The task while adhering to the same underlying principles as Airavat [28], SP-SV Method has added additional functionality, such as a combiner, and refrained from altering the core source code of Hadoop. SP-SV Method is a privacy-protecting data analysis tool. It delivers the promised anonymity by combining Hadoop MapReduce with the differential anonymity approach to aggregate attributes from the datasets being used without revealing any specifics about individual data objects.

As defined by Cynthia Dwork, "The outcome of any analysis is essentially equally likely, independent of whether any individuals join or refrain from joining the dataset," When the computation output for every single input is independent of the input's existence, we designate a calculation on a set of data as being highly private in the input data set.

Take note that we have focused on Hadoop MapReduce security as well as privacy in the SP-SV Method. This indicates that, although we prevent some of the ways intruders may acquire information through information disclosure (using insecure Reducers), while maintaining the privacy of the individual, we nonetheless accept the intrusive party's certainty regarding the existence or nonexistence of any information in the MapReduce outcome.

III. Methodology

A. Working on the Hadoop MapReduce Platform

Hadoop's MapReduce is an open-source initiative and a popular data processing framework that works well for many different kinds of workloads, such as log evaluation, analyzing social networks, searches, and clustering We chose to use the Hadoop platform since a lot of companies, including Amazon, Facebook, Yahoo, including the New York Times [8], have successfully adopted it to run their applications on clusters. MapReduce is the primary tool in Hadoop's toolkit.

To add different kinds of features to Hadoop, multiple modules have been independently created throughout time. But until recently, Hadoop's security was not a top priority for development. The security mechanism's vulnerability has therefore emerged as a major obstacle to Hadoop's progress, despite the platform's growing adoption. Over time, MapReduce and other Hadoop framework components may have difficulties because of a dearth of a uniform security approach and many security risks involved.

The findings [29] state that Hadoop is readily recognized by hackers worldwide. All they have to do is sniff open instances to do this. We chose the Hadoop MapReduce platform and concentrated on addressing its privacy concerns since it is open-source, accessible to a large global user base, and has security flaws. On the other side, the growing importance of data analytics helped us pick this platform.

The designed SP-SV Method is a privacy-protecting data analysis tool. It combines the Differential Privacy technique with Hadoop MapReduce to aggregate characteristics from input datasets while maintaining the promised privacy by not disclosing any information about individual data items [10] [11]. In this work, we have concentrated on Hadoop MapReduce security as well as privacy using the SP-SV Method which is based on varied Differential Privacy for safeguarding the privacy of the person and yet having data of value for analysis.

B. Proposed Method

The proposed work Fig. 1 was evaluated for patient datasets for its usefulness in providing privacy while allowing for data analysis. Comparisons were made before and after applying the proposed varied differential privacy concept with the SP-SV method on the datasets.

Comprehensive approaches have been introduced to present the concept of privacy-preservation. The randomization approach makes sure that no one knows the real data, instead just random information about data sets is revealed, thereby protecting individual privacy. Specifically, Cryptographic Random Number Generators (RNGs) are specialized algorithms designed to produce random numbers with certain properties that make them suitable for cryptographic applications. These properties include unpredictability, uniform distribution, and resistance to various attacks which are aimed at predicting or manipulating the generated numbers.

C. Enforcement of Differential Privacy

In the initial stage, the Mapper code was created the procedure which comprised defining the keys and identifiers. In addition, the privacy parameters "N" and "n" were supplied, and a preconfigured Reducer was chosen. Once the code has been written, compiled, and the jar file has been produced, the next step is to specify the Differential Privacy settings for the Proposed Model. This is necessary in order for the model to generate the right level of noise.

Laplace's Differential Privacy method adds noise to the data, and it can be explained in this way.

$$f(x)+(Lap(\Delta f/epsilon)) \qquad (1)$$

D. Overall Algorithms Steps

1) Input splitting: Input splits are the smaller portions of the input data that are separated. Each split is handled by a map job. Considering input attributes in the dataset as follows Patient Id, Age, Name, Gender, City, Job, Specialist, Disease, Marital Status.

2) Mapping: Every mapping task handles its input splits individually. It reads the incoming data, implements the data anonymization logic [12], and outputs a collection of key-value pairs that are intermediate.

The attributes considered for anonymization are Age, City, Gender and Job. And for every considered attribute, add the epsilon and sensitivity to maintain the privacy of the data.

Anonymization Logic: To achieve differential privacy, Laplace noise is applied to each sensitive attribute's original value.

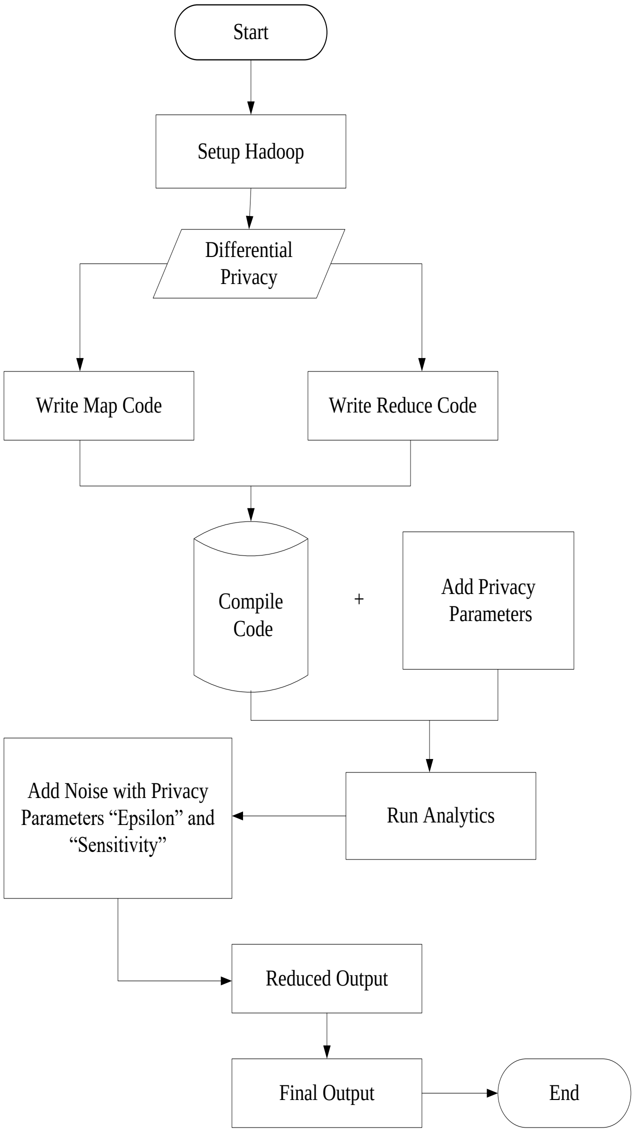

Fig. 1. Proposed flowchart.

The formula for adding Laplace noise is:

$$NoisyValue = OriginalValue + laplace(0, \frac{sensitivity}{\varepsilon})$$

Where:

- $laplace(0, \frac{sensitivity}{\varepsilon})$ represents Laplace noise with mean 0 and scale $\frac{sensitivity}{\varepsilon}$

- $sensitivity$ is the sensitivity of the attribute.

- ε is the privacy parameter.

3) Differential privacy reduction: For a given key, an ordered list of intermediate pairs of keys and values is sent to each mapper. The map function applies the differential privacy method to each key's corresponding values. Using aggregation functions or adding more noise may be necessary in this situation, based on the particular privacy needs of the considered attributes.

4) Intermediate key-value pair shuffling: The map jobs produce intermediate key-value pairs, which are then divided according to the keys and sent to the reducers. Performing this step guarantees that every value linked to the same key ends up in the same reducer.

Reduce Phase:

5) Sorting: The intermediate key-value pairs are arranged according to the keys inside each reducer.

6) Final output: A collection of key-value pairs containing anonymized data is the final output that the reducers generate. This output can be written to an external storage system or saved in HDFS.

E. Overall WorkFlow

The overall workflow of the proposed architecture is set up as in Fig. 2.

1) Setup of the job: The MapReduce job is set up with parameters for the differential privacy method (e.g., ε), as well as input and output pathways, mapper and reducer classes, input and output key-value formats, etc.

2) Job submission: The specified job is sent to the Hadoop cluster.

3) Job execution: Hadoop distributes jobs throughout the cluster nodes and coordinates the mapping process.

4) Task monitoring: We may use command-line tools or the Hadoop JobTracker interface to keep an eye on the status of your task.

When every task has been finished, the job is considered finished, and the final output including differentially private anonymized data is ready for additional processing or analysis.

This methodology guarantees the safeguarding of confidential information inside the input data, all the while for insightful analysis to be conducted on the anonymized data.

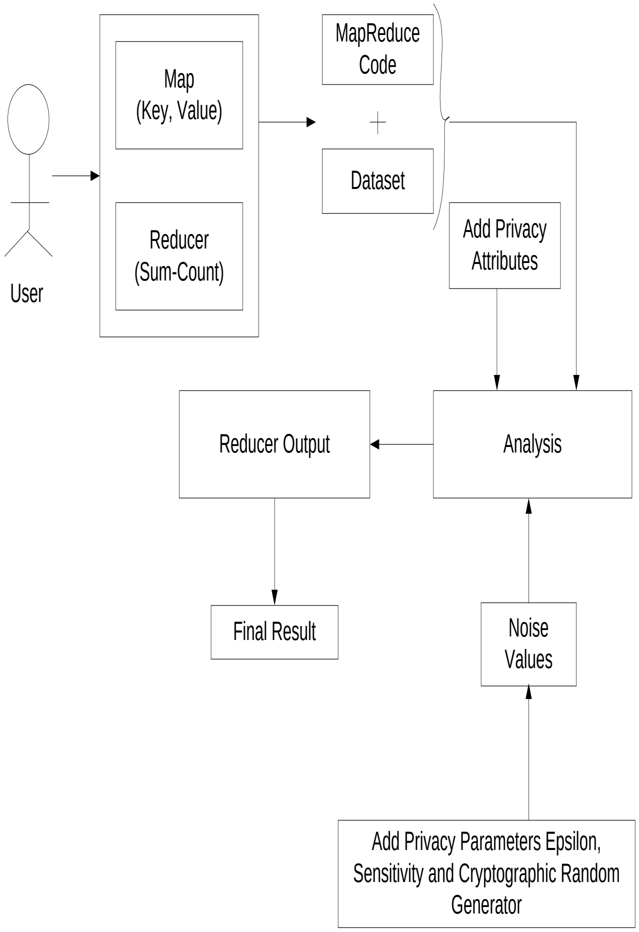

Fig. 2. Proposed architecture.

IV. Algorithms

A. Algotihm 1: Map-Reduce

Input: keys are listed.

The dataset consists of the named identifiers, min-range, max-range and epsilon (ε)

Output: noisy value denoted as L is the output of dataset.

Procedure:

Step 1: The parameters $k_1 \ldots$ to k_n consider for mapping to get output keys.

Step 2: Compute in group by collecting every key mentioned in step1 to generate map.

Step 3: Returns Mean value if max-range is greater than min-range values.

Step 4: else, min-range should be smaller than max-range.

B. Differnetail Privacy Enfocrement Procedure

Step 1: The noise calculation is performed using the values of Epsilon and min-range/max-range.

Step 2: The result is obtained by adding the Reducer-Output and Laplacian Noise.

return Reducer-Output + Laplacian Noise.

The pseudo-code for our algorithm is displayed in Algorithm.

The f(x) function's sensitivity, represented by the symbol Δf, indicates the function's potential level of revealing and incorporates addition of noise with a scale of Δf/epsilon to maintain epsilon-differential privacy.

C. Algorithm 2: Varied Differential Privacy in Proposed Work

```
Input
Mapper-Input = $F(X)$
Privacy Parameter such as epsilon
min-range
max-range
Output
Added Laplace Noise to Mapper Input($F(X)$)
Procedure: Requirements for Differential Privacy:
Step1: Sensitivity, $\Delta F = |max\text{-}range – min\text{-}range|$
Step2: Amount of noise: $L = Lap(\Delta f/epsilon)$
Step3: Apply $L$ to $F(X)$
Return $F(X)$+ Laplace Noise.
```

The Proposed Model in our Differential Privacy code, implemented in the "Mapper" class, requires two privacy parameters: "Epsilon (epsilon)", "Sensitivity" and "Cryptographic Random Number Generators (RNGs)". These parameters are necessary to determine the appropriate noise level to be added to the result and ensure limits on the potential disclosure of information about datasets.

1) Parameter "Epsilon": Epsilon, is a fundamental Differential Privacy parameter that is essential to the Proposed Model. The statistics that are often produced as a consequence of calculating sensitive data that might introduce privacy issues. By calculating the degree of privacy loss brought on by a differential change in data, the parameter quantifies privacy. It is essential to acknowledge that epsilon is not an absolute measure of privacy, but rather a relative one. The degree of secrecy rises as epsilon's value falls and vice versa.

2) Parameter "Sensitivity": Sensitivity is the variable that governs the minimum amount of noise required to be introduced into the output. It is a significant factor in the computation of DP noise is the "Sensitivity" [21]. The term "Impact" refers to the modifications that take place in the result when any input data is eliminated. The Proposed Model incorporates the addition of exponentially distributed noise by the reducers to ensure the enforcement of Differential Privacy.

3) Cryptographic Random Number Generators (RNGs) are specialized algorithms designed to produce random numbers with certain properties that make them suitable for cryptographic applications. These properties include unpredictability, uniform distribution, and resistance to various attacks aimed at predicting or manipulating the generated numbers. The key advantages we can consider as unpredictability. This means that the sequence of random numbers generated should appear statistically random, making it practically impossible for an attacker to predict the next number in the sequence, even if they have access to some of the previously generated numbers.

According to definition of sensitivity, the "Count" function has a sensitivity of 1. The count can be incremented or decremented by a maximum of 1 based on whether an item is added or deleted from the dataset.

$$\text{Max } (|\text{Mmin}| , |\text{Mmax}|) = 1$$

The "Sum" function's sensitivity changes depending on the range. As an example, the sensitivity is 100 on a specified interval of integers from 0 to 100. The output will be influenced by 100 units if 100 is either added or subtracted.

The calculation of sensitivity in the proposed work necessitates the data source to explicitly state the span. Within this range, the calculation provider must provide the minimum as 0 and 100 as the maximum number.

This will be used to find the sensitivity, as it is possible to get a rough estimate of the sensitivity by calculating it within the provided range. The range declaration is determined solely by the data values in a dataset and the query. The data provider must assess their dataset and determine the specific information they need to extract from it. Based on this assessment, they can then establish the lowest and maximum values for the range.

The "Count" function requires the range to have a minimum value of 0 and a maximum value of 1. The range for the "Sum" function is from 0 to the largest value. The sensitivity will be determined and the noise will be computed by specifying the range, Δf.

$$\text{noise} \sim \text{Lap}(\Delta f/\text{epsilon})$$

During the process, the estimated noise will be added to the Mapper's output. The sensitivity of a function corresponds to the amount of information it discloses about whether or not an item is present in the input dataset.

In the Reducer Phase, which is part of a Hadoop MapReduce job. It's responsible for merging anonymized data for the same patient ID.

D. Step by Step Procedures

1) The reduce method takes four parameters:

key: A Text object representing the key.

values: An Iterator<Text> containing the values associated with the key.

output: An OutputCollector<Text, Text> used to collect the output of the reduce operation.

reporter: A Reporter object to report progress and status.

2) Creates a 'HashMap' called 'mergedData' to store the merged data. It will store key-value pairs where the key is a string (presumably an attribute of the patient) and the value is also a string (the value of that attribute).

3) Iterates over the values associated with the key.

4) This line retrieves the next value, converts it to a string, and then splits it into an array of strings using a comma (',') as the separator.

5) This starts another loop that iterates over each part of the split string array.

6) The key-value line splits each part into two strings based on a colon (':') separator.

7) These checks if the split resulted in exactly two parts (a key and a value). If so, it proceeds to the next step.

8) Merge the data by adding the key-value pair to the 'mergedData' map. 'keyValue[0]' is the key and 'keyValue[1]' is the value.

The overall purpose of this code is to merge data from multiple values associated with the same key. Each value is assumed to be a comma-separated string of key-value pairs, where each pair is separated by a colon (':') [9]. The code splits these strings and stores the key-value pairs in a map ('mergedData'). Finally, the merged data is collected as the output of the reduced operation [32].

E. Example

Consider a set of datasets with age, city, gender and job. The original dataset had the values as in Table I.

Choose the attributes for which we apply Differential Privacy based SPSV method to Secure Privacy and Safeguarding Value. The attributes Age, Gender, City, Disease are chosen as sensitive attributes. According to Cynthia Dwork, safeguarding Age, Gender and City is very critical and if could fetch the value for those attributes, identification of individual is not impossible. So we choose them along with our main sensitive attribute, Disease. Other attributes are sliced and truncated.

The Chosen attributes in Table II are encoded and then applied Hadoop's Mapper and Reducer algorithms. The varied Differential Privacy Preservation technique, the SP-SV Method is applied. The encoded and transformed data as shown in Table III is decoded to get disclosure safe data. The safe data can be utilized for analytics with almost no chance for re-identification.

The Diseases and cities are plotted on the original data sets before applying Varied DP, Fig. 3. The plot shows a significant amount of change after the application of the Varied Differential privacy method i.e. the SP-SV method in Table II data, Fig. 4.

The transformed data is useful with respect to the chosen sensitive attributes and as getting back to the original data is difficult and nearly impossible with the usage of Epsilon, Sensitivity factor, Crypto Random Generator, the individual data is safeguarded.

TABLE I. ORIGINAL DATASET

Patient Id	Name	Age	Gender	City	Job	Specialist	Disease	Marital Status
PId-900	Aaditya	45	Male	Belgaum	Engineer	Cardiologist	Headache	Unmarried
PId-901	Rashmi	27	Female	Davanagere	Designer	Gynecologist	Uterine Fibroid	Married
PId-902	Tejasvi	63	Male	Ballari	Painter	Oncologist	Prostate Cancer	Married
PId-903	Lakshmi	35	Female	Belgaum	Architect	Specialist	Heart Problem	Married

TABLE II. SENSITIVE DATA

Age	Gender	City	Disease
45	Male	Belgaum	Headache
27	Female	Davanagere	Uterine Fibroid
63	Male	Ballari	Prostate Cancer
35	Female	Belgaum	Heart Problem

TABLE III. TRANSFORMED ENCODED DATASET

Patient Id	Name	Age	Gender	City	Job	Specialist	Disease	Marital Status
PId-900	Aaditya	67	Male	Ballari	Engineer	Cardiologist	Headache	Unmarried
PId-901	Rashmi	71	Female	Belgaum	Designer	Gynecologist	Cancer	Married
PId-902	Tejasvi	34	Male	Davanagere	Painter	Oncologist	Headache	Married
PId-903	Lakshmi	35	Female	Belgaum	Architect	Specialist	Uterine Fibroid	Married

V. Results

The varied Differential Privacy Technique, SP-SV Method has transformed the original datasets and as the Epsilon values are difficult to guess and makes it almost impossible with Sensitivity factor in the equation, being generated by Crypto Random Number Generator.

The output disease count matches with the original count but has modified with age, gender and city. This result is helpful in generating useful data for analysis yet keeping the individual's identity very safe.

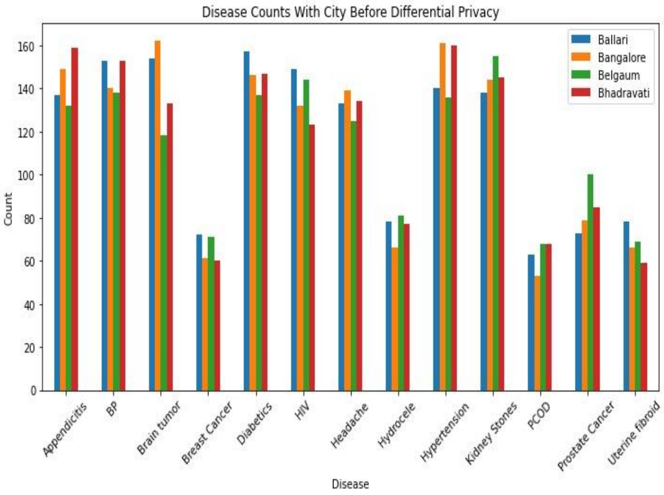

Fig. 3. Count of disease based on city before Differential Privacy (DP).

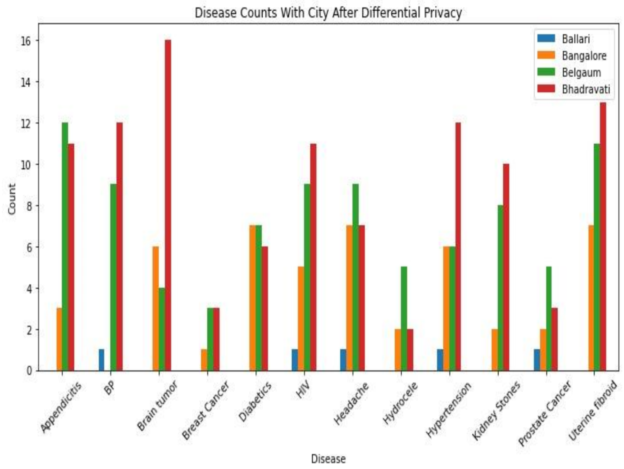

Fig. 4. Count of disease based on city after Differential Privacy (DP).

VI. Conclusion

In this work, we have put forth a MapReduce-based varied computation module that preserves privacy of personal information and ensures the utility of the data. SP-SV Method ensures that the computed output for every given input is independent of its presence or absence in the data by implementing the Differential Privacy based SP-SV method using Hadoop MapReduce. This privacy-preserving module ensures privacy preservation by determining the appropriate noise levels to maintain the trade-off between privacy and final output accuracy.

SP-SV Method restricts the calculations and stops data leaks that go beyond the terms of the data provider. Although Airavat served as an inspiration for this model, the Apache Hadoop code itself was left unaltered unlike Airavat, and SP-SV Method's source code was built entirely from scratch. We were ultimately unable to compare the efficiency of SP-SV Method with Airavat since we were unable to obtain source code of Airavat. However, in line with the fundamental principles of the Differential Privacy Method, an individual is not identified specifically when a specific piece of data is added or removed from the database which satisfies the need for privacy of individual and also provides useful data for analytics.

Precision Farming with AI: An Integrated Deep Learning Solution for Paddy Leaf Disease Monitoring

Pramod K*, V. R. Nagarajan
Department of Computer Science, Karpakam Academy of Higher Education, Coimbatore, India

***Abstract*—Paddy rice, an essential food source for millions, is highly susceptible to various leaf diseases that threaten its yield and quality. This study introduces a cutting-edge hybrid deep learning model designed to address the critical need for accurate and timely identification and classification of paddy leaf diseases. Traditional methods often lack the precision and efficiency required for effective disease detection, necessitating the development of more sophisticated approaches. Our proposed model leverages the feature extraction capabilities of EfficientNetB0 and the hierarchical relationship capturing abilities of the Capsule Network, resulting in superior disease classification performance. The hybrid model demonstrates outstanding accuracy, achieving 97.86%, along with precision, recall, and F1-scores of 97.98%, 98.01%, and 97.99%, respectively. It effectively differentiates between diseases such as Narrow Brown Spot, Bacterial Leaf Blight, Leaf Blast, Leaf Scald, Brown Spot, and healthy leaves, showcasing its robustness in practical applications. This research highlights the importance of advanced technological interventions in agriculture, providing a scalable and efficient solution for disease detection in paddy crops. The hybrid deep learning model offers significant benefits to farmers and agricultural stakeholders, facilitating timely disease management, optimizing resource use, and improving crop management practices. Ultimately, this innovation supports agricultural sustainability and enhances global food security.**

Keywords*—Paddy rice; leaf diseases; hybrid deep learning; efficientnetb0; capsule network

I. INTRODUCTION

Paddy rice, often referred to simply as "paddy," denotes the raw, unhulled grains of rice, encased within their protective husks. Cultivated extensively across the globe, particularly in regions with flooded fields conducive to rice growth, such as Asia, paddy forms the backbone of numerous cuisines and diets. Boasting a diverse array of varieties, paddy rice encompasses a spectrum of characteristics, from grain size and color to taste and texture. Its cultivation entails meticulous processes, including land preparation, seed selection, and often, transplanting into flooded paddy fields. Rich in carbohydrates and supplemented by proteins, fiber, and various nutrients, paddy rice serves as a vital source of nutrition for a substantial portion of the whole population [1]. Post-harvest, paddy undergoes processing to yield different rice types, from polished white grains to nutrient-rich brown rice variants. This processed rice, in its myriad forms, finds its way into an extensive array of culinary creations, from simple staples to intricate delicacies like sushi and biryani. Economically, rice cultivation and trade represent a cornerstone of many nations' economies, supporting millions of livelihoods and playing a vital role in food security and economic stability. Thus, paddy rice stands as not only a dietary staple but also a symbol of cultural heritage, economic vitality, and agricultural resilience.

Paddy leaf diseases present a formidable challenge to rice cultivation globally, encompassing a spectrum of fungal, bacterial, and viral pathogens that afflict the leaves of the rice plant. These diseases manifest through a variety of symptoms including lesions, spots, discoloration, and wilting, ultimately impairing the plant's ability to photosynthesize effectively and thereby compromising yield and quality. Spread through diverse vectors such as wind, water, contaminated seeds, and insect carriers, the transmission of these diseases is facilitated by environmental factors like temperature, humidity, and cultural practices [2]. Combatting paddy leaf diseases requires a multi-faceted approach involving cultural, chemical, and biological strategies. Farmers employ techniques like crop rotation and the use of disease-resistant varieties alongside chemical treatments and biological control agents to mitigate disease spread and severity.

The spectrum of paddy leaf diseases includes bacterial leaf blight, leaf blast, brown spot, leaf scald, and narrow brown spot. Bacterial leaf blight, caused by Xanthomonas oryzae pv. Oryzae, leads to water-soaked lesions and plant wilting. Brown spot, from Cochliobolus miyabeanus, shows small lesions with yellow halos. Leaf blast, by Magnaporthe oryzae, produces lesions shaped like diamonds with gray centers. Leaf scald, caused by Rhizoctonia oryzae, results in elongated, pale streaks on leaves. Narrow brown spot, linked to Cercospora janseana, shows elongated brown lesions with yellow borders [3]. And a healthy foliage exhibits vibrant green coloration and intact leaf structure. Vigilant monitoring and management strategies are crucial for mitigating these conditions and ensuring crop productivity and food security.

Paddy leaf disease detection and recognition hold importance in modern agricultural practices for several compelling reasons. Firstly, early detection allows for timely intervention, which is pivotal in curbing the spread of diseases and minimizing crop damage. By swiftly identifying diseased plants, farmers can implement targeted control measures, thereby mitigating yield losses and preserving crop quality. Moreover, accurate disease detection facilitates precision agriculture, enabling farmers to adopt site-specific management practices tailored to the needs of individual fields [4]. This approach optimizes resource utilization, reduces input costs, and minimizes environmental impact. Staying ahead of disease outbreaks optimizes yields and enhances food security, vital for rice-dependent communities. Technological advancements aid research into disease dynamics and resilient crop development. Accurate disease detection is essential for sustaining

*Corresponding Author.

productivity and fostering eco-friendly farming. The important contribution of this study is given below:

- To create a robust model for detecting paddy leaf diseases utilizing a hybrid deep learning approach.
- To effectively identifies and classifies multiple paddy leaf diseases.
- To minimize error rates and false positive occurrences in the detection process.
- To evaluate and contrast the efficacy of the proposed method with existing models for detecting paddy leaf diseases.
- To support for Sustainable Agriculture

The remaining of the paper is structured as: Section II provides an overview of existing methodologies for detecting paddy leaf disease, laying the foundation for the proposed research. Section III outlined the method details of the proposed approach. The outcomes of the study, including the efficiency of the suggested approach in detecting diseases, are discussed in Section IV. At last, Section V offers remarks summarizing the findings and implications of our work.

II. Literature Review

Kulkarni and Shastri [5] emphasized the significance of early diagnosis by outlining a methodical strategy to use machine learning for paddy leaf disease identification. Training a convolutional neural network (CNN) based on the VGG-16 model involved preprocessing methods using a Kaggle dataset. After training, a successful model was obtained with an accuracy rate of 95%. A hybrid CNN model was introduced by Jesie et al. [6] for the categorization of paddy leaf diseases. The hybrid CNN model performed better than other techniques such as Deep Neural Network (DNN), Deep Belief Neural Network (DBN), and Recurrent Neural Network (RNN). Notable outcomes included accuracy of 97%, under 5% error, F-measure of 92.3%, 93.1% precision, 92.1% recall value.

Trinh et al. [7] detailed a methodology for detecting paddy leaf diseases by the YOLOv8 model, focusing on leaf folder, leaf blast, and brown spot. It collected a dataset of 1634 images from rice fields at the Vietnam National University of Agriculture with data augmentation techniques applied for improved model adaptability. The YOLOv8n architecture was chosen for its balance of accuracy, speed, and efficiency, with modifications to the loss function incorporating Efficient IoU (EIoU) and Alpha-IoU to enhance bounding box regression. Parameter settings were optimized to achieve high precision (89.6), recall (83.5), F1-score (86.4), and mAP (88.9) during model training. Evaluation showed significant improvements over the baseline YOLOv8 model, with enhancements in accuracy across disease classes.

Bi and Wang [8] presented a method for paddy leaf disease detection using a double-branch DCNN (DBDCNN) model integrated with a convolutional block attention module (CBAM). The methodology involved training the DBDCNN model on a dataset comprising annotated rice leaf images. Also compared the performance of the model with established ones like VGG-16, ResNet-50, and MobileNet-V2. Results showed the model achieved a remarkable accuracy of 97.73%, surpassing all comparative models. This high accuracy underscores its potential for accurate disease classification in agricultural settings.

Bharanidharan et al. [9] used a Modified Lemurs Optimization (MLO) Algorithm as a filter-based feature transformation technique to increase the efficiency of recognizing different paddy diseases in thermal pictures of paddy leaves. The authors created the proposed Modified Lemurs Optimization Algorithm by modifying the original Lemurs Optimization, taking influence from the Sine Cosine Optimization. Studying 636 thermal photos of both healthy and sick paddy leaves is part of the analysis. Four machine learning methods are evaluated: the RF, the Linear Discriminant Analysis, the K-Nearest Neighbor, and the Histogram Gradient Boosting. At first, these classifiers show balanced accuracies of less than 65%; however, they perform better when using feature transformation based on MLO. The achievement of an accuracy of 90% using the K-Nearest Neighbor classifier with the suggested feature modification is quite noteworthy.

Iqbal et al. [10] examined a database of paddy leaf diseases, including Brown Spot and Bacterial Blight, utilizing images of healthy and infected leaf for classification. The system predicted and classified rice leaf diseases, aiding both farmers and exporters by estimating disease occurrences and vital production parameters. Prototype picture acquisition and machine vision models enabled real-time detection and categorization in rice cultivation. Notably, KNN achieved 67.18%, Inception V3 reached 93.57%, and VGG19 attained 97.94% accuracy. The study emphasized dataset quality and size in deep learning, highlighting the methodology's potential to enhance rice cultivation and exports.

A CNN-based DL architecture, incorporating transfer learning (TL) techniques, was proposed and implemented by Gautam et al. [11], focused on the significant impact of leaf diseases on paddy crop health. TL models such as VGG19, ResNet, VGG16, SqueezeNet, and InceptionV3 were utilized. The methodology involved preprocessing of leaf images followed by semantic segmentation to isolate regions of interest for fine-tuning TL models. The model specifically targeted biotic diseases affected by bacteria and fungi, achieving an impressive accuracy rate of 96.4%. The model demonstrated superior performance compared to existing approaches.

Advanced deep learning techniques were employed by Yakkundimath et al. [12] to classify rice plant disease symptoms using VGG-16 and GoogleNet CNN models through TL. After rigorous threefold cross-validation, GoogleNet and VGG-16 achieved average accuracies of 91.28% and 92.24%, respectively. The dataset used consisted of 12,000 labeled images representing 24 distinct symptoms across three types of rice diseases. Notably, VGG-16 showed slightly better performance compared to GoogleNet in disease classification. These results suggest promising applications for automating disease identification in rice plants, benefiting agricultural practices and policymaking.

Various machine learning and deep learning techniques were examined by Tejaswini et al. [13] to identify diseases affecting rice leaves, aiming to enhance crop yield for farmers. The study evaluated the effectiveness of different approaches by analyzing metrics like accuracy, recall, and precision. It was found that deep learning models outperformed traditional machine learning methods in disease detection. Notably, a 5-layer convolutional network exhibited the highest accuracy at 78.2%, surpassing models like VGG16, which achieved an accuracy of 58.4%. Additionally, involved classifying rice leaf diseases using various deep learning methods, including VGG19, VGG16, Xception, ResNet, and a custom 5-layer convolutional network. Results indicated that the custom 5-layer convolutional network performed the best, achieving approximately 6% higher accuracy than standard deep learning models.

Haque et al. [14] addressed the issue of rice leaf diseases, which had been a significant concern for global rice cultivation. Recognizing farmers' limited ability to accurately diagnose these diseases, the research opted for YOLOv5, identified as a promising approach. An extensive dataset comprising 1500 annotated images was utilized for training the YOLOv5 model, covering a wide range of disease manifestations. The methodology involved training and evaluating the model to meet specific performance metrics, including recognition precision (90%), recall (67%), mean Average Precision (mAP) value (76%), and F1 score (81%). While the YOLOv5 model demonstrated promising results, certain limitations persisted, such as the need for further validation across diverse datasets and potential challenges in real-world deployment due to computational resource requirements.

Rani et al. [15] undertook a comprehensive exploration of methods for detecting rice leaf diseases. Among various approaches considered, the deep CNN with ResNet-50 was selected for its efficacy in identifying plant diseases. Given the global significance of rice cultivation, safeguarding crops became a priority, necessitating proactive measures against diseases and threats. Utilizing the deep CNN method facilitated the processing of extensive datasets, resulting in disease identification with an impressive accuracy of 97.3%.

In the pursuit of improving paddy disease detection and classification, Almasoud et al. [16] introduced an Efficient DL based Fusion Model (EDLFM-RPD). The methodology incorporated preprocessing steps like median filtering and K-means segmentation to identify affected areas, while feature extraction combined handcrafted Gray Level Co-occurrence Matrix (GLCM) and Inception-based deep features. Classification utilized Salp Swarm Optimization with Fuzzy SVM. A series of simulations were conducted to verify the efficacy of the EDLFM-RPD model, which yielded promising results, achieving a maximum accuracy of 96.170%.

Recognizing the paramount importance of timely disease detection and classification, the Bracino et al. [17] centered on utilizing DL algorithms, including EfficientNet-b0, Places365-GoogLeNet and MobileNet-v2, for this purpose. The targeted diseases encompassed bacterial leaf blight, hispa, bacterial panicle blight, bacterial leaf streaks, downy mildew, and rice tungro disease, reflecting the diverse range of threats to rice cultivation. Through extensive experimentation, it was discerned that EfficientNet-b0 is the most efficient model with accuracy of 97.74%.

Prathima and Nath [18] examined the classification efficacy of various CNN architectures in identifying rice plant diseases. Results revealed that AlexNet achieved the highest accuracy at 89.4%, closely followed by VGG-16, VGG-19, and ResNet-50, which exhibited comparable performance. MobileNet emerged as a viable option for mobile apps development due to its efficiency. The developed Generic Paddy Plant Disease Detector (GP2D2) aimed to equip novice farmers with digital disease detection capabilities akin to expert farmers. Conventional disease identification methods were deemed less effective over large agricultural areas, underscoring the importance of the mobile application. Drones equipped with cameras were proposed for capturing paddy images for disease identification via the app. The study offered valuable insights for selecting appropriate architectures for real-time disease identification applications in paddy plants. The mobile application framework's flexibility allowed for easy customization by updating or replacing the existing model as necessary.

A critical gap exists in the development of DL models that can effectively detect and classify paddy leaf diseases under real-world conditions, addressing challenges such as variability in background, color issues, and the presence of contaminated elements in images. Existing methods, including unsupervised approaches and traditional machine learning algorithms like SVM, KNN, and Back Propagation Neural Network, encounter limitations such as complexity, time consumption, and difficulty in handling noise and lighting problems. Moreover, these methods may struggle with diseases exhibiting similar morphology and color, limiting their applicability across diverse environmental conditions and stages of crop growth. Therefore, there is a pressing need for research focused on enhancing the robustness and scalability of DL models for paddy leaf disease detection and classification, considering aspects such as variable lighting conditions, weather fluctuations, and the presence of multiple disease types simultaneously. Additionally, research efforts should aim to bridge the gap between theoretical advancements and practical deployment in agricultural settings, particularly in resource-constrained environments where computational resources and technical expertise may be limited. Tackling these obstacles will help create better tools to monitor and control paddy leaf diseases, leading to higher crop yields and improved food security.

III. Materials and Methods

Efficient detection and classification of paddy leaf diseases are imperative to optimize agricultural yield and ensure food security, emphasizing the urgency for the development of a robust and scalable deep learning model tailored for real-world applications. A detailed visualization of the proposed method is given in Fig. 1.

A. Dataset

The dataset containing paddy leaf diseases was acquired from Kaggle repository, [23] comprising a total of 2627 images distributed across the training and validation folders. It encompasses six distinct rice leaf diseases, namely Brown Spot, Bacterial Leaf Blight, Healthy, Leaf Scald, and Narrow Brown Spot, Leaf Blast. Some sample images of paddy leaf disease from the dataset are represented by Fig. 2.

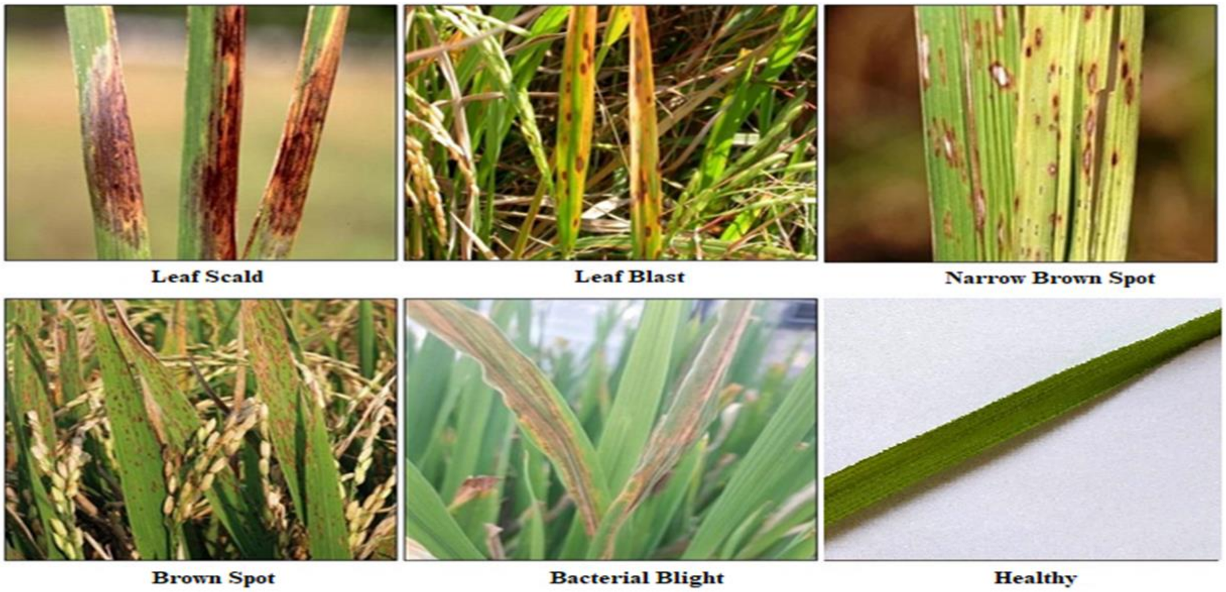

Fig. 2. Dataset sample images.

B. Image Preprocessing and Data Augmentation

Following the dataset collection phase, the images underwent a series of preprocessing and augmentation steps to prepare them for training. Preprocessing involves standardizing the images, ensuring consistent pixel values and dimensions. In this case, pixel values were rescaled to fall within the range of 0 to 1, to aid in model convergence during training. Augmentation methods were then applied to boost the variability of the dataset, enhancing the capability to generalize to unseen data. These techniques included shear transformations, zooming, flipping (both horizontally and vertically), and rotation (up to 30 degrees). These augmentations mimic real-world variations that might occur in the images, such as changes in perspective or orientation. Subsequently, the images were scaled down to a target size of 224x224 pixels, a standard input size. This resizing ensures uniformity in input dimensions across all images, facilitating model training. To optimize memory usage during training, the images were batched into groups of 64. Additionally, the class labels associated with each image were encoded in categorical format. This encoding represents each class label as a binary vector, where each element corresponds to a specific class and indicates its presence or absence of the paddy leaf disease in the image.

C. Architecture of Proposed Model

The pre-processed images are input into the hybrid deep learning architecture proposed in this study. This model combines the EfficientNetB0 model with a Capsule network for enhanced performance in disease classification.

1) EfficientNetB0: EfficientNetB0 is a highly efficient CNN architecture. It balances model depth, width, and resolution through compound scaling, offering advanced performance across various computer vision tasks while minimizing computational demands. EfficientNetB0 is renowned for its modular design, featuring a stem convolutional layer that serves as the initial processing stage for input images as Fig. 3.

Following the stem layer, the architecture comprises multiple sequences of MobileNetV2-like MBConv blocks, which have squeeze-and-excitation mechanisms, shortcut connections, and depth wise separable convolutions [19]. These components collectively contribute to the model's efficiency by reducing computational complexity while preserving representational capacity. The number of MBConv blocks in each sequence, as well as the scaling factors applied to network dimensions, are determined through a compound scaling method. This approach ensures a balanced adjustment of network width, depth, and resolution, thereby optimizing the model's performance across various computational constraints. The layers in the network are scaled by a factor α. If the original network has L layers, the scaled network has approximately $\alpha * L$ layers. The width of each layer (number of channels) is scaled by a factor β. If the original network has W channels in a layer, the scaled network has approximately $\beta * W$ channels. The input image resolution is scaled by a factor γ. If the original input resolution is $R\,x\,R$ pixels, the scaled input resolution is approximately $\gamma * R\,x\,\gamma * R$ pixels. The compound coefficient φ is defined as the geometric mean of $\alpha, \beta, and\ \gamma$ given by Eq. (1).

$$\varphi = \sqrt{}(\alpha * \beta * \gamma) \tag{1}$$

One of the notable features of the EfficientNetB0 architecture is its utilization of global average pooling, which facilitates dimensionality reduction by summarizing spatial information across feature maps. This pooling operation aids in capturing essential features while mitigating the possibility of overfitting, thereby boosting the capacity of generalization. The architecture consists of nine stages, each with specific operators, resolutions, channels, and layers, designed to process input data at different levels of complexity and abstraction. EfficientNetB0 is typically pretrained on large-scale image datasets such as ImageNet, enabling it to learn generic features from diverse visual data [20]. This pretrained model can then be fine-tuned on smaller, task-specific datasets to adapt its learned representations to the nuances of the target domain, making it highly versatile for various image classification task.

2) Capsule network: Drawing inspiration from the hierarchical organization of biological neural structures, Capsule Neural Networks, or CapsNets, represent a type of artificial neural network (ANN) designed to mimic these hierarchical relationships. Unlike conventional neural networks, CapsNets introduce capsules, termed as digit capsules, as fundamental units to better handle hierarchical structures and variations in data [21]. These capsules encapsulate activation information and spatial relationships, outputting pose parameters alongside activations to represent specific entities or object parts. CapsNets employ dynamic routing to refine coupling coefficients based on pose parameter agreement, enhancing recognition of intricate data patterns and capturing complex spatial hierarchies. The CapsNet architecture includes an encoder network, consisting of layers like Convolutional, PrimaryCaps, and DigitCaps, to convert image inputs into vectors containing essential parameterization parameters as shown in Fig. 4.

