harm.	Ethical guidelines, international collaboration.	The ethical implications of using information warfare as a geopolitical tool.
Ethics in Incident Response and Recovery	Ethical decision-making in incident response and recovery efforts.	Balancing transparency and confidentiality, sensitive data handling.	Clear policies, communication plans.	The ethical implications of incident response decision-making and information disclosure.
Privacy-Preserving Machine Learning for Security	Maintaining user privacy while using machine learning for security applications.	Data privacy, model accuracy.	Federated learning, differential privacy.	The ethical implications of using machine learning for security applications and data privacy concerns.

approach that respects fundamental rights while addressing security concerns is vital.

3) Ethical Design and Deployment: The development of technologies with ethical considerations at the forefront is crucial. The cases illustrate that technologies, such as surveillance systems and algorithms, can inadvertently perpetuate biases and inequalities. Ethical design principles, including the mitigation of biases, should be integrated from the inception to prevent unintended negative outcomes.

4) Whistleblower Protection: The role of whistleblowers in revealing ethical misconduct cannot be underestimated. The cases of Edward Snowden and Chelsea Manning underscore the importance of providing legal protections for individuals who come forward with information that serves the public interest. Robust whistleblower protection encourages accountability and transparency.

5) Algorithmic Bias and Fairness: The increasing role of algorithms in decision-making processes introduces the need for algorithmic fairness. Biased algorithms can reinforce existing inequalities and perpetuate discrimination. The cases of biased algorithms in criminal justice and social media manipulation underline the significance of addressing algorithmic bias to ensure just outcomes.

6) Public Awareness and Informed Consent: The cases highlight the necessity of informed consent and public awareness regarding the collection and use of personal data. Individuals should be empowered to make informed decisions about sharing their data and understand the potential consequences of their choices.

7) Continuous Examination and Adaptation: Ethical considerations in information technology are not static. The cases demonstrate the need for ongoing evaluation of the ethical implications of new technologies and their deployment. Policies and practices must adapt to evolving technological landscapes to ensure that ethical standards are maintained.

8) Multidisciplinary Collaboration: Ethical challenges in information technology demand collaboration among technologists, ethicists, policymakers, legal experts, and civil society. Multidisciplinary approaches facilitate comprehensive assessments of the potential risks and benefits, leading to more informed decisions..

9) Cultural Sensitivity and Diversity: The cases highlight the importance of cultural sensitivity and diversity in technology design and deployment. Technologies should be developed with an understanding of diverse cultural norms and values to avoid inadvertently perpetuating biases or causing harm to specific communities.

10)Global Collaboration and Regulation: Given the global nature of technology and its impacts, collaboration among nations and international bodies is essential. These cases emphasize the need for coordinated efforts to develop ethical guidelines and regulations that transcend national boundaries, ensuring consistent standards and accountability in the use of technology worldwide.

11) Corporate Social Responsibility: Technology companies have a responsibility to prioritize social good over profit and to consider the broader societal impacts of their products and services. These cases underscore the importance of corporate social responsibility in guiding ethical decision-making and fostering trust with users and stakeholders.

12) Education and Digital Literacy: Enhancing digital literacy and education around technology ethics is crucial for empowering individuals to navigate the complexities of the digital world. These cases highlight the need for educational initiatives that teach critical thinking skills, ethical decision-making, and responsible use of technology from an early age.

13) Ethical Leadership and Governance: Strong ethical leadership within organizations and governments is essential for fostering a culture of integrity and accountability. Leaders must set clear ethical standards, promote ethical behavior, and hold themselves and others accountable for upholding these standards.

14)Proactive Risk Assessment and Mitigation: Anticipating potential ethical risks and proactively implementing measures to mitigate them is essential in technology development and deployment. These cases emphasize the importance of conducting thorough risk assessments and implementing safeguards to prevent harm to individuals and society.

15) Human-Centered Design: Prioritizing human well-being and dignity in the design of technology is fundamental. Human-centered design approaches ensure that technology serves the needs and values of users, promotes inclusivity, and enhances human flourishing.

16) Interdisciplinary Research and Ethical Inquiry: The cases underscore the value of interdisciplinary research and ethical inquiry in addressing complex ethical challenges in technology. Collaboration between technologists, ethicists, social scientists, and other disciplines fosters a deeper understanding of the ethical implications of technology and promotes innovative solutions.