The PrimaryCaps layer clusters neurons into capsules to capture important patterns, while the DigitCaps layer represents specific entity types and encodes their instantiation parameters. Capsule networks utilize dynamic routing to update coupling coefficients between lower-level and higher-level capsules, aiming to increase agreement between predictions and input vectors [22]. Additionally, CapsNets feature a Decoder Network as illustrated in Fig. 5, responsible for reconstructing input images from the data stored in DigitCapsules, facilitating faithful image reconstruction using instantiation properties. This reconstruction process contributes to both classification accuracy and meaningful image reconstruction, aligning with the training objective of Capsule Networks. It calculates the loss for each training example and output class using Eq. (2).

$$L_n = T_n max(0, m^+ - \|v_n\|)^2 + \lambda(1 - T_n) max(0, \|v_n\| - m^-)^2 \tag{2}$$

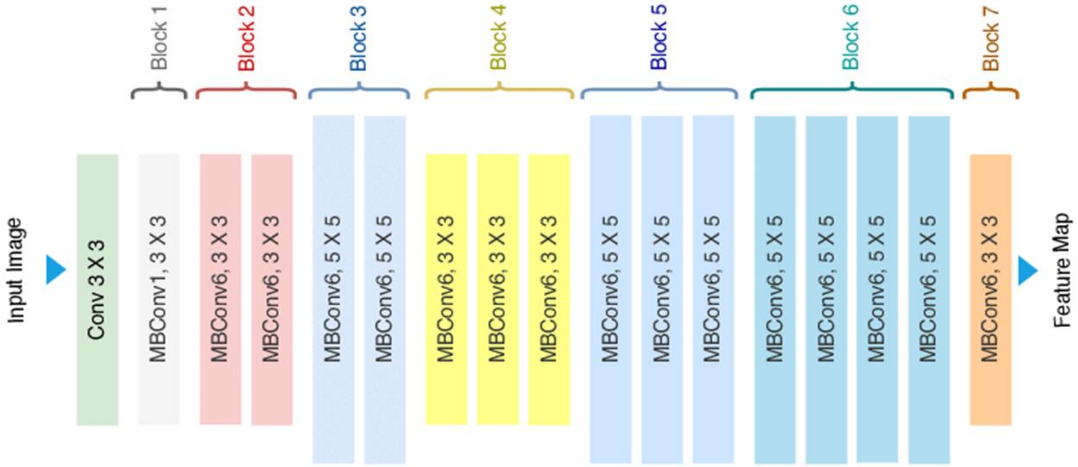

Fig. 3. Fundamental architecture of EfficientNetB0.

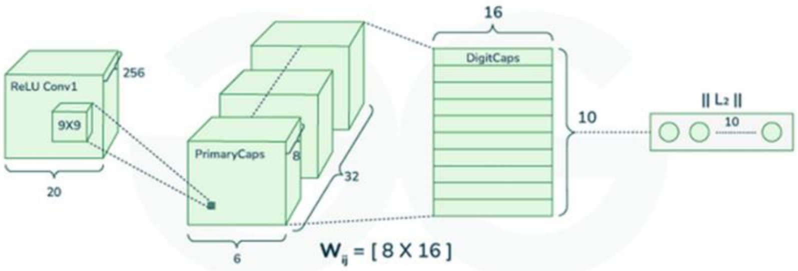

Fig. 4. Encoder network of CapsNet.

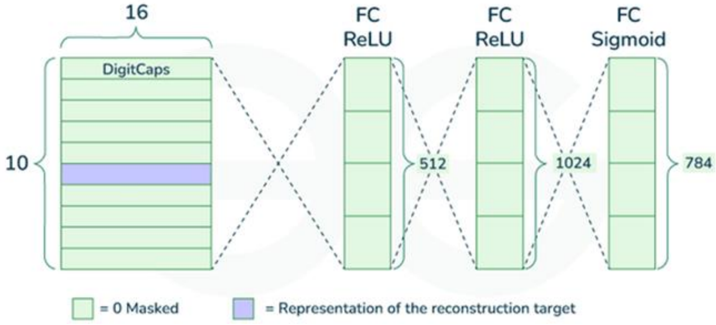

Fig. 5. Decoder network of CapsNet.

where L_n denotes the margin loss for the n-th digit capsule. The binary indicator $T_n$represents the activity vector for the n-th digit capsule as v_n , with its length indicated as $\|v_n\|$ .The positive and negative margins are represented as m^+ and m^-respectively. Additionally, λ signifies the down-weighting factor for the loss from inaccurate digit capsules. Dynamic routing in capsule networks updates coupling coefficients between lower-level and higher-level capsules to enhance agreement. This iterative update process is governed by Eq. (3),

$$c_{ij} = \frac{exp(b_{ij})}{\sum_k exp(b_{ik})} \tag{3}$$

where b_{ij} denotes the log prior probabilities of the coupling coefficients

3) Proposed hybrid model: The proposed hybrid deep learning model combines the strengths of EfficientNetB0 and a Capsule Network to effectively detect and classify diseases in paddy plants. EfficientNetB0 serves as the backbone of the model, leveraging its pretrained weights from ImageNet to capture intricate hierarchical features from input images. This pretrained model is adept at extracting meaningful patterns, edges, and textures from images, providing depiction of the input data. To further process the features extracted by EfficientNetB0, a Global Average Pooling layer is induced.

This layer preserves crucial information while minimizing the feature maps' spatial size, facilitating computational efficiency and preventing overfitting. Following the Global Average Pooling layer, Dense layers are introduced for additional feature extraction and combination. ReLU activation functions, which are fitted to every Dense layer, add non-linearity to the model and improve its ability to represent intricate correlations found in the data. After the Dense layers, the output is reshaped to prepare the data for integration with the Capsule Network. This reshaping step ensures that the features extracted by the preceding layers are appropriately formatted and compatible with the initial requirements of the Capsule Network.

The Capsule layer receives the reshaped output from the Dense layers and performs a series of operations to learn hierarchical features. This includes applying a 2D convolution to the input, reshaping the resulting feature maps, and applying a squashing activation function to encapsulate the activation information and spatial relationships within the data. By doing so, the Capsule layer can effectively encode complex patterns and variations present in the input images. Finally, a dense layer with softmax activation function is employed at the output layer for disease detection. This layer computes the probability distribution over the different disease classes, allowing the model to classify input images into the corresponding category of disease with high accuracy. Thus, the hybrid deep learning model seamlessly integrates the strengths of EfficientNetB0 and Capsule Network, enabling robust and efficient detection and classification of diseases in paddy plants.

4) Hardware and software setup: The model utilized for this study includes an Intel Core i7-6850K 3.60 GHz 12-core processor and a NVIDIA GeForce GTX 1080 Ti GPU with 2760 4MB memory. Google Collaboratory served as the workstation platform. The implementation of the proposed work was done using Python, a widely-used programming language recognized for its readability and ease of use. Python's extensive library ecosystem and dynamic typing, coupled with strong community support, have led to its broad acceptance across diverse industries and fields. Table I outlines the specifications of the hyperparameters utilized in the study.

TABLE I. SPECIFICATIONS OF HYPERPARAMETERS

Hyperparameter	Values
Routings	3
Loss Function	Categorical Cross entropy
No. of epochs	30
Optimizer	Adam
Batch Size	64
Activation Function	ReLu, Softmax

IV. RESULT AND DISCUSSION

A. Performance Evaluation

The assessment metrics given in Table II are utilized to determine the effectiveness of the suggested hybrid architecture.

TABLE II. EVALUATION METRICS

Performance Metrics	Equations
Accuracy	$(TP + TN) / (TP + TN + FP + FN)$
Precision	$TP / (TP + FP)$
Recall	$TP / (TP + FN)$
F1 Score	$2 * (Precision * recall) / (Precision + recall)$
where, TP-true positives, TN-true negatives, FP-false positives and FN-false negatives	

Table III represents the performance evaluation of the proposed model for the detection of paddy leaf disease with respect to accuracy, recall, precision, and f1 score.

TABLE III. EVALUATION REPORT OF PROPOSED METHOD

Performance Metrics	Results Obtained
Accuracy	97.86%
Precision	97.98%
Recall	98.01%
F1- Score	97.99%

The provided analysis examines the effectiveness of the model using various metrics. The accuracy score, at 97.86%, indicates the percentage of instances that were correctly identified out of all. Precision, measuring the accuracy of positive predictions, is exceptionally high at 97.98%, suggesting that the model has a high probability of being accurate when it predicts a favorable result. Similarly, the recall value, indicating the ability to capture true positive cases, is also impressive at 98.01%, implying that the model effectively identifies a significant portion of the actual positive cases. This high precision and recall values collectively represent that the model achieves good equilibrium between minimizing false positives (incorrectly identified positives) and false negatives (missed positives). The F1-Score, a combined measure of precision and recall, further validates the model's performance, yielding a high score of 97.99%. This metric confirms the model's ability to maintain a harmonious trade-off between precision and recall, emphasizing its robustness in classification tasks. Table IV illustrates the classification report of the suggested model which effectively detect the paddy leaf disease.

TABLE IV. CLASSIFICATION REPORT OF SUGGESTED METHOD

Paddy Leaf Disease	Precision	F1-Score	Recall
Leaf Scald	0.97	0.98	0.98
Leaf Blast	0.96	0.98	0.97
Narrow Brown Spot	0.98	0.97	0.97
Brown Spot	0.97	0.98	0.97
Bacterial Leaf Blight	0.97	0.97	0.97
Healthy	0.98	0.97	0.98

Accuracy and loss plots are essential visualizations for evaluating model performance during training. The accuracy plot depicts how the model's predictive accuracy changes over training epochs, while the loss plot shows variations in the model's loss function. These plots offer insights into aspects like model convergence, overfitting, or underfitting, helping to refine the model for better performance. Fig. 6 presents these plots, indicating trends in accuracy and loss across epochs. Fig. 7 presents the confusion matrix, to evaluate the classification model's accuracy. It displays true positives, false negatives, true negatives, and false positives, providing a comprehensive view of classification outcomes. Each cell in the matrix represents a combination of true and predicted labels, highlighting the model's classification performance. The main diagonal represents correct classifications, while off-diagonal elements indicate misclassifications.

The detection output of the suggested hybrid model that effectively detect the paddy leaf disease is shown by Fig. 8.

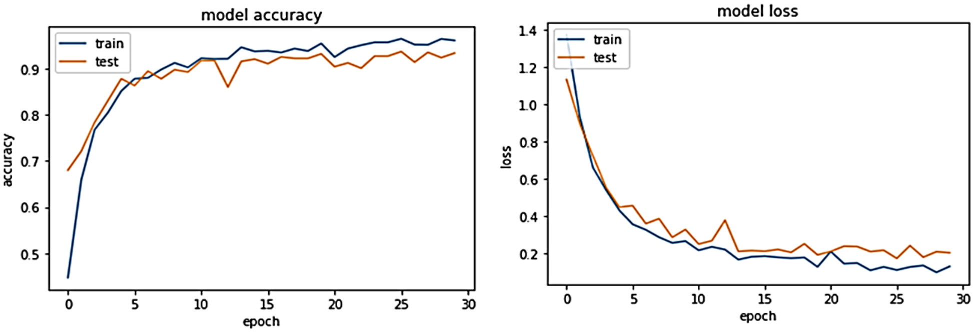

Fig. 6. Accuracy and loss plot of the hybrid model.

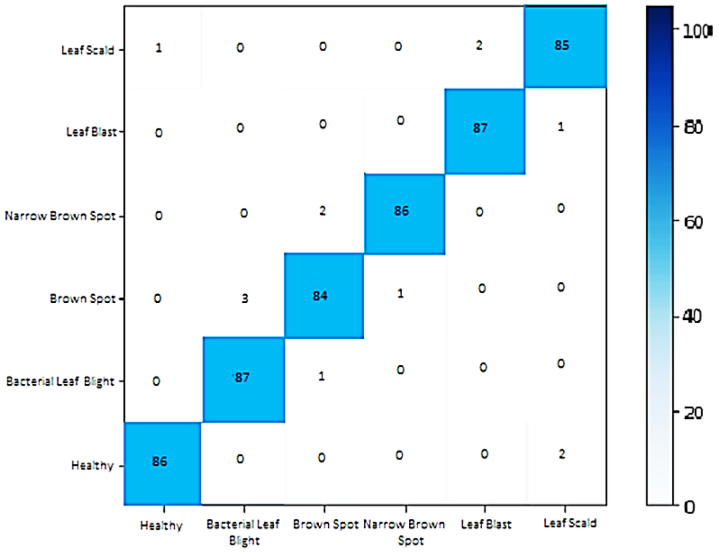

Fig. 7. Confusion matrix of the hybrid method.

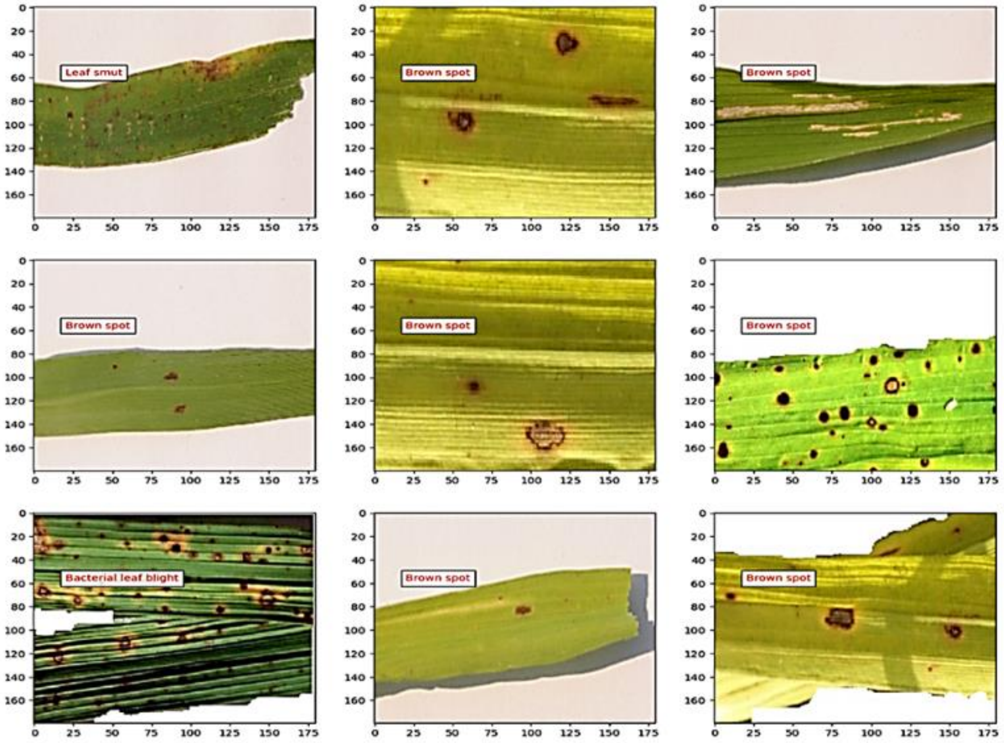

Fig. 8. Detection output.

B. Performance Comparison

Table V compares the performance of the proposed hybrid network with conventional methods based on ML and DL, providing a comprehensive analysis of their effectiveness. The analysis of various deep learning methodologies highlights the superior performance of the proposed hybrid model. While Convolutional Neural Networks (CNNs) such as VGG-16 and advanced hybrid CNN models demonstrated high accuracy, reaching up to 97%, and other models like YOLOv8 and Double-branch DCNN with CBAM also performed well with accuracies of 97.73% and solid precision and recall metrics, the proposed model stands out. By integrating EfficientNetB0 with a Capsule Network, it achieved the highest accuracy of 97.86%, surpassing other approaches. It also excelled in precision, recall, and F1-score, demonstrating its robust capability in delivering superior overall performance compared to existing methods. This suggests that the hybrid model not only achieves better accuracy but also provides enhanced reliability and effectiveness in its predictions.

TABLE V. CLASSIFICATION REPORT OF PROPOSED METHOD

Author	Methodology Used	Results
Kulkarni and Shastri [5]	CNN based on VGG-16 model, preprocessing with Kaggle dataset	Accuracy: 95%
Jesie et al. [6]	Hybrid CNN model outperforming DNN, DBN, LSTM, and RNN	Accuracy: 97%, F-measure: 92.3%, Precision: 93.1%, Recall: 92.1%, Sensitivity: 93.4%, Specificity: 94.27%
Trinh et al. [7]	YOLOv8 model with data augmentation techniques	Precision: 89.6, Recall: 83.5, F1-score: 86.4, mAP: 88.9
Bi and Wang [9]	Double-branch DCNN (DBDCNN) model integrated with CBAM	Accuracy: 97.73%
Bharanidharan et al. [10]	Modified Lemurs Optimization Algorithm with machine learning methods	Balanced accuracy: 90%
Iqbal et al. [11]	Utilized KNN, Inception V3, and VGG19 with varying accuracies	KNN: 67.18%, Inception V3: 93.57%, VGG19: 97.94%
Gautam et al. [12]	TL models such as InceptionV3, VGG16, ResNet, SqueezeNet, and VGG19 with preprocessing and segmentation	Accuracy: 96.4%
Yakkundimath et al. [13]	Transfer learning using VGG-16 and GoogleNet CNN models	VGG-16: 92.24%, GoogleNet: 91.28%
Tejaswini et al. [14]	Various deep learning models including VGG19, VGG16, Xception, ResNet, and custom 5-layer CNN	Custom CNN: 6% higher accuracy than standard deep learning models
Haque et al. [15]	Utilized YOLOv5 model with specific performance metrics	Recognition precision: 90%, Recall: 67%, mAP: 76%, F1 score: 81%
Rani et al. [16]	Deep CNN with ResNet-50	Accuracy: 97.3%
Almasoud et al. [17]	Efficient Deep Learning based Fusion Model (EDLFM-RPD) with preprocessing and feature extraction	Maximum accuracy: 96.170%
Bracino et al. [18]	DL algorithms including MobileNet-v2, EfficientNet-b0, and Places365-GoogLeNet	Average accuracy: 97.74%
Proposed Model	**Hybrid Deep learning model combining EfficientNetB0 and Capsule Network**	**Accuracy of 97.86%, Precision of 97.98%, Recall of 98.01%, and F1-Score of 97.99%.**

V. CONCLUSION

The detection and classification of paddy leaf diseases are critical aspects of modern agricultural practices, contributing significantly to crop management, yield optimization, and food security. This study presents a comprehensive exploration of the suggested hybrid DL model for the effective identification of paddy leaf diseases, addressing the limitations of existing methodologies. Using a combination of the EfficientNetB0 architecture and Capsule Network, the proposed model demonstrates remarkable performance in terms of accuracy, precision, recall, and F1-Score, as evidenced by the evaluation metrics. With an accuracy of 97.86% and precision, recall, and F1-Score values all exceeding 97%, the model demonstrates its capability to precisely detect and classify paddy leaf diseases, including Brown Spot, Leaf Scald, Narrow Brown Spot, Leaf Blast, Bacterial Leaf Blight, and Healthy leaves. Moreover, the hybrid reliability is further underscored by its comparison with conventional approaches, where it consistently outperforms existing methods in terms of accuracy and efficacy. The suggested hybrid DL model represents advancement in the field of agricultural technology, offering an efficient solution for identification and classification of paddy leaf diseases. This model holds immense potential to revolutionize crop management practices, contribute to global food security efforts, and empower farmers with actionable insights for sustainable agriculture. Future work will involve expanding the model to detect a broader range of paddy leaf diseases and integrating it with real-time processing for on-field use. Efforts will also focus on combining the model with environmental data to enhance diagnostic accuracy. Additionally, validating the model through practical field trials will be essential for ensuring its effectiveness in real-world agricultural settings.

ACKNOWLEDGMENT

I would like to express my sincere gratitude to all those who contributed to the completion of this research paper. I extend my heartfelt thanks to my supervisor, my family, my colleagues and fellow researchers for their encouragement and understanding during the demanding phases of this work.

***Abstract*—Depression is common and dangerous if untreated. We must detect depression patterns early and accurately to provide timely interventions and assistance. We present a novel depression prediction method (depressive-deep), which combines preprocess brain electroencephalogram (EEG) and ECG-based heart-rate variability (HRV) signals into a 2D scalogram. Later, we extracted features from 2D scalogram images using a fine-tuned MobileNetV2 deep learning (DL) architecture. We integrated an AdaBoost ensemble learning algorithm to improve the model's performance. Our study suggested ensemble learning can accurately predict asymmetric and symmetric depression patterns from multimodal signals such as EEG and ECG. These patterns include major depressive state (MDS), cognitive and emotional arousal (CEA), mood disorder patterns (MDPs), mood and emotional regulation (MER), and stress and emotional dysregulation (SED). To develop this depressive-deep model, we have performed a pre-trained strategy on two publicly available datasets, MODMA and SWEEL-KW. The sensitivity (SE), specificity (SP), accuracy (ACC), F1-score, precision (P), Matthew's correlation coefficient (MCC), and area under the curve (AUC) have been analyzed to determine the best depression prediction model. Moreover, we used wearable devices over the Internet of Medical Things (IoMT) to extract signals and check the depressive-deep system's generalizability. To ensure model robustness, we use several assessment criteria, including cross-validation. The depressive-deep and feature extraction strategies outperformed compared to the other methods in depression prediction, obtaining an ACC of 0.96, IOTSE of 0.98, SP of 0.95, P of 0.95, F1-score of 0.96, and MCC of 0.96. The main findings suggest that using 2D scalogram and depressive-deep (fine-tuning of MobileNet2 + AdaBoost) algorithms outperform them in detecting early depression, improving mental health diagnosis and treatment.**

I. INTRODUCTION

Mental depression is a global health issue that affects people of all ages and genders [1]. Especially during the COVID-19 epidemic, stress and anxiety have widely affected the health of humans. Early depression pattern detection can improve treatment outcomes, prevent suicidal tendencies, and improve mental health care [2, 3]. Traditional depression diagnosis uses clinical examinations, questionnaires, and interviews [4]. While these methods are useful, they are often subjective and constrained by healthcare providers' biases and expertise [5]. Technology and machine learning have shown promise in improving diagnostic procedures in recent years [6]. Most importantly, based on current data, CAD systems can forecast patient health outcomes [7]. AI has transformed pathology identification using these data. Previous research has proposed EEG and HRV models for early neurological disease identification [8].

Enhanced alpha power, decreased beta power, frontal asymmetry, and diminished connectivity are EEG features [9]. HRV patterns show reduced HRV, increased sympathetic activity, and decreased parasympathetic activity. Some elements may not apply to EEG and ECG patterns since they are distinct [10]. Fig. 1 visualizes EEG and ECG-based HRV signals. Our analysis reveals specific patterns like MDS with marked asymmetry in brain wave activities, while CEA exhibits more symmetrical features. The model discerns depression states using both symmetrical and asymmetrical signal patterns as biomarkers for accurate diagnosis.

EEG patterns (alpha and beta power, frontal asymmetry, and connectivity) indicate brain activity linked to depression. Higher frontal alpha power suggests lower brain activity, while beta power indicates tension or worry. Frontal asymmetry relates to affective and motivational dysregulation. Depressed individuals may show altered brain connectivity. HRV patterns reflect the stress-relaxation balance, with depression causing increased sympathetic or decreased parasympathetic activity. These representations go beyond 'cosine signals' to depict depression's physiological alterations and biological relationships.

EEG and ECG are multimodal data valuable for mental health assessment. EEG non-invasively records brain activity, revealing cognitive and emotional processes [11]. HRV measures autonomic nervous system activity and emotional modulation through heartbeat intervals. EEG and HRV are objective indicators for depressive patterns [12]. Mobile crowd sensors (MCSs) use mobile device sensors for data sharing and behavior tracking, essential for Internet of Medical Things (IoMT) applications. This study uses MCS to quantify symptoms and diagnose depression patterns from EEG and ECG-based signals, analyzing smartphone usage for behavioral insights.

TABLE I. COMPARISON STUDIES ON DETECTING DEPRESSION PATTERNS USING MACHINE LEARNING AND DEEP LEARNING TECHNIQUES, INCLUDING THE DATASET, ACCURACY, AND LIMITATIONS OF EACH APPROACH

Study	Methodology	Dataset	Accuracy (%)	Limitations
[22]	Machine Learning (Nonlinear Features + Logistic Regression)	EEG signals	90.00	Limited to EEG data, may not generalize widely.
[23]	Deep Learning (CNN + LSTM)	EEG signals	99.07 (Right) / 98.84 (Left)	Complex model, computationally intensive.
[24]	Ensemble Learning + Deep Learning (Power Spectral Density)	EEG data from emotional face stimuli task	89.02	Performance may vary with different features.
[25]	Machine Learning (SVM, LR, NB)	EEG-based functional connectivity	SVM: 98.00, LR: 91.70, NB: 93.60	Limited to functional connectivity features.
[26]	Deep Learning (CNN-LSTM)	EEG signals	99.12 (Right) / 97.66 (Left)	Computationally intensive, deep model.
[27]	Deep Learning (CNN)	EEG signals	93.50 (Left) / 96.00 (Right)	Focus on specific hemisphere EEG signals.
[28]	Deep Learning (DWSN)	EEG signals	GMC: 99.95, MODMA: 99.30	May require substantial computational resources.
[29]	Deep Learning (GCN + Attention)	EEG signals	92.87 / 83.17	May require significant training data.
[30]	Machine Learning (VMD + EEG Channel Selection)	EEG signals	Varies based on channel selection	Dependent on channel selection method.
[31]	Deep Learning (MFCC + CNN)	Audio Data (DAIC-WOZ, MODMA, RAVDESS)	Over 90%	Limited to audio-based depression detection.
[32]	Handcrafted Classification Model (TPTLP + KNN)	EEG signals	76.08 (Channel 1) / 83.96 (Top 13 Channels)	May not achieve as high accuracy as deep learning.
[33]	Machine Learning (CNN)	EEG signals	97.00	May not capture complex patterns in EEG data.
[34]	Machine Learning (Decision Tree, Random Forest, etc.)	EEG signals	98.13 (CNN + Band Power)	Limited to EEG data, may not generalize widely.
[35]	Deep Learning (Self-Attention + CNN)	EEG signals	91.06	May require substantial training data.

We combine deep and ensemble learning to predict depression using EEG and HRV data. The MobileNetV2 deep learning model analyzes 2D arrays, and AdaBoost ensemble learning improves predictive power. We aim to test EEG and ECG-based HRV as depression biomarkers, evaluate the model, and identify relevant features for accurate predictions. Our model is an auxiliary tool for mental health assessment and should complement healthcare experts' experience. This depressive-deep system transforms 1D multimodal signals into 2D scalograms using HRV and EEG datasets. After preprocessing, useful features are extracted by fine-tuning MobileNetV2, addressing the challenge of feature selection without overfitting.

The main contributions using fine-tuned MobileNetV2 and AdaBoost to recognize multiple depression patterns from HRV and EEG data are:

1) This work uses MobileNetV2, a lightweight deep learning model, and AdaBoost, an ensemble learning method.

2) This new approach improves depression pattern identification from multimodal ECG and EEG data by combining their capabilities into one 2D scalogram.

3) This research shows depression pattern prediction outperforms existing methods. The MobileNetV2 and AdaBoost models outperform earlier methods in mental health diagnosis, demonstrating the potential of sophisticated machine learning.

4) The model's potential for early depression diagnosis and treatment is highlighted. This strategy could improve mental health by monitoring and supporting depressed people via wearable gadgets or smartphone apps.

Our developed model is detailed in the subsequent article sections. In Section II, we described the literature review. Afterwards, the article begins with a full discussion of EEG and ECG signal preprocessing procedures to create 2D scalograms in Section III. Next, we present the MobileNetV2 deep learning model's design and fine-tuning, then integrate the AdaBoost ensemble learning method to improve prediction performance. The study presents MODMA and SWEEL-KW datasets in Section IV with assessment metrics for model accuracy, sensitivity, specificity, precision, F1-score, MCC, and AUC. We also address IoMT-based wearable device deployment to test the model's generalizability. Finally, we compare our technique to others and show that the depressive-deep model is better at early depression identification. Section V describes the discussion of this paper and finally, the paper concludes in Section VI.

II. LITERATURE REVIEW

The literature on depression diagnosis using ECG-based HRV and EEG data explores deep learning and ensemble learning in mental health diagnoses, highlighting research gaps and new methodologies. Depression has serious social and economic effects. Researchers have used HRV and EEG data to detect depression patterns. This section reviews experiments using MobileNetV2 and AdaBoost to analyze HRV and EEG data.

In study [13], a novel EEG-based depression detection method employs MobileNetV2 deep learning and SVM classifiers to analyze EEG spatial and temporal patterns. In study [14], HRV data predicts depression using AdaBoost, combining weak classifiers for reliable predictions. MobileNetV2's architecture in study [15] addresses deep learning on mobile devices with minimal complexity and improved performance. In study [16], HRV-based depression diagnosis using AdaBoost improves model performance and recognition accuracy. The literature shows increasing use of MobileNetV2 and AdaBoost for diagnosing depression from HRV and EEG data. These strategies could improve mental health diagnoses. More research is needed to address data availability, interpretability, and real-world applicability issues, enhancing depression detection technologies. Relevant papers on HRV and EEG data in machine learning include studies on model evaluation metrics like RMSE and MAE [17].

Sathyanarayana and Krishnan propose a hybrid deep learning model using CNNs and LSTM networks to assess EEG and HRV data [18]. Shi et al. use a brain-functional network-based EEG feature selection method for depression recognition [19]. This study examines nonlinear complexity in brain functional fMRI signals in schizophrenia [20], while Subhani et al. assess brain functional connectivity using deep learning with resting-state fMRI data [21]. Previous systems [22–27] using deep learning architectures like CNN and LSTM with 1D EEG signals recognized limited depression patterns. Sharma et al. (2024) proposed a Deep Wavelet Scattering Network (DWSN) for automated depression identification using EEG signals [28], achieving high accuracy. Zhang et al. (2024) used a graph convolution network with an attention mechanism for depression detection in public datasets [29].

Aljalal et al. (2024) detected minor cognitive impairment using variational mode decomposition and machine learning with few EEG channels [30]. Das and Naskar (2024) proposed an MFCC-CNN model for depression identification from audio signals, achieving over 90% accuracy [31]. Tasci et al. (2023) used cross-validation for identifying MDD with EEG signals [32]. Ksibi et al. (2023) employed CNN and machine learning for detecting depression patterns in EEG data [33]. Khadidos et al. (2023) used band power features for depression identification, achieving high accuracy with CNN models [34]. Xia et al. (2023) used an end-to-end deep learning model for EEG-based depression classification, achieving high accuracy [35]. These studies advance mental health diagnosis through various EEG signal processing methods and machine learning models. Table I compares these state-of-the-art studies.

III. Proposed Methodology

Fig. 1 displays the systematic flow diagram. This study used numerous essential phases. First, we obtained ECG-based HRV and EEG data from both depressed and non-depressed individuals using wearable heart rate monitors and specialist devices. We protected data privacy through ethical approval and informed permission. Preprocessing included HRV data normalization, artifact removal, and EEG data filtering and artifact removal. Next, we transform the preprocessed ECG and EEG data into 2D scalogram images. We fine-tuned MobileNetv2 to extract features from HRV dynamics and brain activity patterns. The suggested model architecture integrated MobileNetV2, a lightweight deep learning model, with AdaBoost ensemble learning. We assessed the model performance using cross-validation metrics such as accuracy, sensitivity, specificity, precision, F1-score, and AUC. SMOTE created synthetic depressed samples to correct the class imbalance. We used Python, scikit-learn, and TensorFlow for hyperparameter tuning and optimization. The study noted limitations like the short dataset and potential overfitting and advised caution when interpreting model results. The study used ECG-based HRV and EEG data and advanced machine learning to improve depression pattern recognition and mental health diagnoses.

TABLE II. Data Description Captured from MODMA and SWELL-KW Datasets

Dataset	Properties	Values
MODMA [36]	Subjects with depression	30
	Channels	128
	Sampling rate (Hz)	1000
SWELL-KW [37]	Subjects	32
	Subjects with depression	25
	Male/female ratio	8/17
	ECG	6
	Sampling rate (Hz)	0.0 to 1000
Total	Number of Subjects	45

A. Data Acquisition

We collected heart rate variability (HRV) based on ECG and brain activities through EEG data from a diverse group of participants, which included individuals with different patterns of depression and those without depression. We obtained the HRV data using wearable heart rate monitors and captured the EEG data using a specialized electroencephalogram (EEG) device. The EEG [36] and ECG data [37] are available online. People commonly use a heart rate monitor or an electrocardiogram (ECG) device to capture HRV signals. These devices are non-invasive and can accurately measure variations in time intervals between successive heartbeats. The remaining paragraphs describe the details of the datasets in Table II.

EEG signal data utilized in this study are sourced from the MODMA dataset [36], a multi-modal open dataset designed for research on mental disorders. The dataset includes EEG data obtained from individuals wearing a conventional 128-electrode elastic cap or a newly developed wearable EEG collector with three electrodes, suitable for a broader application. Specifically, this investigation focuses on analyzing resting-state EEG signals collected from individuals equipped with the 128-channel cap. Inclusion criteria for participants in the MODMA dataset require them to be aged between 18 and 55, have normal or corrected-to-normal vision, and possess at least an elementary level of education. Some patients were diagnosed with major depressive disorder (MDD). Moreover, patients with MDD should not have used psychotropic drugs within the two weeks preceding data collection, and control group participants should have no history of mental illness in their families. To maintain sample integrity and enhance the generalizability of results, individuals with pre-existing mental illnesses, brain injuries, significant physical ailments, or severe suicidal tendencies were excluded from the MODMA dataset.

For MODMA and SWELL-KW signal average durations, our study used EEG- and ECG-based HRV data with 5 min sessions. This length is the same as resting-state EEG and short-term HRV methods. It gives us a balanced way to obtain useful physiological information about depressed states while still making sure the participants are comfortable. These 5 min sessions often capture a complete image of brain activity and heart rate variability, laying the groundwork for our depression-related pattern analysis without burdening subjects. Fig. 2 shows the visual representation of EEG and ECG-based HRVE signals.

B. Signal Preprocessing

Preprocessing steps on multimodal (EEG, ECG) signals is performed to remove noise and accurately extract depression patterns. EEG data are initially preprocessed for depression pattern analysis using a bandpass filter. This filter isolates frequency components linked to depression-related brain activity. A typical filter, the Butterworth bandpass filter, focuses on a specified frequency range, usually 1–30 Hz. This filtering stage reduces noise and highlights important frequencies. The EEG data are then used to determine connection characteristics. Coherence or phase synchronization analysis yields these traits. The outcome is a connection matrix, with each member representing EEG channel connectivity strength. These findings show complicated brain area relationships, which might help explain depression. EEG characteristics are normalized by the algorithm for uniformity and comparability. This step centers the data at zero mean and scales them to unit variance. The method standardizes the features by determining the mean and standard deviation for each feature over all EEG samples. Normalization removes biases and guarantees that all characteristics contribute equally to the analysis.

ECG signal preprocessing begins with data preparation for analysis. Depending on the dataset and needs, these processes may involve resampling HRV signals to a specified sampling frequency and applying low-pass filters to reduce noise and artifacts. Resampling synchronizes ECG and EEG data for useful analysis. After preparing ECG data, the system extracts depression-related HRV characteristics. Autonomic nervous system components like sympathetic and parasympathetic activity are routinely measured. These measurements are calculated for each ECG segment using feature extraction. These traits reveal depression's physiological elements. The preprocessed EEG and ECG characteristics are saved separately for analysis in the final stage, as shown in Fig. 3. These characteristics are now ready for machine learning or statistical analysis to discover depressive tendencies. We can construct models or conduct statistical studies using these processed characteristics to better understand depression patterns and enhance diagnosis and therapy.

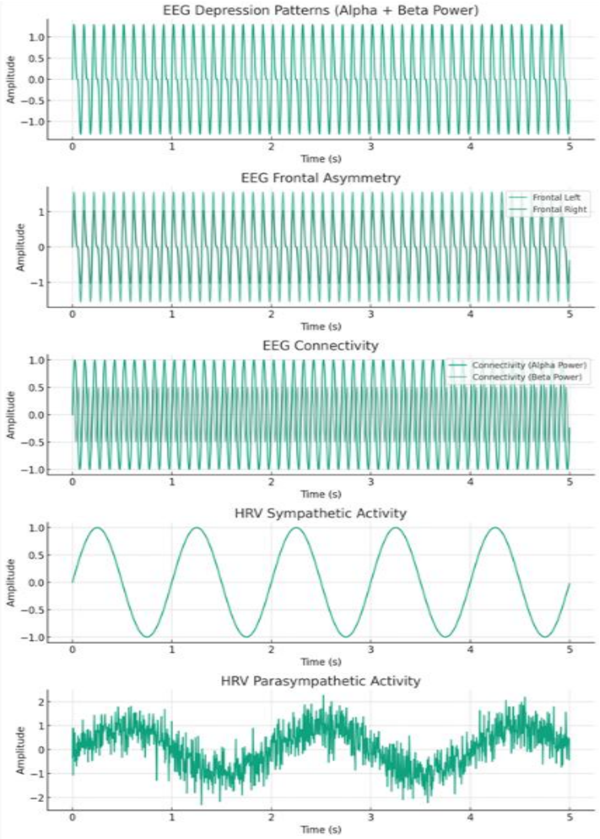

Fig. 2. A sample EEG- and ECG-based HRV multimodal signals from MODMA and SWELL-KW datasets.

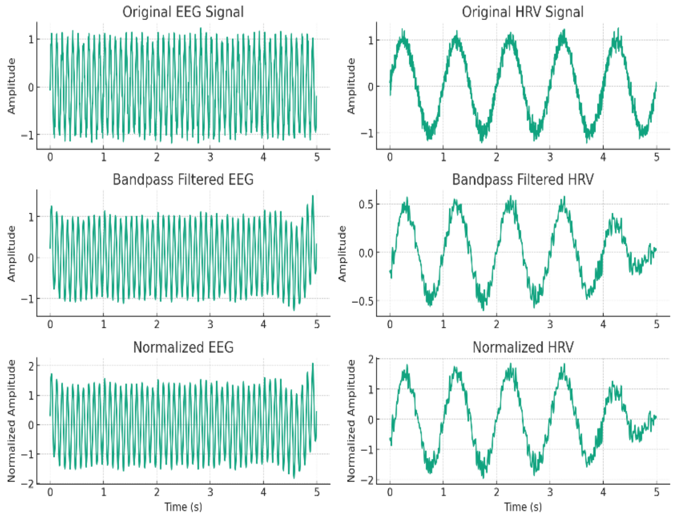

Fig. 3. A visualized diagram of EEG- and ECG-based HRV original and preprocess signals.

C. Signal Transformations

This modified algorithm takes preprocessed EEG and ECG signals as input and generates 2D scalogram-like images by applying continuous wavelet transform (CWT) to both signals, as shown in Fig. 4. It then combines the resulting images to form a single scalogram-like depression pattern. The following paragraphs explain the process. The first stage is preprocessing EEG and ECG signals. This preprocessing involves noise filtering, signal normalization, and segmenting continuous data into digestible parts. This cleans and standardizes signals for analysis. We separate the signals into time-window-sized parts after preprocessing. Zero-padding standardizes these segments' lengths. Standardization is essential for fair segment comparison and analysis. The next stage applies the continuous wavelet transform to each EEG and ECG segment. The CWT uses a scaled and shifted dynamic window (the main wavelet) to assess these segments' frequency content over time. This approach is ideal for EEG and ECG signals because it can analyze high and low frequencies with acceptable resolution and capture the temporal evolution of multiple frequency bands. The CWT produces EEG and ECG scalograms.

Scalograms are 2D image patterns that show a signal's frequency components across time. The intensity of the image corresponds to the amplitude of these components at different frequencies and periods. Combining EEG and ECG scalograms creates a single, complete pattern in a 2D image. This image shows probable depression patterns by combining EEG and ECG data. We normalize the combined scalogram pictures for size, brightness, and contrast to facilitate comparison and study. This standardization lets scalogram patterns be seen, algorithmically evaluated, and compared, as shown in Fig. 4. We divide EEG and ECG data into small patches. Each component represents a short data period. We add zeros to short bits to make them all the same size. This guarantees fair comparisons of all components. Over time, we examine how frequencies like high and low pitches change in each piece of data. This reveals depressive tendencies. Each data point is transformed into a "scalogram" using the CWT transform. We mix EEG and HRV scalograms to create one image. This graphic depicts depression's effects on brain activity and heart rate. For simple comparison, we keep our photographs the same brightness and blackness. After performing this for all our data, we have 2D depression pattern images. Each 2D image illustrates patterns from our EEG and ECG data that might help us understand depression. Preprocessed EEG and HRV data are converted into 2D images for image.

The continuous wavelet transform (CWT) uses a dynamic window called the main wavelet to distinguish it from the short-time Fourier transform (STFT). This wavelet is scaled and shifted during transformation, providing large low-frequency and short high-frequency time intervals. The STFT uses constant window sizes, whereas the CWT can adapt to different window sizes to evaluate both high- and low-frequency components in a time series [34]. CWT is ideal for EEG analysis due to its versatility. To maximize resolution, the approach uses smaller scales for high frequencies and bigger scales for low frequencies. In practice, CWT or STFT depends on signal properties and analytic aims. The CWT advantages include great flexibility, accurate frequency localization, and thorough time-frequency information. STFT is more economical and may be suited for simpler applications where fine-grained time-frequency analysis is not necessary. The CWT transform technique is calculated by Eq. (1) as:

$$\mathrm{W}_{x}(\mathrm{s},\tau) = \frac{1}{\sqrt{s}}\int_{-\infty}^{\infty} x(t)\,\psi'\left(\frac{\mathrm{t}-\tau}{s}\right)dt \qquad (1)$$

The continuous Wavelet Transform (CWT) is a technique that creates scalograms from EEG and ECG data. It analyzes data, typically a continuous-time signal, using multiple wavelet expansions and time offsets, notably the Morlet Continuous Wavelet. The resulting CWT scalograms provide an interpretable view of the local time-frequency energy density in the signal. Each signal segment is transformed into a scalogram picture, making the data more accessible for examination. Our work involved the production of 500 photos, 100 for each segment, demonstrating the interpretability of the analysis. These scalogram pictures, with their detailed frequency components, unveil the temporal and frequency properties of blood volume changes throughout cardiac cycles, engaging the viewer in the analysis process. Finally, the example scalogram pictures of three individuals, possibly demonstrating the post-CWT transformation data, may reveal signal differences or distinctive characteristics.

A major step in developing scalogram-based images was using the Morlet wavelet as a continuous wavelet transform (CWT). Next, the algorithm requires a list of pre-processed EEG and ECG signal segments representing data time intervals. Each segment has values indicating signal amplitudes at discrete times. The approach initializes an empty 2D NumPy array named "image_matrix". The scalogram information for each signal segment will be stored in this array, with rows representing segments and columns indicating time or frequency bins. Steps taken by the algorithm for each EEG and ECG segment in the input list: (1) Based on segment duration and sampling rate, calculate segment data points. (2) To guarantee consistency, pad the segment with zeros if it is shorter than required. (3) Calculate the segment scalogram using CWT. The transformation depends on the Morelet wavelet type. (4) Use the scalogram absolute value to measure frequency component magnitude. (5) Resize the scalogram to fit the picture length provided by desired_length. This method creates a 2D scalogram as shown in Fig. 4 to show the frequency content of several signal segments. Time-varying frequency components of data can be analyzed. The overall algorithm steps are shown in Algorithm 1.

Algorithm 1: Generating 2-D scalogram image from Preprocessed EEG and ECG signals

D. Features Extraction

This table lists the MobileNetV2 and AdaBoost hyperparameters needed to train and optimize the models for early depression diagnosis using EEG- and ECG-based HRV inputs. The dataset, challenge, and computational resources for the research will determine these hyperparameter values. Tuning these hyperparameters can greatly affect model performance and generalizability. In our approach, we use scalograms extracted from EEG- and ECG-based HRV to input a fine-tuned MobileNetV2 model for depression pattern recognition. Freezing several basic MobileNetV2 layers, adding a classification layer, tweaking hyperparameters like learning rate and dropout rate, and training on the fine-tuning dataset are carried out by the algorithms. This method refines hyperparameters until performance is attained. The depression pattern detection model is generated by testing the fine-tuned MobileNetV2 model on a test set.

Specifically optimized for mobile devices, MobileNetV2 is a CNN architecture with a unique structure as shown in Fig. 5 that establishes connections between bottleneck layers. Moreover, it employs deep folds in the intermediate expansion layer to extract nonlinear features effectively. The MobileNetV2 architecture comprises 32 layers of initial convolution followed by 19 bottleneck layers. In this research, we introduce a customized MobileNetV2 design incorporating two innovative fine-tuning strategies for the identification of 2D depression images.

MobileNetV2 has various benefits over other deep learning systems. It thrives on tiny datasets with difficult training and substantial overfitting risk. MobileNetV2 reduces overfitting, making it a good visual classification algorithm. It optimizes memory utilization and reduces errors, making it fast and efficient. The MobileNetV2 architecture speeds transaction execution, facilitating testing and parameter tuning. The transfer learning method of fine-tuning uses pre-trained CNN models to classify new tasks efficiently. While constructing a CNN model from the start is time-consuming and computationally costly, fine-tuning is an efficient option. Main strategies for using pre-trained transfer learning models include feature extraction, categorization, and fine-tuning. This method uses the pre-trained CNN model to extract features. New layers tailored for the destination dataset's classes replace the model's final, completely linked layers. The pre-trained model collects key information and classifies additional layers. Fine-tuning is achieved by changing and training selected top layers of the pre-trained CNN model and adding classifier layers. This method lets the model tailor its high-level feature representations to the task. Later layers in the model are more specialized, and fine-tuning modifies them for the new dataset without losing generic in-formation from pre-training. In time-sensitive applications like depression pattern identification with limited training data, fine-tuning is crucial. It optimizes pre-trained models, saving time and effort by building on past information. Deep learning and model training for specific tasks are optimized using this method, even with a smaller dataset. Fine-tuning adapts the pre-trained model's general knowledge to the new classification task, yielding results like training from the start with less data. Fine-tuning hyperparameters for MobileNetV2 involves optimizing the model's performance by selecting the best combination of hyperparameters based on the specific dataset and task at hand, as visually displayed in Fig. 6.