Table IV presents an overview of ethical considerations in information technology, along with their descriptions, providing valuable insights into the multifaceted ethical landscape of IT. Each consideration is accompanied by a detailed description that illustrates its significance and implications within the context of technology development and deployment. By outlining these ethical considerations, the table offers a comprehensive framework for understanding and addressing the ethical challenges inherent in the rapidly evolving field of information technology.

Table V provides a comprehensive overview of the strategies and considerations employed in resolving prominent information technology (IT) ethical dilemmas. Each case represents a significant challenge within the IT landscape, encompassing issues such as privacy, security, transparency, and accountability. Through careful analysis, this table outlines the ethical pathways navigated and the strategies applied to address these complex issues. By highlighting the diverse approaches taken to mitigate ethical concerns, this table offers valuable insights into the evolving ethical landscape of IT and the multifaceted considerations necessary for ethical decision-making in this domain.

VI. Conclusions

The rapid advancement of emerging technologies, such as artificial intelligence (AI), blockchain, and the Internet of Things (IoT), presents a complex landscape for ethical decision-making. Ethical considerations are paramount in the ongoing development of emerging technologies. As these technologies increasingly influence various aspects of daily life, ensuring they are developed and deployed ethically is crucial for maintaining public trust, preventing harm, and promoting fairness. Ethical decision-making helps navigate the complexities of technological advancements, balancing innovation with societal well-being. It fosters responsible innovation, where technology serves the common good rather than exacerbating inequalities or causing unintended harm. This paper provided a comprehensive examination of ethical considerations in information technology across various domains, including artificial intelligence, cybersecurity, big data analytics, and quantum computing. Through the analysis of real-world cases and literature review, the paper has highlighted the paramount importance of transparency, accountability, fairness, and privacy protection in technology development and deployment. The paper includes an in-depth exploration of ethical challenges and proposed solutions to address emerging issues. By offering guidance for policymakers, industry professionals, and educators, this paper aims to promote ethical behavior and responsible innovation in IT, ultimately contributing to the creation of a more ethical and trustworthy digital ecosystem.

The key findings of this paper highlight several critical aspects:

1) Diverse Ethical Frameworks: A variety of ethical frameworks, including utilitarianism, deontological ethics, virtue ethics, and principles-based approaches like the ACM and IEEE codes, offer distinct perspectives on addressing ethical challenges in IT. These frameworks emphasize principles such as honesty, fairness, privacy, and responsibility, providing a robust foundation for ethical decision-making.
2) Data Privacy and Security: The increasing volume of data generated by emerging technologies necessitates stringent data privacy and security measures. Regulations like the GDPR underscore the importance of protecting user data and maintaining transparency regarding data usage.
3) Bias and Fairness in AI: AI algorithms often inherit biases from their training data, leading to unfair outcomes. Regular audits and transparent methodologies are essential to mitigate these biases, ensuring AI systems are fair and equitable.
4) Accountability and Responsibility: As technology becomes more autonomous, assigning accountability becomes more challenging. Clear guidelines and accountability frameworks are needed to ensure that ethical breaches can be addressed effectively.
5) Impact on Employment and Society: Emerging technologies have significant implications for employ-

TABLE IV. A Comprehensive overview of future directions of Information Technology ethical Considerations