MobileNetV2 comprises two types of blocks: residual blocks with a stride of 1 and non-residual blocks with a stride of 2, primarily used for downsizing. The model consists of 155 layers, including the classification layer. Our approach utilizes this model to extract features from 2D depression images. In our proposed model, we leverage 154 pre-trained network layers from the convolutional base, with the addition of two extra layers—one at the start for preprocessing and one at the end for task-specific classification—using the Adaboost classifier.

Fig. 5. A MobileNet-based CNN model with a novel fine-tuning mechanism for depression patterns detection.

The classification process, illustrated in Fig. 6, involves passing inputs through the layers obtained during the fine-tuning process. Initially, we train the entire model for 50 epochs before fine-tuning. In the first fine-tuning step, we unfreeze the last 50 layers of the convolutional base and create new training loops, totaling 80 epochs (as indicated by green bars in Fig. 7). For the second fine-tuning phase, we progressively unfreeze layers from the end of the convolutional base using a step function. We reduce the number of unfrozen layers by five for every eight cycles, shown in green bars in Fig. 7. In our last approach, instead of following a predefined order, we determined the number of epochs and which layers to unfreeze based on a predefined exponential equation (Eq. (2)). This equation allows us to adaptively decrease the number of training cycles from the last layer to a specified depth during training.

$$\sigma(x) \ = \frac{1}{1+e^{-x}} \qquad (2)$$

Using this approach, we can preserve more pre-trained generic information. CNN models' later layers often possess specialized learned properties, while the initial layers focus on generic properties like edges, shapes, and textures. We use a learning rate of 0.0001 and the Adam optimizer for training. The fine-tune stage minimizes model size and speeds up detection; however, MobileNetV2's conventional layer is limited. The model's accuracy matches CNN's. Thus, MobileNetV2 network optimization is essential. This study replaces standard convolutions with "depth-wise separable convolution" to improve the MobileNetV2 architecture. Depth-wise separable convolution reduces training weight factors and floating-point workloads, making the model lighter, quicker, and more accurate. Standard convolution extracts characteristics using different convolution kernels by simultaneously controlling the input channel and convolution window. In depth-wise separable convolution, two jobs are carried out separately. To ensure equal input and output channels, the initial convolution in space is performed individually on each input channel using a single 1-dimensional kernel. To project the calculated channels onto a new channel space, point-based convolution with a 1 × 1 kernel (PointwiseConv) is used, as shown in Fig. 7. The classical convolution is represented by Eq. (3). While the depth-wise separable convolution is mathematically represented by Eq. (3)–(6):

$$Basic - Conv(\theta, x)_{(i,j)} = \sum_{h,w,c}^{H,W,C} \theta(h, w, c).x(i + h, j + w, c) \qquad (3)$$

$$DepthwiseConv(\theta,x)_{(i,j)} = \sum_{h,w}^{H,W} \theta(h, w) \ * x(i + h, j + w) \qquad (4)$$

$$PointwiseConv(\theta,x)_{(i,j)} = \sum_{c}^{C} \theta_c \times (i,j,c) \quad (5)$$

$$SeparableConv\left(\theta_p,\theta_d,x\right)_{(i,j)} = PointwiseConv_{(i,j)}(\theta_p, DepthwiseConv_{(i,j)}(\theta_d,x)) \quad (6)$$

Fine-tuning hyperparameters often involves conducting a grid search or random search over the hyperparameter space and evaluating the model's performance on a validation set.

The hyperparameter values that result in the best performance are then selected for the final model as described in Algorithm 2, ensuring MobileNetV2 is well-suited for the early detection of depression patterns using EEG and HRV signals. To detect depression patterns early, utilizing EEG and HRV data, MobileNetV2's parameters and design must be fine-tuned. Customizing pre-trained models for broad computer vision applications on big datasets is common. Fine-tuning MobileNetV2 involves these steps:

Algorithm 2: Fine-tunning MobileNet architecture for features extraction

```

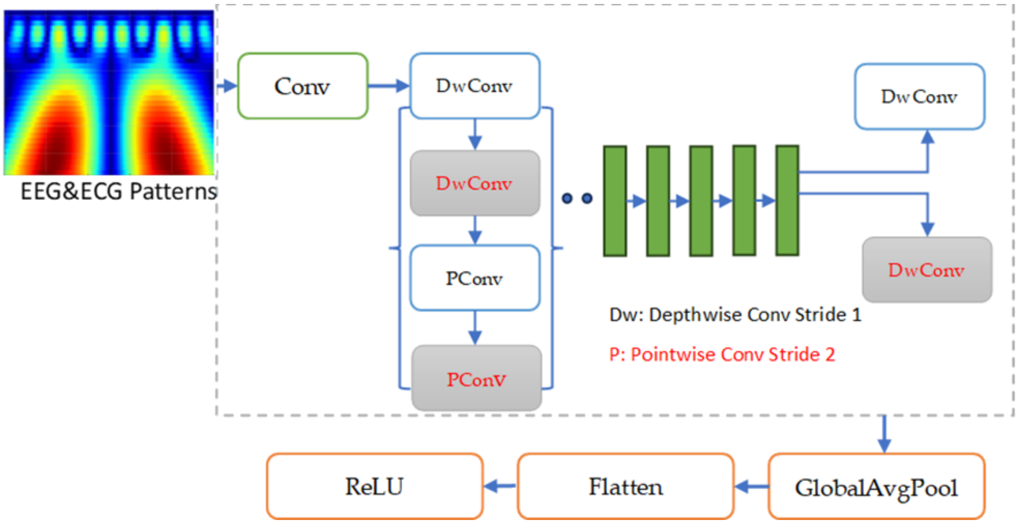

Fig. 6. A MobileNet-based CNN model with a novel fine-tuning mechanism for depression pattern detection.

Load ImageNet weights into the pre-trained MobileNetV2 model. These pre-trained weights provide a foundation for fine-tuning visual elements. Freeze Mo-bileNetV2's earliest layers to avoid overfitting and preserve low-level feature knowledge. These layers record basic patterns and textures that are transportable be-tween activities. Change MobileNetV2's classification layer to identify depressive patterns. This new layer may have fully linked (dense) layers, dropout layers for regularization, and an output layer with enough classes (depressed and non-depressed), depending on the job. Set a slower, fine-tuning learning rate. Fewer learning rates allow the model to make fewer alterations to pre-trained weights, eliminating abrupt changes that might damage learned features.

We train the improved MobileNetV2 model using EEG- and ECG-based HRV measurements with depression labels. Batch normalization and data augmentation promote generalization and prevent overfitting. Based on validation findings, alter hyperparameters such as learning rate, dropout rate, and the number of neurons in the new classification layer. Unfreeze more layers. If the fine-tuned model performs poorly on the validation set, unfreeze more MobileNetV2 layers to let it adjust its learned features to the job. Fine-tune the model until the validation set achieves the required accuracy and generalization. Assess the fine-tuned model: Finally, test the fine-tuned Mo-bileNetV2 model on a second test set to detect depression patterns from EEG and HRV signals. To assess the model's performance, provide accuracy, sensitivity, specificity, and AUC. Following these processes, the fine-tuned MobileNetV2 network uses its pre-trained information and adapts to fresh data to detect depression tendencies early, utilizing EEG and ECG signals.

E. Patterns Recognition

In our second experimental approach, we replaced the softmax classifier, which serves as the top layer of the MobileNet V2 model, with a dropout AdaBoost classifier. We made this substitution to explore an alternative to the traditional deep CNN with a softmax top layer. Our objective was twofold: first, to potentially enhance performance, and second, to mitigate the risk of overfitting during classification testing.

The complete MobileNet V2 architecture comprises 17 consecutive bottleneck residual blocks, followed by a standard 1 × 1 convolution layer, a global average pooling layer, and a softmax classification layer. Consequently, a set of valuable features was extracted from 2D scalogram patterns using the output of the global average pooling layer within the MobileNet V2 base model. Once this feature extraction process was finalized, the extracted features were inputted into an AdaBoost classifier.

AdaBoost is a linear model employed to address data classification challenges. AdaBoost excels at solving both linear and non-linear classification problems. In essence, AdaBoost's primary role is to determine or compute a separating line that effectively distinguishes multiple classes for any given case. It operates by taking input data and producing an optimal line that effectively separates these classes. This optimal line signifies a generalized separator that accommodates all classes as a well-rounded classification boundary. The Adaboost must handle multi-class classification in our study. In other words, we required AdaBoost to classify five depression patterns, each containing 500 distinct depression classes. AdaBoost resolves multi-class classification problems by transforming the single multi-class problem into numerous binary classification problems, processing them using a standard AdaBoost linear classification approach via the one-versus-all methodology. The one-versus-all approach involves building binary classifiers that distinguish between one specific label and all other labels. It is important to note that AdaBoost predictions yield outcomes similar to those obtained using the softmax function. However, the distinction lies in AdaBoost's emphasis on finding the maximum margin between data points from different classes, whereas the softmax function minimizes cross-entropy or maximizes log-likelihood.

Our approach uses an ensemble learning approach based on a fine-tuned MobileNet architecture with an AdaBoost classifier to accurately predict depression patterns like major depressive state (MDS), cognitive and emotional arousal (CEA), mood disorder patterns (MDP), mood and emotional regulation (MER), and stress and emotional dysregulation (SED). These depression patterns have been gathered from two publicly available datasets, MODMA and SWEEL-KW. Real-time signal processing on wearable IoT devices requires computational efficiency, which MobileNetV2 provides due to its lightweight architecture. Therefore, this model balances processing speed and prediction accuracy with depth-wise separable convolutions. AdaBoost, an ensemble learning technique, improves the model's predictive accuracy by combining numerous weak learners to produce a strong predictive model, minimizing bias and variation to assure prediction dependability. This methodological fusion outperformed other depressive pattern prediction methods.

It is also important to discuss how the amount of the extracted pattern affects model performance. Our ensemble learning-enhanced model may steadily improve its prediction ability by absorbing more patterns. While a limited number of patterns may initially limit performance, the model's design enhances its predictive abilities with increased data exposure, thereby improving its ability to identify depressive states.

IV. EXPERIMENTAL RESULTS

Several important parts make up the experimental setup for finding early signs of depression using machine learning and deep learning with scalogram-like patterns. This section outlines the experimental design, model training, evaluation, and performance metrics used in the study. To detect depression patterns early, utilizing machine learning and deep learning using EEG and ECG-based HRV inputs in the form of a 2D scalogram, software libraries, frameworks, and hardware must be configured. Here are the main environment setup tasks: Create a Python environment, ideally virtual, to separate project dependencies. Install Python 3.6.15. Download TensorFlow or PyTorch, a deep learning framework for neural network training. These frameworks provide MobileNetV2 pre-trained models and fine-tuning tools. Jupyter Notebook provides interactive and repeatable research. You can combine code, graphics, and markdown in one document. CPU, RAM, and storage must fulfill the computational needs of training deep learning models on the given dataset. Consider GPUs for quicker training if available.

Table III lists the study's MobileNetV2 and AdaBoost hyperparameters for depression detection. MobileNetV2 settings include learning rate (0.001), batch size (128), epochs (40), dropout rate (0.3 or 0.5), optimizer (Adam), convolutional layer filters (128), alpha (width multiplier, 0.75), and input picture size (224 × 224). The base estimator (logistic regression), number of estimators (200), learning rate (0.1), loss function (exponential), and maximum depth of weak learners (5) are AdaBoost settings. The model's learning and depression pattern recognition depend on these hyperparameters.

Image classification requires loss function and accuracy during transfer learning (TL) training. Optimizers optimize network weights and learning. This step minimizes DL layer training loss functions. In this work, ADAM, SGD, Adadelta, AdaBelief, and RMSprop optimizers changed each pre-trained TL model layer's weight and acceleration time. The optimizer in DL algorithms controls weight and bias during network fitting. The optimizer prioritizes this. We choose the best layer feature map, filter size, activation function, pool size, dropout, and fine-tuning hyperparameters. To get the best settings, optimization was done. The role of each optimizer in deep learning is explained. In contrast, AdaBelief optimization chooses deep learning framework assessment hyperparameters. This research employs 12 hyperparameters. Studying hyperparameters and fine-tuning layers, including freezing the top or bottom network layer. To find the best layers and hyperparameters, automated and fine-tuning approaches are being tested. When assessing the hyperparameter and fine-tuning pre-trained layers, AdaBelief sets a default value. The second stage analyzes transfer learning (TL) models after automatic hyperparameter tweaking and fine-tuning against all TL models using different optimizations. The third section evaluates TL with frozen layers during automated hyperparameter adjustment. Every TL model has hyperparameters and fine-tuning.

Table IV compares the average processing time for transfer learning (TL) algorithm stages and the suggested architecture on the MODMA and SWELL-KW datasets. We tested VGG16, AlexNet, Xception, MobileNet, Inception, and MobileNet-Finetune. We present preprocessing, feature extraction, training, prediction, and processing time for each approach. This stage prepares the data for analysis. AlexNet (20.4 s), Xception (19.2 s), MobileNet (15.3 s), Inception (12.7 s), and MobileNet-Finetune (2.8 s) preprocess faster than VGG16 (24.9 s). Data feature extraction selects relevant characteristics. VGG16 has the longest feature extraction time at 17.4 s, followed by AlexNet (15.5 s), Xception (16.2 s), MobileNet (14.2 s), Inception (12.5 s), and MobileNet-Finetune (2.3 s), the last being the fastest.

This stage trains the model with the extracted characteristics. At 220.5 s, VGG16 takes the longest to train, followed by AlexNet (230.5 s), Xception (235.5 s), MobileNet (230.5 s), Inception (268.5 s), and MobileNet-Finetune (120.5 s). Prediction relies on the training model. VGG16 takes 12.8 s to forecast, followed by AlexNet (10.8 s), Xception (7.8 s), MobileNet (9.8 s), Inception (8.8 s), and MobileNet-Finetune

TABLE III. HYPERPARAMETERS USED IN THIS STUDY ARE OUTLINING MOBILENETV2 AND ADABOOST FOR IDENTIFICATION OF DEPRESSION PATTERNS

Model	Hyperparameter	Description	Possible Values
MobileNetV2	Learning rate	Step size for updating model parameters	0.001
	Batch size	Number of samples used in each training batch	128
	Number of epochs	Number of times the model iterates over dataset	40
	Dropout rate	Fraction of neurons to randomly drop during training	0.3, 0.5
	Optimizer	Algorithm for optimizing model weights	Adam
	Number of filters	Number of filters in convolutional layers	128
	Alpha	Width multiplier to reduce model size	0.75
	Input image size	Dimensions of the input image	224 × 224
AdaBoost	Base estimator	The weak learning model used in boosting	Logistic Regression
	Number of estimators	Number of weak learners in the ensemble	200
	Learning rate	Weight of each weak learner in the ensemble	0.1
	Loss function	The loss function used for boosting	Exponential
	Maximum depth	Maximum depth of the weak learners (trees)	5

TABLE IV. AVERAGE PROCESSING TIME ON TRANSFER LEARNING (TL) ALGORITHMS COMPARED TO PROPOSED ARCHITECTURE BASED ON ALL SELECTED PATTERNS (MAJOR DEPRESSIVE STATE (MDS), COGNITIVE AND EMOTIONAL AROUSAL (CEA), MOOD DISORDER PATTERNS (MDPS), MOOD AND EMOTIONAL REGULATION (MER), AND STRESS AND EMOTIONAL DYSREGULATION (SED)) FROM MODMA AND SWEEL-KW DATASETS

Method	Preprocessing	Feature Extraction	Training	Prediction	Overall
VGG16	24.9 s	17.4 s	220.5 s	12.8 s	275.6 s
AlexNet	20.4 s	15.5 s	230.5 s	10.8 s	277.2 s
Xception	19.2 s	16.2 s	235.5 s	7.8 s	278.7 s
MobileNet	15.3 s	14.2 s	230.5 s	9.8 s	269.8 s
Inception	12.7 s	12.5 s	268.5 s	8.8 s	302.5 s
MobileNet-Finetune	2.8 s	2.3 s	120.5 s	2.6 s	128.2 s

TABLE V. THIS TABLE REPRESENTS THE COMPUTATIONAL COMPLEXITY BASED ON TYPICAL ASPECTS LIKE THE NUMBER OF PARAMETERS, FLOATING-POINT OPERATIONS PER SECOND (FLOPS), AND MEMORY REQUIREMENTS

Model	Number of Parameters	FLOPs	Memory Requirement
VGG16	138 million	15.5 billion	High
AlexNet	60 million	1.5 billion	Moderate
Xception	22 million	8.4 billion	Moderate
MobileNet	4.2 million	569 million	Low
Inception	23 million	5.7 billion	Moderate
MobileNet-Finetune	3.2 million	1.3 billion	Low

(2.6 s), the fastest. All stage processing times are in this column. The longest processing time is 275.6 s for VGG16, followed by AlexNet (277.2 s), Xception (278.7 s), MobileNet (269.8 s), Inception (302.5 s), and MobileNet-Finetune (128.2 s), the shortest. This table shows that MobileNet-Finetune is the most efficient solution for the investigated datasets due to its faster processing time across all stages.

It is vital to note that computational complexity depends on model architecture, implementation, and evaluation hardware. Based on the above hardware characteristics, we are calculating explicit computational processes.

Table V shows that earlier, more parameterized models like VGG16 and AlexNet had higher computational complexity and memory needs. Modern models like MobileNet are efficient, reducing computational and memory needs. The proposed "MobileNet-Finetune" denotes a custom-tuned version of MobileNet with computational complexity and memory demand tailored to specific workloads to maintain efficiency and optimize performance. FLOPs and memory needs are described in this table.

By following these steps, the proposed system is ready for the early detection of depression patterns using ML and DL with an ensemble of scalogram-like EEG- and ECG-based patterns. This setup allows researchers to experiment with different models and hyperparameters systematically, ensuring reproducibility and facilitating further research in the field of mental health diagnostics. We evaluated the proposed system using these criteria and compared it to pre-trained transfer learning techniques. We also utilized AUC to demonstrate the training and validation dataset's efficacy with a 10-fold cross-validation test. Fig. 7 shows the proposed SqueezeNet-Light model's best plot loss, accuracy, AUC, and recall on the train and validation sets with data augmentation across 40 epochs.

Fig. 8 illustrates the loss and accuracy trends concerning the epochs during the training and validation phases of the proposed depressive-deep system. The loss curve shows model parameter optimization as the loss function decreases after training. The model's prediction performance on both the training and validation datasets improves as the accuracy curve rises across epochs. These graphs reveal Deep's training dynamics and generalization capabilities in recognizing depressed patterns. This study trains its deep learning model via backpropagation. The right optimizer is chosen to guarantee this deep learning model converges. The deep learning literature uses optimizers like SGD, RMSprop, and adaptive moment estimation (Adam). Because adaptive optimizers are beneficial, the Adam optimizer with an initial learning rate of 10^{-4} was used for this investigation. Due to computer memory limits, the batch size was twenty, with 29 steps. Model training lasted 40 epochs.

Fig. 9 illustrates the confusion matrix depicting the results obtained by the proposed depressive-deep model in comparison to normal human assessments for the identification of various depression patterns, including major depressive state (MDS), cognitive and emotional arousal (CEA), mood disorder patterns (MDPs), mood and emotional regulation (MER), and stress and emotional dysregulation (SED). This matrix shows how the model performs across different depression patterns, allowing comparisons with human assessments and revealing areas of agreement and disagreement. In this figure, our study includes a 'normal' class with depression patterns to evaluate the depressive-deep model's diagnostic skills. This categorization helps the model discriminate between depressed states and non-depressive states. This class dataset, with the same size as other depression patterns, was collected from publicly available datasets (MODMA and SWEEL-KW). By comparing the model's predictions to human evaluations, we want to show that it may help mental health practitioners identify people without depression for early intervention and individualized therapy.

The confusion matrix in Fig. 10 shows the results of the suggested depressive-deep model for identifying MDS, CEA, MDP, MER, and SED depression patterns compared to non-depressive or normal patterns. This matrix provides a detailed analysis of the model's predicted accuracy and opportunities for improvement across depression categories.

Table VI presents the performance evaluation of the proposed depressive-deep model for the identification of five distinct depression patterns. Each row represents a different combination of feature extraction (f) and classification (c) methods. The metrics assessed include accuracy (ACC), sensitivity (SE), specificity (SP), precision (P), F1-score, and Matthew's correlation coefficient (MCC). The results indicate that the depressive-deep model, utilizing fine-tuned MobileNet V2 for feature extraction and AdaBoost for classification, achieved the highest performance across all metrics, with an accuracy of 0.96, sensitivity of 0.98, specificity of 0.95, precision of 0.95, F1-score of 0.96, and MCC of 0.96. Currently employed clinical diagnostic tests exhibit significant limitations, particularly in terms of the false negative rate. The false positive and false negative rates of a model can be visualized using specificity and sensitivity scores.

Table VII for depression pattern identification reveal notable trends. The SOTA comparisons were performed on various current studies, which we had implemented and tested on selected depression patterns. While traditional machine learning approaches like those in [22] achieve respectable accuracies (90.00%) with nonlinear features and logistic regression on EEG data, they may lack generalizability. Deep learning models such as the CNN + LSTM model in [23] achieve impressively high accuracies (99.07% right, 98.84% left) on EEG signals but are complex and computationally intensive. Similarly, ensemble learning coupled with deep learning, as seen in [24], achieves competitive accuracies (89.02%) but may be sensitive to feature selection. Methods focusing on specific EEG features like functional connectivity in [25] or specific patterns in [27] yield high accuracy (up to 96.00%) but may be limited in scope. Meanwhile, more advanced deep learning architectures like the DWSN model in [28] achieve near-perfect accuracy (up to 99.95%) but may require substantial computational resources. In contrast, the proposed depressive-deep architecture achieves competitive accuracy (up to 96.00%) while potentially addressing issues of computational complexity and feature scope present in some state-of-the-art methodologies.

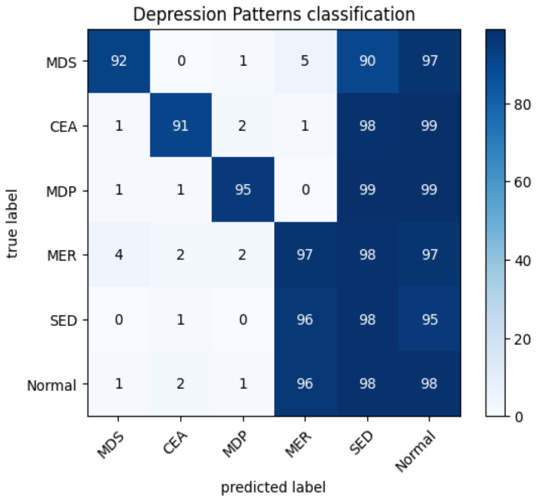

Fig. 9. Confusion matrix for results obtained by a proposed depressive-deep model with various identification of depression patterns such as major depressive state (MDS), cognitive and emotional arousal (CEA), mood disorder patterns (MDPs), mood and emotional regulation (MER) and stress and emotional dysregulation (SED) patterns.

However, when we applied these state-of-the-art systems to five different depression patterns and utilized our dataset, they achieved very low accuracy, as described in Table VII. For comparison, we have selected a diverse set of studies representing different methodologies for depression pattern identification. These include traditional machine learning approaches such as machine learning with nonlinear features and logistic regression [22], as well as more advanced deep learning architectures like deep learning with CNN and LSTM [23] and deep learning with DWSN [28]. Studies focusing on specific EEG features like functional connectivity [25] and specific hemispheres [27] also include ensemble learning methods. Additionally, the comparison encompasses various combinations of machine learning algorithms such as SVM, LR, and NB [25], as well as hybrid models like CNN-LSTM [26]. This selection provides a comprehensive overview of the methodologies employed in the field of depression pattern identification, allowing for a thorough evaluation of the proposed depressive-deep architecture against state-of-the-art approaches. The table compares different models used for identifying depression patterns based on their performance metrics. Each model is assessed for its accuracy, sensitivity, average processing time, and number of parameters. Among the models, the proposed depressive-deep architecture, employing MobileNet V2, stands out with a high accuracy score of 0.96 and sensitivity of 0.98. Importantly, it achieves

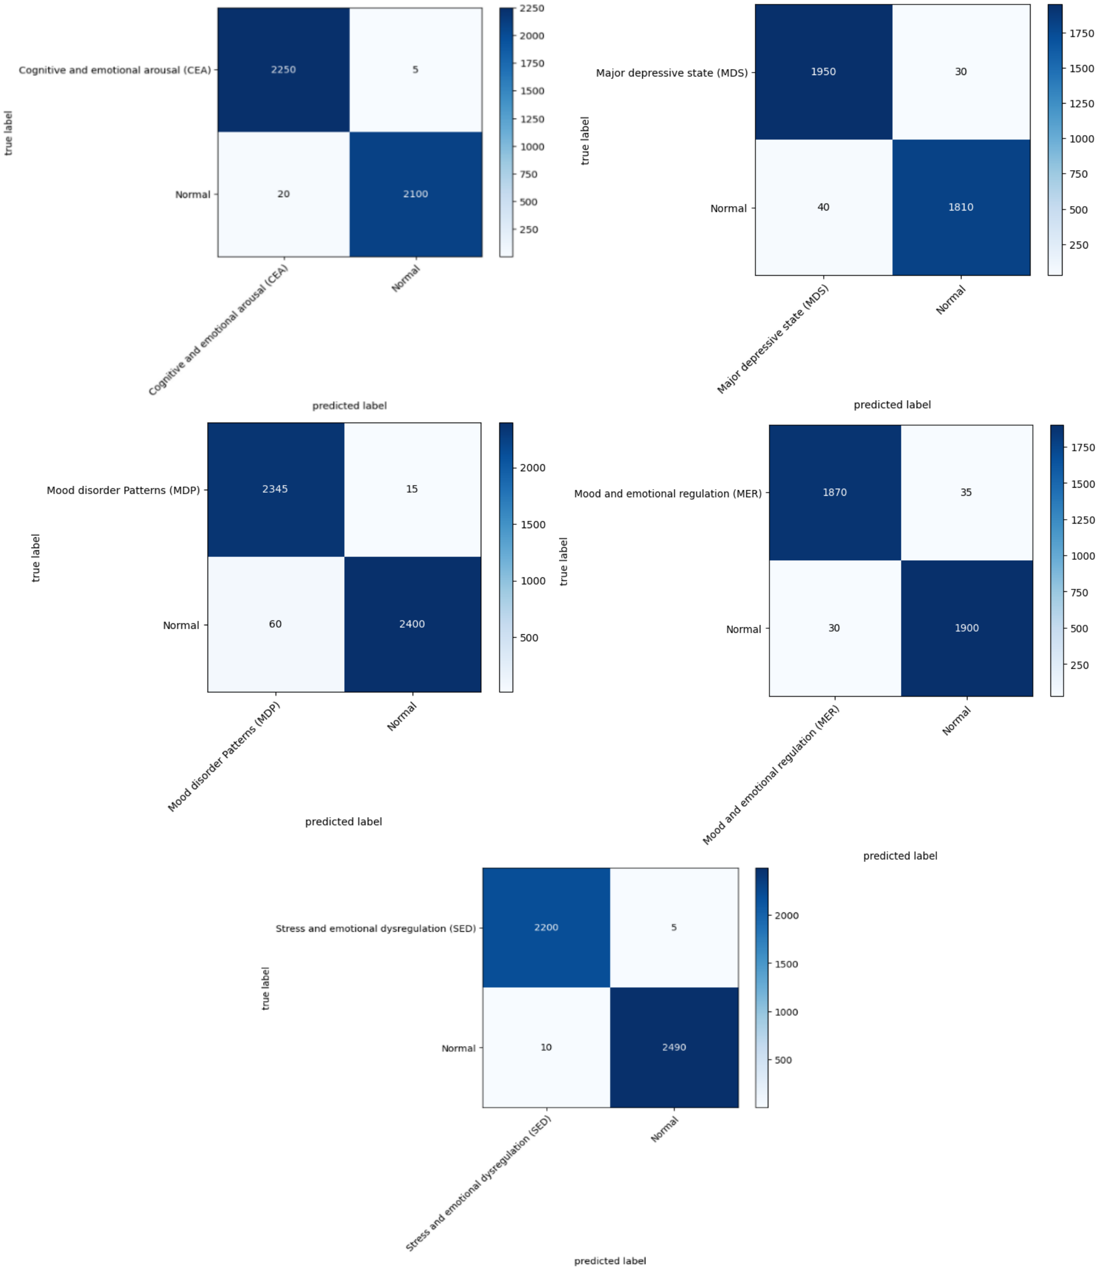

Fig. 10. Confusion matrix for results obtained by a proposed Depressive-Deep model with various identification of depression patterns compared to normal human. Those patterns are major depressive state (MDS), cognitive and emotional arousal (CEA), mood disorder patterns (MDP), mood and emotional regulation (MER) and stress and emotional dysregulation (SED).

these impressive results while requiring substantially fewer parameters (12.54 million) compared to other models. This suggests that the proposed architecture offers a promising approach for accurately detecting depression patterns with efficiency. The NeuroSky Mind Wave headset serves as the primary brain–computer interaction (BCI) device [38,39] utilized in this study, offering a single-channel interface for EEG signal acquisition. Coupled with a Raspberry Pi board, an example of an IoT device, the MindWave headset enables the capture of EEG signals, while ECG signals are obtained using the MikroElektronika Heart Rate Variability (HRV) ECG sensor. To check model generalizability, we have included five patient signals. These devices are lightweight and non-invasive, making them suitable for continuous monitoring throughout the day. Our first findings indicate that shorter, carefully planned sessions might provide substantial predictive utility, while longer monitoring periods may improve model performance by recording a wider variety of physiological responses. We observed that several-hour sessions can produce enough data to uncover depressive trends in this investigation. This period balances comprehensive data with gadget wear in daily living.

TABLE VI. PERFORMANCE OF PROPOSED DEPRESSIVE-DEEP FOR IDENTIFICATION OF FIVE HEART AND BRAIN PATTERNS BASED ON ENSEMBLE-BASED SCALOGRAM IMAGES

Model (Features Extraction (f) + Classification(c)	* ACC	* SE	* SP	* P	* F1-Score	* MCC
f = MobileNet V2, c = Softmax	0.90	0.87	0.88	0.87	0.88	0.90
f = CNN, c = MobileNet2	0.91	0.89	0.88	0.90	0.89	0.90
f = MobileNet V2, c = AdaBoost	0.92	0.88	0.89	0.90	0.91	0.91
Depressive-Deep: f = Fine-tune MobileNet 2,c = AdaBoost	0.96	0.98	0.95	0.95	0.96	0.96

TABLE VII. STATE-OF-THE-ART COMPARISONS FOR IDENTIFICATION OF BRAIN AND HEART PATTERNS

Study	Model	* ACC	* SE	Average Time (s)	Parameters
[22]	Logic Regression	0.74	0.76	5.242	--
[23]	CNN + LSTM	0.86	0.80	3	20.24 M
[24]	Ensemble DL	0.97	0.91	2.5	248.35 M
[25]	SVM-LR-NB	0.86	0.96	6.5	--
[26]	CNN-LSTM	0.88	0.88	3.136	24.56 M
[27]	CNN	0.91	0.91	4.5	267.20 M
[28]	DWSN	0.90	0.90	4	343.67 M
Proposed	MobileNet V2	0.96	0.98	0.043	12.54 M

* SE: sensitivity, ACC: accuracy.

These signals are then processed to extract patterns indicative of depression. For the classification of depression patterns, a fine-tuned and lightweight MobileNetV2 model, integrated with an Adaboost network, was employed. The model was trained and evaluated using TensorFlow on the Colab Google platform. To enable deployment on IoT devices [40], like Raspberry Pi boards, the TensorFlow model was further optimized into a TensorFlow Lite model.

The described study focuses on the use of IoMT-based wearable devices for identifying depression patterns through a proposed model called depressive-deep. This model is designed to detect various types of depression patterns, including major depressive state (MDS), cognitive and emotional arousal (CEA), mood disorder patterns (MDPs), mood and emotional regulation (MER), and stress and emotional dysregulation (SED). The results obtained from the depressive-deep model are visualized in two figures. Fig. 11 illustrates the distribution of each category of depression patterns, providing insights into the prevalence or occurrence of different types of depression. This result helps researchers and practitioners understand the depressive-deep model's performance and effectiveness in identifying depression patterns using IoMT-based wearable devices. On average, 96% accuracy is achieved by the proposed system.

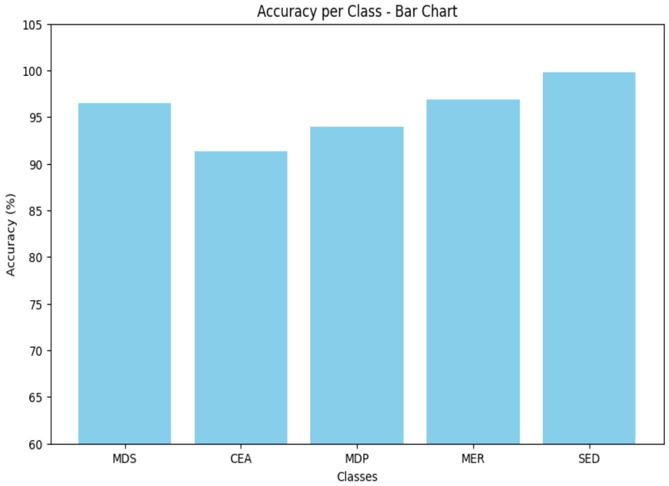

Fig. 11. IoMT-based wearable identification depression patterns results obtained by proposed depressive-deep model with various identification of depression patterns such as major depressive state (MDS), cognitive and emotional arousal (CEA), mood disorder patterns (MDPs), mood and emotional regulation (MER) and stress and emotional dysregulation (SED). Figure (a) shows the distribution of each category of brain and heart depression patterns.

V. Discussions

This work used an ensemble of EEG and HRV data in 2-D scalogram pictures to detect depressive patterns using machine learning and deep learning. These new computational tools can help diagnose and treat depression early, improving mental health outcomes.

MobileNetV2 and AdaBoost ensemble learning showed promising depression prediction results. The lightweight MobileNetV2 architecture handled HRV and EEG data and performed well. Using AdaBoost in ensemble learning made the model more accurate, sensitive, specific, precise, and higher in F1-score and AUC, making it a strong depression classifier. The 96% accuracy shows that these methods may early detect depression and provide therapy. Fig. 4 shows the suggested Depressive-Deep model's scalogram. This scalogram shows major depressive state (MDS), cognitive and emotional arousal (CEA), mood disorder patterns (MDP), mood and emotional regulation (MER), and stress and emotional dysregulation. The scalogram shows these different depression patterns holistically by integrating EEG and HRV data, revealing the intricate relationships and dynamics of depressed states.

The data analysis section describes how machine learning and deep learning using an ensemble of scalogram-like EEG and HRV patterns may detect depressive patterns early. This method allows researchers to systematically test different models and hyperparameters, ensuring repeatability and advancing mental health diagnosis. Fig. 5 shows the loss and accuracy trends during training and validation of the proposed Depressive-Deep system, demonstrating model parameter optimization and prediction performance improvement. The discussion also covers deep learning model training, stress optimizer selection, and model convergence. In Fig. 8, the AUC values for recognizing depression patterns from scalograms show the Depressive-Deep system's discriminatory capability before and after network fine-tuning. Confusion matrices in Fig. 9 an Fig. 10 show how well the model identifies depressive patterns, allowing comparisons with human judgments. Table V further compares the suggested Depressive-Deep model's accuracy and sensitivity across feature extraction and classification approaches, showing its superiority. Comparing the proposed Depressive-Deep architecture to state-of-the-art depression pattern identification methods shows that it achieves competitive accuracy while addressing computational complexity and feature scope issues. Finally, Table VII compares model performance characteristics, showing that the Depressive-Deep architecture is more accurate and efficient. These findings demonstrate the depressive-deep system's ability to detect depressive patterns early, advancing mental health diagnoses.

Despite the encouraging results, this study admits some limitations that should be addressed when interpreting the data. Small datasets may limit the model's generalizability; therefore, validation on bigger, more diverse datasets is necessary. Deep learning models like MobileNetV2 are difficult to comprehend, requiring greater study into ways to explain their judgments.

Future studies can use neuroimaging and self-report questionnaires to better understand depression trends. Additional deep learning architectures and transfer learning methods may increase model performance and interpretability. Actual specialists and mental health professionals will help translate the suggested model into actual practice to improve depression identification and treatment. The new study re-fines the machine learning and deep learning models for early depression identification, utilizing EEG and HRV data. The research team is optimizing hyperparameters, im-proving feature selection, and testing the interpretation of model predictions. We are also validating the model on larger and more diverse datasets to ensure its resilience and generalizability across populations. To assess the model's clinical applicability, mental health specialists and clinical experts are working together. The study team is using domain expert comments to make the model more practical and adaptable to clinical situations. This iterative approach guarantees that the model meets clinical demands and integrates seamlessly into the healthcare system.

Future studies will go beyond EEG and HRV depression identification. The team wants to use neuroimaging, self-reported questionnaires, and wearable sensor data to measure mental health holistically. The model can capture more physiological and behavioral indicators related to mental health issues by using several data modalities, resulting in a more accurate and tailored diagnosis. To increase model performance and interpretability, transfer learning and deep learning architectures are another possibility. We can fine-tune pre-trained models for depression identification using EEG and HRV data, potentially enhancing efficiency and accuracy.

Implementation of the suggested concept into user-friendly applications or tools for mental health professionals and individuals is underway. The objective is to create an accurate and easy-to-use tool for early depression identification and continuous monitoring to enhance mental health outcomes and reduce the burden of global mental health problems. The study team also plans to undertake longitudinal studies to test the model's ability to forecast depression onset and track treatment success. Understanding the model's predictive powers beyond diagnosis will help identify depression risk fac-tors and enable focused therapy.

Current and future work aims to transform mental health diagnosis using machine learning and deep learning. The research aims to produce a tool that aids early diagnosis and provides mental health providers with significant information for tailored treatment planning by refining and expanding the model. The ultimate objective is to enhance mental health diagnosis, management, and treatment worldwide to improve well-being and results. The model was accurate, although the study acknowledged a tiny dataset. The model needs additional validation on larger and more diverse datasets to be more generalizable. Exploring various deep learning architectures and transfer learning methods may increase model performance and interpretability. Smartphones are essential for people. Mobile Crowd Sensors (MCS) uses mobile device sensors and computing [12]. MCS lets users exchange data and get insights to measure and track shared activities. This strategy is essential for the development of IoT applications. MCS will be used to identify depression-like characteristics in the future. Moreover, a future study will compare multi-day and single-day observations to determine the minimal time for reliable forecasts. We want to find the best balance between model accuracy and user convenience. We appreciate your ideas and believe that studying measurement length and prediction accuracy is essential for BCI and IoT-based mental health monitoring system implementation.

Our research compares accuracy, sensitivity, specificity, precision, F1-score, MCC, and AUC of the proposed depressive-deep model to state-of-the-art depression detection techniques to demonstrate its benefits. Our model outperforms existing approaches with a 96% accuracy rate using the lightweight and efficient MobileNetV2 architecture and the AdaBoost ensemble learning algorithm. EEG and HRV data integrated into 2D scalograms provide a holistic view of depressive patterns, allowing the model to capture intricate relationships and dynamics in the data, making early depression detection more comprehensive and effective.

The findings suggest that machine learning and deep learning can detect depression patterns in EEG and HRV data early. A visual diagram of a scalogram generated by a proposed Depressive-Deep model to embed all depression patterns such as major depressive state (MDS), cognitive and emotional arousal (CEA), mood disorder patterns (MDP), mood and emotional regulation (MER), and stress and emotional dysregulation (SED) into one scalogram using EEG and ECG-based HRV signals. The model's accuracy and interpretability make it a viable tool for mental health providers to diagnose depression quickly and individually. The study lays the groundwork for mental health diagnostics research and stresses the worldwide impact of AI-based technologies. This work shows that machine learning and deep learning may detect depression patterns in EEG and HRV data early. The model uses MobileNetV2 and AdaBoost and is accurate and interpretable, revealing depression's physiological signs. While there are still issues, this research sets the groundwork for mental health diagnostics and shows how AI-based tools might improve global mental health outcomes.

VI. Conclusion

In this study, we introduce depressive-deep, a novel approach for predicting depression using a combination of preprocessed EEG and ECG-based HRV signals. We generated a 2D scalogram by combining ECG and EEG signals. These accurate predictions were made using the MobileNetV2 deep learning architecture and AdaBoost ensemble learning. They were for major depressive state (MDS), cognitive and emotional arousal (CEA), mood disorder patterns (MDPs), mood and emotional regulation (MER), and stress and emotional dysregulation (SED). We made sure the system could be used by anyone by pre-training the depressive-deep model on the MODMA and SWELL-KW datasets and using wearable IoMT devices to collect signals. Rigorous validation through cross-validation and other criteria demonstrated the robustness of our model. With a remarkable 96% accuracy in depression prediction, surpassing previous methods, our approach highlights the potential of machine learning in early depression detection, thereby enhancing mental health diagnosis and treatment outcomes. We require further research and validation to enhance our strategy and guarantee its clinical effectiveness.

Small datasets may limit the model's generalizability, requiring validation on bigger and more diversified datasets. DL models like MobileNetV2 are difficult and require further study to enhance forecast interpretability.

A Systematic Review on Assessment in Adaptive Learning: Theories, Algorithms and Techniques

Adel Ihichr, Omar Oustous, Younes El Bouzekri El Idrissi, Ayoub Ait Lahcen
National School of Applied Sciences, The Engineering Sciences Laboratory at Ibn Tofail University, Kenitra, Morocco

***Abstract*—Computerized knowledge assessments have become increasingly popular, especially since COVID-19 has transformed assessment practices from both technological and pedagogical standpoints. This systematic review of the literature aims to analyze studies concerning the integration of adaptive assessment techniques and algorithms in Learning Management Systems (LMS) to generate a global vision of their potential to enhance the quality and adaptability of learning, and to provide recommendations for their application. A review of international indexed databases, specifically Scopus, was conducted, focusing on studies published between 2000 and 2024. The PICO framework was used to formulate the search query and the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) framework to select 66 relevant studies based on inclusion and exclusion criteria such as publishing year, document type, subject area, language, and other factors. The results reveal that integrating adaptive assessments positively impacts the quality of learning by generating short tests dynamically adapted to students' skills, learning styles, and behaviors. Furthermore, the findings identify various techniques and algorithms used, as well as their main features and benefits. These tools tailor adaptive learning programs to meet students' specific needs, preferences, and proficiency levels, thereby enhancing student motivation and enabling them to engage with material that matches their knowledge and abilities. In conclusion, the systematic review emphasizes the significance of integrating adaptive assessments in educational environments and offers tailored recommendations for their implementation to provide adaptive learning. These recommendations can be adopted and reused as guidelines to develop new and more sophisticated assessment models.**

Keywords—Adaptive assessment; adaptive learning; test; education; techniques

I. Introduction

Adaptability changes the method of delivering education, and learners use adaptive learning systems (ALS) as part of blended learning or fully online learning, it can be obligatory with credit or optional courses without any credit [1]. The aim of ALS is to alter instructions using a set of predefined rules to provide learning materials adapted to the needs and behavior of the student [2]. In addition, learner assessment is one of the principal moments in the educational process [3], it offers the possibility to construct a continuous and reversible process, over the learning life cycle of the student. According to OECD [4], assessment is the process of measuring and/or collecting and using evidence and proof about the outcomes of students.

Many people usually imagine when they first hear the word assessment that it solely refers to the collecting and analyzing of some information about a learner. However, assessment can also involve interpreting and acting on information gathered about a learner's understanding and/or performance in relation to educational goals.

Given the critical importance of adaptive assessment in enhancing educational outcomes and the evolving landscape of personalized learning [5], it is imperative to develop effective assessment mechanisms that can adapt to individual learner needs. Adaptive assessment systems have emerged as a promising approach to improve the precision and relevance of student evaluations. These systems utilize advanced algorithms and theoretical frameworks to dynamically adjust the difficulty and content of assessments based on real-time analysis of student performance and behavior [6]. Furthermore, assessment can also involve interpreting and acting on information gathered about a learner's understanding and/or performance in relation to educational goals. The principal challenge posed is not just the availability of learning content to learners but also the ability to present knowledge in the right place, time, and form.

Despite the promising potential of adaptive assessment to transform educational practices, comprehensive and systematic research in this domain remains limited. This study aims to address this gap by conducting a thorough literature review of the current state-of-the-art in adaptive assessment. The findings will provide valuable insights for researchers and practitioners, helping them understand current research trends, identify gaps, and develop more effective adaptive assessment tools. Ultimately, this research seeks to contribute to the advancement of adaptive assessment systems, which are essential to modern educational environments, thereby enhancing student learning experiences and outcomes.

This research stems from the need to understand the most recent advances in adaptive assessment within educational practices. The main contribution of this study is to identify how various assessment implementations and methods naturally emerge to meet the demand for measuring learning outcomes.

To achieve this objective, a systematic review of numerous studies collected from the Scopus database was conducted, employing inclusion and exclusion criteria. Subsequently, through the analysis of our selected studies, a framework was derived for an effective integration of adaptivity in knowledge assessment. The necessity for developing adaptive assessment-driven framework stems from the significant dropout rates observed in traditional assessment offered to students. In response to this challenge, a framework that offers adaptive, personalized advanced learning assessment was embraced, helping to place the student at the center of the learning process to maximize learning outcomes.

Following the review and examination of the 66 studies included in the research, three key themes were identified. These themes encompass the role of knowledge assessment in learning and education as a scaffolding instrument, the identification of the most used adaptive assessment theories, algorithms, and the proposed guidelines for defining the main characteristics of an effective adaptive assessment.

The paper is organized into several key sections to offer a comprehensive understanding of adaptive assessment in educational practices. Section II examines adaptive learning in detail, addressing its definition, role, advantages, and various assessment methods. Section III outlines the research approach, detailing the formulation of research questions, search strategy, and criteria for selecting studies. Section IV provides a thorough analysis of the included studies, covering statistical descriptions, key theories and models underlying adaptive assessment, and recommendations for future directions. Section V presents a discussion that synthesizes the findings, highlighting the strengths, and practical implications of the reviewed adaptive assessment methods. Finally, the conclusion summarizes in Section VI, the significance of adaptive assessment in enhancing ALS, providing a clear and detailed perspective on the role and influence of adaptive assessment in contemporary education. This structure is designed to offer a comprehensive overview and critical analysis of adaptive assessment's impact on educational practices.

II. Literature Review

Adaptive learning has revolutionized educational practices by tailoring the learning experience to individual student needs. This section explores the different aspects of adaptive learning, focusing on its definition, role, advantages, approaches, and various assessment methods.

A. *Adaptive Learning*

Adaptive learning, by definition, is a methodology to adjust and personalize a learning process notably content to a learner, in order to fit to different situations and circumstances [7]; thus, adaptive learning gives the possibility to make a learner a collaborator in the process of education instead of a passive recipient of information [8] because each learner has a specific optimal learning path composed of many connected dots and each dot represents a knowledge component or a skill [9]. Adaptive learning considers many aspects, such as the learner's current level [10], individual needs [11], the learning style [12], and different interactions with students to individualize all components of the learning process: content, interface, learning style and assessment [13]. Therefore, adaptive learning allows a student to progress to more challenging material based on their performance, while providing additional support to others to help them master skills. This approach ensures that learners are not constrained by the class pace but can follow their own individual learning pace [9]. Thus, the instructor and learner can make the right decision at the right moment by following the learning curve and learning trajectories [14]. In summary, adaptive learning seeks to tailor the educational experience to help students achieve their learning objectives by emulating the personalized, one-on-one interaction between a teacher and a learner.

B. *The Role of Assessment in Adaptive Learning*

"What we assess is what we value. We get what we assess, and if we don't assess it, we don't get it" is a statement declared by psychologist Lauren Resnick [15] which shows the importance of the assessment as the main and the critical step in the educational process, over twenty years ago, evaluation and assessment were considered a challenging research issue in education [16]. Many Adaptive Learning Systems (ALS) focus more on assessment than on content [17]. Assessment data collected from students' responses is used to personalize the learning process, creating tailored paths based on results. These paths are continuously updated with each assessment [13]. Thus, learners' assessment is considered a crucial factor for a successful e-learning process.

C. *Types of Knowledge Assessment*

Knowledge assessment can be globally divided into three types: summative, formative and pre-assessment. Generally, summative assessment is more dominant than formative assessment in e-learning [9] but the last two types have shown more potential, especially in adaptive learning [18] and researchers have shifted the focus to these two types.

1) Summative assessment: Also known as assessment of learning, this type of evaluation occurs at the end of the learning cycle to measure learner achievement and verify mastery of a curriculum unit [19]. It assesses the cumulative progress of the learner.

2) Formative assessment: Also called assessment for learning, it occurs throughout the learning cycle to provide both tutors and learners with feedback information to assist their learning experience and improve it [19]. This type assesses the quality of learning by positioning assessment between teaching and learning (current progress) instead of being positioned only at the end of the process [9], when formative assessments are so deeply embedded in the learning environment that the separation between assessment and learning is completely fuzzy and so unnoticeable to the students, this concept is known as stealth assessment [20]. Formative assessment allows us to refine the learning trajectory, increase the engagement and enthusiasm of a student to achieve a course and develop his self-regulation.

3) Pre-assessment also known as diagnostic assessment, this kind of assessment measures each learner's prerequisites, providing the teacher with a clear picture of the learners' level of skills [21]. It is frequently succeeded by a sort of compensatory instruction to eliminate obstacles and offer different kinds of remedial activities [18]. It is usually initiated at the entrance of a learning course. It is designed to gauge the current student's prior learning to detect learners' needs, competencies, preconceptions, and prior knowledge, to orient them toward the most suitable curriculum.

D. *Learning Outcomes Assessed in Online Learning*

Wei et al. [8] defined three principal learning outcomes assessed in online learning, to know cognitive, behavioral, and effective learning outcomes (see Fig. 1), based on a study of 65 peer-reviewed articles. The study demonstrated that these three aspects are correlated.

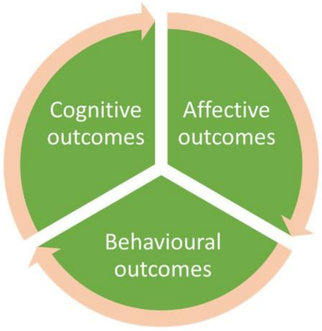

Fig. 1. Learning outcomes assessed.

1) Cognitive outcomes: Correspond basically to obtained knowledge and intellectual skills. Knowledge is all information that a student has learned from a topic, but intellectual skills concern different abilities, such as reasoning, thinking processes and decision making.

2) Behavioral outcomes: Refer to measuring learner engagement by monitoring his behavior while course learning such as duration and times of learning, participation in forums and discussion, submission of tasks, completion of tests.

3) Affective outcomes: Correspond to perceptions of students, their satisfaction with the course, appreciation of their learning experience and benefits expected by them after enrolling in a course.

In his paper, Shepard [22] suggested that most learning and assessment in higher education concentrates on cognitive outcomes rather than on affective outcomes, and behavior.

E. Methods of Assessment

A variety of assessment methods were developed by researchers to optimize the cognitive load, implement adaptive learning systems, and measure learning outcomes, such as the following:

1) Computer-graded tests: This method is gradually replacing the traditional method called instructor graded assignments, which allow instructors to diagnose their students closely and with more efficiency [23]. This method is used to recognize and accredit student learning, and it allows the generation of immediate feedback that is linked to the parameter configuration so that each answer is either right or wrong.

2) Self-assessment: This method is implemented in WEAS [24] and MAPS [25]. It allows students to self-assess their performance based on criteria and standards already fixed by teachers. It is a useful manner to prepare for the exam [26]. Generally self-assessment is combined with feedback and hints [27], so students participate in active learning by improving their knowledge and detecting possible misconceptions.

3) Peer assessment: This method is implemented in MAPS [25]. It is considered an educational activity where the assessor and the assessed have similar statuses, and each one assesses learning outcomes, quality, and the level of the other; it requires a mutual relation based on trust. Peer review, peer grading, peer feedback and peer evaluation are all synonyms of peer assessment [28]. Lu and Zhang [29] demonstrate that students benefit more from acting as assessors than from being assessed. Li [30] has proven that quality increases if peer assessment is done anonymously. One of the advantages of this method is the creation of a competitive atmosphere between students despite their social aspects.

4) First-step rapid diagnostic assessment: Kalyga [31] described this method as a diagnostic process in which each student studies a task for a limited time and is asked to put his first step toward the solution, so the tutor can determine the level of mastery of the student depending on his first step. If the learner possesses the required knowledge component, the final answer will be provided immediately; otherwise, the search process will commence.

5) Concept map: It is a graph in which nodes symbolize concepts, and the directed labeled links that interconnect the nodes represent relations between concepts. This research in [32] uses concept maps as a method for assessing students' comprehension of content by allowing them to display their understanding of concepts and connections between concepts in a graphic format. Using concept maps to assess learner knowledge at the level of understanding has many benefits, and this method is implemented in the Concept Mapping Tool.

F. From Traditional Assessment to Adaptive Assessment

The previous section highlighted the importance of knowledge assessment in providing adaptive learning. Now, this adaptability is also integrated into the assessment itself to achieve adaptive assessment. In contrast to conventional testing, which is based on fixed items that every examinee must tackle regardless of their knowledge level, adaptive assessment allows for the selection of questions based on the examinee's performance. An adaptive assessment provides a short, personalized test, its items change depending on the response of the student, and the difficulty of each question is correlated to the answer to the previous question [13]. In addition, the decision to stop testing is dynamically related to the student's performance shown in the test [33]. In brief, adaptive assessment seeks to avoid presenting easy questions to capable students, who are likely to answer correctly. Similarly, challenging questions are not presented to struggling students, who may find them difficult.

G. Advantages of Adaptive Assessment

Adaptive assessment retains the advantages of classical assessment in enhancing the learning process, but there are additional advantages that make adaptive assessment more efficient and effective, such as: Energizes and individualize the assessment process [13], reduce the length of the test by at least 60 percent, so it can detect the level of a learner with fewer questions [34], reduces the duration of the test by reducing the number of questions and items [35], increases motivation of the learner by suggesting easier questions [36], gives self-reliance [36], avoids annoying students by providing tests adapted to their level of knowledge and skill [21], provides more detailed statistics used to refine learning trajectory and to correct curriculum [13], helps ITS to make a rapid diagnosis of a student's characteristics and knowledge level to update their models [37], allow tutors to better differentiate between candidates by considering time analysis of responses [38], reduce cheating because the test is tailored to each learner due to presence of questions banks which offer possibility to vary questions [39], give the possibility to each learner to tackle his course and tests at any time, and from any place, and enhancing the quality of feedback given to learners in real time.

H. Approaches Followed in Implementing Adaptive Assessment

From the articles of Lendyuk et al. [36] and Al-Rajhi et al. [40], three approaches of tests in adaptive assessment can be deduced; after a short description of each one, Table I provides a comparison between these three approaches:

1) Pyramidal testing: It is used to assess learners without giving them a preliminary test, so all examinees take the same test with a middle level of difficulty, then the next task and question is related to the previous answer, if it is correct then the difficulty will increase and vice versa. Many variations of pyramidal testing have been developed such as constant step sizes, variable step sizes, truncated pyramids, and multiple-item pyramids.

2) Flexilevel testing: It programs the first task with a definite level of difficulty chosen by the tutor. Each level has one item, and the difficulty of the next item depends on the answer of the learner. It increases if the answer is correct and vice versa.

3) Stradaptive test: Stratified adaptive, in which many levels or strata of difficulties are defined. Each one group's test items have approximately the same average difficulty. These strata are classified in order of difficulty, so the next item is selected from the upper strata if the previous answer is correct; otherwise, the system suggests an item from the bottom.

TABLE I. COMPARISON BETWEEN TYPES OF ADAPTIVE TESTS

Type of adaptive test	Preliminary test	Difficulty level of the first question	Number of items by difficulty level	Next question
Pyramidal testing	No	Middle level	Depends on its variations	Depends on response
Flexilevel testing	Yes	Difficulty defined by the tutor	One	Depends on response
Stradaptive test	Yes	is typically set to be of moderate difficulty	Many	Next question from strata upper or downer depending on the response

III. MATERIALS AND METHODS

The integration of adaptive assessment in learning management systems has opened a new chapter in educational research. Historically, studies on educational assessment have primarily focused on traditional methods. However, with the advent of adaptive assessment, the landscape of evaluating student performance and learning outcomes has transformed significantly. Before delving into the detailed findings of our systematic review, we will provide, in this section, an overview of the research approach, including the formulation of research questions, the search strategy, and the criteria for selecting relevant studies.

A. General Background

This study aims for a systematic review that delves into how adaptive assessment is used in adaptive learning, shedding light on its contributions and implications. Insights were drawn from indexed articles and reviews from the esteemed Scopus database. Using the PICO framework and logical operators (AND, OR, NOT), a search question was elaborated to guide the research endeavours.

B. Research Question

The objective of this study is addressed by answering the following research questions:

- RQ1: In studies involving knowledge assessment, what is the role of assessment in adaptive learning, methods used in implementing assessment, and benefits of adaptive assessment?
- RQ2: What are the theories, algorithms and techniques underlying adaptive assessment in learning and how do these elements differ from each other?

C. Search Strategy

Following the PICO framework, the scientific articles were gathered from the largest database of scientific publications, namely Scopus. The authors focused on research in assessment and its features. A combination of keywords was used in the research study, taken from the title, abstract and keywords such as" adaptive learning" AND" assessment". The Boolean operators, parentheses, and stars were used wherever possible. Keyword synonyms were also used to obtain a more comprehensive search (as detailed in Table II). This meticulous approach aimed to maximize the potential results of our study.

D. Selection Strategy

1) Quantitative filtering: Following the formulation of the search query (Table II), a quantitative selection approach was employed, utilizing tools like Zotero software. The PRISMA framework was adhered to for analyzing and filtering the found studies based on inclusion and exclusion criteria outlined in (Table III).

2) Qualitative filtering: After the quantitative filtering, a qualitative selection was conducted based on:

- Title analysis according to the presence of the study's keywords.
- Abstract analysis based on sample and results.
- Content reading and synthesizing.

Table IV shows an overview of the number of articles found and included.

TABLE II. KEYWORDS IN THE SEARCH QUERY

IV. ANALYSIS AND FINDINGS

Adaptive assessment leverages advanced theoretical frameworks to enhance the precision and effectiveness of evaluating student knowledge. This section offers a comprehensive analysis of the included studies, detailing statistical descriptions and exploring the primary theories that underpin adaptive assessment.

A. Statistical Description of the Included Studies

1) Databases: the scientific articles were gathered from the largest database of scientific publications, namely Scopus. The authors focused on research in assessment and its features.

2) Publishing year: Fig. 3 below shows a representation of selected studies according to publishing year, and it can be noticed that most of the papers were published after 2011, which explains the growing interest in improving assessment as a main component of the adaptive learning process.

3) Countries: As shown in Fig. 4, United States is having maximum number of included studies (27.5%), followed by Spain (07%), then Greece and China.

B. *Theories Used in Adaptive Assessment*

To the best of our knowledge, IRT (item response theory) and KST (knowledge space theory) are the two most powerful theoretical frameworks used in the development of efficient and effective adaptive assessment tools. This section first presents IRT, then KST, and finally a comparative table between the two theories in terms of the specific goals and requirements of knowledge assessment is drawn up.

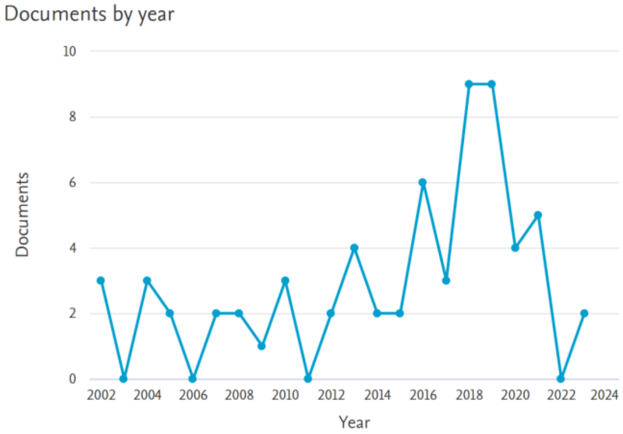

Fig. 3. Division of the included studies according to publishing year.

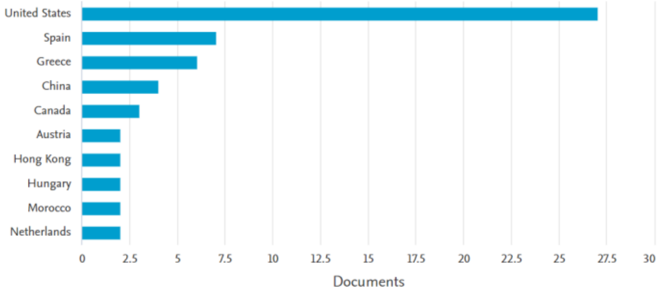

Fig. 4. Document by country.

Item response theory (IRT): is one of the most used theories in adaptive assessment, and its origins date back to Rasch and Lord in the 1950s. This theory supposes that an answer to a question is related to an unknown latent numerical θ, corresponding to the knowledge of the topic being assessed [41], so it describes how students interact with questions in tests; in other words, IRT tries to link observable actions as answers, responses to unobservable characteristics. This psychometric theory is used to estimate learner knowledge, and to develop learners' cognitive or non-cognitive measurement, to select the appropriate next question at each moment and to decide when the test is over [38]. Lendyuk et al. [36] explain that this variable nature of latent parameters provides the possibility for adaptable assessment, and mention that this combination between learner level and item difficulty on single measuring is the best advantage of IRT. Various IRT models exist, including Rasch, the 1PL model, the 2PL model, and GRM, chosen depending on item characteristics [42]. IRT is based on four principal assumptions: monotonicity (if the trait level increases, the probability of a correct answer also increases); one-dimensionality (one dominant latent trait to measure); local independence (for each level of ability, responses to separate items are mutually independent); and invariance (item parameters can be estimated from any position on the item response curve). See the handbook of Van der Linden [43] for more information about IRT.

1) *Knowledge Space Theory (KST):*

In 1985, Doignon and Falmagne invented knowledge space theory (KST) which is based on probabilistic and combinatoric models [44]. In KST, each domain of knowledge is a collection of skills and concepts that must be learned by a student, and some skills are prerequisites of others, so if a learner acquires a skill, it becomes easier to master another; in other words, KST recognizes skills that are achievable without mastering any other skills [45]. KST is based on data collected from student answers to a set of questions reflecting different ability levels. These questions are not necessarily arranged in hierarchical order, and the answer can be correct or incorrect, so each student has a response state; for example, a learner who responds to questions 3, 4 and 5 correctly has a response state (3, 4, 5). For a test that contains seven questions, there are 27 possible response states, from a null state to the full response state in which the student responds to all questions correctly. After KST forms a subset called the knowledge structure, it contains possible knowledge states [46]. The KST provides an accurate statement of what the student knows, does not know, and is ready to learn next. There are many research articles that explain the use of KST in assessment such as article published by Arasasingham et al. [46] used Knowledge Space Theory to assess student understanding of stoichiometry, and the paper of Doble et al. [47] that examined several reliability measures for developing KST-based adaptive evaluation measures. Additionally, Fang et al. [48] construct student models based on knowledge space theory and can identify the student's present knowledge level through both initial and regular evaluations, including student task progression.

IRT and KST are both used in adaptive assessment but differ in their approach, focus, and other dimensions. Table V provides a comparison between the two theories.

C. *Algorithms and Techniques Used in Adaptive Assessment*