Ethical Consideration	**Description**	**Legal Implications**	**Technological Impact**	**Social Consequences**	**Economic Factors**	**Environmental Considerations**	**Cultural Relevance**	**Examples**
Transparency and Accountability	Ensuring openness in actions and decisions, and taking responsibility for their outcomes.	Compliance with data protection laws and regulations.	Implementation of transparency features in technology.	Trust-building in society and improved user confidence.	Financial penalties for non-compliance.	Adoption of sustainable practices in data management.	Respect for cultural norms regarding information sharing.	- Companies disclosing data breaches promptly.
Balancing Rights and Security	Finding equilibrium between individual liberties and collective safety.	Legal frameworks for surveillance and data collection.	Development of encryption and privacy-enhancing technologies.	Preservation of civil liberties and human rights.	Economic investments in security measures.	Consideration of energy consumption in security protocols.	Cultural attitudes towards privacy and security.	- Government surveillance programs respecting privacy rights.
Ethical Design and Deployment	Incorporating moral principles into the creation and use of technology.	Compliance with ethical guidelines and industry standards.	Integration of ethical design principles in product development.	Reduction of harm and promotion of user well-being.	Investment in ethical design training and resources.	Adoption of eco-friendly materials and manufacturing processes.	Respect for cultural values and ethical norms in design.	- Developing AI systems that minimize bias in decision-making.
Whistleblower Protection	Safeguarding individuals who expose misconduct within organizations.	Legal protection against retaliation and job loss.	Implementation of whistleblower reporting mechanisms.	Promotion of organizational integrity and accountability.	Potential legal costs and reputational damage.	Minimization of environmental impact of retaliation measures.	Respect for cultural attitudes towards whistleblowing.	- Edward Snowden revealing NSA surveillance programs.
Algorithmic Bias and Fairness	Ensuring fairness and impartiality in algorithmic decision-making.	Compliance with anti-discrimination laws and regulations.	Development of bias detection and mitigation techniques.	Mitigation of systemic biases and promotion of equity.	Consideration of economic disparities in algorithmic design.	Reduction of energy consumption through algorithmic optimization.	Sensitivity to cultural diversity in algorithmic training data.	- Biased hiring algorithms favoring certain demographics.
Public Awareness and Informed Consent	Educating individuals about their rights and enabling them to make informed choices.	Compliance with data privacy laws and regulations.	Implementation of user-friendly consent mechanisms.	Empowerment of individuals in controlling their data.	Economic investments in data literacy programs.	Adoption of energy-efficient data storage and processing systems.	Sensitivity to cultural attitudes towards data privacy.	- Users understanding privacy policies before sharing personal information.
Continuous Examination and Adaptation	Regularly evaluating and adjusting ethical standards and practices.	Compliance with ethical guidelines and best practices.	Integration of feedback mechanisms for ethical assessments.	Adaptation to changing societal norms and expectations.	Financial investments in ethical audits and reviews.	Implementation of eco-friendly technologies and processes.	Respect for cultural values in ethical evaluations.	- Tech companies updating their data protection policies in response to changing regulations.
Multidisciplinary Collaboration	Collaborating across diverse fields to address ethical challenges comprehensively.	Compliance with interdisciplinary research standards.	Creation of cross-disciplinary ethical review boards.	Promotion of diverse perspectives and holistic approaches.	Economic investments in interdisciplinary research initiatives.	Consideration of environmental impacts in collaborative efforts.	Sensitivity to cultural differences in collaborative settings.	- Ethicists, technologists, and policymakers working together to regulate AI development.

TABLE IV. A Comprehensive overview of future directions of Information Technology ethical Considerations (continued)

Ethical Consideration	Description	Legal Implications	Technological Impact	Social Consequences	Economic Factors	Environmental Considerations	Cultural Relevance	Examples
Cultural Sensitivity and Diversity	Considering diverse cultural perspectives and avoiding bias in technology design.	Compliance with cultural sensitivity guidelines and regulations.	Incorporation of cultural diversity in product development.	Promotion of inclusivity and respect for cultural differences.	Economic investments in diversity training and awareness programs.	Adoption of sustainable materials and manufacturing practices.	Respect for cultural norms and traditions in design.	- Developing translation apps that respect regional dialects and cultural nuances.
Global Collaboration and Regulation	Working together internationally to establish consistent ethical standards.	Compliance with international treaties and agreements.	Development of global ethical frameworks and standards.	Promotion of global cooperation and mutual understanding.	Economic investments in international regulatory compliance.	Consideration of global environmental impacts in regulatory efforts.	Sensitivity to cultural differences in international negotiations.	- Nations collaborating to set guidelines for ethical AI use.
Corporate Social Responsibility	Integrating social and environmental concerns into business operations and decisions.	Compliance with corporate social responsibility (CSR) guidelines.	Implementation of CSR initiatives and philanthropic projects.	Improvement of corporate reputation and public trust.	Economic investments in sustainability and community development.	Adoption of eco-friendly business practices and supply chain management.	Consideration of cultural values and community needs in CSR efforts.	- Tech companies investing in renewable energy and community initiatives.
Education and Digital Literacy	Providing knowledge and skills for navigating the digital world responsibly.	Compliance with educational standards and curriculum requirements.	Implementation of digital literacy programs and resources.	Empowerment of individuals in using technology safely and ethically.	Economic investments in educational technology and resources.	Adoption of energy-efficient technologies in educational settings.	Sensitivity to cultural differences in educational content.	- Schools teaching students about online privacy and cybersecurity.
Ethical Leadership and Governance	Exemplifying and enforcing ethical behavior within organizations and governments.	Compliance with ethical codes of conduct and governance frameworks.	Promotion of ethical leadership and decision-making processes.	Fostering of organizational integrity and accountability.	Economic investments in ethical leadership training and development.	Implementation of eco-friendly policies and practices in governance.	Respect for cultural norms and values in leadership approaches.	- CEOs prioritizing ethical conduct and accountability in their companies.
Proactive Risk Assessment and Mitigation	Identifying and addressing potential ethical risks before they escalate.	Compliance with risk management standards and protocols.	Implementation of risk assessment tools and processes.	Prevention of ethical breaches and harmful consequences.	Economic investments in risk mitigation strategies and technologies.	Adoption of eco-friendly risk management practices.	Sensitivity to cultural attitudes towards risk and precautionary measures.	- Tech companies conducting ethical impact assessments before launching new products.
Human-Centered Design	Designing technology that prioritizes human needs and well-being.	Compliance with human-centered design principles and guidelines.	Integration of user feedback and usability testing in design.	Improvement of user satisfaction and quality of life.	Economic investments in user experience (UX) research and design.	Implementation of eco-friendly design materials and processes.	Consideration of cultural preferences and values in design.	- Creating accessible interfaces for users with disabilities.
Interdisciplinary Research and Ethical Inquiry	Conducting collaborative research to explore ethical implications of technology.	Compliance with research ethics and integrity standards.	Establishment of interdisciplinary research teams and projects.	Advancement of ethical understanding and innovative solutions.	Economic investments in interdisciplinary research initiatives.	Adoption of eco-friendly research methods and practices.	Sensitivity to cultural differences in research methodologies.	- Ethicists collaborating with engineers to explore the ethical implications of AI development

ment and societal structures. Ethical considerations must address potential job displacement and the equitable distribution of technological benefits.

There are several avenues for future research and exploration in the field of ethical information technology. Experimental studies are needed to assess the effectiveness of proposed ethical frameworks and solutions in real-world settings, identifying areas for improvement and refinement. Additionally, further research should address emerging ethical challenges resulting from advancements in technology, such as the proliferation of deep learning algorithms and the ethical implications of emerging technologies like blockchain and biometrics. Interdisciplinary collaboration and dialogue are essential for developing comprehensive and inclusive approaches to address ethical challenges. Moreover, ongoing education and awareness initiatives are crucial for promoting ethical literacy and fostering a culture of ethical responsibility in the IT sector. By investing in education and awareness, stakeholders can empower individuals to navigate ethical challenges effectively and contribute to the creation of a more ethical and sustainable digital future. To further enhance the ethical development of emerging technologies, future research should include the following areas:

1) Ethical Framework Integration: Research on integrating multiple ethical frameworks to create a unified approach that can be easily applied in diverse technological contexts.
2) AI Transparency and Explainability: Developing methods to improve the transparency and explainability of AI systems, making their decision-making processes more understandable and accountable.
3) Dynamic Ethical Guidelines: Creating adaptive ethical guidelines that can evolve with technological advancements, ensuring they remain relevant and effective.
4) Cross-Cultural Ethics: Investigating how ethical frameworks can be adapted to different cultural contexts, recognizing that ethical norms and values vary globally.
5) Long-Term Societal Impact: Longitudinal studies on the societal impact of emerging technologies, particularly concerning employment, privacy, and social

equity.

6) Ethics in Autonomous Systems: Exploring ethical issues specific to autonomous systems, including self-driving cars and autonomous drones, focusing on accountability and safety.

By addressing these research areas, the field can better navigate the ethical challenges posed by emerging technologies, ensuring that innovation progresses in a manner that is socially responsible and aligned with human values.