Knowledge assessment based on efficient techniques enhances the reliability of intelligent tutoring systems (ITS) by reducing the impact of human factors. This section divides and summarizes prominent algorithms and techniques used for assessing learner knowledge according to their technical differences, presenting a new taxonomy (see Fig. 5). The proposed taxonomy categorizes existing techniques into four groups: (1) techniques based on Bayesian Networks, (2) techniques based on logistic models, (3) techniques based on artificial intelligence, and (4) techniques based on learning styles and others.

TABLE V. COMPARISON BETWEEN IRT AND KST

	IRT	KST
Year of appearance	1980	1999
Process	Psychometric paradigms	Combinatorics, statistics, and stochastic processes
Unit of assessment	Item	Response state
Focus	modelling the connection between the test items and the examinee skills and performance	modelling the basic knowledge structure of a domain
Approach	Quantitative,statistical approach	Qualitative,behavioural approach
Objectif	modelling the statistical relationship between test question properties (as example: difficulty) and the likelihood that a student will respond correctly to the question.	modelling the prior connections between the concepts of a domain and represent them in the format of an oriented graph, and use this graph structure to orient the choice of the test items
Item selection	IRT can use either nonprobabilistic or probabilistic algorithms to select items tailored to level examiners and consider the characteristics of the items.	KST typically uses a nonprobabilistic algorithm to select items tailored to level examinee and the underlying knowledge structure of the domain.
Item types	Practically always made of multiple-choice questions or other dichotomous item types	Almost never is made of multiple-choice questions but can be used with a wider variety of item types, including open-ended.
The number of significantly different categories of test scores	Relatively small	Relatively big
Item selection	IRT can use either nonprobabilistic or probabilistic algorithms to select items tailored to the level examiners and consider the characteristics of the items.	KST typically uses a nonprobabilistic algorithm to select items tailored to the level examinee and the underlying knowledge structure of the domain.
Item types	Practically always made of multiple-choice questions or other dichotomous item types	Almost never is it made of multiple-choice questions but can be used with a wider variety of item types, including open-ended.
The number of significantly different categories of score in tests	Relatively small	Relatively large

1) Techniques Based on Bayesian networks:

a) Bayesian Networks (BN): A Bayesian network is a technique based on Bayes' theorem that maps out cause and effect relationships in the form of a graphic representation. It is used to predict the probability that a factor is the most contributing factor in the occurrence of an event [49]. BN is well-suited for modeling content domains in learning assessments at various levels. Culbertson [50] details this in his state-of-the-art review, which describes the application of BN across 40 educational assessment systems in diverse domains. BN allows students to predict mastering in un-assessed sub-domains by utilizing results from assessed sub-domains, so assessment will be more effective in making precise and quick teaching decisions and optimizing the time invested in testing [50], especially when there is scarcity and uncertainty in data [51]. Collins et al. [52] used BN to provide an adaptive assessment of several features in a unique test. Xing et al. [53] suggest in their paper a Bayesian network model to assess dynamically the engagement of students in engineering design tasks DBNs are more powerful than BN in their ability to update in realtime the estimation of learner performance across multiple tests. DBNs can be used to infer previous, current and the future learner states. DBNs are a way to expand a static BN to model probability distributions over several points in time [42]. This technique serves two important functions in machine learning: classification and pattern discovery to capture and analyze information over time.

b) Bayesian Knowledge Tracing (BKT): BKT is a widespread approach based on BNs. This approach tries to model a learner's skill by calculating the probability of mastering a skill based on a set of parameters: guessing, slipping, the probability that a skill is already mastered, and the probability that the skill will be learned. BKT takes into account the time sequence for estimating the new skill and supposes that each skill learned is never forgotten [54]. BKT can involve sudden changes in knowledge. Researchers have developed several variants of BKT (Table VI), such as BKT-IDE [55], in which sliding and guessing are linked to the question to account for its difficulty, BKT-ILE [56] which considers the student's initial performance to be dependent on the question, and BKT-PPS [55], in which the accuracy of the learner's first tense is dependent on his or her initial performance. On the other hand, a version of the BKT was developed, Dynamic Bayesian Knowledge Tracing (DBKT) is used to model relationships and hierarchies between prior knowledge based on dynamic Bayesian networks. In DBKT, a student's knowledge mastery is also mapped by binary latent variables and can be inferred from the learning experiences of the student [57]. This approach considers various prior knowledge together in a unique model.

c) Comparaison between BKT and DBKT: Bayesian Knowledge Tracing (BKT) and Dynamic Bayesian Knowledge Tracing (DBKT) are two distinct methods for assessing learner knowledge, differing in several aspects. In general, DBKT provides a more complete and flexible assessment approach by considering prior knowledge, time dynamics and background characteristics. Table VII synthesizes some of the main distinctions between BKT and DBKT.

2) Techniques Based on logistic model:

a) Performance Factor Analysis (PFA): PFA is an algorithm following a statistical modeling approach that uses the logistic model to be sensitive to the most sought-after indicator in an evaluation: the performance measure or student's ability [58]. This technique is primarily sensitive to the relative ratio of correct to incorrect responses in an assessment, which allows for fine-tuning of the assessment's adaptability, and this sensitivity to accuracy can be used to measure learning, particularly its quality. In the article by Maier et al. [59], it is demonstrated that several issues need to be considered when utilizing PFA, such as parameter degeneration, especially for benchmarks where the learner's initial data are limited.

b) Knowledge Tracing Machine (KTM): The KTM model benefits from factoring machines (FM) to extend other logistic models (such as PFA) to larger scales. FMs were initially suggested as a broad predictor that runs on any real-valued vector of characteristics, that can model all the interactions across variables using factorized parameters. FMs are used to encode additional data about the student or the task in the model; in this way, KTM is particularly suited to modeling the student's knowledge mastery using a sparse set of weights for all the characteristics involved in the assessment [57]. In their article, Vie and Kachima [60] note that KTMs could be used to provide adaptive testing by selecting the next most appropriate item to be presented to a student, depending on the previous responses.

Both PFA and KTM can employ logistic regression models to predict the likelihood of a learner answering a question correctly; however, their approaches differ. Table VIII provides a comparison of the two techniques.

TABLE VI. COMPARISON BETWEEN BKT-IDE, BKT-ILE, AND BKT-PPS

	BKT-IDE	BKT-ILE	BKT-PPS
Question Difficulty	Related to sliding and guessing	Dependent on initial performance	Not directly addressed in the current question
Prior Performance	Not directly considered	Dependent on question difficulty	Used to adjust the first attempt probability

TABLE VII. COMPARING BKT AND DBKT

	BKT	DBKT
Based on	BN	DBN
Field of knowledge	Modeling a particular skill or concept	Takes into account several skills or concepts linked together in a single model
Time Dynamics	It is hypothesized that learning is independent of time	Considers the time dynamic of student learning and uses a sequence of responses to infer the state of knowledge over time.
Background characteristics	Does not expressly consider contextual factors such as feedback or advice.	Integrates background characteristics that may impact the student's learning experience
Model Flexibility	More flexible complex than DBKT	Less flexible than BKT

TABLE VIII. COMPARING PFA AND KTM

	Probabilistic Factor Analysis (PFA)	Knowledge Tracing Model (KTM)
Approach	Latent variable	History of answers
Logistic Model	Estimating the probability based on latent state of knowledge, item difficulty, and guessing parameters	Estimating the probability based on the current knowledge and item difficulty
Model Flexibility	Less flexible	Flexible
Item Selection	Yes	Yes
Feedback	No	Yes
Data Requirements	Large amount of data	Small amount of data

3) Techniques Based on artificial intelligence:

a) Machine learning techniques: Machine learning (ML), considered a part of artificial intelligence (AI), is one of the most challenging application areas in the field of learning assessment. It can be applied to improve item-based assessments [61]. In addition, the support vector machine, a supervised classification technique in machine learning, can diagnose students' knowledge mastery, especially in smaller test programs such as classroom assessments [62]. In brief, ML can generate computerized adaptive assessments that continuously provide feedback to instructors and staff on students' learning progress, the support they need, and their advancement toward learning goals.

Furthermore, the utilization of natural language is regarded as the most valuable technique for evaluating learning outcomes because it allows learners to display a deep comprehension of a given concept, but evaluating, rating, and giving feedback on writing assignments consume much time and effort, and can be biased by an unjust human assessor. In this context, researchers provide automated essay scoring (AES) as an emerging and growing technology of assessment in which computers replicate a written assignment’s human evaluation by using multiple grading approaches, such as statistics, machine learning, and natural language processing (PNL) techniques [63]. ML can help rank students’ handwritten assessments [64]. Using artificial intelligence techniques such as natural language processing and deep learning, AES systems can assess different dimensions of an assignment [65], such as grammar, syntax, and content, by examining learners’ writing skills and recognizing their individual weaknesses and strengths.

b) Deep Knowledge Tracing (DKT): Deep Knowledge Tracing (DKT) [66], a pioneering algorithm that uses flexible deep recurrent neural networks to model student learning and trace their knowledge, is used to extract latent structure between assessments. DKT relies on RNN and LSTM models, which offer significant advantages by capturing complex representations of knowledge from assessments over time. This capability allows for substantially improved prediction performance across datasets from previous assessments. In addition, the learned model can be used to design the next assessment more suited to the student. DKT can suggest assessments that are more adaptive to individual needs and skip or delay questions that appear to be too easy or too difficult.

c) Fuzzy logic theory: Fuzzy logic theory, introduced by Zadeh in 1965, and adapted to assessment by Biswas in 1995 [67] has been widely used in educational assessment, Fuzzy logic is an artificial intelligence technique that can be considered ideally suited to provide a personalizable test, as it can successfully address the uncertainty and human subjectivity that characterize the identification of learner knowledge and learning needs [68]. Since all educational assessments deal with uncertainty, the ability of fuzzy logic to weigh these uncertainties makes it an excellent AI core in assessment systems. This application increases average class success and reduces test anxiety [69]. The authors of this article [70] utilize fuzzy logic to model learners’ skills and knowledge, employing fuzzy sets to determine the difficulty and order of the questions on the test.

4) Technique *Based on learning styles:*

a) FSLSM.: The Felder-Silverman Learning Styles Model (FSLSM) is employed by some assessment tools to provide the appropriate items according to the student’s capabilities and preferences based on learning styles that are divided into four dimensions, namely, processing, perceiving, inputting, and understanding [40]. According to a recent survey conducted by Nabizadeh et al. [71], FSLSM is the model most frequently adopted by many LMSs to understand the student’s preferred learning style and tailor evaluations more closely to their particular skills and preferences, which can help to improve learning outcomes. It is important to note, however, that the use of learning styles in assessment is somewhat debated, and some researchers such as Abyaa et al. [72] and Kirschner [73], have advocated that there is limited proof to sustain the idea that adapting education to fit individual learning styles truly enhances learning outcomes.

5) Other techniques:

a) Revised Bloom Taxonomy (RBT): Bloom’s Revised Taxonomy (RBT) is a framework used to articulate and classify learning objectives for assessment. It helps in defining and organizing what students are expected to learn as a result of instruction, guiding the creation of tests that align with these learning goals. It produces a classification of learning goals organized into six levels: Remember, Understand, Apply, Analyze, Create and Evaluate. Many searchers have implemented the RBT to develop effective and efficient assessments that reflect the six levels. It explores hierarchical cognitive processes, through a mix of question types so that the system can choose the proper one for each level to adapt its assessments. It generates three lower-level knowledge questions and adjusts their difficulty based on the student’s background from previous tests [74]. For example, if the student has scored low on the assessments, the system selects items of average to medium difficulty, while if the student is more experienced, questions of high difficulty are chosen. It is necessary to learn the knowledge and skills of the previous level to progress to a higher level of knowledge. Finally, adaptive assessment using RBT has many strengths such as easy detection of students’ deficiencies and a gradual rise in question difficulty to revise the whole course content and better structure the learning process to enhance students’ new abilities.

b) Game-based digital assessment (GBDA): is regarded as one of the pivotal approaches to stimulating authentic and accurate behavioral outcomes by conducting a stealth assessment [75], it can also be used to screen for reading difficulties with less time and cost, while enabling the content of educational games to be tailored to individual learners [76].Furthermore, Alonso-Fernandez et al. [77] used gameplay traces to assess the increase in awareness (affective dimension) as the difference between the post-test mean score and the pretest mean score for each player.

D. Knowledge Assessment Framework to Generate Adaptive Learning

Among the assessment tools studied, such as PIAT [40], AskMe [78], and ASSA [79], most follow a framework similar to the one depicted in Fig. 6 for monitoring students' progress. This framework employs a loop strategy. In the initial step, a test estimates the learner's current knowledge. Based on the test results, the system suggests appropriate curriculum materials with difficulty levels that align with the learner's predicted knowledge. To address any gaps identified by the tests, this loop is repeated until the system determines that the learner has acquired sufficient skills to complete a topic. Thus, each student engages in a series of tasks that are dynamically generated based on their responses. These tasks and items, stored in a database, represent all possible knowledge levels aligned with the content.

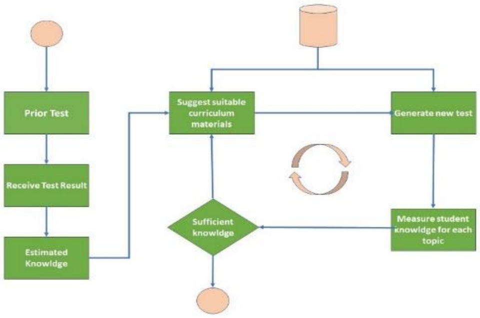

Fig. 6. A framework schematic representation of an adaptive assessment.

E. Recommendations

The future of adaptive assessment is full of promise regarding individualization, precision, and the incorporation of different learning modes into the design of the assessment. It is evident that technology such as big data and AI are reshaping the future of learning assessment. The present adaptive assessment model is gradually becoming obsolete as teachers and learners adopt intelligent solutions to enhance their testing experience. These solutions have the potential to enhance engagement and accessibility in the assessment process. This paper will explore potential future directions for designing the next generation of adaptive assessments, considering recent technological advancements.

First, AI provides a variety of new tools and technologies that can help to enhance engagement, such as gamification, conversational AI, or virtual and augmented reality. These tools can help make the testing process more engaging and enjoyable, by encouraging students to participate earnestly in the assessment and evaluation process. These technologies can help to assess students on real-world complex concepts and skills, such as engineering tasks, surgery, and aviation, and can provide assessment tools that can interact with humans through natural language such as ChatGPT.

Second, technology-driven approaches can help in removing obstacles by allowing students to take tests regardless of their geographic location. In addition, the inclusion of rich media features, such as videos, interactive simulations, and interactive games, can be particularly helpful for students with learning disabilities, who may have trouble with real-world assessment models by benefiting from assistive technologies that help them to break down barriers to assessment.

Third, IoT devices can be employed to capture a student's attention, which is essential in learning assessment. This will facilitate capturing student behaviors in online learning assessment strategies.

Fourth, intelligent assessment should involve tools/mechanisms to identify cheating, plagiarism as well as when learners are memorizing the answers to assignments.

In addition, the next generation of adaptive assessments should meet the following characteristics:

- Capable of accommodating thousands, if not millions, of students taking tests simultaneously, so all schools and universities must be equipped with a sophisticated technology infrastructure to enable computer-based adaptive assessment at an accessible cost.
- Provide large databases of items in all domains, these items must be scalable and can be fitted into any adaptive learning system based on universal open standards,
- Generalizable to other fields outside of science, technology, engineering, and mathematics (STEM) disciplines to cover other areas such as business, literature, education, arts, and humanities.
- Be able to motivate learners to assume more control and responsibility on assessment tests.
- Prioritize the development of digital environments that are secured, and with transparent policies describing the usage and protection of data from further unauthorized or abusive access.
- Strive to ensure equity among students when subjected to different assessments.
- Use adaptive assessment data to sustain an educational norm and to inform the development of policy.
- Improve the new skills of all educational stakeholders, such as digital literacy, as assessment processes are challenged by a multiform dimension that is not restricted to writing or reading words and demands new IT competencies.
- Collecting feedback from all stakeholders enables continuous refinement and improvement of assessment tools, resulting in a more focused, tailored, and favorable testing environment.

As the world becomes increasingly digital, further innovations in this area are anticipated, aiming to make assessments for learning more accessible, engaging, and effective for all learners. This progression may lead to a transition from traditional adaptive assessments to what could be termed "Deep Assessment".

V. Discussion

In this systematic review, we examined several key aspects of adaptive assessment: (1) the primary algorithms utilized in adaptive learning systems (ALS); (2) the effectiveness, strengths, and functioning of these assessment methods; and (3) a comparative analysis of these models, including a comprehensive summary of prominent algorithms and techniques for assessing learner knowledge, which led to the development of a new taxonomy. Our review revealed that different algorithms are used to track and evaluate student knowledge, each possessing distinct characteristics and capabilities.

The primary objective of this review is to synthesize the various models and theoretical frameworks that influence the effectiveness of adaptive assessment in educational practices. Our findings indicate that IRT and DKT are among the most significant algorithms used in adaptive assessment systems.

IRT, an algorithm with origins dating back to Rasch and Lord in the 1950s, remains one of the most widely used theories in adaptive assessment. Based on a logistic model, IRT has endured over the years through continuous development and enhancement by researchers. Various IRT models, such as the Rasch model, 1PL, 2PL, and GRM, have evolved into powerful tools for adaptive learning systems. This ongoing development has made IRT increasingly robust, offering an optimal solution for adaptive learning systems and ensuring its relevance and effectiveness in modern educational practices. Numerous educational systems and tools implement IRT, including SIETTE [80], CONCERTO [81], PASS [40], YIXUE [82], APelS [83], Persofit [84], eDia [18], The MISTRAL [85], and ALEAS [86].

In contrast, Deep Knowledge Tracing (DKT) is a very recent algorithm introduced in 2015 that benefits significantly from advancements in artificial intelligence. DKT utilizes deep recurrent neural networks (RNNs and LSTMs) to model student learning and trace their knowledge. By capturing complex knowledge representations over time, DKT significantly enhances prediction performance across assessment datasets, leveraging the growth of AI to provide cutting-edge solutions for adaptive learning. However, our review did not find any ALS currently implementing DKT. This absence can be attributed to the recency of the algorithm and its ongoing development, highlighting an area for future research and potential application.

Our systematic review has several unique advantages and particularities compared to other reviews in the field. While several researchers have examined the use of assessment in adaptive learning systems, our review integrates and builds upon these studies to offer a more comprehensive perspective. For example, Wei [8] explored multiple types of assessment instruments and approaches beneficial for teachers and tutors, and Nikou and Economides [19] reviewed mobile-based assessment across major educational technology research journals. Shute and Rahimi [9] focused on computer-based assessment for learning in elementary and secondary education, highlighting the potential for integrating instruction and assessment. Xiong and Suen [10] examined assessment approaches for open online education from both formative and summative perspectives, and Goss [87] reviewed student learning outcomes in higher education and academic libraries. Additionally, Moris et al. [5] demonstrated the value of formative assessment and feedback in higher education.

Our review offers several distinct advantages. First, it provides comprehensive integration by combining findings from multiple studies, resulting in a holistic overview that includes various types of adaptive assessment methods, models, and theoretical frameworks. Second, we develop a new taxonomy of prominent algorithms and techniques, offering a structured and detailed classification that can guide future research and applications in adaptive assessment. Third, our review spans multiple disciplines, ensuring that the findings are applicable across various educational contexts and not limited to a single field.

In conclusion, the evolution of adaptive assessment technologies, from the longstanding and continually improving IRT models to the innovative and AI-driven DKT, highlights the dynamic nature of this field. As educational practices increasingly incorporate these advanced algorithms, future research should focus on integrating the strengths of both traditional and modern approaches to further enhance the precision, adaptability, and effectiveness of adaptive learning systems.

VI. Conclusion and Future Research

This article has shed light on the essential role played by assessment, in particular adaptive assessment, in the implementation and progress of ALS. The COVID-19 pandemic has had a lasting impact on education [88], and it has proven that ALS will no longer be just an add-on, a nice thing to use, but will forever be a fundamental, essential part of teaching, learning and assessment. Therefore, the assessment of learning must change to prepare for a world more deeply infused with smart technologies and a mode of teaching that tends towards distance and personalization. However, there are many hurdles, limitations and barriers that hinder easy and smooth integration and use of technology in knowledge assessment such as system gaming which is defined as an attempt to pass a question or task by systematically taking advantage of the properties and regularities of the system rather than thinking about the test. However, there are several directions for further and highly evolving research in adaptive assessment that attempts to produce innovative solutions and smart algorithms to address these barriers to build trust in technology to make a fair and adaptive assessment capable of measuring a learner’s performance and improving their educational experience. In addition, there is a need to develop research on the use of simulations and digital games in assessment and to develop methodologies or tools to assess learners in a mobile learning environment.

This work offers an initial exploration of adaptive assessment, aiming to provide a deeper understanding of its mechanisms, benefits, types, and the various techniques and algorithms used in its implementation. While not exhaustive, this article serves as a foundational reference and is intended to be a work in progress. Researchers are invited to contribute to its further development and refinement. Overall, this article suggests that adaptive assessment remains a promising field for measuring student knowledge in the right place, at the right time, and in the right form. However, it is important to approach the assessment of written production with caution in existing adaptive assessment methods. To fully address areas beyond

STEM, such as social-emotional learning, critical thinking, creativity, and executive functions, these assessments must be adapted and extended accordingly. To sum up, the study shows that assessments, especially adaptive ones, take a large place in adaptive learning environments. Furthermore, this review can be adopted and reused as a guideline to develop new and more sophisticated assessment models.

Given the rapid advancements in AI and the emerging era of big data, which are driving the evolution of adaptive learning systems (ALS) [89], Our future research is to enhance DKT by integrating the strengths of other models studied in this article and applying our proposed framework.

ACKNOWLEDGMENT

This work was supported by the Ministry of Higher Education, Scientific Research and Innovation, the Digital Development Agency (DDA) and the CNRST of Morocco under Project No. 451/2020 (Smart Learning).

Implementation of Slicing Aided Hyper Inference (SAHI) in YOLOv8 to Counting Oil Palm Trees Using High-Resolution Aerial Imagery Data

Naufal Najiv Zhorif, Rahmat Kenzie Anandyto, Albrizy Ullaya Rusyadi, Edy Irwansyah
Computer Science Department-School of Computer Science, Bina Nusantara University, Jakarta, Indonesia

***Abstract*—Palm oil is a commodity that contributes significantly to Indonesia's national economic growth, with a total plantation area of 116,000 hectares. By 2023, Indonesia is projected to produce approximately 47 million metric tons of palm oil. One of the major challenges in the manual counting of oil palm trees in a large area of a plantation is the labour-intensive, time-consuming, costly, and dangerous nature of the work in the field. The use of aerial imagery allows for the mapping of large areas with comprehensive data coverage. This study proposes a method of mapping oil palm plantations for the counting of oil palm trees using high-resolution aerial images taken with drones. Furthermore, the use of artificial intelligence (AI) methods and deep learning (DL) with the You Only Look Once (YOLO) model for object detection has demonstrated good accuracy in previous studies. This research will utilize the YOLOv8m object detection model and the slicing method, namely Slicing Hyper Aided Hyper Inference (SAHI), which is anticipated to enhance the precision of object detection models on high-resolution aerial imagery. The study concluded that the use of the SAHI slicing method can significantly enhance the accuracy of the model, as evidenced by a Mean Absolute Percentage Error (MAPE) value of 0.01758 on aerial imagery equivalent to 73.2 hectares, with a detection time of 5 minutes and 45 seconds.**

Keywords—Oil palm tree; YOLOv8; SAHI; aerial imagery; tree counting

I. Introduction

Palm oil ranks as one of the most extensively used edible oils worldwide, with global production reaching 79.31 million metric tons in 2023. This represents a 2% increase from the previous year, when 78 million metric tons were produced. In 2023, Indonesia stands as the foremost producer of palm oil, with an output of 47 million metric tons, followed by Malaysia with 19 million metric tons [1]. To achieve the production figures, Industrial plantations in Indonesia have grown by 116,000 hectares in 2023 [2]. Palm oil represents a significant contributor to Indonesia's national economic growth, serving as a cornerstone of the country's commodity exports. Nevertheless, the monitoring of oil palm plantations remains a significant challenge. The manual monitoring process is labor-intensive, time-consuming, costly, and poses inherent risks to workers on oil palm plantations. To address these challenges, aerial imagery technology can be employed to supplement and enhance the limitations of manual monitoring methods, offering more accurate and efficient results while reducing the risks faced by workers. The utilization of aerial imagery technology facilitates the monitoring of plant health, the mapping of oil palm plantation areas, and the detection of oil palm plants [3].

However, the data complexity of aerial imagery necessitates the use of a robust analytical methodology. To analyze the data, artificial intelligence (AI) technology can be employed through techniques such as machine learning (ML) and deep learning (DL) to produce accurate aerial image analysis [4]. When employing AI for the detection and enumeration of oil palm trees, the algorithmic process necessarily entails a learning phase to facilitate the identification of these trees. Subsequently, the resulting detection data can be utilized to ascertain the total number of oil palm trees within the designated area.

One of the most widely used deep learning algorithms for object detection is the convolutional neural network (CNN). This has led to the development of several derivatives, including the region-based convolutional neural network (R-CNN), the faster region-based convolutional neural network (Faster R-CNN), and the mask region-based convolutional neural network (Mask R-CNN) [5]. The CNN algorithm has previously been employed in research to detect and enumerate oil palm trees in high-resolution remote sensing images [6]. Nevertheless, in the context of real-time detection, CNN’s performance still needs improvement, even in the advanced development of CNN, namely Faster R-CNN [7]. The You Only Look Once (YOLO) algorithm exhibits superior real-time performance.

The YOLO object detection deep learning model has been designed to achieve high-performance levels in real-time detection. However, despite this, its accuracy remains below that of the Faster R-CNN model [8]. Furthermore, the YOLO model has been observed to experience difficulties in the detection of smaller objects [7]. Nevertheless, the YOLO model does possess an advantage in terms of its speed and performance in real-time object detection.

This research will implement artificial intelligence, specifically the deep learning YOLO algorithm, as a model for palm oil tree detection and Sliced Aided Hyper Inference (SAHI) [9] to enhance the precision of YOLO detection on high-resolution aerial imagery. The data utilized in this study was obtained from aerial images captured using unmanned aerial vehicles (UAVs) in the oil palm plantation region of North Sumatra, Indonesia.

The structure of this paper consists of previous work, methodology, results, discussion, and conclusion. In the previous work section, discussed previous research that is relevant to this research and what the focus of this research is. Methodology discusses the methods that are used in this research, starting from data collection, pre-processing, and model development to the model evaluation method used. The result section discusses the results of the training model, model detection by comparing the results without the SAHI method and by using the SAHI method, and the results of the model evaluation. The discussion part discusses the results of the research that has been done and compares it with research that has been done before. Besides that, it will also discuss the contributions obtained from this research, its shortcomings, and suggestions for further research. Conclusion will discuss the conclusions of the research that has been done.

II. Previous Work

Previous researchers have employed the deep learning YOLO model for oil palm tree detection with a variety of datasets (see Table I). According to a study by [10], the efficacy of YOLOv3 for oil palm tree detection using remote sensing data was evaluated, and the result was an evaluation value of 0.057627 based on the MAPE metric. In a related study, the authors employed YOLOv3, v4, and v5m to detect oil palm trees using aerial imagery data collected from VTOL drones in oil palm plantations in Jambi province, Indonesia. The F1-Score evaluation value for YOLOv3 was 97.28%, for YOLOv4, it was 97.74%, and for YOLOv5m, it was 94.94%. The research conducted by [12] utilizing the Deep Learning Faster R-CNN algorithm for the detection, counting, and geolocation of palm trees achieved an evaluation value of 94% in precision, 84% in recall, and 83% in AP IoU values in plantation areas in the Kharj region of Saudi Arabia. A study conducted by study [13] utilizing YOLOv8 and aerial imagery data yielded an overall accuracy value of 98.50% in the oil palm plantation area in West Kalimantan province, Indonesia. The study in [14] and [15] conducted a similar study using YOLOv5 to perform detection and classification. The classification was divided into five categories: healthy, smallish, yellowish, mismanaged, and dead palms. The F1-Score evaluation values ranged from 0.82 to 0.895. In a recent study [16], the modified YOLOv3n algorithm was employed to perform real-time detection in oil palm plantation areas, resulting in an F1-Score of 0.91 and a mAP of 97.20.

This research project will focus on the detection and counting of oil palm trees through the implementation of artificial intelligence, precisely by utilizing the deep learning algorithm YOLO as a model for oil palm tree detection and Slicing Aided Hyper Inference (SAHI) [9] to enhance the accuracy of YOLO detection on high-resolution aerial imagery. The data utilized in this study was obtained from aerial imagery captured using a drone in the oil palm plantation industry area in North Sumatra, Indonesia.

TABLE I. PREVIOUS RESEARCH

No	Topics	Author and Year	Methode	Evaluation
1.	Palm Oil Tree Counting with Remote Sensing Imagery	Mukhes Sri Muna et al., 2022 [10]	YOLOv3	5.76% (MAPE)

III. Methodology

The research comprises several stages, including data collection, using drones to obtain images for datasets, and model evaluation. The data is then pre-processed, dividing the images captured by the drone into four different categories: training data, validation data, test data, and evaluation data. This allows for the model to be tested. The next stage is model development, which involves setting up the YOLOv8m [17] training model and YOLOv8m training model and setting up Slicing Aided Hyper Inference (SAHI) [18]. Finally, the model is evaluated using images that are distinct from those used in the dataset. The research process is illustrated in the flowchart “Fig. 1”.

A. Data Collecting and Research Area

The data collection location for this research was an oil palm plantation situated in the Gunung Bayu area, Afdeling IV, blocks 13L, 13M, 12AK (Dataset), 14AC, 14AE, 14AF (Evaluation), North Sumatra, Indonesia “Fig. 2”.

The dataset was collected using a Trinity F90+ drone “Fig. 3” flying 200 meters above ground level, which captured RGB images. Table II shows drone specification.

B. Data Pre-processing

The recently acquired data will undergo a preliminary processing phase before integrating into the model's datasets and evaluation data. The following describes the preprocessing stages that will be employed.

1) The images captured by the drone will undergo a stitching process utilizing the Agisoft Metashape software. The outcome of this process is a comprehensive representation of each garden block in the form of a GeoTIFF file.

2) GeoTIFF images will be converted into .png format using the ArcGIS Pro software.

3) The image will be sliced using Adobe Photoshop. The slicing process employs a guide layout comprising 13 columns and 13 rows. Each sliced image has a size of 1399 x 1392 pixels “Fig. 4”.

4) The annotation process is conducted using Roboflow, with a total of 200 images utilized as a dataset comprising 111 images for training, 50 images for validation, and 39 images for testing. When performing annotation, augmentation techniques such as flip (horizontal, vertical), and 90° rotate (clockwise, counterclockwise, upside down) are employed, resulting in an increased training dataset size to 516 images “Fig. 5”.

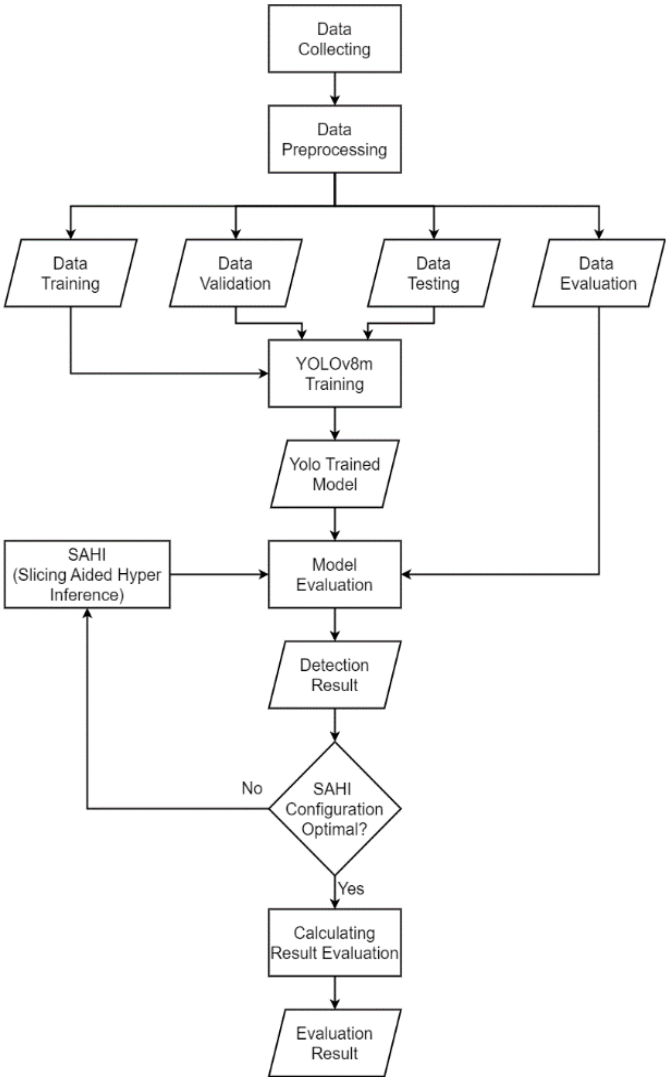

Fig. 1. Research flowchart.

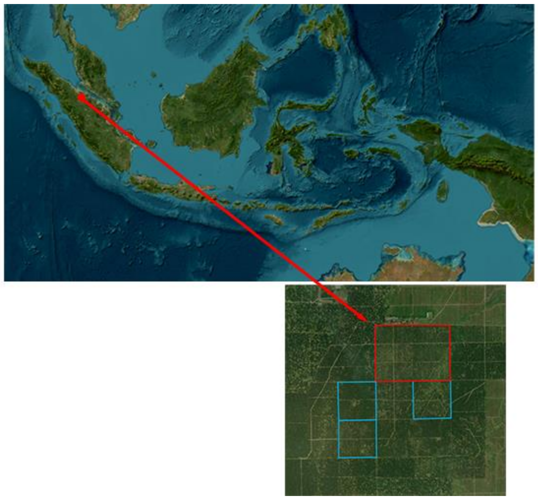

Fig. 2. Research area is located in North Sumatra, Indonesia, at 99.3620323°E and 3.1182583°N. The blue rectangle indicates the extent of the farm area included in the dataset, while the red rectangle represents the farm area utilized for model evaluation purposes.

TABLE II. DRONE SPECIFICATION USED FOR DATA COLLECTION [19]

Specification	
Transmitter Frequency	2.4 GHz
Command and Control Range	5 – 7.5 Km
Max Flight Time	90 Minutes
Camera Sensor	Sony RX1R II 42.4 MP
Max Range, Area	100 Km, 700 hectares

Fig. 3. Trinity F90+ drone.

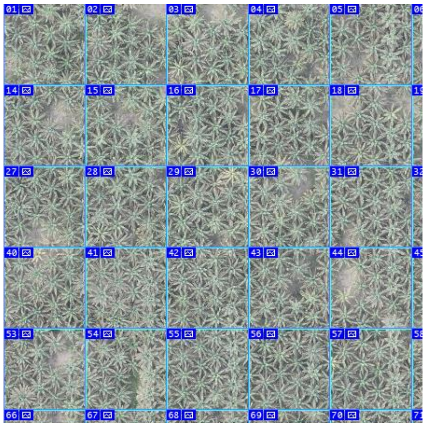

Fig. 4. The slicing process for dataset images results in an image with a size of 1399 x 1392 pixels for each image that has been sliced.

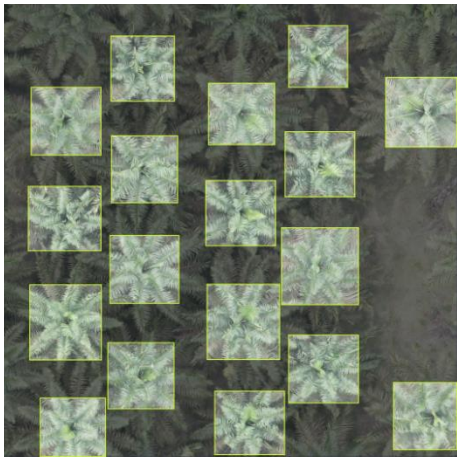

Fig. 5. The annotation process, conducted using Roboflow, is confined to the middle of the crown of the oil palm tree. This is done to ensure that the bounding box detection results do not overlap.

C. Model Development

The YOLOv8m model was trained using Google Collaboratory, which was equipped with 85 GB of memory and a 40 GB NVIDIA A100 GPU. The training process utilized an image size of 800 pixels, and the other parameters were set to their default values (see Fig. 6).

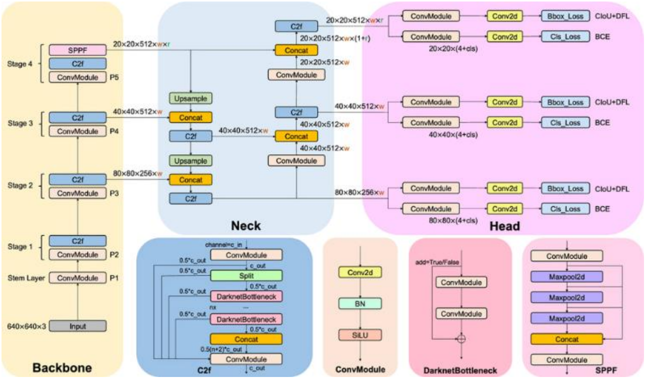

Fig. 6. YOLOv8 model architecture [20].

The next step is to implement SAHI (Fig. 7) by utilizing the weight of the training model results that have previously been carried out. This study employs a slicing height of 3000px and a slicing width of 3000px, a model confidence threshold of 0.55, and an overlap height ratio and overlap width ratio of 0.2 (default setting).

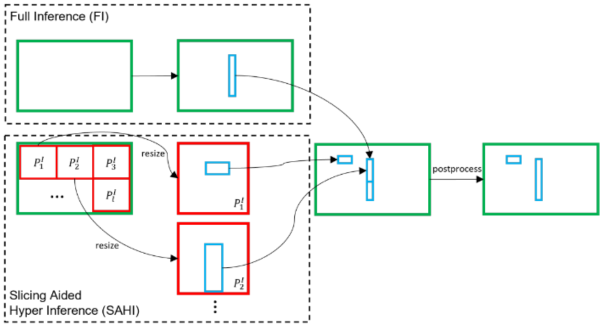

Fig. 7. Slicing Aided Hyper Inference Method (SAHI) [9].

D. Model Evaluation Method

To evaluate the performance of the detection model, this study uses the Mean Absolute Percentage Error (MAPE). This is achieved by comparing the number of detections made by the model with the actual number of objects in the field.

$$MAPE = \frac{1}{n}\sum_{t=1}^{n}\left|\frac{A_t - F_t}{A_t}\right| \quad (1)$$

IV. Result and Discussion

A. Training Model Result

The results of the YOLOv8m training model, with using an image size 800 pixel, indicate a Recall value of 0.899, a Precision value of 0.932, and an F1-Score value of 0.916. The training model was executed for 78 epochs, with a total runtime of 9 minutes and 39 seconds.

The results of training and validation models "Fig. 8", show that the Training loss moves down consistently.

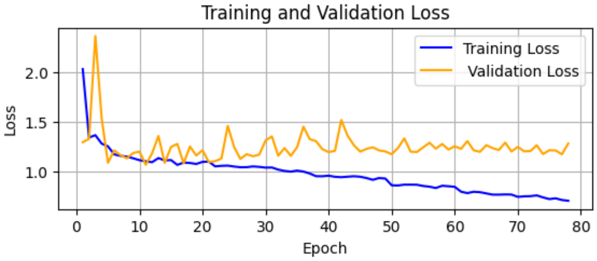

Fig. 8. YOLOv8 Training and validation models.

With a drastic decrease at epoch two from a value of 2.013 to 1.339, a slight spike in loss occurs at epoch three and then back down. In Validation loss, there is a very drastic increase in loss at epoch 3, with a loss value of 2,336, where the previous value was 1,327. The loss then returned to 1,534, after which the validation loss experienced significant fluctuations until epoch 53, after which the validation loss became more stable, but there was no significant improvement. Although the movement of validation loss does not mirror that of training loss, as illustrated in "Fig. 8", the training model does not shows signs of overfitting.

"Fig. 9" illustrates the values of precision, recall, and F1 score.

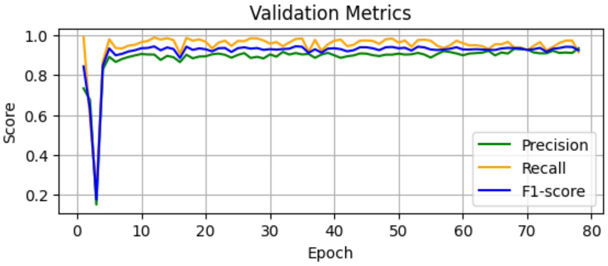

Fig. 9. YOLOv8m Precision, Recall, and F1-Score.

This illustrates a notable decline in these values at the epoch tree, from 0.733 of precision, 0.993 of recall, and 0.844 of F1-score to 0.150 of precision, 0.213 of recall, and 0.176 of F1-score. However, there was a subsequent surge in these values, reaching 0.829 of precision, 0.868 of recall, and 0.848 of F1-score. A further decline was observed at epoch 16, although this was not statistically significant. The values decreased from 0.890 of precision, 0.976 of recall, and 0.931 of F1-score to 0.865 of precision, 0.908 of recall, and 0.886 of F1-score.

B. Evaluation Model Result

For detection without the SAHI method "Fig. 10", the detection results on an area of 73.2 hectares with a confidence value of 0.55, which is the same confidence value used for detection with SAHI, show that the model does not detect any trees. At a confidence value of 0.1, there is a bounding box that does not show good detection results. A test using a confidence value of 0.55 and a plantation area of 1 hectare showed good detection results.

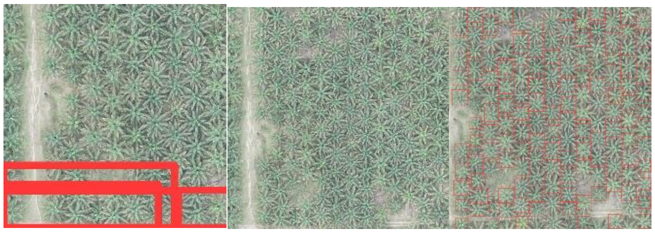

Fig. 10. (a) Detection result without SAHI with confidence 0.1 on 73,2 hectare, (b) Detection result without SAHI with confidence 0.55 on 73,2 hectare, (c) Detection result without SAHI with confidence 0.55 on 1 hectare.

To evaluate the model, data in the form of images with a size of 36336 pixels × 27084 pixels are utilized. The image encompasses three plantation blocks (14AC, 14AE, and 14AF) with an area of 73, 2 hectares "Fig. 10".

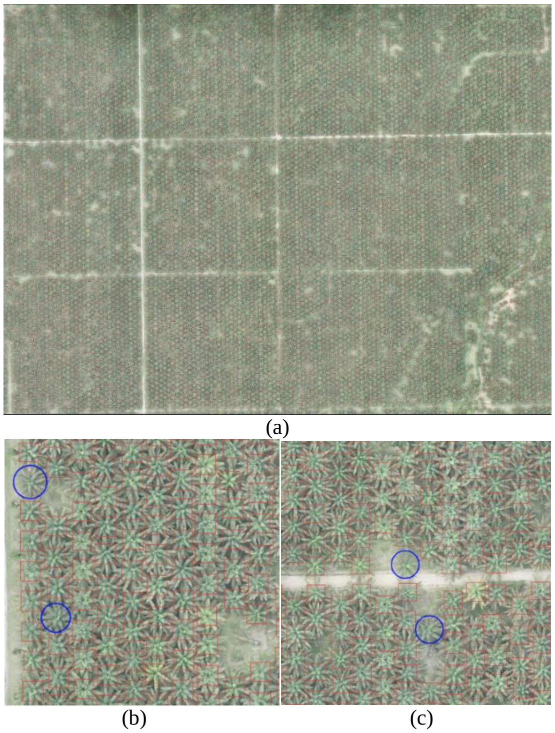

Fig. 11. (a) Palm oil plantation of 73,2 hectare that was detected. (b, c) Palm tree detection result at close range. The red bounding box is the model detection result and the blue circle is the oil palm tree not detected by the model.

The results of the SAHI method "Fig. 10" indicate that the model has identified 9,498 oil palm trees, whereas the actual number of oil palm trees is 9,668. Block 14AC has contains 3,154 trees, Block 14AF has contains 3,278 trees, and Block 14AE has contains 3,236 trees, for a total of three blocks containing 9,668 oil palm trees. Fig. 11 shows palm oil plantation.

To calculate the accuracy of the oil palm tree detection result by the model, the Mean Absolute Percentage Error (MAPE) is used as a measure of model accuracy, according to the results of the MAPE calculation Table III.

TABLE III. MAPE CALCULATION RESULT

	Without SAHI			With SAHI
Confidence	0.1	0.55	0.55	0.55
Area (hectares)	73,2	73,2	1	73,2
Model Detection	0	0	147	9498
Actual Trees	9668	9668	151	9668
MAPE	1	1	0.02649	0.01758

The MAPE result shows the model error in the number of oil palm tree detection results compared to the actual number. The MAPE value is close to 0, so the model has good accuracy [21].

For detection that does not use SAHI on an area of 73.2 hectares using a confidence value of 0.1 and 0.55, get a MAPE value of 1 or 100% because no palm trees are detected by the object. However, in an area of 1 hectare with a confidence value of 0.55, a MAPE value of 0.02649 or 2.64% is obtained, which is a good value in an area of 1 hectare without using SAHI.

And in an area of 73.2 hectares with using SAHI, a MAPE value of 0.01758 or 1.75% is obtained, which is a very good value for detection in an area of 73.2 hectares.

C. Discussion

YOLOv8m produces high accuracy with a Mean Absolute Percentage Error (MAPE) value of 0.0175 or 1.75% on aerial imagery with a resolution of 36336 x 27084 pixels, equivalent to 73.2 ha. This area is six times larger than the previous study [11] and 73 times larger than the study [13].

However, the results of this study are limited by the longer detection times observed when compared to previous research, such as that presented in study [11] and [13]. In research [11], the slowest detection took 45 seconds (YOLOv4) and the fastest 21 seconds (YOLOv5m) on an area of 12 ha. In this study, with the same large area of 12 hectares, the results took 45 seconds, but when compared with YOLOv5m, it was 14 seconds longer. In research [13], the time taken to detect oil palm trees on an area of 1 hectare was found to be 16.1 ms, which is considerably faster than the results of this study, where the same task on an area of 1 hectare took 6 seconds. However, this research has been able to address one of YOLO's weaknesses, namely the difficulty of detecting small objects, as demonstrated in "Fig. 9" and "Fig. 10".

Using datasets that need more diversity leads to suboptimal detection results on trees exhibiting unhealthy, dry, or dead characteristics. To enhance future research, it is recommended to utilize a more diverse and comprehensive set of datasets, thereby enabling the model to effectively identify oil palm trees with unhealthy, dry, or dead tree characteristics. Additionally, performing hyperparameter tuning during the training process can further optimize the model training outcomes.

V. Conclusion

In this study, the detection and counting of palm oil trees on high-resolution aerial images has been carried out using the Deep Learning YOLOv8m method in conjunction with the Slicing Aided Hyper Inference (SAHI) method. The results of testing the model on an image of an oil palm plantation area with a resolution of 36336 pixels x 27084 pixels, which corresponds to an area of 73.2 hectares and comprises three gardens, are presented below. In the blocks (14AC, 14AE, and 14AF), there are 9,668 oil palm trees in the garden area, with the model successfully detecting as many as 9,498 trees. The model's high level of accuracy can be attributed to the use of a small dataset and minimal tuning. This results in a MAPE value of 1.75% and a processing time of 5 minutes and 45 seconds for an image of 73.2 hectares. The combination of YOLOv8 and SAHI is highly recommended for object detection on aerial and satellite images due to its high accuracy on high-resolution aerial image.

Abstract*—Educational technology is increasingly focusing on real-time language learning. Prior studies have utilized Natural Language Processing (NLP) to assess students' classroom behavior by analyzing their reported feelings and thoughts. However, these studies have not fully enhanced the feedback provided to instructors and peers. This research addresses this issue by combining two innovative technologies: Federated 3D-Convolutional Neural Networks (Fed 3D-CNN) and Long Short-Term Memory (LSTM) networks and also aims to investigate classroom attitudes to enhance students' language competence. These technologies enable the modification of teaching strategies through text analysis and image recognition, providing comprehensive feedback on student interactions. For this study, the Multimodal Emotion Lines Dataset (MELD) and eNTERFACE'05 datasets were selected. eNTERFACE contains 3D images of individuals, while MELD analyzes spoken patterns. To address over fitting issues, the SMOTE technique is used to balance the dataset through oversampling and under sampling. The study accurately predicts human emotions using Federated 3D-CNN technology, which excels in image processing by predicting personal information from various angles. Federated Learning with 3D-CNNs allows simultaneous implementation for multiple clients by leveraging both local and global weight changes. The NLP system identifies emotional language patterns in students, laying the foundation for this analysis. Although not all student feedback has been extensively studied in the literature, the Fed 3D-CNN and LSTM algorithm recommendations are valuable for extracting feedback-related information from audio and video. The proposed framework achieves a prediction accuracy of 97.72%, outperforming existing methods. This study aims to investigate classroom attitudes to enhance students' language competence.

***Keywords*—Convolutional neural network; federated learning; LSTM; Natural Language Processing; SMOTE**

I. Introduction

Emotions are important not just in human relationships, but also in interactions between humans and computers. Because this may have an impact on an individual's psychological state, such as concentrate, decision making, and task-solving abilities. Convolutional neural network that analyses visual data and provides an accurate information in image processing. CNN extract attributes and detects patterns in images by using linear equation ideas, namely convolution procedures. CNN can be programmed to handle both speech and extra signal data, even if their primary goal is to interpret images. The fusion of Natural Language Processing (NLP) and 3D-CNN techniques sparked an innovative method of English language learning. By harnessing three-Dimensional Convolutional Neural Network (3D-CNN) image recognition and Long Short Time Memory (LSTM) text analysis providing the overall feedback of student's interaction. 3D- CNN can be good at detecting video as well as audio recognition, recommendation systems, visual segmentation, medical imaging analysis, and processing of natural languages, brain–computer user interfaces and financial history data.

Akhtar, Ekbal, and Cambria [1] recognised significant improvements have been made to this field of study, each research approach has benefits and downsides. It remains difficult to evaluate the results they produce, owing to the usage of various datasets and feature extraction approaches. Even for the same datasets, different approaches typically yield varying degrees of appropriateness for feature sets. The most significant question, therefore, is not which approach is best, but whether the conclusions might be used more broadly. It is thus more profitable to try to improve the outcomes of each categorization. Ensemble learning aims to effectively enhance the overall efficiency of the network by mixing the outputs of several candidate systems. Usama et al. [2] proposed algorithms based on deep learning have demonstrated amazing performance in the areas of NLP and computer vision. As a result, there is still an increase of using text analytical techniques like convolutional and RNN analysis to extract meaningful information. One of the key factors contributing to these models' performance involves feature retrieval. Furthermore, characteristics were passed from a single layer to another inside the network, as well as from a single network to a different network. However, multilevel and multitype combination of features remain explored in analysis of sentiment. So, this study utilizes the three datasets to demonstrate the benefits of extracting and combining multilevel and multitype features from various neural networks. Multilevel features come from many layers of an identical network, whereas multitype features are from varying network.

Caroppo, Leone, and Siciliano [3] proposed this technique can help blind people by capturing their emotions automatically to understand facial emotions, also robots to communicate flexibly with people for providing better service. It also can be used to extract a large number of opinions by tweets in social media users from conversational data in social networks in emotion recognitions in conversation. Some of the applications, such as assistive technology, security, medical, communications and robotics has been receiving attention of emotion recognition. Mental activities of the observed subject will be the result of outcoming different facial expressions. As a result, it is important to explore exclusive methods for automatic detection of facial emotions for older adults in order for creating intelligent systems capable of customizing, for example, the response of the circumstances. Soleymani, Pantic, and Pun [4] framed the network EEG and outermost physiological signals from the user's database capture the responses of emotional videos by CNN image processing into five classes namely happy, sad, disgust, angry, fear, and surprise. The accuracy rate of EEG signals achieved at 41.7%. However, this technique failed to improve the accuracy rate of classification in low feature level fusion of EEG signals and outermost physiological signals.

Wensong and Xiange [5] studies majorly concerns for education administrations and teachers has constantly been how to monitor students' emotional changes in real time during online instruction. An advanced machine learning network framework based on the fusion of several methods of attention and CNN is suggested, using the unique roles of global, part of speech, and position attentive methods in text processing. First, the traditional ChnSentiCorp_htl_all data set is used to investigate the blending features between the different types of concentration processes and CNN in order to determine how successful it is to combine the three attentiveness mechanisms with CNN. Li et al. [6] deep learning model is the main foundation for text categorization. On the other hand, important distinctive words and a strong contextual semantic link are features of online collaborative conversation. The reliability of results from classification may decrease if solely the deep learning approach is utilized for text classification because there may be inadequate knowledge of contextual semantic connections and ignoring of important feature words. As a result, this paper suggests a multi-feature integration model that extracts the context of the text features using the BiLSTM method, its local features using CNN, its average representation features using an average pooling model, and its text's word vector representation using BERT.

A multimodal emotion recognition technique in language learning is implemented for recognising emotion and sentimental analysis using Audio and video clips. To address this visual modality, firstly sampling the dataset by SMOTE technique. While CNNs are highly skilled at extracting characteristics from textual and visual data, NLP approaches allow for the analysis and comprehension of natural language. These two methods applied to enhance the language learning experience in real time by providing feedback to learners. In this research, investigated how real-time English language learning may be improved by the application of NLP and CNN approaches. Evolving optimization selects key audio and video features, which are then sent to the upgraded Federated distributed model for deep CNN classification. A weighted fusion method is used to combine the audio and visual modalities for improved emotion recognition performance. Finally, emotions are distributed for several decentralized systems.

The key contributions of this framework are summarised as follows:

- Using the SMOTE approach to address the problems with dataset imbalance. By oversampling and under sampling, it creates the minority classes.
- To determine the feelings and sentiments of several learners, a Federated 3D-CNN and NLP architecture is built. By use of federated learning and the decentralization of datasets among devices within a client-global server architecture, the study ensures that confidential information is safely sent while maintaining the privacy of individuals.
- The impact of picture categorization and processing the complete data sequence for feedback connection are increased when Deep Federated Learning 3D-CNN and LSTM Network are combined.
- The Federated CNN model identifies the six main emotion kinds that student's exhibit and gives administrators and students an overall evaluation.

The rest of the section is structured as: Section II examines the related work on audio-visual emotion identification. Section III refers to the problem statement. Section IV describes the proposed procedure in detail, followed by Section V which includes the results and discussion. Finally, Section VI summarises the findings of the proposed work with a conclusion.

II. Related Work

Imran et al. [7] proposed a cross-Cultural Polarity and detecting the emotion using LSTM. During the pandemic situation (COVID-19) a range of comparable feelings all over the nations and the judgments made by their individual governments are differentiable. Social media has been overwhelmed with messages about COVID-19, pandemics, lockdowns, and hashtags, both are good and bad in nature. Despite their geographic proximity, several adjacent nations responded differently to their neighbor countries. Some of the countries reacted as worry and animosity where some countries reacted as normal reaction. The goal of this study is to assess the reaction of individuals from varying backgrounds cultures and people's emotion about following actions done by various governments. The sentiment140 orientation analysis dataset is concerned in this study, it achieved the highest possible performance. This framework undergoes multimodal Long Short-Term Memory (LSTM) technique for analyzing sentiment and emotion polarity. Yet this system classifies as only positive or negative emotions not recovers the exact emotions of social media users.

Kucherlapati and Varma Mantena [8] proposed a framework to analyze the emotions of students during seminars. When the seminar starts the admin would capture the images of students in the seminar by face expression recognition method. The graphical representation of inclined gradients is utilized for face detection, while the k-near-neighbors method is used for face identification, which has the best accuracy. The suggested system, in addition to presenting an overview of all attendance individuals, also includes a comment box where individuals can offer text-based input. Sentiment Analysis, when applied to feedback using the NLP, provides an accurate representation of the members' thoughts, expressed by a histogram indicating the total amount of members who chose good, negative, or neutral input. By using the IEMOCAP dataset, it possesses an accuracy of 97%. Although it predicts a high accuracy rate the overall output emotion of all students cannot be recognized. Only positive and negative emotions are predicted.

Chatterjee et al. [9] introduce a comprehensive approach that electronic home products analyze emotions. In the consumer field SER Speech Emotion Recognition was implemented through home products. Two datasets were used to predict the sentimental analysis are Ryerson Audio-Visual Database of Emotional Speech and Song (RAVDESS) and Toronto Emotional Speech Set database (TESS) contains young and old voice samples. Mel-Frequency Cepstral Coefficient (MFCC) was applied to extract the accurate speech by pitch and frequency. The dataset examined the well robustness of movie scenes. A dimensional Convolutional Neural Network 1D-CNN is used to augment and classify accurate emotions. By using the valid dataset this approach gives 90.48%, 95.79% and 94.47% while classification. This improves the connection between the user and smart home assistance and offers more effective feedback. Yet it doesn't address a greater number of subjects such as voices of varying ages, gender categories etc.

Wang et al. [10] proposed a perspective computer simulation to recognise facial expressions in online education. Online teaching method opening is increased on pandemic situations COVID19. So, the efficiency and applicable reliability of education-based online classes has been arising question. This framework belongs to deep learning model based on 3D-CNN technique. During online classes students undergo different kinds of emotions. From the viewpoint of computer emotion recognition stimuli, the method face expression recognition algorithm with online courses is collide with this framework, student's face images are collected from e cameras. From this method online caretakers can identify the student's effectiveness. These input images get coordinate with Cohn -Kande dataset. The facial expressions of the students are analysed and classified into 8 different kinds of emotions. However, students' expressions may not fully capture their emotions when there are many students in the online class. Liliana [11] it recognizes the student's facial expressions inside the classroom. It will find out whether the student is in anger or in surprise mode. This paper uses the collection of images dataset Cohn Kanade (CK+) which is collected by faces for facial recognition experiment. The system performance gain average accuracy rate of 92.81% still low.

Above all framework works with the Centralized CNN network. The lack of emotion prediction when shadow falls on students individually. Only positive and negative classifiers shown as result doesn't provide any feedback to user in some of the framework. The Electroencephalography signals used for emotion recognition doesn't predicts the accurate emotions. Most of the framework are not flexible for both audio and video recognising dataset. The existing framework either works for audio or video. Some of the result doesn't put any concern for CNN image processing architect to gain the better result. But the proposed framework undergoes the best 3D-CNN technique for image preprocessing it examines the accurate emotions. By colliding both suitable audio MELD and eNTERFACE video datasets. By implementing Natural Language Processing (NLP) its transcripts the voices into linguistic patterns which made the framework more effective. Current emotion recognition frameworks using EEG and visual data face challenges with low accuracy and slow learning rates, often confusing intermediate emotion states like Afraid. Many operate unimodally, recognizing only visual emotions and ignoring spoken cues. This results in incomplete feedback for administrators and students, hindering the effectiveness of emotion recognition systems.

III. Problem Statement

According to the review mentioned above, all of the current frameworks have poor levels of accuracy and have rather slow learning rates for identifying video clips [12]. Using EEG data and visual modalities, early frameworks confused between the in-between state levels of (Afraid, Angry, Happy, Sad, Surprise, and Neutral). [13]. Occasionally, it is unable to accurately identify whether the pictures in the video clip are at an intermediate level of emotion (afraid or furious). Certain articles are in unimodal mode, meaning that spoken emotions are not detected; only visual emotions are recognized. The previous approach doesn't give administrators or students any comprehensive input. This possible disadvantage affects how well emotions are recognized and how much recognition is given. By extracting characteristics from audio and video levels, the suggested methodology seeks to close this research gap by accurately detecting high-level emotion states. Federated learning is implemented in this way, which improves learning speed. Through the use of deep federated 3D-CNN and LSTM methods, the feature achieves an accuracy rate of six state-level emotions.

IV. Proposed Materials and Methods

In this proposed framework, a deep learning method in federated 3D-CNN was implemented to forecast the learner's emotion, based on stacking layers. Thus, it results the implemented block performs an augmentation task on the inputted dataset images. Input dataset images are get sampled if they have any overfitting problem. The overfitting problem are detected by Smote technique. When the dataset images get pre-processed, they can be used to training and testing procedure of the network (i.e. recognition step). In the training/testing step, a sequence of images eINTERFACE and MELD text datasets are given to the network. By using proposed federated method allocating different weights to local clients by the global system. So, it will get trained by the images and voice by NLP to detect emotions of the leaners. Last procedure for preprocessing is converting the input RGB Red Green Blue image into a grayscale intensity image. The first stage of preprocessing is increasing the minority class that is identifying and detecting the oversampling problems in MELD and eNTERFACE'05 dataset using SMOTE (Synthetic Minority Oversampling Technique). Each emotion expression comes under three levels of emotional intensity i.e., (Positive, Negative, Neutral) Emotion (Anger, Disgust, Fear, Joy, Neutral, Sad, Suprise) is final forecasting prediction of learner's emotion and provide overall feedback to admin and learners as shown in the Fig. 1.

A. *Data Collection*

Most of the framework multimodal emotion recognition have single-minded on MELD database as shown in the Fig. 2. In order to differentiate the contribution of this paper, the chosen databases are MELD and eNTERFACE'05. A valid MELD and eNTERFACE'05 is a multimodal database contains the collection of image dataset regarding seven different kinds of emotion Ho et al. [14]. The framework of pretrained input images and text are collected from two dataset used to classify the emotions by recognising audio and visual.

This dataset was improved and expanded to generate the Multimodal Emotion Lines Dataset (MELD). The conversation contexts in MELD are identical to those in Emotion Lines, but in addition to text, it also includes visual as well as audio components. MELD contains around 1400 exchanges and 13,000 words from the Friends television series. Several speakers took part in the conversations. Any one of these seven emotions assigned to each statement made in a discussion. Each speech in MELD additionally includes a sentiment annotation (good, negative, or neutral). The eNTERFACE dataset comprises examples of video sequences with the necessary information that have been segmented to the next level Nguyen et al. [15].

B. *Data Pre-Processing*

In this proposed framework, a deep learning method in federated CNN was implemented to forecast the learner's emotion, based on stacking layers. Thus, it results the implemented block performs augmentation task on the inputted dataset images. Input dataset images are get sampled if they have any overfitting problem. The overfitting problem are detected by Smote technique. When the dataset images get pre-processed, they can be used to training and testing procedure of the network (i.e. recognition step). In the training/testing step, a sequence of images and text MELD and eINTERFACE datasets are given to the network. The MELD dataset gets pre-processed by NLP method conversion of voices into natural language text and get classified by CNN network. Then allocating different weights to local clients by the global system. So, it will get trained by the images to detect emotions of the client. Last procedure for preprocessing is converting the input RGB Red Green Blue image into a grayscale intensity image.

The followed step of the preprocessing procedure is to extract the voices to text by NLP method and crop the image and the learners image get cropped and it will find the perfect match facial expression images in the dataset. This procedure keeps the CNNs face detection by prompting the eye aspect ratio, discarding all background information and patches of image from the background which are not matches to the facial expression. Denoised region which has already cropped delimits the image automatically. Final stage of preprocessing is the conversion of clients RGB coloured images into a black and white grayscale intensity picture. Because of RGB – Grayscale conversion, the facial features are extracted accurately. After the cropping procedure, different size of facial images is obtained. So, the cropped photos are got down sampled to 96×96 pixels using linear interpolation to remove variations in face size and maintain uniform pixel spacing. At last, the final step converts the fair coloured image into a grayscale image. Fig. 3 shows working of natural language processing.

C. *Synthetic Minority Over-Sampling Technique - SMOTE*

SMOTE Oversampling can predict accurate data imbalance. Under sampling deals class-imbalance problem in the MELD and eINTERFACE dataset. In the oversampling method, SMOTE can predict better accuracy rate in practical application. The pipeline of SMOTE which predicts new samples is as followed by the Fig. 4.

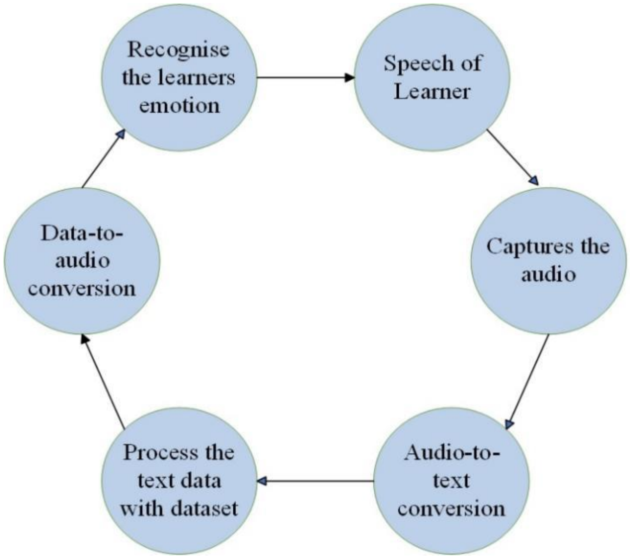

Fig. 3. Working of NLP (Natural Language Processing).

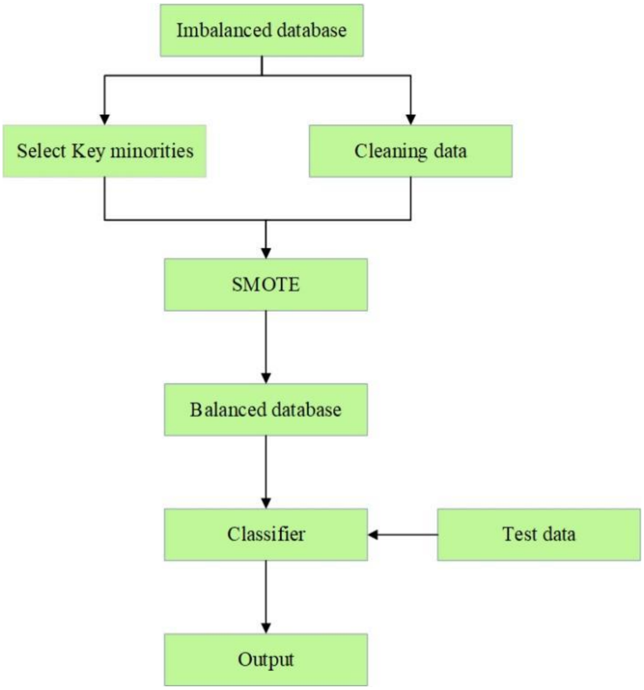

Fig. 4. Flowchart of SMOTE (Synthetic Minority Oversampling Technique).

The followed step of the preprocessing procedure is to crop the image and the clients image get cropped and it will find the perfect match facial expression images in the dataset. This procedure keeps the CNNs face detection, discarding all background information and patches of image from the background which are not matches to the facial expression. Denoised region which has already cropped delimits the image automatically. Final stage of preprocessing is the conversion of clients RGB coloured images into a black and white grayscale intensity picture. Because of RGB – Grayscale conversion, the facial features are extracted accurately. After the cropping procedure, different size of facial images is obtained. So, the cropped photos are got down sampled to 96×96 pixels using linear interpolation to remove variations in face size and maintain uniform pixel spacing. At last, the final step converts the fair coloured image into a grayscale image. Now by SMOTE oversampling improves the data imbalance Yan et al. [16].

D. *Federated Learning in Image Classification*

Federated learning is a machine learning technique in which an algorithm undergoes training over multiple iterative of independent sessions, each using its own dataset. This framework contrasts with standard centralized methods for machine learning which polyconnected with local datasets into a single training session, as well as assuming that local data samples are evenly distributed to all clients. Federated learning allows multiple clients to create a single, strong machine learned approach without sharing data, resolving crucial challenges like privacy of data, security purpose, access rights, and access to numerous of heterogeneous data. Its applications cover industries such as Internet of Things, telecommunications, defence and medicines. Federated learning technique trains the algorithm through multiple individual local devices, each using its own dataset. In this proposed federated framework two different datasets are classified to multiple clients. A set of users are interfaced to enumerate that return datasets.

Step 3: Averaging the new learning
Step 1: Server sharing initial Learnings L1

Fig. 5. Federated learning.

Their only purpose of federated system is to allow the selected subsets of the data for simulations. The main purpose of federated learning is decentralizing the local models by performing their own mandated technique. Dataset1 contains MELD and dataset2 contains eINTERFACE video and audio emotion recognising datasets. Dataset1 used by Learner 1 and dataset2 used by Learner 2 as shown in the Fig. 5. The independent local bodies interfaced the deep 3D - Convolutional Neural network but client1 process based on MELD dataset and client2 process based on eINTERFACE dataset. The initial stage is sharing the Learnings L1 i.e., sharing the local devices with two different datasets. Then updating the weights depending on the datasets and generating new learnings L2 using private data new learning L2 = avg (data1 + data2). Finally, by averaging the two learning the two datasets are combined in each learning as shown in Fig. 5. The iteration process is evoked in a convolution neural network. Each device performs the CNN technique with learned datasets.

E. *Deep Federated CNN-Based Facial Extractions*

Convolutional Neural Network is a widely used approach when it comes under any image processing or predictions and in performing any image-related task. This 3D-CNN network typically comprises several fundamental layers i.e., a sequence of frames that are repeated as necessary. In these layers, the convolutional layer plays a crucial role. In this layer, 3D-CNN filters systematically traverse the input image, computing values through a method as the dot product. This process works when filter moves horizontally and vertically across the large dataset input image. As already said, there will be a sequence of layers with the resulting values from the convolutional layer for the min and max pooling extraction process which are then passed to the pooling. A pooling filter is effectively reducing the size of information obtained from the output of the previous layer which is obtained from the initial image. Then the iterative process is repeated until it extracts the relevant features from the input image.

F. *Long Short-Term Memory for Handling Entire Data Sequence*

Long Short-Term Memory models are used for prediction and sentimental analysis and provide some feedback. By compiling a dataset of textual samples that have been annotated with the appropriate emotion (positive, negative, or neutral). After that, the raw data is processed. Tokenization of which divides texts into specific phrases. Recurrent neural networks (RNNs) of the long short-term memory type are excellent at preprocessing and predicting textual patterns of input. An embedding layer transforms words into vectors of numbers in the LSTM model, and a number of LSTM layers captures. After the model predicts an emotional response, feedback can be given by contrasting the emotion with the real emotion (if available). If the emotion predicted and the real-life emotion match, the model works as intended and no more intervention is required. The user can correct the forecast to offer feedback if it fails to reflect the real mood. By retraining on the updated data or adjusting the current factors, this feedback may be utilized for improving the model. All things considered, LSTM models for sentiment analysis offer an automated method for assessing and categorizing the sentiment of text input, and the model's predictions may be continuously enhanced and improved feedback. In the context of multilevel fusion in CNN-LSTM architectures, the integration occurs at different stages to leverage the complementary strengths of both Convolutional Neural Networks and Long Short-Term Memory networks. At the initial level, feature maps extracted by the CNN from image data are fed into the LSTM network, allowing the LSTM to capture spatial dependencies and patterns encoded in the visual information. This fusion enables the LSTM to learn contextual information from the images, enhancing its ability to make predictions based on the sequential nature of the data. Additionally, at a higher level, the output sequences generated by the LSTM are combined with features extracted from text data using CNNs. This fusion incorporates textual context into the model, enabling it to capture semantic relationships and linguistic nuances. By integrating information from multiple modalities at different levels, the multilevel fusion in CNN-LSTM architectures facilitates a comprehensive understanding of complex data, leading to improved performance in tasks such as sentiment analysis, emotion detection, and multimodal learning.

1) *Model to represent the features fusion approach*: After the model predicts a sentiment, feedback can be given. The algorithm worked as intended and no more steps are required if the forecast and the actual emotion match. A user can alter a forecast to offer feedback if it does not accurately reflect the emotion. Retraining the updated data or adjusting the current model parameters are two methods that may be employed to modify the model using this feedback. LSTM models offer an automated method for analysing and categorizing text data's emotions, and the model's predictions may be continuously enhanced and improved upon through feedback. Rather than approving CNN features to RNN in a sequential manner as performed in previous works, it individually learns CNN as well as RNN category features by using embedding videos and words as input for both CNN and RNN, then merging the two kinds of attributes to get multitype features fusion. Finally, a sentiment analysis into the combined set of features map. Three layers of convolution with various filter widths were employed within CNN. To obtain the final feature mapping from CNN, feed the word integrating to the convolution layer and record multilevel features following the maximum-pooling layer, as seen in Fig. 6. As seen in Figure, multilayer CNN and RNN are used to accomplish integrated multilevel and multitype feature fusion at the merged layer following the acquisition of multilevel feature fusion from CNN.

Fig. 6. Structured diagram of the proposed CNN and RNN (LSTM).

Consider an input of convolutional layer size of Weight(X) $X \times X \times D$ and Dout number of kernels with a spatial size of y with stride Z and amount of padding P, then the size of output volume can be determined by the following Eq. (1):

$$X'_{out} = \frac{X-Y+2P}{Z} + 1 \quad (1)$$

The number of iterations or repetitions process for convolutional and pooling method depends on the content of facial feature being predicted. By fine-tuning this 3D-CNN architecture, desired output can be predicted, making it an easy and effective tool for various image-related processing technique in this framework Ghosh et al. [17]. In this method, a 3D-CNN predict the key points of face which were first trained in this method Kumar et al. [18]. A cascading sequence of compression and pooling layers is used to carefully extract and fine tuning the information that is retrieved once features have been extracted from the input. If an activation map of size $X \times X \times D$, a pooling kernel of spatial size Y, and stride Z, then the size of output volume can be determined by the following Padding Eq. (2):

$$X'_{out} = \frac{X-Y}{Z} + 1 \quad (2)$$

This flattened representation is then modified to enable its smooth incorporation into a fully linked layer, which is a crucial point at which the model performs complex prediction tasks. The final output layer, the last phase of this complex process, presents a complete set of 68 facial key points that have been painstakingly extracted from the image, providing a sophisticated and in-depth comprehension of the underlying visual components. Hence the emotions are recognised by deep learning federated CNN model. Hence the result was predicted as Happy, Sad, Neutral, surprise, Disgust, Angry based on the expression delivered by user Mase et al. [19].

G. *Functional Flowchart for Sentimental Analysis*

The proposed framework, a deep learning method in federated CNN was implemented to forecast the client's emotion, based on stacking layers. Thus, it results the implemented block performs a pre-processing task on the inputted dataset images. Input dataset images are get sampled if they have any overfitting problem. The overfitting problem are detected by Smote technique. When the dataset of text files get pre-processed by Natural Language Processing (NLP), they can be used to training and testing procedure of the network (i.e. recognition step).

In the training/testing step, a sequence of audio and video MELD and eINTERFACE datasets are given to the network. Then allocating different weights to local clients by the global system. So, it will get trained by the images to detect emotions of the client. The last procedure for preprocessing is converting the input RGB Red Green Blue image into a grayscale intensity image. The first stage of preprocessing is increasing the minority class by identifying and detecting the oversampling problems in MELD and eNTERFACE'05 dataset using SMOTE (Synthetic Minority Oversampling Technique) and finally forecasting the emotions after CNN and LSTM classification by providing feedback to learners and admin as shown in the Fig. 7.

V. Results and Discussion

In this proposed framework, a multimodal emotion recognition technique is implemented for recognising facial expressions using Audio and video clips. To address this visual modality, firstly sampling the dataset by SMOTE technique. The framework Federated 3D-CNN is implemented through Python and thus it predicts 97.72% accuracy in detecting emotions using the accurate predicting datasets MELD, eNTERFACE. And a sequence of keyframes from the image and define an aspect ratio to detect the transformation of sequence keyframes by training or splitting the data. Then the appropriate and exact facial emotion features are distributed by decentralized system i.e., to improve learning speed and kept the data very privacy at each learner and admin device. Once key features of the face have been recognised, they are passed for emotion recognition into the process of optimized classifier. Evolving optimization selects key audio and video features, which are then sent to the upgraded Federated distributed model for deep Federated 3D-CNN classification. A weighted fusion method is used to combine the audio and visual modalities for improved emotion recognition performance. Finally, the average emotions are distributed with suitable feedback for several decentralized learner and admin systems.

A. *Experimental Results*

Setting up the eINTERFACE, AFEW and RAVDESS datasets, then performing preprocessing. These might include instances of labelled emotions in audio or face expressions. Divide the data into sets for testing and training to evaluate the model's performance. Preparing the dataset Mel-frequency cepstral coefficients (MFCCs) are features that may be derived from raw audio signals in order to study them.

Fig. 8 displays No of Samples per class before applying SMOTE (Synthetic Minority Over-sampling Technique), an analysis of the dataset revealed an imbalanced class distribution. In the binary classification problem at hand, Happy, Sad, Angry, Disgust, Surprise and Fear [number of samples]. The MELD dataset values are Anger=1109, Disgust=271, Fear=268, Joy=1743, Neutral=4710, Sad=683, Surprise=1205. The imbalance raised concerns about potential challenges in model training and classification performance. The decision to apply SMOTE was driven by the need to address this class imbalance systematically, ensuring a more representative and balanced dataset for subsequent analyses.

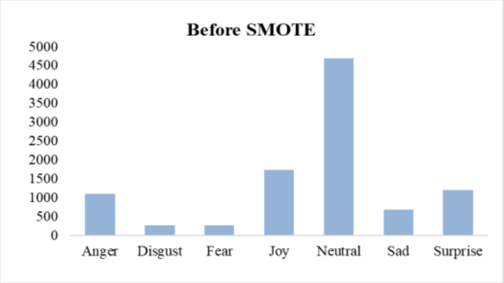

Fig. 8. No of samples per class before SMOTE in MELD dataset.

Fig. 9 displays No of Samples per class before applying SMOTE (Synthetic Minority Over-sampling Technique. The process of creating synthesis cases of the minority class increases the number of specimens per class following the use of SMOTE to rectify the imbalance of classes in a collection of data. By doing oversampling and under sampling process, SMOTE creates artificial examples across the boundary segments that link instances of minority classes that already exist. The median of all emotions is 1427. Eq. (3) it determines the SMOTE (synthetic minority oversampling technique).

$$X'_i = x_i + \lambda(x_j + x_i) \tag{3}$$

Eq. (4) explains about inverse document frequency (IDF),

$$IDF(T) = log\frac{n+1}{DF(T)+1} + 1 \tag{4}$$

Eq. (5) term frequency-inverse document frequency (TF-IDF),

$$TF - IDF(T) = TF(T) * IDF(T) \tag{5}$$

Eq. (6) F1 measure,

$$F1 = \frac{2*Precision*Recall}{Precision+Recall} \tag{6}$$

The objective is to improve the model's generalization to minority class trends while balancing the class distribution. The SMOTE parameters that are selected, including the appropriate degree of over-sampling, determine the precise rise in the total amount of samples per class. SMOTE helps lessen the effects of an unbalanced class distribution by injecting synthetic examples, which eventually leads to computerized learning frameworks that are more reliable and accurate.

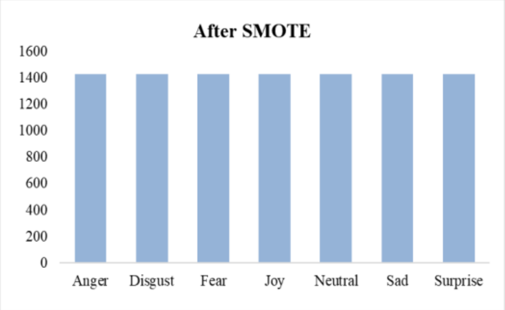

Fig. 9. No of samples per class after SMOTE in MELD dataset.

B. *Training and Validation Accuracy*

Using a weighted fusion method, determine the recognition accuracy for each emotion class. The suggested method fared well for identifying anger, joy, sorrow, and neutral mood. However, performances for deciding surprised and contempt were much lower. This finding is significantly influenced by the unbalanced data distribution reported in Table I. The training data contains the most video examples for annoyance, joy, and neutral, with only a few movies for disgust, anxiety, and surprised. Furthermore, human faces communicate powerful emotions like anger and delight. Fig. 9 compares the Training and Testing Accuracy for Client 1, 2 and 3 and shows how these networks learn and generalize across 100 epochs in different ways. With time, these losses diminish, suggesting that the model is acquiring up new skills and becoming more efficient. While the training accuracy increases more gradually over the course of the epochs, the testing accuracy also gradually increases like training accuracy and then on reaching further epochs.

TABLE I. AVERAGE ACCURACY OF MELD AND INTERFACE DATASET

Emotional class	Accuracy (%)
Anger	89.91
Disgust	94.56
Fear	54.67
Joy	93.87
Neutral	89.56
Sadness	95.81
Surprise	92.74

The training and testing accuracy of a Fed 3D-CNN + LSTM model and a CNN model for three individual learners are shown in Fig. 10. The figure shows how well each model predicts results using both data that it was trained on and data that it has never seen before.

Fig. 11 compares the Training and Testing Loss for Networks A, B, and C and shows how these networks learn and generalize across 100 epochs in different ways. With time, these losses diminish, suggesting that the model is acquiring up new skills and becoming more efficient. While the training loss declines more gradually over the course of the epochs, the testing loss begins at a greater value than the training loss and then abruptly declines before falling about epoch 20.

C. *Performance Evaluation*

Metrics for performance assessment are crucial for evaluating machine learning models' efficacy and dependability quantitatively, especially when it comes to categorization tasks like diagnosing skin lesions. Below is a thorough description of a few measures employed in performance evaluations:

1) Accuracy: The proportion of accurate forecasts to all predicted outcomes is known as accuracy. When a collection of data is balanced, this measure works well. The results reported by this metric might not be accurate representations of how well the model performed when there's an overwhelming class in the data set is given in Eq. (7).

$$Accuracy = \frac{True\ Negative+True\ Positive}{TruePositive+FalsePositive+TrueNegative+FalseNegative} \quad (7)$$

2) Precision: The deep learning algorithm's precision is a metric for determining how many anticipated positives are actually true positives. This statistic is helpful whenever the cost of a false positive is high for the efficacy of the model, like in the case of an email spam identification algorithm that is given in Eq. (8).

$$Precision = \frac{T*p}{T*p+F*n} \quad (8)$$

3) Recall: The Recall of the model in counting the number of positives out of all real positives is measured by recall. When False Negative is costly for model quality, such as in fraud detection models, this statistic is helpful and is given in Eq. (9).

$$Recall = \frac{T*p}{T*p+F*n} \quad (9)$$

4) F1-Score: The F1 score that is computed for this purpose assesses the correlation between the data's positive information and the classifier's predictions is given in Eq. (10).

$$F1\ score = \frac{2T*p}{2T*p+F*p+F*n} \tag{10}$$

To recognise the facial emotions flows through federated system. The experiment results show that RNN provides superior accuracy in terms of facial emotion recognition and it predicts 57-87% Mase et al [19]. Finalizing the emotional categories from social media. Emotions can be analysed by reacting, commenting for post, tweets etc. Love, happy, violence, sad and fear these following categories work under Flickr dataset which produce the accuracy rate. The Methods SVM on high level features of VGG-ImageNet, fine-tuning on pretrained models like RESNET, Places205-VGG16 and VGG ImageNet it predicts the accuracy 68% Gajarla and Gupta [20].

Table II visually represents the performance measures of the Federated 3D-CNN compared to traditional methods. The Fig. 12 illustration provides a clear and insightful overview of proposed model excels in metrics when compared it with the conventional approaches, emphasizing its superiority in emotion prediction. The effectiveness of deep learning techniques (GoogleNet and AlexNet) at recognizing facial movements, especially the presence of emotional content and the precise emotion character of such expressions, with an accuracy rate of 87% Giannopoulos, Perikos, and Hatzilygeroudis [21]. This work offers a comparison analysis of several approaches and algorithms that have been looked at for identifying emotions on people's faces using FERC (CNN-LSTM). This study has an accuracy rate of 78-96% by using the Viola Johnes Face Detection dataset Moolchandani et al [22].

TABLE II. COMPARING THE PERFORMANCE OF PROPOSED METHOD WITH EXISTING METHOD

Approach	Dataset	Accuracy (%)
Places205, ResNet-50, VGG	Flickr	67.68%
FLT+C3D	FACES Lifespan	74.38%

D. Discussion

The suggested system achieves high emotion identification accuracy while maintaining data privacy by integrating Federated 3D-CNN with multimodal emotion recognition. It provides a complete method for improving emotion detection performance in decentralized learning environments by weighted integration of audio and visual modalities. Current algorithms suffer from low learning rates and low accuracy when it comes to recognizing emotions from video recordings, sometimes misinterpreting the same emotion states. Moreover, several frameworks suffer from imprecision in recognizing emotions, especially in transitional states like "afraid" or "angry," which may prevent them from providing administrators and students with comprehensive feedback [12]. Previous studies in emotion detection and sentiment analysis for language learning faced challenges with limited accuracy and real-time performance due to insufficient model complexity. They often struggled to integrate spatial and temporal data effectively, resulting in less effective emotional feedback and adaptive learning responses. [13]. To solve these shortcomings, the proposed architecture, on the other hand, combines auditory and visual aspects and uses federated learning to increase accuracy and learning speed. Using deep federated 3D-CNN and LSTM algorithms, which identify emotions at a high-level granularity of six emotion states, significantly improves the accuracy of emotion recognition. Even yet, there is still a chance that the recommended technique may encounter issues, such as scalability issues when working with large datasets and potential biases in emotion recognition. To address these limitations, future work should focus on studying other deep learning architectures, optimizing the federated learning process, and expanding the current understanding of emotion detection by integrating additional modalities.

VI. Conclusion and Future Work

This study presents a novel approach for enhancing language learning environments by utilizing real-time emotion detection and sentiment analysis through the integration of Federated 3D-CNN and LSTM networks. By leveraging these advanced technologies, the study addresses the limitations of traditional methods in providing comprehensive feedback on student interactions in classroom settings. The proposed framework accurately predicts human emotions, achieving a prediction accuracy of 97.72%, and offers valuable insights into students' emotional language patterns. The integration of text analysis and image recognition enables the modification of teaching strategies to better cater to individual student needs, ultimately aiming to enhance students' language competence.

Moving forward, several avenues for future research emerge from this study. Firstly, the proposed framework could be further validated and refined through longitudinal studies conducted in diverse educational settings to assess its scalability and generalizability. Additionally, incorporating real-time feedback mechanisms into the framework could enhance its utility in facilitating immediate adjustments to teaching strategies based on students' emotional states. Furthermore, exploring the application of the framework in other educational domains beyond language learning, such as STEM education or special education, could broaden its impact and applicability. Moreover, investigating the ethical implications and privacy concerns associated with deploying emotion detection technologies in educational settings is essential for ensuring responsible implementation. Finally, advancements in hardware capabilities and algorithmic developments may offer opportunities for optimizing the computational efficiency and performance of the framework, paving the way for more widespread adoption in educational practice.

Abstract—**In programming education, code-mixed text using multiple languages or dialects simultaneously can significantly hinder learning outcomes due to misinterpretation and inadequate processing by traditional systems. For instance, students with bilingual or multilingual backgrounds may face difficulties with automated code reviews or multilingual coding tutorials if their code-mixed queries are not accurately understood. Motivated by these challenges, this paper proposes a Federated Bi-LSTM Model for Feature Extraction and Classification. This model leverages Bidirectional Long Short-Term Memory (Bi-LSTM) networks within a federated learning framework to effectively accommodate various code-switching methodologies and context-dependent linguistic elements while ensuring data security and privacy across distributed sources. The Federated Bi-LSTM Model demonstrates impressive performance, achieving 99.3% accuracy nearly 19% higher than traditional techniques such as Support Vector Machines (SVM), Multilayer Perceptron (MLP), and Random Forest (RF). This significant improvement underscores the model's capability to efficiently analyse code-mixed text and enhance programming instruction for multilingual learners. However, the model faces limitations in processing highly specialized code-mixed text and adapting to real-time applications. Future research should focus on optimizing the model for these challenges and exploring its applicability in broader domains of computer-assisted education. This model represents a substantial advancement in language-aware computing, offering a promising solution for the evolving needs of adaptive and inclusive programming education technologies. This advancement has the potential to transform language-sensitive computing, providing significant support for multilingual learners and setting a new standard for inclusive programming education.**

Keywords—Code-mixed text; text processing; federated learning; bidirectional long short-term memory; programming education; real-time applications; computer-aided education

I. Introduction

Computer programming learning can be considered as a training process that helps students enhance their computational thinking abilities. Computational thinking is an essential skill that enables individuals to build and utilize the conceptual framework of computing. That is, computational thinking capacity encompasses a wide range of abilities, including logical reasoning, algorithmic choosing, and organized thinking, all of these can be applied to problem handling in a variety of learning situations or everyday life, not only in the academic arena of computational science. They provided a theoretical framework for computational analysis divided into five main groups: conditioned logic, algorithmic development, troubleshooting, simulations, and decentralized computation. These sections focus on the skills required for programming for computers, such as developing, designing, understanding, altering, and using programs [1] [2] [3]. This paradigm also exposed the social cooperative aspect of programming labour through distributed computation. These talents are the capabilities required for the generations to come to create knowledge and solve challenges in their online environments, implying that they represent a new education for all people in a digital age. Computational thinking abilities are essential not just for developers of computers, but for all prospective global citizens. This is because certain nations have recently added capacities for computational thinking in their school requirements [4] [5]. To accurately assess students' computational reasoning skills, a dependable and user-friendly tool for instructors and computers educators is required. From an educational standpoint, investigating learners' beliefs regarding their own skills in programming for computers, or self-esteem for computer programming, could offer an easy solution. It can happen that certain learners might reject the subject matter of programming in computers due to dissatisfaction and their computational thought processes five categories could appear differently depending on the methods [6] [7].

India's linguistic diversity, shaped by a long history of foreign contact, results in widespread bilingualism and frequent code-mixing. English, an adopted language, is deeply embedded in the educational system, fostering comfort with bilingual communication among the populace. This phenomenon leads to the development of unique speech variants like Hinglish (English-Hindi) and Benglish (English-Bengali) [8]. Code-switching alternating between languages or dialects within a conversation is a common occurrence. Unlike code-mixing, which integrates words, phrases, and morphemes from different languages into a single sentence, code-switching involves shifting between different grammatical structures or components within the same interaction [11] [12]. However, the frequent use of code-mixed text poses significant challenges in educational settings, particularly in programming education. Traditional systems often misinterpret such text, leading to inadequate processing and hindering learning outcomes [9] [10]. This paper addresses these issues by proposing a Federated Bi-LSTM Model for Feature Extraction and Classification. The model utilizes Bidirectional Long Short-Term Memory (Bi-LSTM) networks within a federated learning framework to handle various code-switching methodologies and context-dependent linguistic elements while ensuring data security and privacy across distributed sources. Previous research has explored different aspects of sentiment analysis and language processing, yet handling code-mixed text in programming education remains an unresolved challenge. Traditional sentiment analysis systems struggle with complex linguistic phenomena such as sarcasm, humour, and cultural references, which are often overlooked. The proposed model represents a significant advancement in language-aware computing, offering a robust solution for accurately analysing code-mixed text and enhancing programming instruction for multilingual learners.

The mixing of codes is the use of grammar and vocabulary from various languages in the identical phrase. Code Mixing is a phenomenon of language that can happen in a multilingual environment where people communicate multiple languages at the same time [13] [14]. The issues in the Hindi-English code-mixed text were identified utilizing a PoS tag-annotated corpus [15]. To address the issue of shallow processing of Hindi-English code-mixed online information, an algorithm can recognize the script of the phrases, normalize them to their standardized forms, apply a PoS tag, and split them into pieces [16]. It is common in multilingual society and provides significant challenges to NLP applications such as sentiment analysis. The lack of a standard grammar for code-mixed sentences makes it difficult to determine composing language, which is necessary for sentiment evaluation utilizing based on rules and artificial intelligence techniques. In addition, when combining is up to each individual, there is no set mixing recommendations, which is a significant disadvantage. As an outcome, so as to analyse emotion on code-mixed information, novel programming representations must be created. Machine learning approaches play a vital role in characteristic extraction for processing code-mixed textual content, specifically in the context of computer programming training. By leveraging techniques including NLP and deep learning, those strategies' purpose to identify and extract relevant features from code-mixed textual content, which includes multiple languages. Feature extraction strategies might also encompass tokenization, component-of-speech tagging, syntactic parsing, and semantic evaluation to the particular traits of code-mixed textual content in computer programming. These extracted capabilities aid as inputs to machine learning methods for diverse responsibilities which include code recommendation, blunders detection, and automatic assessment of programming assignments. Effective characteristic extraction is critical for reinforcing the accuracy and efficiency of code-blended text processing structures in computer programming education, ultimately facilitating better learning practices and belongings for scholars in multilingual environments.

The problem statement arising from the reviewed research turns around effectively processing and understanding code-mixed text throughout various languages in different contexts. Code-mixed text poses challenges for sentiment evaluation, classification, and proficiency due to linguistic versions, cultural references, and casual language usage. Existing techniques struggle with imbalanced datasets, lack of complete lexicons, and limitations in generalizability to various linguistic contexts. Pre-processing strategies may not absolutely capture the intricacies of code-mixed languages, leading to errors in class and sentiment evaluation [19] [23]. These challenges prevent accurate extraction of functions and category of code-mixed text, impacting responsibilities along with sentiment evaluation and language identity. Therefore, there may be a need for superior models which could effectively pre-process code-mixed textual content, extract applicable capabilities, and accurately classify it, overcoming the limitations of current methods to facilitate better understanding and evaluation of code-blended data.

This paper aims to address the challenges of processing code-mixed text in programming education, particularly for multilingual learners. It introduces a Federated Bi-LSTM Model for Feature Extraction and Classification, leveraging Bidirectional Long Short-Term Memory (Bi-LSTM) networks within a federated learning framework. The model is designed to handle various code-switching methodologies and context-dependent linguistic elements while ensuring data security and privacy. The paper emphasizes the model's high accuracy and significant improvement over traditional techniques, highlighting its potential to enhance programming instruction for multilingual learners. Additionally, it discusses limitations in processing specialized code-mixed text and adapting to real-time applications, proposing future research directions to optimize the model and explore its broader applicability in computer-assisted education.

The key contributions of the study are given below:

- This work presents a novel Federated Bi-LSTM Model designed specifically for teaching computer programming through code-mixed text processing. In a federated learning framework, this model incorporates Bidirectional Long Short-Term Memory (Bi-LSTM) neural networks in a novel way, guaranteeing that feature extraction and classification tasks are carried out effectively while adhering to strict data privacy standards.

- This study addresses several issues related to Code-Mixed Text Processing, such as contextual language aspects, different code-switching methods, and adaptability to different programming languages and learning environments. The suggested paradigm provides a complete way to handle code-mixed text by overcoming these obstacles.

- Federated Bi-LSTM outperforms SVM, MLP, and RF with an accuracy of 99.3%. This demonstrates how well it works to improve code-mixed text feature extraction and classification, boosting the dependability of teaching resources for programming.

- Through its accommodation of varied linguistic origins, the paradigm fosters inclusion and increases accessibility and equity in programming education.

This study's rest of the section is organized as follows. Section II includes the previous research on the code-mixed data processing. Problematic statement discussed in Section III. Section IV discussed the proposed method and the outcome of findings. Finally, Section V provides the conclusion of the paper.

II. Related Works

Gasiorek and Dragojevic [17] discussed about the participants viewed English-based web materials from fake groups which had either no mixing codes, Hawaiian terms without parenthetical interpretations, or Hawaiian words with English interpretations. Compared with inadequate mixing codes, code-mixing without glosses disturbed manufacturing, making members feel less accepted in the workplace. Code-mixing with gloss did not affect communication for individuals from Hawai'i, where it is widespread, but it did for others. No changes in being accepted were seen among mixing of codes with gloss and no combination of codes configurations. The findings suggest that mixing of codes in textual structured resources may result in expenses and advantages, and that these effects are dependent on the audience's familiarity with mixing of codes as a method and the structure of code-mixing. It may additionally limit the generalizability of the findings to other linguistic or cultural contexts. The results of code-mixing on workplace popularity and dispatch, doubtlessly overlooking other crucial elements that could have an impact on these outcomes, which include individual language ability levels. The study's reliance on self-pronounced perceptions of contributors can also introduce bias or inaccuracies within the statistics accumulated. The study's scope is limited to examining the effects of code-mixing with and without glosses, potentially overlooking other versions in code-mixing practices that would also affect verbal exchange and popularity inside the place of workplace.

Kodirekka and Srinagesh [18] discussed the Sentiment extraction from English-Telugu code-mixed data. The programming language used to access data from the API provided by Twitter must be a mixed Telugu and English code. That data consists of phonetically typed, noisy, lexicon-borrowed, code-mixed, unstructured text, and misspelled words. The identification of languages and emotional labels for classes are applied to every tweet in the collection of tweets as the first phase. The work of data standardization comes in second, and classification, the last phase can be accomplished in three ways: lexicon, machine learning, and deep learning. As part of the lexicon-based strategy, assign an appropriate language identifier to each and every tweet. Transliterate the roman script into Telugu words when the language used in the tag is in that language. Sentiment extraction from Telugu words is done using TeluguSentiWordNet, and sentiment extraction from English tokens is done using English SentiWordNets. This work proposes and applies, using data that has been normalized, an aspect-based sentiment analysis method. Sentiment scores are extracted using deep learning and machine learning approaches, and the outcomes are contrasted with earlier research. Its reliance on sentiment lexicons won't effectively capture the complexities of sentiment in code-blended textual content. These lexicons may not cover all viable versions and contexts of sentiment expressions in Telugu and English, main to inaccuracies or biases in sentiment extraction. Method of transliterating Roman script into Telugu words can also introduce errors, mainly for code-mixed text containing slang, abbreviations, or unconventional spellings. A factor-based totally sentiment evaluation method may forget about positive elements applicable to code-blended text, inclusive of cultural references or linguistic conventions unique to Telugu-English mixing. The evaluation with earlier studies may not absolutely interpretation for differences in dataset composition, preprocessing techniques, or evaluation metrics, restricting the validity of the contrasted consequences.

Madasamy and Padannayil [19] discovered that challenging to extract relevant information from large amounts of text. Social media has presently offered numerous options for scholars and professionals to do proper studies in this field of study. A large amount of the written material on social media platforms is in English or a code-mixed language of the region. In a nation that is bilingual like India, mixing of codes is common in social media debates. Multilingual customers usually utilize Roman script, an easier means of communication, rather than the local script when publishing comments on social media, and they commonly blend it with English in their native language. Stylish and syntactic inconsistencies present substantial obstacles in analyzing code-mixed text employing traditional methods. This research uses the ICON-2015 and ICON-2016 NLP tool challenge data sets to describe the novel word embedding via letter base encoding as characteristics for POS tagging code-mixed text in Indian languages. The suggested word embedding characteristics are contextually added, and the algorithm was trained using the widely used Support Vector Machine (SVM) classifier. Its dependence on the ICON-2015 and ICON-2016 NLP device assignment datasets, which won't completely represent the range and complexity of code-mixed text located in social media systems. These datasets may not capture the extensive range of linguistic versions, cultural references, and informal language utilized in real-international social media conversations. Word embedding techniques for part-of-speech (POS) tagging code-blended text in Indian languages may not generalize well to different language pairs or code-mixing situations outdoor of the Indian context. Use of Support Vector Machine (SVM) classifier might also constraint its overall performance in comparison to greater advanced device studying or deep getting to know strategies, in particular while dealing with the stylistic and syntactic inconsistencies essential in code-mixed text. POS classification might also overlook other critical elements of code-mixed text processing, consisting of sentiment analysis.

Tareq et al. [20] addressed that online review comments regularly mix languages, use foreign characters, and do not follow traditional grammar conventions. A shortage of identified code-mixed data in a low-resource languages such as Bangla complicates computerized sentiment analysis. To solve this, this study collected online feedback on various goods and created an augmented Bangla-English code mix database. On these sentiments collections we also evaluate several additional models from the available research. To increase cross-lingual contextual awareness, this study describes an inexpensive but successful data augmentation strategy that can be used using current word embedding methods and does not require an additional database. The outcomes from the experiments indicate that using our data augmentation method to train word-embedded algorithms may assist the model's accuracy in gathering the cross-lingual connections for code-mixed sentences. This can enhance the overall efficacy of current machine learning models in both supervised learning and zero-shot cross-lingual flexibility. The dataset used in this study may not completely establish the range of code-mixed languages. The effectiveness of the proposed data augmentation strategy may additionally range throughout one-of-a-kind languages, and its generalizability to different low-aid languages beyond Bangla can be limited. Sentiment evaluation cannot recollect the whole variety of factors that may affect model overall performance, inclusive of domain-precise language variations in sentiment analysis. Word embedding strategies for go-lingual contextual focus may also inattention to different approaches or strategies that could enhance the model's accuracy. The evaluation of the model efficacy may be restricted through the provision and representativeness of the accumulated online feedback data.

Srinivasan and Subalalitha [21]investigates the issue of disparity between classes in sentimental analysis, highlighting its significance. There has been limited research on sentimental analysis with an unequal class label distribution. The paper also discusses another facet of the issue, which incorporates the idea of "Code Mixing." Code mixed data includes text that alternates among two or more languages. Unequal class distribution is a frequently seen phenomenon in code-mixed data. Existing research has primarily focused on sentiment analysis in monolingual data, rather than code-mixed data. This work tackles all of these challenges and proposes a strategy for analysing sentiments for a class imbalanced code-mixed dataset using a method of sampling along with Levenshtein distance measures. Specific method of sampling combined with Levenshtein distance measures to deal with class imbalance in code-mixed datasets for sentiment evaluation. This method may additionally offer insights into mitigating class disparity, its effectiveness can be sensitive to the characteristics of the dataset and the languages involved inside the code mixing. The proposed method's applicability to specific languages or code-mixing eventualities is probably limited, as sampling techniques and distance measures to yield various outcomes across linguistic contexts. The assessment of sentiment analysis performance using this approach won't absolutely capture the challenges inherent in real-world code-combined facts.

Jain, Jindal, and Jain [22] offered a solution for code-mixed Hindi-English social media writing that includes language recognition, detection, and rectification of both non-word and real-word problems that happen concurrently. Each recognized languages have unique obstacles and difficulties. Errors are recognized separately in every language, and a suggested list of incorrect terms is generated. Following that, a fuzzy graph between distinct phrases from the suggested lists is created utilizing various semantic relationships in Hindi WordNet. The context-embedded data and fuzzy graph-based similarity measurements are utilized to identify the correct term. Several studies are carried out on various social media databases sourced from the social media platform, YouTube, Twitter, feedback, blog posts, and Messenger. This method may be restrained by means of accuracy of Hindi WordNet, probably leading to inaccuracies in the identification of accurate phrases, especially for much less common or specialised vocabulary. The effectiveness of the solution may range throughout different social media platforms and textual content sorts, as the linguistic patterns and code-mixing phenomena can range notably between platforms and user communities. It can be stimulated with the aid of the best and representativeness of the social media databases used for evaluation, as biases or inconsistencies of data to affect the generalizability of the findings. The solution's scalability to other language pairs or code-mixing eventualities past Hindi-English can be restricted, as the proposed technique might not fully generalize to different linguistic contexts.

Shanmugavadivel et al. [23] suggested a method that uses a code-mixed collection of Tamil and English languages. To address the group's imbalances issue, resample is used, and the effect is evaluated. Initial processing incoming textual information can help code-mixed data categorization by eliminating extraneous content. The purpose of this study is to investigate the influence of pre-processing on Tamil code-mixed data using a variety of methods for pre-processing such as symbol elimination, repeating text elimination, and spelling and grammar, sign, and numerical removal. The pre-processed text is used to train classical deep learning, machine learning, transfer learning, and hybrid deep learning models, and the precision of each model is evaluated before and following preprocessing. Conventional machine learning methods rely on several weighing methods for choosing features. The primary goal this study's findings are to create hybrid deep learning algorithms that combine CNN with LSTM and CNN with Bi- LSTM in order to automatically gather both global and local characteristics from code-mixed data for sentiment evaluation and then categorize the Tamil code-mixed information to identify favourable, adverse, mixed feelings, and unknown state. The effectiveness of hybrid deep learning frameworks has been assessed through assessing them to modern approaches that included various conventional methods. The dependence on pre-processing techniques for dealing with code-mixed data, which won't completely capture the intricacies of Tamil and English languages. The effectiveness of CNN with LSTM and CNN with Bi-LSTM models can be stimulated through elements including hyperparameter tuning and dataset length. The assessment of the models' effectiveness may also be restrained by means of the choice of metrics used, possibly overlooking positive distinctions in sentiment analysis. The assessment of modern strategies might not absolutely capture the improvements in the subject, as more recent strategies. The generalizability of the findings may be confined if the dataset used isn't always representative of actual global code-mixed statistics throughout specific domain names or contexts.

Nelatoori and Kommanti [24] present a Co-Attentive Multi-task Learning framework based on transfer learning for understanding Hindi-English (Hinglish) texts with limited resources. The collaborative goals of rationale/span identification and hazardous comment categorization form a strong multifaceted learning purpose. This task interaction element is intended to take advantage of the bidirectional awareness provided by the categorization and span forecasting activities. The model's combination function of loss is derived from the separate loss coefficients of these two jobs. Though an English harmful span identification dataset exists, there is currently no Hinglish code-mixed text database. As a result, they created a set of data that includes harmful span classifications for Hinglish code-mixed text. Harmful span classifications in Hinglish code-combined text. The synthetic generation of facts won't fully seize the range and complexity present in actual-world situations, probably excluding the version's ability to generalize effectively. The absence of a longtime Hinglish code-combined text database increases worries approximately the version's adaptability to diverse linguistic variations and contexts within Hinglish. The effectiveness of difference in a constrained-aid placing will also be restrained via the supply and representativeness of the pre-skilled models, probably affecting the version's overall performance on unique responsibilities. The selected multi-mission approach may introduce dependencies between tasks, and the version's performance can be sensitive to the stability between cause/span identification and risky remark categorization goals.

Above studies highlights the challenges and solutions in code-mixed textual content processing across different domains. One look at explores the impact of code-mixing on administrative centre dynamics, revealing how glosses have an effect on communication and popularity. Another discusses sentiment extraction from English-Telugu code-mixed data, providing lexicon-based totally and deep learning methods. Focus on word embedding for POS tagging in Indian code-mixed text is seen in another study. Introducing a Bangla-English code-mixed sentiment dataset and a statistics augmentation technique is the point of interest of a distinct examine. Addressing sentiment evaluation in imbalanced code-mixed datasets is another thing explored. A method for correcting mistakes in Hindi-English code-blended social media content material is proposed in a single examine. Pre-processing and deep learning models for Tamil-English code-combined sentiment evaluation is offered in every study. A Co-Attentive Multi-Undertaking Learning framework for Hindi-English textual content know-how is advanced. That research makes a contribution insight into the complexities of code-mixed text processing and suggests diverse methodologies to cope with those demanding situations, even though with capacity boundaries in generalizability and effectiveness.

III. Proposed Federated Bi-LSTM Model for Feature Extraction and Classification in Code-Mixed Text Processing

The data collection system for SentMix-3L, a Bangla-English-Hindi code-combined dataset, involves several steps. Firstly, a wide variety of text information is combined from computer programming, boards, and different online resources in which code-mixed conversations are regularly occurring. The collected data undergoes preliminary preprocessing to take away noise, consisting of inappropriate content material or reproduction entries. Subsequently, the textual content is tokenized to interrupt it down into words or tokens, considering the linguistic distinctions of all 3 languages involved. After tokenization, the sentences are labelled primarily based on language to ensure proper handling of code-mixed segments. This step is crucial for retaining the integrity of the code-mixed dataset and allowing accurate evaluation. Following sentence classification, the data is partitioned into suitable training, validation, and test sets for model improvement and assessment. The Federated Bi-LSTM Based Feature Extraction and Classification process then makes use of a decentralized method to model training, where Bi-LSTM architectures are deployed at multiple nodes, maintaining nearby data. The models are learned domestically through the use of federated learning techniques, changing version updates even maintaining data privateness. Model aggregation is done to mix the local models' parameters, creating an international version capable of extracting functions and classifying code-mixed text accurately. This methodology guarantees effective data preprocessing, language-aware tokenization, and decentralized model training for strong feature extraction and classification in code-mixed textual content processing. Fig. 1 provides the block illustration of the proposed federated Bi-LSTM model.

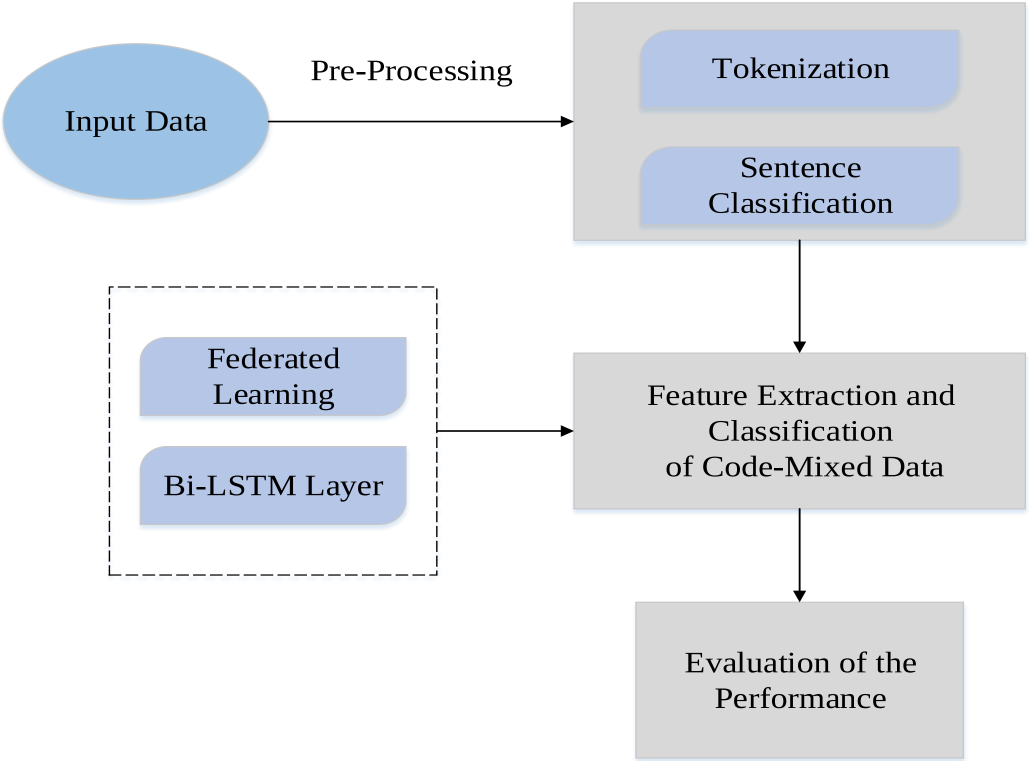

Fig. 1. Block illustration of the proposed federated Bi-LSTM model.

A. *Data Collection*

The data collection process for SentMix-3L, a Bangla-English-Hindi code-combined dataset for sentiment evaluation. This dataset became especially intended to address the need for resources in code-blended sentiment evaluation throughout multiple languages to gather data, researchers employed various techniques to make sure variety and representativeness. This procedure involved significant manual looking and scraping strategies to acquire a variety of code-mixed textual content samples encompassing Bangla, English, and Hindi languages. The researchers collaborated with language experts and native speakers proficient in Bangla, English, and Hindi to verify the authenticity and accuracy of the gathered data. Stringent quality control measures had been implemented to filter out noise and inappropriate content, ensuring that the dataset comprised significant times appropriate for sentiment analysis duties. The very last dataset, consisting of 1,007 instances, underwent thorough validation to confirm its suitability as a level for sentiment analysis inside the context of code-blended textual content processing across three languages. The data collection technique for SentMix-3L involved a mixture of manual curation, expert validation, and high-quality assurance techniques to create a treasured useful resource for advancing research in code-combined sentiment evaluation [25]. Table I gives the sample of SentMix-3L dataset.

TABLE I. SAMPLE OF SENTMIX-3L DATASET

	English	Hindi	Bangla	Other	All
Standard Deviation	2.94	5.81	8.39	9.70	19.19
Average	5.96	15.03	31.91	35.98	88.87
Types	1073	1474	8167	9092	19686
Tokens	5998	1474	32133	36232	89494

B. *Data Pre-Processing using Tokenization and Sentence Classification*

Data pre-processing is an essential phase in improving and extracting relevant findings from the information. It removes shortcomings and discrepancies in data. Inaccuracies in data can lead to incorrect or incomplete data, affecting its precision. During the phase of preprocessing, execute these procedures:

1) Tokenizing: To improve the quality of the data, unnecessary content, such as Hyperlinks and html text, is deleted utilizing regex-based pattern recognition after data acquisition. The sentences were tokenized into words using NLTK Tokenizer. The sentences with fewer than five phrases were eliminated due to their noise and lack of data. To implement the NLTK tokenizer for Bangla and Hindi, modify the result to adjust for differences in punctuation between English, Hindi, and Bangla.

2) Sentence classification: The database is separated into three scripts: English-Hindi, English-Bangla, and English (monolingual). The sentences that are not written in English-

Hindi or English-Bangla script will be removed in the initial phase.

```
Sentence Classification Algorithm
Input: Sentence
Codes: $\alpha$refers the English script, $\beta$ refers the English-Hindi script, $\gamma$ refers the English-Bangla script
Output:$\alpha,\beta,\gamma$ (sentence classification)
Stage 1: Read the input
Stage 2:Calculate the length of input
Stage 3: Split the input into$v_1, v_2, \dots \dots .v_n$
Stage 4: Each terms refers $v_i = 1$ to n
        if $v_i$=English
            Increase the value of count
 else, Stop
End for

Stage5: if value of the count =words extracted from input
$\alpha$, or$\beta$, or $\gamma$
Stage 6: End
```

The sentence classification system distinguishes between code-mixed (β, γ) and non-code-mixed (α) phrases. The system receives phrases as input and divides them into words ($v_1, v_2, \dots \dots .v_n$). The linguistic detector checks every single word in the sentence to determine if it is English or not. Code mixed phrases are those that include non-English terms. Using the sentence classification technique, 600 sentences were identified as (α) and eliminated from the sample.

C. Federated Bi-LSTM based Feature Extraction and Classification in Code-Mixed Text Processing

Federated Bi-LSTM (Bidirectional Long Short-Term Memory) is a novel approach in code-mixed text processing that addresses the challenging situations modelled by using code-mixed textual content, in which multiple languages are mixed in the same sentence. This approach utilizes federated learning data of, a decentralized method to educate Bi-LSTM models on data chosen from exceptional sources without centralizing the data. The Bi-LSTM neural structure is employed for feature extraction from code-mixed textual content. Bi-LSTM networks are especially powerful in capturing long-range dependencies and contextual data in sequential information. By processing text bidirectionally, these networks can effectively capture the features present in code-mixed language. The trained Bi-LSTM models are then used for classification on code-mixed textual content, along with language identification, and sentiment analysis. The federated learning framework assurances privacy and data security by means of allowing models to train locally on distributed data resources without sharing raw data. Fig. 2 shows the architecture diagram of Bi-LSTM.

Federated learning is a decentralized learning approach that incorporates data from various sources using privacy-protected technology to generate a worldwide framework. During training of models, individuals are able to share necessary details regarding the model (variables, framework, range, etc.) using various methods (e.g., simple text, data encryption, sound), but local data used for training is not shared. The exchange of information protects local user data and reduces the risk of information leakage. Federated learning models can be distributed and implemented by multiple users [26]. The training procedure can be divided into three parts:

Step 1- Initialization of Task: The central server sets the learning the desired level, variables, and output components, then sends a global model (v_g^0) to the device.

Step 2-Training and Update of the Training Model:The global framework v_g^t has been obtained from the server where it is stored, and $t$denotes the present learning process. The device i learns the model's data on its own and modifies parameters such as v_i^t. The purpose of the training process is to discover the most suitable localized version by reducing the loss functions ($l(v_i^t)$ and uploading it to a server using the latest local version variable (v_i^a). It is given in Eq. (1).

$$v_i^a = arg_{v_i^t}\, minimum(l(v_i^t)) \tag{1}$$

Step 3-Accumulation and update of the Global Model: In Eq. (2), the server collects the parameters of the model from participating components, combines them as well upgrades the global model (v_g^{t+1}).

$$l(v_i^t) = {}^1\!/_n \sum_{i=1}^{n} l(v_i^t) \tag{2}$$

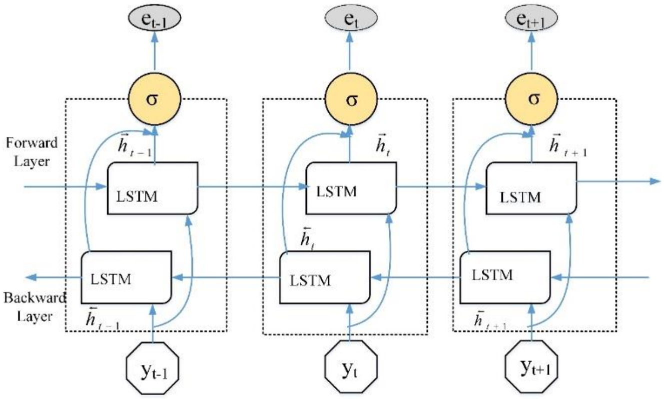

Fig. 2. Architecture diagram of Bi-LSTM.

The Bi-LSTM network captures features of input before and following processing. The present position of the Bi-LSTM secret layer is q_t. The forward-looking hidden layer state ($\overrightarrow{h_t}$) and the backwards hidden layer state ($\overleftarrow{h_t}$) can both find t. t is composed of two parts. The current state of the forward hidden layer. The currently active inpute_t and the forward-looking hidden layer state are used to determine the value of $t + 1$ at time $\overrightarrow{h_{t-1}}$. The backwards layers that are hidden values include. The present input and backwards hidden layer state ($\overleftarrow{h_{t+1}}$) determine t at time $t + 1$. The computation method is as follows:$v_i = (1,2,3, \dots \dots .6)$ represents the amount of weight transferred from a single layer of cells to subsequent. It is given in Eq. (3), (4) and (5).

$$\overrightarrow{h_t} = f(v_1 e_t + v_2 \overrightarrow{h_{t-1}}) \tag{3}$$

$$\overleftarrow{h_t} = f(v_3 e_t + v_5 \overleftarrow{h_{t+1}}) \tag{4}$$

$$q_t = g(v_4 \overrightarrow{h_t} + v_6 \overleftarrow{h_t}) \tag{5}$$

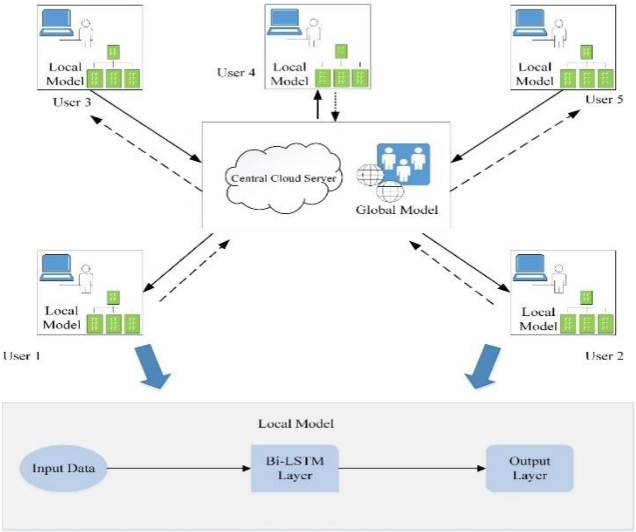

Fig. 3. Federated Bi-LSTM framework.

Federated Bi-LSTM in Code-Mixed Text Processing involves many steps. First, code-mixed textual content from numerous resources is collected and pre-processed to ensure consistency. Then, a federated learning framework is recognized, wherein multiple nodes preserve their information regionally to ensure privateness. Each node trains a Bi-LSTM neural network regionally to extract features from the code-mixed textual content. The models are trained in the usage of approaches to replace parameters. After local training, model updates are aggregated using federated averaging to create a global model. This global model is then evaluated on a separate validation to assess its overall performance in classification tasks. The technique can be iterated to refine the models in addition, incorporating feedback and updates from the federated learning knowledge of the framework. This method ensures accurate classification at the same time as keeping data privacy and security across disbursed data sources. Fig. 3 shows the framework for federated Bi-LSTM Model in code-mixed text processing.

IV. Results and Discussion

This study enables the automatic extraction of relevant features from code-mixed textual content, permitting better understanding and analysis of programming concepts conveyed in mixed-language contexts. Through strategies along with federated Bi-LSTM, effectively capture the difficult relations between different programming languages and human languages. General outcomes imply that those machine learning strategies can appropriately identify and extract code snippets, programming key phrases, and syntactic structures embedded within code-mixed textual content. They contribute to enhancing the learning enjoy by students by offering automated support in understanding multilingual programming environments, selling inclusivity, and catering to diverse linguistic backgrounds. However, challenges remain in adapting these strategies to precise programming languages, managing with versions in code-mixed textual content structures, and making sure of robustness across special academic contexts.

A. *Training and Testing Accuracy*

Fig. 4 presents the training and testing accuracy of a federated Bi-LSTM of version at specific epochs for the duration of the training manner. Each row corresponds to a selected epoch, indicating the wide variety of iterations through the training dataset. The training accuracy measures the model's performance at the data it changed into educated on, while the testing accuracy evaluates its overall performance on unseen statistics, providing an estimate of how properly the model generalizes to new times. Because the training progresses, both training and testing accuracies may additionally begin rather low. This is expected because the version learns to become aware of styles and relationships within the data. As training continues, the model's overall performance typically improves, pondered in increasing accuracy positions for each training and testing datasets. The fluctuations in accuracy ratings among epochs may also imply versions inside the model's potential to generalize. The conjunction of training and testing accuracies closer to better values to later epochs, suggests that the variety is becoming more robust and effective in both studying from and generalizing to new data, resulting in progressed universal overall performance.

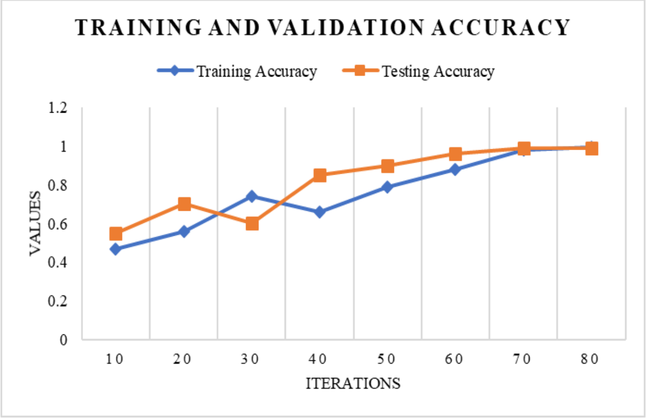

Fig. 4. Training and validation accuracy of federated Bi-LSTM.

B. *Training and Testing Loss*

Fig. 5 illustrates the training and testing values at various epochs all through the training process of a system mastering version. Loss, in this context, refers to a measurement of the type's predictions align with the real goal values. Lower loss values indicate higher alignment and, consequently, higher model overall performance. At some point in the early epochs, both training and testing loss values may additionally start incredibly high. This is expected because the version's parameters are initialized randomly, and it has no longer learned to appropriately expect the goal values. As training progresses, the version adjusts its parameters via optimization techniques like gradient descent to limit the loss characteristic. Throughout the training manner, the system's performance typically improves, leading to reducing loss values for each the training and testing datasets. Lower training loss suggests that the version is effectively from the learning data, even as lower trying out loss suggests that the model is generalizing nicely to unseen data.

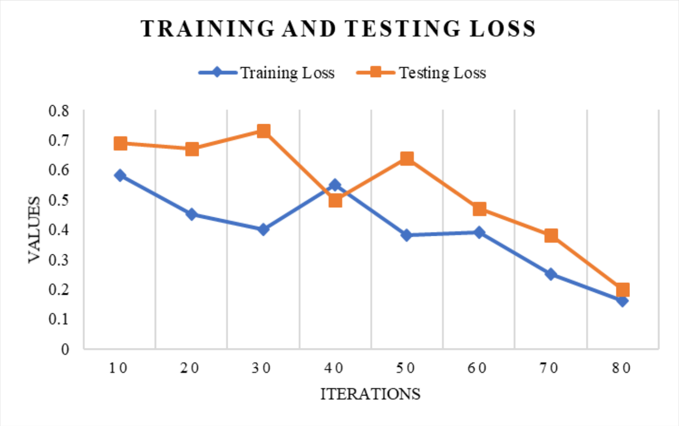

Fig. 5. Training and validation loss of federated Bi-LSTM.

C. Evaluation of Performance

Table II and Fig. 6 offer the performance metrics, inclusive of accuracy, precision, recall, and F1 score, for distinct device machine learning strategies: Support Vector Machine (SVM), Multi-Layer Perceptron (MLP), Random Forest (RF), and the Proposed Federated Bi-LSTM model. Accuracy measures the overall correctness of the model's predictions, at the same time as precision displays the proportion of efficaciously expected fine instances among all instances predicted as positive. Recall suggests the percentage of successfully expected high-quality instances amongst all real superb times, even as the F1 score is the harmonic mean of precision and don't forget, providing a balanced degree of a model's performance. Comparatively, the proposed Federated Bi-LSTM version outperforms the traditional machine learning methods, reaching considerably better accuracy, precision, remember, and F1 rating. This demonstrates the effectiveness of leveraging Bi-LSTM networks within a federated getting to know framework for code-combined textual content category duties. The advanced performance of the Federated Bi-LSTM model underscores its potential for appropriately classifying code-mixed text processing retaining data privacy and protection throughout distributed data sources.

TABLE II. COMPARISON OF PERFORMANCE METRICS

Methods	Accuracy (%)	Precision (%)	Recall (%)	F1 score (%)
SVM[27]	76.98	74.98	73.61	74.05
MLP[27]	80.22	78.08	78.8	78.31
RF[27]	77.65	75.81	75.81	75.67
Proposed Federated Bi-LSTM	99.3	99	98.9	99.5

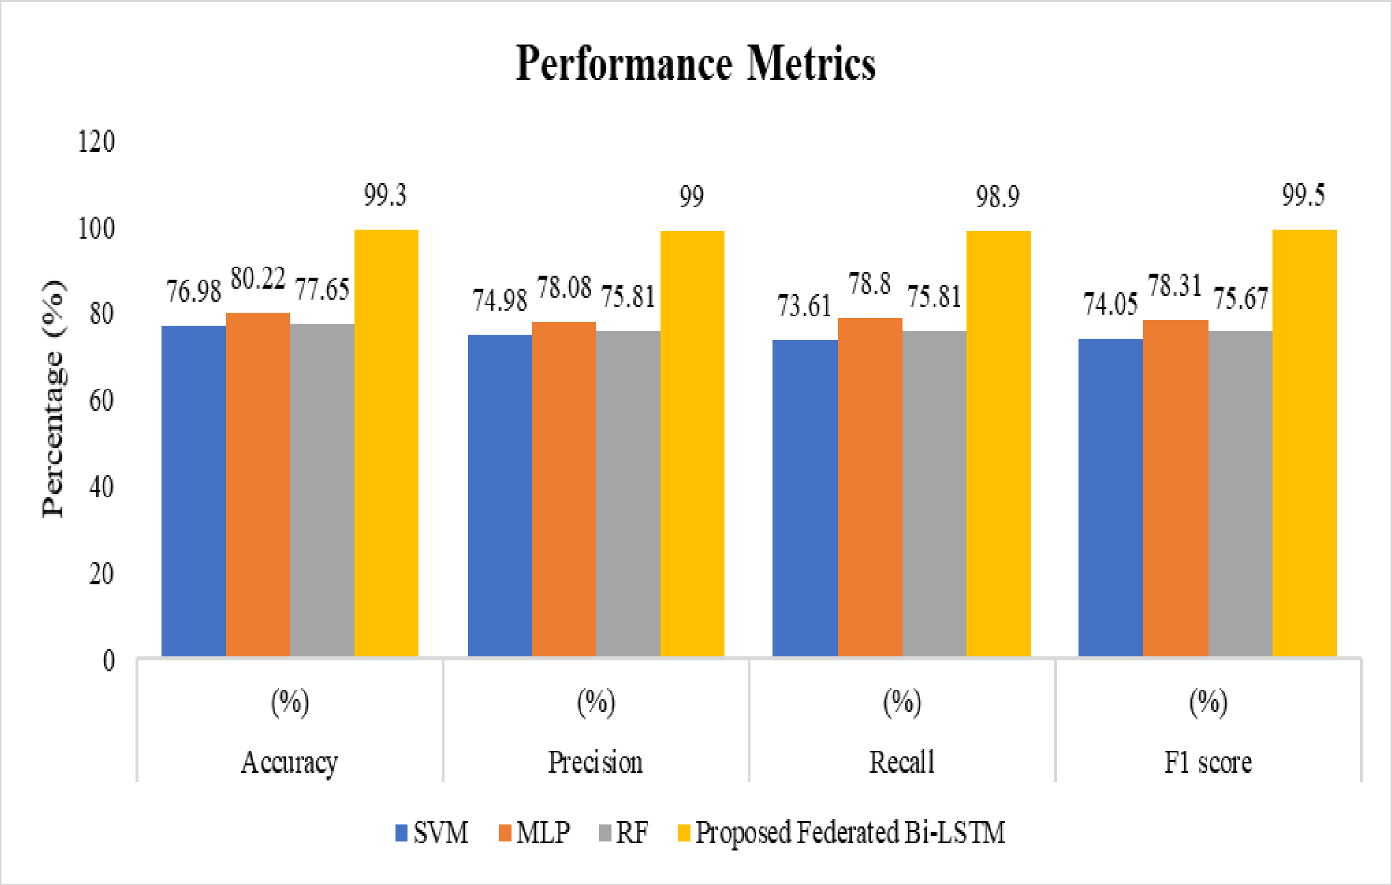

Fig. 6. Comparison of performance metrics.

D. Error Metrics Comparison

Table III and Fig. 7 offers the Root Mean Squared Error (RMSE) and Mean Absolute Error (MAE) metrics for both Support Vector Machine (SVM) and the proposed Federated Bi-LSTM model, these metrics are generally used to assess the performance of regression models by measuring the distinction among anticipated and real values. Comparing the two models, the Federated Bi-LSTM version demonstrates appreciably lower RMSE and MAE values as compared to SVM. This shows that the Federated Bi-LSTM model provides greater correct predictions with smaller errors. The superior overall performance of the Federated Bi-LSTM model shows its effectiveness in capturing complicated styles and relationships in the records, in particular within the context of code-mixed text processing. The decrease errors values show the assistance of the Federated Bi-LSTM model signify its capability to enhance predictive accuracy and improve effects in regression responsibilities, showcasing its suitability for numerous packages wherein particular predictions are essential.

TABLE III. COMPARISON OF ERROR METRICS

Metrics	SVM[28]	Proposed Federated Bi-LSTM
RMSE	0.2971	0.14
MAE	0.2304	0.076

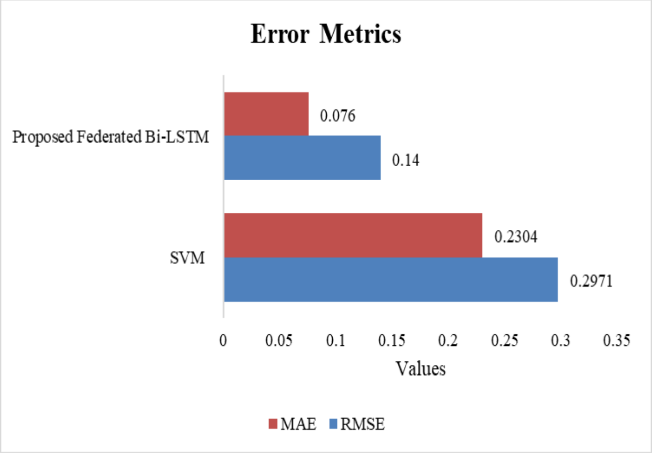

Fig. 7. Comparison of error metrics.

E. Discussion

The results of the evaluation between Support Vector Machine and the proposed Federated Bi-LSTM version, as indicated by Root Mean Squared Error (RMSE) and Mean Absolute Error (MAE) metrics, highlight the superiority of the Federated Bi-LSTM model in regression requirements. With an extensively lower RMSE and MAE, the Federated Bi-LSTM model demonstrates its capacity to offer more accurate predictions with smaller errors compared to SVM [27]. This suggests that the Federated Bi-LSTM model is skilful at capturing the intricate patterns and relationships inside the data, in particular in complicated contexts which includes code-mixed textual content processing. The decrease error values done by the Federated Bi-LSTM version represent its capability to establish predictive accuracy and reliability, underscoring its suitability for regression obligations throughout various domain names.

The rate of overall performance among SVM and the proposed Federated Bi-LSTM version underscores the importance of leveraging advanced deep learning architectures, particularly in situations concerning complicated data structures like code-mixed text. The Federated Bi-LSTM model's advanced potential to capture patterns and dependencies in the facts is vital for attaining more accurate and reliable regression predictions. This suggests that the adoption of modern deep learning techniques, blended with federated learning frameworks, can notably enhance the effectiveness of regression models, paving the manner for advanced results in various applications in which unique predictions are crucial.

V. CONCLUSION AND FUTURE WORK

The development of the SentMix-3L dataset and implementation of the Federated Bi-LSTM model are some of the huge strides toward conducting code-mixed text processing and sentiment analysis using multiple languages. With careful methods in collecting data and robust pre-processing methods used, SentMix-3L itself builds a useful tool for any researcher trying to find sentiment evaluation in code-blended text. The Federated Bi-LSTM model with the use of federated learning principles in Bi-LSTM neural networks gives better performance in accurate feature extraction and classification of code-mixed texts keeping the data private and secure. The results of such research and the potential use of machine learning techniques, in general, help learn through federated learning with Bi-LSTM models for applications in the task of solving complex linguistic phenomena and a better understanding of different multilingual contexts. However, utilizing these techniques now effectively across specific programming languages and generalizing robustness across the diversity of educational settings presents its challenges. For instance, integration into specific programming languages with unique syntaxes often presents a challenge to the system, such as in cases of real-time processing, something that is required of JavaScript for web development or Python for data science. At the same time, the effectiveness of the model could depend on the kind of different educational settings characterized by levels of digital infrastructure and language proficiency differences of students.

Work in the future on this model would aim to work in a better and fine-tuned way for some specific languages and to handle the variations in code-mixed structures of the text. On the other hand, enlarging data to add more diversity in examples of language and real-life utilization could enhance the applicability and reliability of the model. Moreover, the error metrics of the proposed model and that of traditional models, for instance in Support Vector Machine, compare very well, further asserting the supremacy of this approach. Hence, lower error values for the Federated Bi-LSTM model are generally indicative of their potential to improve the predictive accuracy and possibly refine the outcome of various applications that heavily rely on very accurate predictions. For instance, this model could be especially useful when analysing interactions on social media sites, with real-time and accurate sentiment analysis being crucial for cases in point, or in educational tools designed to support bilingual students. The union of innovative data-collection strategies with advanced machine learning techniques and rigorous evaluation methodologies paves the way for new lines of research on the processing of code-mixed text and sentiment analysis. These changes will impact drastically in making language learning more efficient, inclusive, and relevant for educational and real-life contexts across diverse linguistic backgrounds.

***Abstract*—In an era marked by a proliferation of online reviews across various domains, navigating the extensive and diverse range of opinions can be challenging. Sentiment analysis aims to extract and interpret sentiments from these vast pools of data using computational linguistics and information retrieval techniques. This study focuses on employing deep learning methods such as Deep Belief Networks (DBN) and Gated Recurrent Units (GRU) to classify reviews into positive and negative sentiments, addressing the issue of information overload in Product Reviews. The primary objective is to develop an efficient sentiment analysis system that reliably categorizes reviews as positive or negative. The study introduces a novel sentiment analysis framework combining Deep Belief Networks and Gated Recurrent Units for online product review classification, enhancing accuracy through advanced feature extraction and classification techniques. The comprehensive preparation pipeline—comprising data splitting, stemming, stop word removal and special character separation—enhances dataset refinement for improved classification accuracy. The proposed framework consists of four main phases: pre-processing, feature extraction, classification, and evaluation. During the preparation phase, the dataset is meticulously cleaned and refined to reduce noise and enhance signal quality. Significant features are then extracted from the pre-processed data using advanced feature extraction algorithms. The DBN-GRU model leverages these features for sentiment classification, effectively distinguishing between positive and negative attitudes. The framework's performance is subsequently evaluated to assess its efficacy in accurately classifying reviews. The combination of in-depth pre-processing procedures and the DBN-GRU technique yielded promising results in sentiment categorization. The framework demonstrated a high accuracy of 98.74% in differentiating between positive and negative sentiments, thereby facilitating the effective analysis of online reviews. This study presents a robust framework for sentiment analysis, utilizing the DBN-GRU method to classify online reviews. Through extensive preprocessing and advanced classification techniques, the system addresses the challenges of noise and information overload in online reviews, providing valuable insights for both consumers and businesses.**

***Keywords*—Sentimental analysis; product review; deep learning; DBN-GRU**

I. INTRODUCTION

The modern human lifestyle includes online buying daily. There are several e-commerce platforms available in the IT industry to accommodate customer expectations. Customers may update the product review for the purchases on any e-commerce site. Nowadays, every e-commerce customer has the privilege of reading product reviews on various buying websites [1]. These are typically referred to as product ratings. A range of ratings from 1 to 5 is that entire product ratings are, after all. A higher grade indicates a higher level of product quality. In addition to evaluating the goods, customers may provide their opinions. Feeling, experience, and sentiment are the three key components of any user review [2]. These variables differ from person to person. Any consumer who wants to comprehend the review must spend some time on several websites before buying a certain product. Many customers will become disinterested in purchasing the products. Recent advancements in social media sites have provided companies and organizations with the opportunity to receive assessments from their customers and through the use of consumer comments [3]. These articles are published online through social media and websites and may be in the form of text, voice, video, or a combination of all three. Specifically, social networking text data is described by short, semi-structured, unorganized sentences that are frequently filled with ordinary language. As a result, sentimental analysis and vectors models for this text data are difficult to generate and take a lot of effort [4].

Sentiment analysis is the management of emotions, opinions, and subjectively communication. Sentiment analysis, which looks at a number of tweets and comments, gives the knowledge about what the general population thinks. It is an accurate way to forecast a number of significant events, such as the popularity of film at the blockbusters and presidential race [5]. The evaluation of a particular entity, such as a person, a product, or a location, is done using public reviews, which can be obtained on numerous websites like Yelp and Amazon. The perspectives might be categorised as good, positive, or moderate. Sentiment analysis aims to identify individual the evaluative tone of main outcomes [6]. The desire for sentiment classification has grown as a result of the growing requirement to analyse and organise the complex data that results from social establishment's secret information.

By utilising polarities and combinations, sentiments encompass a wide range of highlighted values, including tri-grams and bi-grams. As a result, using training methods for different Support vector machine (SVM), sentiments are assessed as both positive and negative components [7]. Neural Networks (NN) are employed in sentiment analysis to determine the belongingness of labels. Extracted data at the consideration of the potential is aided by the contextual connections between a number of edges and vertices of an interconnected network run by Bayesian networks. By using the best possible terms and phrases on social media platforms, learning and data integrity can be attained. The construction of the data's negative and positive properties at the word system level uses data tokenization. In order to increase the precision of social media data, methods are being used to minimise sentiment classification errors [8].

The procedure of recognising and categorising the viewpoints or opinions represented in a text span utilizing retrieval of information and computational linguistics is known as opinion mining (also known as sentiment analysis) [9]. Instead of the issue itself, the viewpoint that is voiced about it is given weight. In our information-seeking behaviour before making a decision, opinion is crucial [10]. Personal blogs and online review platforms make it easier to obtain opinions on goods or services utilising information technology. By identifying characteristics and elements of the item that have been remarked on in each document, the primary goal of opinion mining is to ascertain the polarity of comments [11].

Sentiment analysis is a method for identifying and understanding the sentiments expressed in text. Thanks to the data surge in social media platforms like Twitter, and LinkedIn, individuals now have potential approaches to express their thoughts on particular goods, persons, and regions [12]. The individual's feedback is often displayed as textual information. Each day, social media sites and online businesses send and receive millions of texts and emails. Investigating and analysing the tone of the opinion is crucial. Textual data and NLP with AI skills are used to determine whether an opinion is positive, negative, or neutral. Opinion mining and emotion research are autonomous of any one network or industry [13]. It is pervasive on all kinds of social media and in a variety of fields, including management, health insurance, finance, and many more. Additionally, it is quite beneficial for the growth of numerous organizations and companies. Furthermore, sentiment analysis provides business knowledge that can be used to decide wisely and effectively [14]. Despite the fact that they each possess their own distinctive qualities, they can sometimes be used indiscriminately. Sentiment categorization shows the sentiment polarity by assigning classifiers to the content or fragment. Sentiment perspective is a sort of text summarization that arranges text data in accordance with the consciousness – of thoughts. Sentiment orientation refers to the subjective polarity of an opinion, regardless of whether it is correct or incorrect. The subjectively or objectively nature of the presented text or review data must be distinguished using the subjective analysis approach.

Lexicon-based approaches and machine learning techniques like Deep Learning can be used to classify sentiment. Lists of words and phrases having positive and negative meanings are often the foundation of the lexicon-based sentiment analysis technique. For this strategy, a dictionary of words with assigned negative and positive emotion values is necessary. These approaches are straightforward, adaptable, and computationally effective. They are therefore mostly employed to address generic sentiment analysis issues. However, lexicon-based approaches in human-labelled texts rely on human effort and can have limited coverage. They also rely on discovering the sentiment lexicon that is used to analyses the text. The key contributions of this study can be summarized as follows:

- The DBN-GRU model outperforms other models like DBN, GRU, and LSTM, ensuring reliable sentiment analysis and a better understanding of customer feedback for businesses.
- The study implements a comprehensive data preprocessing pipeline that includes data splitting, stopword removal, stemming, and special character isolation. This thorough approach significantly enhances data quality, reducing noise and improving classification accuracy.
- The proposed DBN-GRU model achieves an outstanding accuracy in classifying sentiments from product reviews, outperforming traditional models such as DBN, GRU, and LSTM. This high level of accuracy demonstrates the model's robustness and reliability in sentiment classification tasks.
- Utilizing a large dataset of 70,000 product reviews from Amazon, spanning categories like electronics, mobile phones, and instruments, the study validates the model's effectiveness across different domains. This broad application highlights the model's versatility and scalability.
- The data pre-processing process, including splitting, stemming, stop word removal, and special character separation, enhances dataset refinement, improves feature extraction, and reduces noise for accurate real-time sentiment classification.
- The deep belief network component of the model facilitates superior feature extraction, capturing intricate patterns and sentiments in the data, which are crucial for accurate sentiment classification.
- The study evaluates the model's performance using a wide range of metrics, including accuracy, precision, recall, F-measure, specificity, and sensitivity. This thorough evaluation provides a holistic view of the model's effectiveness and reliability.

- The novelty of this work lies in the innovative integration of DBN and GRU models, leveraging their complementary strengths to enhance sentiment analysis accuracy and efficiency. Unlike traditional methods, the hybrid approach combines deep feature extraction with the ability to handle sequential data, providing a more nuanced and robust sentiment analysis.

The remainder of this paper is structured as follows: The literature review is addressed in Section II. Section III provides a brief explanation of the suggested method. With the aid of graphs and tables, Section IV illustrates the outcome of the suggested strategy. In Section V, the research is finished.

II. Related Work

Li Yang et al. [15] proposed a Sentiment Analysis for Chinese e-Commerce Reviews relying on Sentiment Words and Learning Techniques. People may now purchase and use things online more frequently than ever before thanks to the remarkable technological breakthroughs in Internet technology. Mood analysis of a large number of customer reviews on e-commerce sites can effectively boost customer pleasure. The article indicates a novel attention-based Bidirectional Gated Recurrent Unit Neural Network and Convolution neural sentiment classification method dubbed SLCABG. It focuses on a language of emotions. By fusing the advantages of sentiment words with DL technology, the SLCABG approach tackles the drawbacks of the present sentiment analytical technique of brand assessments. The SLCABG system combines the advantages of sentiment words and DL techniques. The sentiment vocabulary is used to first enhance the sentiment features in the reviews. As a result, Cns and GRU networks are used to identify the main attitude features and contextual features from the reviews, and the functional form is then used to assess them. Sort the qualities that feeling judges into categories. The article cleans and scans the authentic book evaluation of the well-known Chinese e-commerce site dangdang.com, which is totally in Chinese, for testing and training purposes. The data is beneficial for various applications in the field of Chinese attitude research because it has a level of one million orders of magnitude. The empirical findings indicate that the technique may greatly increase the efficiency of sentiment analysis of text. However, the industry research suggested the technique could only divide attitudes into positive and negative categories, rendering it useless for situations where there is a limited supply of attitude clarifications.

Using DNN and weighted word embeddings, Aytug Onan presented a sentiment analysis of customer evaluations [16]. One of the main goals of processing usual language is sentiment analysis, which involves extracting sentiments, ideas, views, or judgments about a certain issue. The internet is an unorganized, comprehensive information resource with a wide variety of paper communication, including evaluations and viewpoints. Private decision-makers, Government, and commercial groups may all benefit from understanding emotion. Researchers offer a DL-based method for sentiment analysis of invention evaluations from Twitter in this article. The suggested scheme incorporates Long Short-Term Memory Networks (LSTM)- Convolutional neural networks (CNN) architectures and IDF-TF weighted Gloves word embeddings. Five phases make up the LSTM-CNN architecture: a dense layer, a weighted embedding layer, an LSTM layer, a max-pooling layer, and a convolution layer. In the exploratory study, numerous word embedding techniques with various weighting function have indeed been compared to traditional deep neural network designs to see how well they predict the outcome. According on the empirical findings, the suggested deep learning framework operates better than the traditional deep learning techniques. However, Document length might be a limitation, and therefore no one method will necessarily produce the best prediction results including all different kinds of text categorization problems.

Text Review Sentiment Analysis Using Lexicon-Enhanced James Mutinda et al. [17] suggested using a CNN using the Bert Integration Scheme. Within the discipline of naturally occurring language processing, the study of attitude has gained importance. The technique can be applied in a variety of settings, such as politics, economics, and online review systems for businesses. To be effective, sentiment analysis involves trustworthy text summarization techniques that can convert words into precise vectors that accurately represent the text information. ML -based techniques and lexicon-based methods are two types into which text reconstruction techniques can be classified. According to studies, both methods have drawbacks. For illustration, pre-trained word embeddings produce vectors by neglecting additional factors like word sentiment orientation and instead focusing on word distance, commonalities, and appearances. The study introduces a sentiment categorization method that combines a CNN, N-grams, sentiment lexicon, and BERT, in an effort to overcome such restrictions. Words chosen from a portion of the input sentence are vectorized in the system using N-grams, sentiment lexicon, and BERT. CNN is a deep neural system classifier that maps features and assigns a sentiment category as an output. Three open datasets are used to assess the suggested approach. The model's performance measures include F-measure accuracy and precision. According to the test findings, the suggested method performs more effectively than the currently available state-of-the-art approaches. The article has certain restrictions. Only the convolutional neural network was employed in the constructed method.

Zhengjie Gao et al. [18] suggested Target-Dependent Sentiment Classification With BERT. Sentiment examination is one of the frequently used applications of machine-assisted textual analysis, which has been rapidly developing alongside online technology. Conventional sentiment analysis techniques call for intricate feature engineering, and embedded interpretations have largely dominated leader boards. Nevertheless, because of their context-independence, they have limited representational strength in rich context, which negatively affects how well they do Natural Language Processing activities. The current standard for character recognition is BERT, which outperforms previous pre-trained language models in 11 Natural language processing tasks by a significant margin. BERT has been used less frequently for sentiment categorization at the relation to the issue since it is a particularly difficult assignment. With outputs located at target words and an additional phrase with the objective built in, researchers develop three target-dependent versions of the BERT base paradigm. Studies on three types of data demonstrate that, in contrast to conventional features engineering techniques, embedding-based approaches, and older BERT implementations, the TD-BERT approach provides different state-of-the-art efficiency. The investigations aim to determine if context-aware representations of BERT may produce a comparable performance gain in aspect-based sentiment analysis given its effective delivery throughout many NLP applications. It's fascinating to see that merging it with advanced NN that traditionally conducted superbly with integrated caricatures did not always enhance efficiency above that of the basic BERT-FC version. On the contrary side, inclusion of the goal information demonstrates steady improvement in accuracy, and the experiment reveals the best strategy to use that knowledge. Yet, the classification performance of neutral situations is substantially lower than that of instances with a distinct polarity, and it is much more difficult to handle cases with mixed emotion polarities relating to the same target or various features.

The Sentiment Analysis of Explanations Texts Based on BiLSTM was developed by Guixian Xu [19]. A substantial amount of comments text is created on the Web as a result of the quick growth of social networks and online technologies. In the age of big data, it is beneficial to use AI technologies to mine the emotional tendencies of feedback in order to quickly comprehend online public sentiment. Artificial intelligence includes sentiment analysis technologies, and its study is particularly important for determining the sentiment trends of the comments. The basis of sentiment classification is the text summarization issue, and different words each participate to classification in a different way. The majority of the most current sentiment classification experiments use generalised phrase models. However, generalised sentence reconstructions only include the semantic aspects of the phrase and overlook its emotive significance. The work suggests an improved TF-IDF method that incorporates attitude data into language modeling to construct weighted word vectors. In order to effectively incorporate essential data and enhance the representation of the comments matrix, the filled expressions are input into BiLSTM. The sentiment tendency of the remarks is used by the feed-forward NN classifier to establish its categorization. In the same conditions, the proposed sentiment analysis strategy is compared to the sentiment analytical methods of NB, convolution neural network, recurrent neural networks, and Long short-term memory. The findings of the experiment demonstrate that the precision, F1 score, and recall, of the suggested sentiment analysis approach are greater. The technique has been proven to be successful with highly accurate remarks. Nevertheless, the BiLSTM-based sentiment analysis technique for comments takes a while to train.

Amlan chakrabarti and Paramita Ray made a suggestion utilizing a combination of rule-based and Deep Learning (DL) techniques; aspect-level sentiment analysis is improved [20]. The communication problems have drastically evolved as a consequence of social networking sites. Material from various social media platforms may be effectively used to analyse user opinions. Therefore, the creation of a platform that can assess consumer perceptions of their goods and services using social media would be advantageous to the companies and add value to their operations. DL has gained a lot of traction in the previous few years in fields like speech recognition and picture categorization. Nevertheless, there is little study on the application of deep learning to sentiment analysis. It has been noted that the current machine learning techniques for sentiment analysis can fail to capture certain underlying elements and may not be particularly helpful. As a result, researchers suggest a deep learning method for extracting aspects from texts and analysing user sentiment in relation to those aspects. Every component of the controversial statements is tagged using a seven layer deep convolutional neural network. Researchers have combined the DL technique with a variety of regulation methods to increase the efficacy of the feature extraction method and the emotional parameter selection. By employing a present collection of aspects classifications and the clustering approach, they also attempted to enhance the current rule-based strategy to feature extraction. Researchers then compared the suggested technique to some of the most advanced systems. The accuracy obtained from the suggested approach is higher than that of the most modern techniques but the technique only uses a limited number of datasets.

Feiran Huang developed direct memory access (DMA) fusion for image-text sentiment analysis. Sentiment analyzing of social media data sets is essential for understanding public perceptions, positions, and opinions about a specific event. This technique has various uses, including the forecasting of elections and the appraisal of products. The evaluation of multimodal social media information has received less attention than the study of a single modality. The majority of the multimodal sentiment analysis techniques now in use only integrate several data modalities, which yields unsatisfactory sentiment categorization effectiveness. In the study, researchers introduce a new image-text sentiment analysis model called DMA Fusion to take use of the racist and discriminatory characteristics and intrinsic connection between semantic and visual content with combined fusion architecture. Two distinct unimodal attention approaches are suggested to develop efficient emotion classifier for the textual and visual modalities, respectively. These models are particularly intended to automatically concentrate on exclusionary areas and crucial phrases that are most connected to the sentiment. In order to take use of the individual's interaction between textual and visual signals for joint sentiment classification, an intermediary fusion-based multimodal attention approach is then developed. The 3 attention categories are then combined for sentiment predictions using a delayed fusion approach. Manually labelled and weakly labelled datasets are used to illustrate the success of the technique in several tests. However, the accuracy of the model is not greater when compared to the other techniques [21].

III. Methodology

The deep learning techniques provided here serve as the foundation for the proposed approach for forecasting the review-related emotions. Dataset collection, data pre-processing, feature extraction and classification using the DBN-GRU model, evaluation metrics, and result analysis are the steps of the proposed system. The proposed methodology's framework, which was applied in the current investigation, is exposed in Fig. 1.

A. Data Collection

A dataset created from public datasets was used in the tests to gauge the effectiveness of the suggested strategy. Since Amazon is one of biggest e-commerce sites, a huge number of reviews may be found there. We made use of data from Amazon called item data. Here three categories from Amazon's product reviews that collectively chosen which contain about 70000 product reviews: electrical reviews, mobile phone and accessory evaluations, and instrument reviews. Whereas 5000 evaluations are for instruments, 29000 are for technology, and 36,000 are for cell devices.

B. Data Pre-Processing

The process of preparing and cleaning the texts for categorization is known as pre-processing the data. The wording of product reviews typically contains a significant amount of noise and non - informative sections. It is frequently noted that the information collected by scraping might not be suitable for inclusion in an algorithm. The data that was scraped might contain misspelt words or other information that wouldn't be helpful to the algorithm. Contrarily, the bulk of the message's sentences have very little bearing on the narrative's total perceived. By keeping such phrases, the issue becomes more complex to categorize because each phrase in the texts is treated as a one-dimensional construct. The idea behind having the data properly which was before is that doing so should improve classification performance and speed up data classification, allowing for real-time sentiment classification. The several stages of the procedure include stem, dividing, deleting stop-word, and isolating special characters are shown in the Fig. 2.

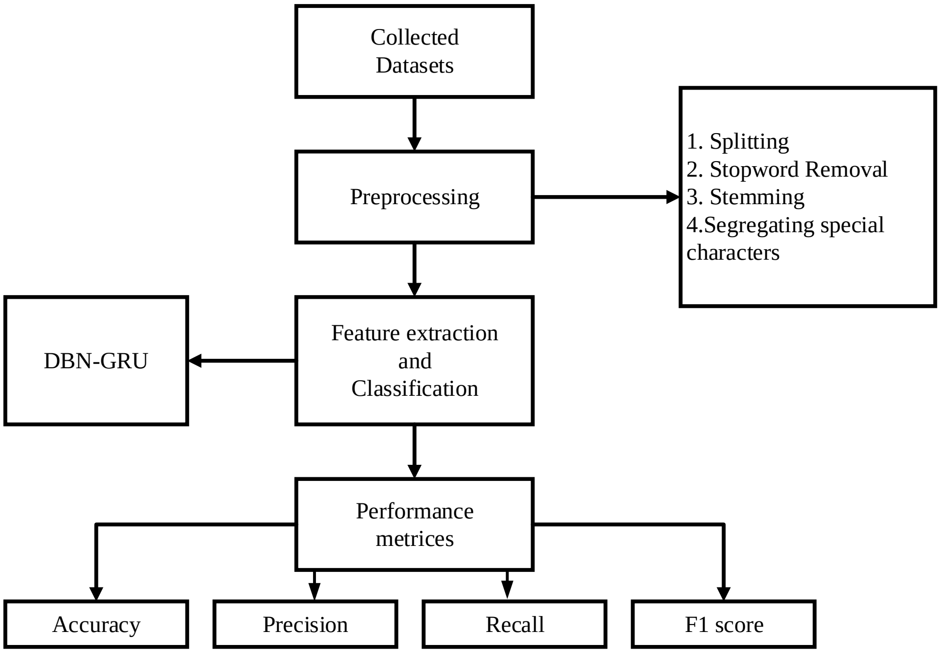

Fig. 1. Proposed model.

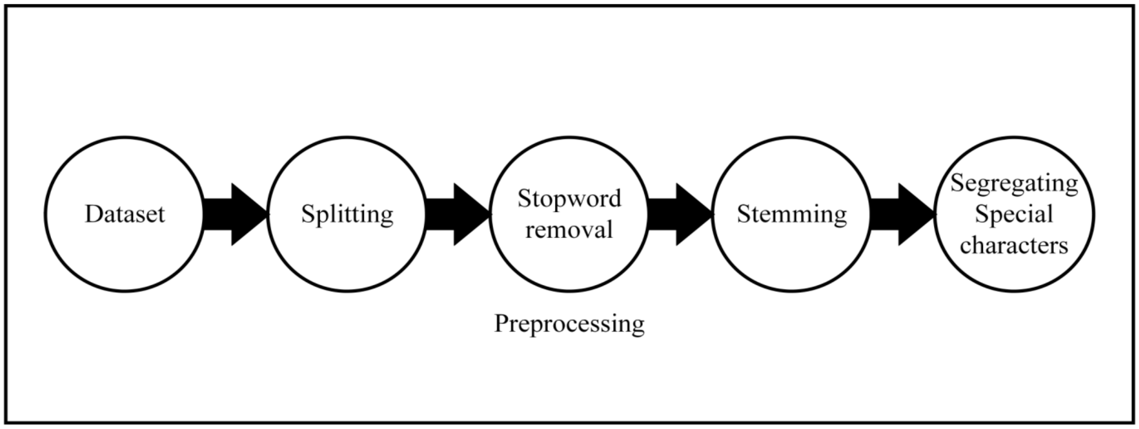

Fig. 2. Stages of Pre-processing.

1) Splitting: Dividing refers to the division of data into two or even more divisions. Evaluating the information in one portion of a two different split and training the algorithms in the second part of the divide are common practises. This method ensures the development of data structures and the activities that rely on data structures. To do this, splitting estimates a series of conditional probabilities, the sum of which is the desired outcome.

2) Stopword removal: Stop words should be eliminated to expand the enactment of the feature selection algorithm since they are frequently used and high frequency terms. The feature extraction approaches may quickly identify the remaining important words in the review corpus after the stop words removal method decreases the dimension of the data sets. High frequency stopwords include "of," "a," "she," "it," "the," "I," "he," "at," "and," and "about," among others. These words are typically referred to as "functional words" because they don't convey any sentimental content. In this experiment, we eliminate stop words to shrink the file index without affecting the accuracy of the user.

3) Stemming: Stemming is an important element in the pre-processing phase of extracting features. Each of the text's words is transformed into their stem or root form throughout this procedure. Stemming is a quick and easy method that simplifies the feature extraction process. The fundamental stemming procedure converts the words "automatic," "automate," and "automation" into the stem "automat." The prominent English language stemming algorithm is Porter's stemmer. The fundamental stemming procedure can change the words in the manner described in Table I in the following manner.

TABLE I. STEMMING

List of words	Stem form
Playing, Plays, Played,	Play
Argues, Argue, arguing, argued,	argu

4) Segregating special character: In general, special characters like the hyphen (-) and the slash (/) are separated since they don't provide any value. According to the use case, characters are eliminated. Usually, we eliminate the $ or any other currency sign if we are carrying out a task in which the currency is irrelevant (such as sentiment analysis).

C. Feature Extraction and Classification

The relevant features are extracted and classified using DBN-GRU mechanism. The proposed method, DBN-GRU approach of emotion recognition, reconstructs the positive and negative comments to relieve the emotions from the product review data to generate product recommendation which not only intervenes in the emotional direction of subjects in a targeted way, but also recommends the product based on their reviews.

1) Deep belief networks (DBN): The deep belief network is a neural system composed of many Restricted Boltzmann Machine layers, in which the outputs of one RBM serves as the inputs for the next, and the hidden layer of the preceding Restricted Boltzmann Machine serves as its visible layer. The present layer's RBM may only be trained throughout the training procedure after the final layer's RBM has been fully trained. It may be viewed as a discriminating model as well as produces better results. Unsupervised learning's goal is to minimise the dimensionality of characteristics while maintaining as many of the initial characteristics' properties as feasible. Its goal is to minimise the categorization error rate from the standpoint of supervised learning. The method of extracting features, or how to achieve a more accurate feature expression, is the core of the DBN algorithm regardless of whether unsupervised learning or supervised learning is being used. Fig. 3 depicts the unique DBN network topology.

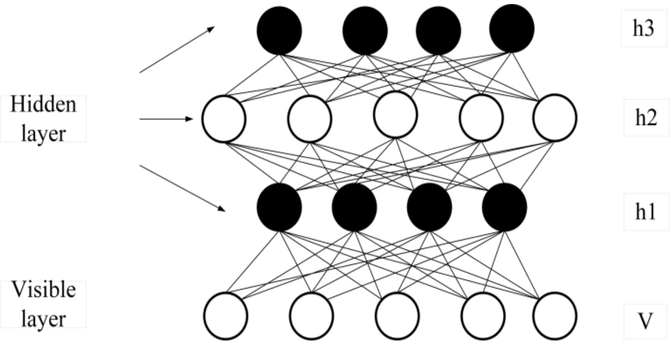

Fig. 3. DBN network structure.

2) Gated recurrent unit (GRU): In recurrent neural networks, the GRU model was most commonly employed to address the gradient vanishing problem (RNN). GRU contains three major gates and an inner cell state, making it more efficient than LSTM. Within the GRU, the data is held in a safe location. The reset gate just provides prior knowledge, but the update gate provides both previous and future information. The current memory gate utilizes the reset gate to maintain and save the necessary data from the system's previous state. The inputs modulation gate concurrently gives the input zero-mean qualities and permits the insertion of nonlinearity. The following Eq. (1) and Eq. (2) are the definitions of the fundamental GRU of rest and updated gates' mathematical formulation:

$$U_t = \sigma\,(X_t.Z_{xu} + F_{t-1}.Z_{hu} + d_u) \tag{1}$$

$$V_t = \sigma\,(X_t.Z_{xv} + F_{t-1}.Z_{hv} + d_v) \tag{2}$$

where Z_{xu} and Z_{xv} present weight parameters, while the d_v , $d_u$are biased. Fig. 4 represents the fundamental design of the GRU model.

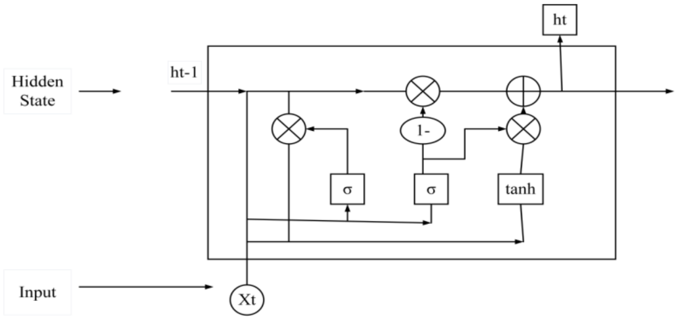

Fig. 4. The fundamental design of the GRU model.

IV. Results and Discussion

The findings of numerous tests are presented to evaluate the effectiveness of the classifier in this section. Based on accuracy, we evaluate the classifier on each of the feature metrics produced by every information extraction and compare the findings to the performance obtained by executing the classifier on unprocessed data. Utilizing the product review datasets, the sentimental analysis is done. The datasets undergo the pre-processing stage and then the pre-processed data is used for the feature extraction and classification. The feature extraction and classification are carried out by the DBN-GRU classifiers to classify the product reviews as positive, and negative.

A. *Performance Evaluation*

Evaluation metrics are crucial for gauging categorization performance. The most frequently employed tool for this is an accuracy measure. The proportion of a test dataset that is properly categorised by a classifier indicates the classifier's accuracy for that dataset. We also used some other measures to assess classifier performance because the accuracy metric alone is insufficient to provide appropriate decision-making. Measures of accuracy, precision, recall, and F1-score were used to evaluate the efficacy of the suggested technique. Also evaluated are accuracy metrics like false negative and false positive rates. The Matthews Correlation Coefficient and Negative Predictive Value are also assessed because these are the indicators that are most frequently used for classifying effectiveness. The following are descriptions of each metric's definitions:

- TP (True Positive) denotes the quantity of correctly categorised data.
- FP (False Positive) refers to the number of accurate data that was incorrectly categorised.
- The term "False Negative" (FN) refers to instances when wrong data have been classed as valid.
- TN (True Negative) refers to the classification of inaccurate data values.

1) Accuracy: The classifier's accuracy indicates how frequently it makes the right guess. The percentage of accurate forecasts to all other guesses is known as accuracy. It is shown in Eq. (3).

$$Accuracy = \frac{Tpos+Tneg}{Tpos+Tneg+Fpos+Fneg} \quad (3)$$

2) Precision: The amount of correctly classified returns is measured by a classifier's precision, or how accurate it is. Reduced false positives result from higher accuracy, whereas more false positives result from lower precision. The ratio of correctly categorised instances to all instances is known as precision. It is characterised by Eq. (4).

$$P = \frac{Tpos}{Tpos+Fpos} \quad (4)$$

3) Recall: The amount of effective data a classification produces, or its sensitivity, is determined by recall. Greater recall reduces the number of FN. Recall is the proportion of correctly categorised instances to all of the expected instances. This is demonstrable by Eq. (5).

$$R = \frac{Tpos}{Tpos+Fneg} \quad (5)$$

4) F-measure: The unified metrics known as F-measure, which is the weighted mean of accuracy and recall, is created by combining precision and recall. It is characterised by Eq. (6).

$$F\ measure = \frac{2\times precision \times recall}{precision\times recall} \quad (6)$$

5) Specificity: The percentage of favourable events that were predicted. In Eq. (7), the expression is provided.

$$Specificity = \frac{T_N}{T_N+F_P} \quad (7)$$

6) Sensitivity: The percentage of circumstances when a negative outcome was predicted. Eq. (8) presents the formula.

$$Sensitivity = \frac{T_P}{T_P+F_N} \quad (8)$$

7) False positive rate: The percentage of situations when a positive outcome was expected but turned out to be untrue. Eq. (9) presents the formula.

$$FPR = \frac{F_P}{T_N+F_P} \quad (9)$$

8) False negative rate: The percentage of cases that is positive even though they were expected to be negative. Eq. (10) presents the formula.

$$FNR = \frac{F_N}{T_P+F_N} \quad (10)$$

9) Matthews correlation coefficient and negative predictive value: One of the most often used indicators of categorization effectiveness is the Matthews Correlation Coefficient (MCC). It is widely accepted as a trustworthy approximation that can be applied although when class sizes vary significantly. The equation for the Matthews correlation coefficient is found in Eq. (11).

$$MCC = \frac{T_P T_N - F_P F_N}{\sqrt{(T_P+F_P)-(T_P+F_N)(T_N+F_P)(T_N+F_N)}} \quad (11)$$

The subject-to-outcome ratio is defined as the proportion of subjects with genuinely negative findings to all subjects with unsatisfactory results. The percentage of times that every forecast was completely wrong is known as the negative predictive value. In Eq. (12), the formula is provided.

$$NPV = \frac{T_N}{T_N + F_N} \tag{12}$$

The value of the suggested strategy is compared to that of other classification approaches in this portion of the study.

Fig. 5 shows schematically the specificity, sensitivity, and reliability of the proposed DBN-GRU in contrast to previous methods. When compared to DBN, GRU and LSTM approaches, improved DBN-GRU offers superior characteristics. Table II compares the suggested approach's Precision, Recall, and F-measure values to those of previous approaches.

TABLE II. COMPARISON OF PRECISION, RECALL AND F-MEASURE

Methods	Precision	Recall	F-Measure
Proposed DBN-GRU	0.968109	0.968109	0.968109
DBN	0.924829	0.924829	0.924829
GRU	0.920273	0.920273	0.920273
LSTM	0.835991	0.835991	0.835991

Fig. 6 displays the proposed improved DBN- GRU's FPR and FNR graphs along with the results of earlier technologies. It demonstrates that the FPR and FNR ratios of the proposed enhanced DBN-GRU are lower than those of the already employed approaches, such as DBN, GRU, and LSTM.

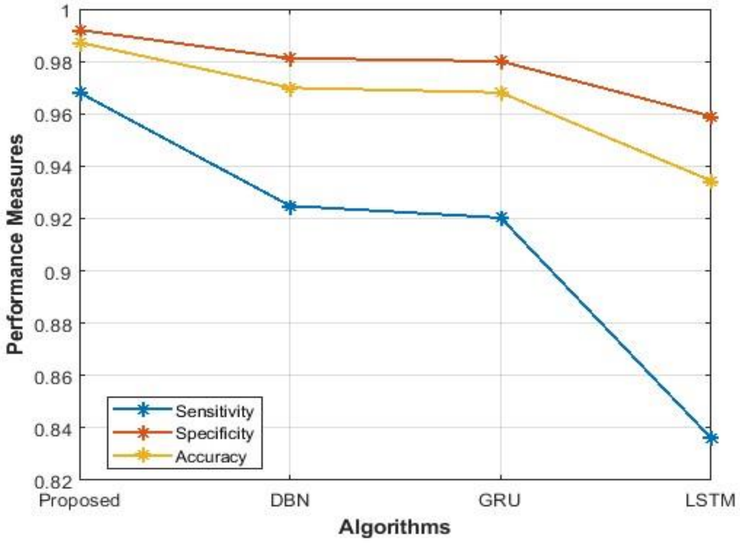

Fig. 5. Comparison graph of accuracy, sensitivity, and specificity.

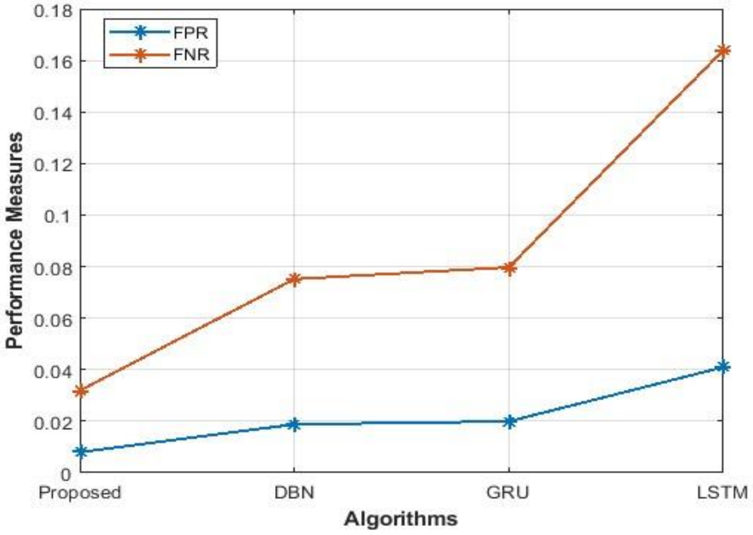

Fig. 6. Comparison graph of FPR and FNR.

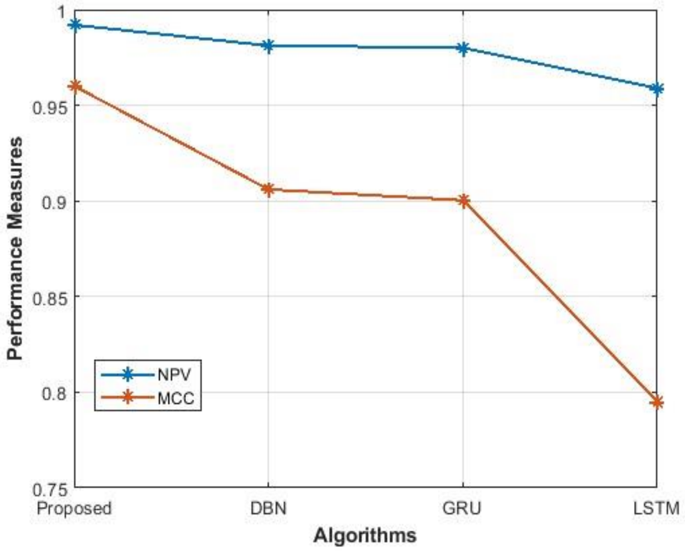

Fig. 7. Comparison graph of MCC and NPV.

The Matthews Correlation Coefficient and Negative Predictive Value graphs of the proposed augmented DBN-GRU created using conventional techniques are shown in Fig. 7. It demonstrates that the recommended enhanced DBN-GRU has a higher MCC and NPV than the current DBN, GRU, and LSTM.

Graphical representations of the recall and accuracy of the recommended technique are shown in Fig. 8 and Fig. 9. The Figures show that the proposed DBN-GRU is superior to that of the existing techniques proposed earlier.

In contrast to past methods, the recommended technique was constructed utilising an improved version of the sentimental analysis in product review data. Additionally, it leverages augmentation and has a 98.72 percent accuracy rate for sentimental analysis of product reviews.

B. Discussion

Previous sentiment analysis models, such as DBN, GRU, and LSTM, faced limitations in handling extensive and diverse datasets due to their inability to effectively address information overload and noise in data preprocessing. These models struggled with balancing precision, recall, and overall accuracy, often resulting in suboptimal sentiment classification [22]. The proposed DBN-GRU model overcomes these limitations by incorporating a comprehensive pre-processing pipeline that includes data splitting, stemming, stop word removal, and special character separation, ensuring refined and clean datasets for improved feature extraction and classification. This approach enhances the classifier's ability to accurately distinguish between positive and negative sentiments, achieving a high accuracy rate of 98.74%. However, the proposed study still has limitations, such as dependency on the quality of pre-processed data and potential overfitting due to the model's complexity. Additionally, while the model excels in the specified product review categories, its performance may vary across different domains and types of reviews, requiring further validation and potential adjustments for broader applicability. Despite these limitations, the DBN-GRU model represents a significant advancement in sentiment analysis, offering robust and reliable classification of online reviews.

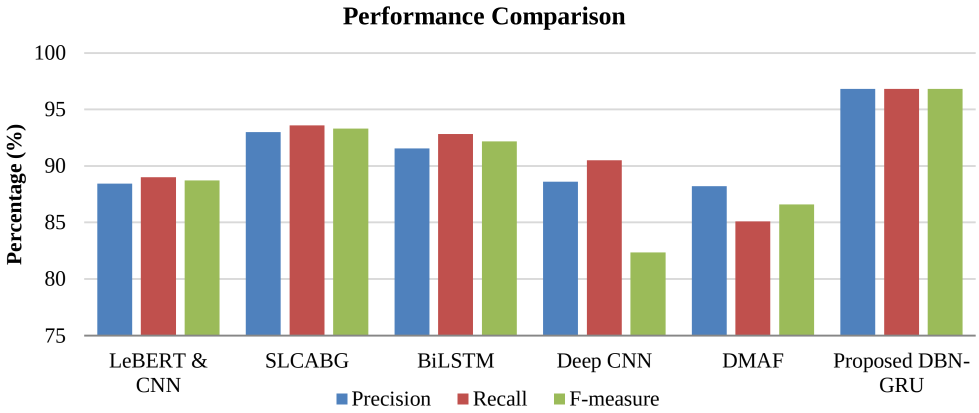

Fig. 8. Effectiveness of suggested technique over other methods.

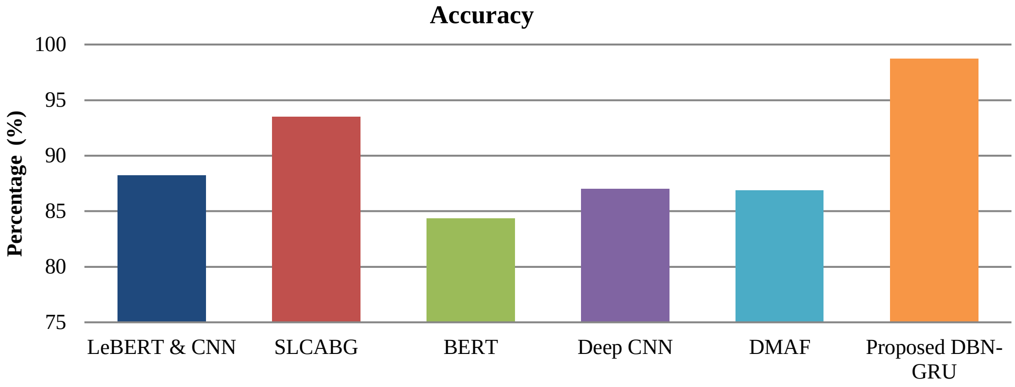

Fig. 9. Accuracy comparison of suggested technique over other methods.

V. Conclusion and Future Work

The study successfully demonstrates the effectiveness of the DBN-GRU hybrid model for sentiment analysis of product reviews. By leveraging a large dataset comprising 70,000 reviews across three categories (electronics, mobile phones, and instruments), the proposed method achieves an impressive accuracy of 98.74%. The robust preprocessing pipeline, which includes data splitting, stopword removal, stemming, and special character isolation, significantly enhances the quality of the input data, contributing to the model's high performance. The DBN-GRU model excels in extracting and classifying relevant features, outperforming traditional methods such as DBN, GRU, and LSTM in terms of accuracy, precision, recall, and F-measure. This study provides a comprehensive framework for sentiment analysis, addressing the challenges of noise and information overload in online reviews and delivering valuable insights for consumers and businesses alike.

Future research can focus on refining the DBN-GRU model to further enhance its applicability and efficiency. One area of improvement could be the expansion of the dataset to include a broader range of product categories and review languages, thereby increasing the model's generalizability. Additionally, optimizing the model for real-time sentiment analysis could be explored, enabling immediate feedback for users and businesses. Reducing the computational requirements of the model will be crucial for its deployment on edge devices, making it accessible in resource-constrained environments. Finally, integrating advanced natural language processing techniques and exploring unsupervised learning approaches could further refine the feature extraction process and improve the model's overall performance.

***Abstract*—Big Data analytics has become an essential tool for IT management, enabling data-driven decision-making in various areas, such as resource allocation and strategic planning. This research examines the use of ARIMA (Auto Regressive Integrated Moving Average) models to improve decision-making in IT management. ARIMA is a popular time-series forecasting method that provides predictive skills, allowing businesses to foresee future patterns and base decisions on historical data analysis. ARIMA models are beneficial in strategic planning by predicting market trends, service demand, and IT resource utilization, which helps firms make proactive resource allocation decisions and maximize operational efficiency. Additionally, ARIMA aids predictive maintenance techniques by forecasting equipment failures and maintenance needs, enabling businesses to reduce downtime and interruptions in critical IT systems. For resource allocation, ARIMA simplifies IT budget optimization by predicting spending needs and identifying potential cost-saving areas. Through accurate forecasts of future budgetary requirements, ARIMA facilitates smart financial resource allocation, investment prioritization, and efficient cost containment, all while optimizing value delivery. Furthermore, ARIMA supports risk management initiatives by evaluating and predicting risks associated with IT projects, operations, and investments. Analyzing historical data and identifying potential risks and vulnerabilities, ARIMA enables firms to mitigate risks, limit adverse effects on business operations, and enhance decision-making processes. Integrating ARIMA into data-driven decision-making processes for strategic planning and resource allocation in IT management has great potential to improve organizational efficiency, agility, competitiveness, and effectiveness. Implemented using Python, the proposed approach has an MSE of 1.25, making it more efficient than current techniques like exponential smoothing and moving average.**

Keywords—Autoregressive integrated moving average; big data analytics; strategic planning; IT management; time-series forecasting

I. Introduction

Organizations must successfully use enormous volumes of data to improve performance, streamline operations, and inform strategic decision-making in the quickly changing field of IT [1], [2]. Big Data analytics has become a game-changing strategy for IT management as a result of this difficulty. Utilizing cutting-edge analytical methods and tools to process, examine, and extract useful information from sizable and intricate databases is known as big data analytics [3], [4]. The widespread use of digital technology, together with the rapid expansion of data produced by diverse sources such sensors, gadgets, apps, and online interactions, has resulted in the collection of enormous amounts of data, which are sometimes referred to as "big data." The magnitude, velocity, and diversity of big data frequently make traditional tools and methods for handling and analyzing it insufficient, forcing the adoption of new strategies and technologies [5].

Big data analytics in IT management encompasses a wide range of technologies and use cases, including capacity planning, risk management, cybersecurity, resource allocation, and performance monitoring [6]. By utilizing big data, organizations can gain a comprehensive understanding of their IT infrastructure, detect emerging trends and patterns, and identify anomalies and threats. This enables them to make informed, data-driven decisions to optimize IT operations and investments. Big data analytics enhances the ability of businesses to extract value from their data assets, leading to increased efficiency, productivity, and innovation [7]. Through advanced analytics, organizations can uncover opportunities for process optimization, product innovation, customer engagement, and revenue growth. Analyzing large volumes of data, businesses can gain insights into their IT environments, anticipate future requirements, and address potential issues proactively [8]. This proactive approach not only improves operational efficiency but also strengthens the organization's capacity to innovate and adapt to evolving market conditions. By integrating big data analytics into their IT management practices, organizations can make better-informed decisions, optimize resource allocation, and achieve sustainable growth. Ultimately, leveraging big data analytics allows businesses to enhance their competitive edge and drive ongoing improvements in their IT operations and overall performance.

In this era of digital transformation, organizations that embrace Big Data Analytics for IT management stand to gain a significant competitive advantage. However, realizing the full potential of Big Data Analytics requires a strategic approach, investment in technology infrastructure, talent development, and a culture of data-driven decision-making across the organization [9]. This paper explores the principles, methodologies, best practices, and challenges associated with Big Data Analytics for IT management. It examines the role of Big Data Analytics in driving strategic initiatives, optimizing resource allocation, and enhancing overall organizational performance [10].

In the current digital era, enterprises are overloaded with enormous volumes of data produced by several sources inside their IT architecture [11]. IT administration has both possibilities and problems as a result of this data explosion. Organizations have to deal with the challenges of organizing, interpreting, and gaining value from this data on the one hand [12]. However, the abundance of data presents hitherto unseen possibilities for resource allocation, strategic planning, and well-informed decision-making. Big Data analytics has become a game-changing method for IT administration, enabling businesses to use data to drive strategic goals and maximize resource usage [13]. Organizations may obtain meaningful insights from massive amounts of data by utilizing automation technologies, machine learning algorithms, and sophisticated analytical approaches. This allows them to make data-driven decisions.

In this regard, enterprises looking to acquire a competitive edge in the quickly changing digital world of today find great potential at the nexus of IT management and big data analytics. Organizations may efficiently address issues like performance optimization, risk management, and cost reduction while also opening up new avenues for innovation, efficiency, and growth by adopting data-driven decision-making. This essay examines the function of big data analytics in IT administration and how it affects resource allocation and strategic planning decisions that are based on data. It looks at the approaches, resources, and best practices related to using big data for IT management while showcasing case studies and real-world examples from a range of sectors. Additionally, the paper explores data governance, privacy problems, organizational culture, and other issues that come with taking a data-driven approach to IT administration. In addition, it addresses new developments and potential paths in the field of big data analytics for IT management, providing useful information on how businesses may stay on the cutting edge and use data as a tactical advantage. The goal of this article is to give a thorough review of big data analytics for IT management and how it helps with resource allocation and strategic planning by enabling data-driven decision-making. Organizations may position themselves for success in a world that is becoming more and more data-driven by realizing the promise of big data analytics and adopting a data-driven attitude.

The key contributions of the article are,

- The article presents ARIMA models as a potent instrument for improving IT management decision-making. The predictive power of ARIMA, a popular time-series forecasting method, is emphasized as it helps businesses identify future trends by using analysis of past data.
- ARIMA models are used to anticipate a number of factors that are essential for strategic planning in IT management, including as market trends, service demand, and the use of IT resources. Organizations may proactively manage resources, maximize operational efficiency, and make well-informed decisions that are in line with corporate goals with the help of this forecasting capabilities.
- By predicting equipment failures and maintenance needs in vital IT systems, the study supports predictive maintenance techniques. This improves overall system dependability and operational continuity by allowing enterprises to reduce downtime and interruptions.
- By precisely estimating expenditure needs and spotting areas for cost savings, ARIMA helps optimize IT expenditures. This makes it possible for businesses to maximize value delivery while carefully allocating financial resources, setting investment priorities, and successfully controlling expenses.

The remainder of the article includes related works, problem statement, methodology and results in Sections II, III, IV and V. The paper is concluded in Section VI.

II. Related Works

Decisions remain crucial for society, organizations, and scholars [14]. To achieve data-driven decision-making in the future, decision study must realign to include new subjects such as massive data sets, analytics, machine learning, and automated decision-making. Consequently, decision models must be significantly altered to reflect these new realities. This study introduces DECAS, a contemporary data-driven decision theory that builds upon conventional decision theory by proposing three primary claims: (1) big data and analytics should be viewed as distinct components; (2) collaboration between analytics and decision makers can produce collaborative reasoning that surpasses traditionally centered rationality; and (3) integrating data and analytics with conventional decision-making components can lead to better choices. The DECAS theory is developed and explained through various data-driven decision scenarios, demonstrating how these integrations enhance decision quality and effectiveness. This approach aims to align decision-making processes with the evolving landscape of information technology and analytics, ensuring more informed and accurate decisions in the years to come.

The research examines the experiences of promotional divisions transitioning to fully data-driven decision-making organizations. It compares a managed approach, where senior management enhances the influence of individuals with analytical skills, with a natural strategy of decentralized sensemaking [15]. To gather data, 15 in-depth interviews were conducted with advertising and analytics specialists in the US and Europe involved in BDA deployment, complemented by a survey of 298 managerial professionals in the US working in marketing and statistics. The findings support the reasoning that BDA sensemaking is initiated by executives and comprises four main activities: acquiring external expertise, enhancing the quality of digitized data, experimenting with big data analytics, and disseminating big data analytics information. Executive management increases the impact of BDA-skilled staff members and facilitates sensemaking to further the movement towards data-driven decision-making. The research suggests that while a shift towards enterprise analytics enhances the marketing group's access to higher-quality resources, the reliability of promotional insights obtained via BDA may be impeded by this strategy. This study offers a framework for improving the standard of data-driven decision-making and understanding in marketing.

The main problem facing PRM is that its current methods and instruments are unable to keep up with the increasing levels of rivalry, market volatility, detrimental business models, and an explosion in the variety of advances in technology and creativity [16]. As a result, assets are either abundant or scarce, and expenses are created. The main resource management issues that the asset-intensive EPC sector faces are covered in the present piece. In order to pinpoint the main sources of the problems, the Ishikawa graph and Pareto chart were also used to model and analyze them. This paper creates a combined blockchain-IoT structure to provide business data and increase the efficiency of the PRM procedure for the EPC businesses taking into account the aforementioned difficulties. The created framework gives the EPC businesses the ability to record data in real-time and coordinate resources autonomously. It also increases the ability for decentralization, unreliable interactions, safety, and accountability, all of which enhance process flexibility. This paper offers a fresh perspective on leveraging blockchain in conjunction with the benefits of IoT devices. It also provides guidance to additional asset-intensive sectors looking to redesign their PRM in a way that is more adaptable.

According to the Industry 4.0 plan, businesses can meet client demands faster thanks to the digitalization of the supply chain [17]. This suggests that broad data accessibility, fast expanding social media platforms, and high internet usage have a substantial impact on consumer buying trends and purchasing behaviours. With the integration of relevant supporting structures, this trend empowers businesses to begin making digital changes based on client requirements. In accordance with sharing data, a materials resource administration and allocation strategy involving supply chain participants is designed in this study. By employing the suggested hybrid Industry 3.5 approach, producers could flexibly choose actions and effectively assign common components to increase their consumer's fulfilment rate with the use of constantly upgraded sharing of data of consumers' periodic predicted demand. For this framework, a case analysis of a highly capital-intensive semiconductor industry is also provided. The findings demonstrate the scientific worth of the cooperative approach to material resource administration in intelligent supply chains, which may be able to meet the necessary 90 percent client material fulfilment rate.

The article examines the process of big data's effect on financial decision-making by examining four aspects: the way big data enhances forecasting's details, the way big data makes decisions more relevant, the way big data creates novel advantages for companies, and the way big data encourages changing decision-making [18]. It depends on the theories of knowledge imbalance, principal-agent, and managing risks. Secondly, it highlight the real-world leadership issues and the impact of using big data platforms to address them by analyzing particular application instances of corporate big data in finance decisions. An organization that successfully integrates finance and business will be more capable to steer corporate development and raise standards of leadership internally, both of which will boost its primary competitiveness. The incorporation of different financial administration components, such as managing budgets, capital administration, fixed managing assets, and accounting for finances, to the business activities of firms is fundamentally how industry and finance are integrated. Lastly, the paper's study will serve as a guide for other businesses of similar kinds looking to use big data to improve financial decision-making. When big data is applied, purchasing management, controlling production, capital budgeting, and investment decision-making yield greater financial returns than in the past. The conclusion is that large amounts of information can be utilized to support company decision-making comprehensively in the big data era. This can help break down financial and business obstacles, increase forecasting and prior alerting capacity, optimize organizational framework and employees, while enhancing decision-making effectiveness and accuracy. The use of large-scale data technologies is now essential for improving company value and supporting financial decision-making.

The aim is to formulate a fact-based and data-driven approach to PPM [19]. In order to move profitability evaluation from the business level to the item level, the research looks at the manner in which the PPM method is absorbed in businesses and suggests a framework that encompasses all PPM improvement areas. The PPM procedure along with other significant company procedures, data-driven decision-making, corporate data resources, and corporate IT are the main areas of emphasis for this research. The results show that before modifying corporate IT to use information resources for data-driven, based on reality PPM, the important strategic significance of the PPM process with associated objectives and performance metrics need to be integrated. Effectively connecting the PPM process, corporate-wide controlled data resources, and commercial IT platforms to reach their full capability for informed choices throughout lifetime provides the tools for a data-driven strategy. The novel contribution is the introduction of a notion for data-driven, based on reality PPM that is distinct from technologies.

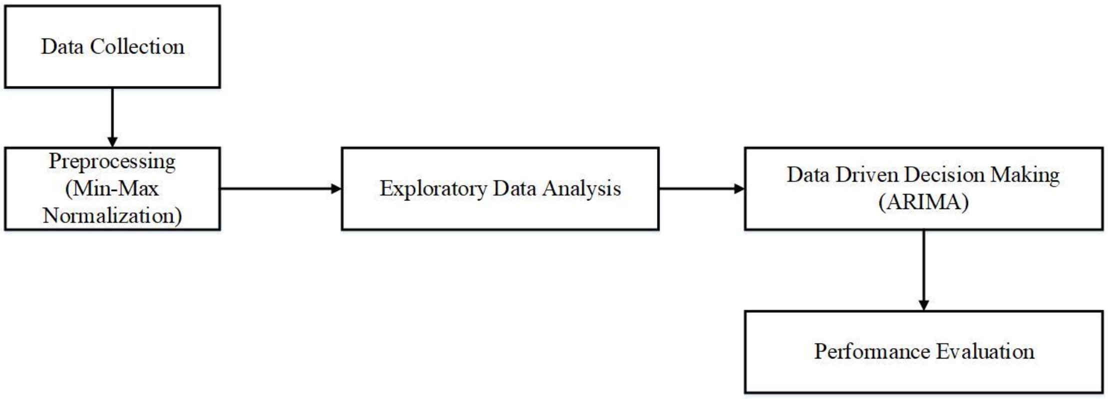
In the realm of data-driven decision-making, the landscape is evolving to accommodate emerging technologies such as big data analytics, machine learning, and automation. This shift necessitates a reevaluation of decision theory and models to incorporate these new components effectively. Meanwhile, research into the transition of promotional divisions towards data-driven decision-making organizations reveals contrasting approaches: a managed method emphasizing the influence of analytical skills at the senior management level versus a decentralized approach of sensemaking. Findings suggest that executive leadership plays a pivotal role in facilitating sensemaking and advancing data-driven decision-making. Similarly, challenges faced by asset-intensive sectors like the EPC industry prompt the exploration of innovative solutions such as a combined blockchain-IoT framework to enhance project resource management. The integration of Industry 4.0 principles into supply chain management highlights the transformative impact of digitalization on meeting consumer demands and fostering collaboration among supply chain participants. Moreover, the utilization of big data in financial decision-making demonstrates its potential to enhance forecasting accuracy, relevance of decisions, and overall business performance. Lastly, a fact-based and data-driven approach to PPM is advocated, emphasizing the integration of PPM processes with corporate data resources and IT platforms to enable informed decision-making at both the business and item levels. These studies collectively underscore the importance of embracing data-driven strategies and leveraging technological advancements to drive organizational success and innovation in various domains.

III. Problem Statement

Current big data analytics techniques in IT administration, particularly concerning resource allocation and strategic planning, have significant shortcomings. Existing approaches, such as moving average and exponential smoothing techniques, often lack the predictive accuracy and scalability required to effectively forecast IT resource utilization, service demand, and market trends. These limitations result in suboptimal decision-making outcomes due to their inability to capture the complex patterns inherent in IT data, leading to inaccuracies and inefficiencies [18]. To address these drawbacks, there is an urgent need for a more advanced and reliable forecasting technique. The proposed solution is the use of ARIMA models. ARIMA's sophisticated time-series forecasting capabilities enable organizations to analyze historical data and anticipate future trends more reliably and accurately. By incorporating ARIMA into data-driven decision-making processes, organizations can improve strategic planning efforts, allocate resources more efficiently, and foster innovation. This integration will ultimately lead to better business performance and success in the rapidly evolving field of IT management.

IV. Proposed ARIMA for Decision Making in IT Management

In the process of employing ARIMA for strategic data-driven decision-making in the realm of IT management, several crucial steps are undertaken. Initially, data collection gathers relevant information pertaining to IT resources, performance metrics, and historical trends. Subsequently, preprocessing techniques such as Min-Max normalization are applied to ensure uniformity and scale across the dataset, enabling more effective analysis. EDA follows, where patterns, trends, and outliers are identified to gain deeper insights into the dataset's characteristics. Finally, ARIMA models are employed to detect patterns with predictive capabilities to inform strategic decision-making processes, optimize resource allocation, and enhance operational efficiency within the dynamic landscape of IT management. It is depicted in Fig. 1.



Data Collection
Preprocessing (Min-Max Normalization)
Exploratory Data Analysis
Data Driven Decision Making (ARIMA)
Performance Evaluation

Fig. 1. Proposed methodology.

A. Data Collection

The IT incident log dataset, sourced from Kaggle, provides a comprehensive collection of records documenting various incidents encountered within an IT infrastructure [20]. This dataset encompasses a diverse range of incidents, including but not limited to system failures, network outages, software errors, security breaches, and user-reported issues. Each incident entry typically includes detailed information such as the timestamp of occurrence, severity level, description of the incident, affected components or systems, resolution status, and any associated notes or comments. With its rich and varied dataset, this resource serves as a valuable asset for IT professionals, researchers, and data analysts seeking to analyze patterns, trends, and root causes of IT incidents, as well as to develop predictive models for incident management and prevention strategies.

B. Preprocessing using Min-Max Normalization

Preprocessing the IT incident log dataset using Min-Max Normalization involves transforming the numerical attributes to a common scale, typically ranging from 0 to 1, while preserving the distribution and relative differences between the data points. This technique is particularly useful when dealing with features that have varying scales or ranges, ensuring that each attribute contributes equally to the analysis without skewing the results. By applying Min-Max Normalization, outliers and extreme values are normalized to fit within the designated range, reducing the impact of outliers on subsequent analyses while retaining valuable information embedded in the dataset. This preprocessing step lays the foundation for more accurate and reliable analysis of the IT incident data, facilitating tasks such as clustering, classification, or anomaly detection. Min-max Normalization is given in Eq. (1).

$$n= min_{new}+ (max_{new} - min_{new}) \times (\frac{n-min_x}{max_x-min_x}) \quad (1)$$

Min-Max Normalization enhances the interpretability and comparability of the dataset, making it easier to identify patterns, trends, and relationships between attributes. Normalizing the numerical features to a common scale ensures that no single attribute dominates the analysis due to its scale or magnitude, thus preventing bias in subsequent modeling or visualization tasks. Additionally, Min-Max Normalization simplifies the implementation of machine learning algorithms, as it reduces the computational complexity and convergence issues associated with normalized data. Overall, preprocessing the IT incident log dataset using Min-Max Normalization improves the robustness, efficiency, and effectiveness of subsequent analyses, enabling stakeholders to derive actionable insights and make informed decisions to enhance IT incident management and prevention strategies.

C. Exploratory Data Analysis

Exploratory Data Analysis (EDA) is a crucial preliminary step in analyzing the IT incident log dataset, aimed at gaining insights into the dataset's structure, characteristics, and underlying patterns. This process involves systematically exploring the dataset through various statistical and visualization techniques to uncover trends, anomalies, and relationships between variables. Initially, summary statistics such as mean, median, standard deviation, and quartiles are calculated for numerical attributes, providing a concise overview of central tendency and variability. Similarly, categorical attributes are summarized by counting the frequency of each category, offering insights into the distribution of data across different classes or groups.

Subsequently, data visualization plays a pivotal role in EDA, allowing for intuitive exploration and interpretation of the dataset. Histograms are utilized to visualize the distribution of numerical attributes, enabling the identification of potential skewness, outliers, or multimodal patterns. Box plots complement this analysis by providing a visual representation of the distribution's spread and highlighting any deviations from the central tendency. Additionally, scatter plots are employed to visualize relationships between pairs of numerical attributes, facilitating the detection of correlations, clusters, or trends within the data. Heatmaps further enhance the analysis by visualizing the correlation matrix, enabling the identification of strong, moderate, or weak correlations between variables.

EDA encompasses outlier detection, missing values analysis, and feature engineering to ensure data quality and relevance for subsequent analyses. Outliers, if present, are identified using statistical methods or visualization techniques and evaluated for potential impact on the analysis. Missing values are addressed through imputation or deletion strategies, ensuring completeness and accuracy of the dataset. Feature engineering involves creating new features or transformations from existing variables to capture relevant information and enhance predictive modeling capabilities. Through systematic exploration and analysis, EDA provides a solid foundation for subsequent data-driven decision-making processes, empowering stakeholders to derive actionable insights and formulate effective IT incident management strategies.

D. Employing ARIMA for Strategic for Data-Driven Decision Making

The role of ARIMA models in strategic data-driven decision-making is paramount, particularly in domains such as IT management where accurate forecasting is crucial for informed decision-making. ARIMA models play a vital role in analyzing historical time-series data and predicting future trends, enabling organizations to anticipate changes, allocate resources efficiently, and optimize strategic planning efforts. By capturing the underlying patterns and dynamics in time-series data, ARIMA models provide valuable insights into IT resource utilization, demand forecasting, and market trends, empowering decision-makers to make informed choices that align with organizational goals and objectives.

ARIMA models facilitate proactive decision-making by identifying potential risks and opportunities well in advance. By leveraging historical data and analyzing trends over time, ARIMA enables organizations to anticipate market fluctuations, predict equipment failures, and forecast demand for IT services, among other factors. This proactive approach to decision-making allows organizations to mitigate risks, capitalize on opportunities, and stay ahead of the curve in a rapidly evolving business landscape. Overall, ARIMA serves as a powerful tool for strategic data-driven decision-making in IT management, enabling organizations to optimize resource allocation, enhance operational efficiency, and drive business success.

ARMA is the outcome of combining the Moving Average (MA) and the Autoregressive (AR), two simpler models. Because researchers sometimes append the residuals to the end of the model equation during assessment, the "MA" portion comes in second. Assume for the moment that "X" is a randomly selected time-series statistic. This therefore may be a simple Autoregressive Moving Average model.

$$x_t= \mathrm{d} + \phi_1 x_{t-1} + \theta_1 \epsilon_{t-1}+ \epsilon_t \quad (2)$$

First of all, the variables x_t and x_(t-1) represent the values of the current period and the prior period, respectively. Similar to how we used the AR model, they use the previous data as a foundation for future estimates. The error values for the same two periods are t and t-1 in a similar way. They use the error term from the prior quarter to adjust their projections. If we know how far off were from our prior estimate, it can create a more accurate one this time. As usual, "d" is merely a regular constant factor. In essence, users are free to replace this element with any other. When there isn't a beginning point like that, researchers just assume that d=0.

The two variables that remain are ϕ_1 and θ_1. To understand the current time, the first, or ϕ_1, often specifies which part of the value from the preceding one, x_(t-1) is important. In relation to the previous error term ϕ_(t-1), the latter value, 1, denotes the same. Like the preceding models, these values have to be between -1 and 1 to prevent the coefficients from growing. In increasingly complex models,

〚ϕ_1〛_1, and θ_1 naturally represent the relevance of the values and the terms of error for the "i-th" lag. For example, expression 4 expresses the percentage of the value from four times ago that is still relevant, whereas expression 3 specifies the part of the residual from three periods ago that is important now.

Before moving on, a few points regarding building ARMA models must be made clear. In this instance, every model of the type is defined by the two "orders". It call the first order the "AR" order and the second order the "MA" order. The moving-average components are indicated by the first letter, while the autoregressive sections are indicated by the second. Consequently, the residuals of up to B delays as well as the previous values up to A time ago are included in an ARMA (A, B) model.

$$x_t = \phi_1 x_{t-1} + \phi_2 x_{t-2} + \theta_1 \epsilon_{t-1} + \theta_2 \epsilon_{t-2} + \theta_3 \epsilon_{t-3} + \epsilon_t \quad (3)$$

It's critical to understand that the values of the two orders, A and B, are not necessarily equal. This is significant because, frequently, the error term ϵ_(t-1) + or the prior value x_(t-1) loses significance first. Because of this, a lot of useful prediction models have different orderings for the Moving Average and Autoregressive functions. The data drive decision making is depicted in Fig. 2.

V. Results and Discussion

The process of data-driven decision-making in the realm of IT management entails several crucial steps, beginning with data collection from diverse sources such as IT incident logs or performance metrics. Subsequently, preprocessing techniques like Min-Max Normalization are applied to standardize the data and mitigate the impact of varying scales, ensuring consistency and comparability. EDA follows, enabling insights into data patterns, distributions, and correlations, essential for identifying trends and anomalies. Finally, employing ARIMA models for strategic decision-making harnesses the predictive power of time-series analysis, facilitating accurate forecasts of IT resource utilization, demand trends, and market dynamics.

A. *Resource Allocation*

Resource allocation refers to the strategic process of distributing available resources, including financial, human, technological, and physical assets, among competing demands or objectives within an organization. This process involves assessing the needs, priorities, and constraints of various projects, departments, or initiatives, and making decisions to allocate resources in a manner that maximizes efficiency, effectiveness, and value creation. Resource allocation entails balancing trade-offs and optimizing the utilization of resources to achieve organizational goals, such as increasing productivity, enhancing performance, minimizing costs, and achieving competitive advantage. Effective resource allocation relies on data-driven decision-making, strategic planning, and continuous monitoring and evaluation to adapt to changing circumstances and ensure alignment with organizational priorities and objectives.

Table I presents a comparative analysis of current and optimized resource allocations across various IT resources, including servers, storage, bandwidth, CPU cores, and RAM. The table highlights significant improvements achieved through data-driven decision-making in resource allocation. For instance, there is a 20% decrease in the allocation of servers, CPU cores, and RAM, indicating more efficient utilization of these resources without compromising performance. Similarly, the optimized allocation of storage reflects a 20% reduction in resource usage, contributing to cost savings and resource optimization. The most notable improvement is observed in bandwidth allocation, with a remarkable 99% increase, signifying a strategic reallocation of resources to meet growing demands for network connectivity and data transfer. Overall, the table underscores the tangible benefits of data-driven decision-making in optimizing resource allocation, enhancing efficiency, and maximizing value within the IT infrastructure of the organization. It is depicted in Fig. 3.

TABLE I. RESOURCE ALLOCATION

IT Resource	Current Allocation (Units)	Optimized Allocation (Units)	Improvement (%)
Servers	100	80	20% decrease
Storage	500 TB	400 TB	20% decrease
Bandwidth	1 Gbps	2 Gbps	99% increase
CPU Cores	1000	800	20% decrease
RAM	10 TB	8 TB	20% decrease

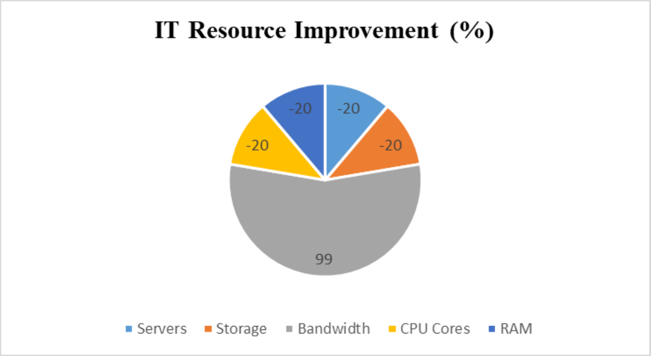

Fig. 3. IT resource improvement.

B. Security

Security refers to the state or condition of being protected against unauthorized access, misuse, disclosure, disruption, or destruction of assets, resources, information, systems, or networks. It encompasses a range of measures, practices, technologies, and policies implemented to safeguard valuable assets and ensure confidentiality, integrity, availability, and authenticity. Security aims to mitigate risks and threats posed by various internal and external factors, including malicious actors, cyberattacks, natural disasters, and human errors. It involves the identification, assessment, and management of vulnerabilities and risks, as well as the implementation of controls and safeguards to prevent, detect, and respond to security incidents effectively. Security is essential across all domains, including information technology, physical infrastructure, finance, healthcare, and national defense, to protect organizations, individuals, and society from potential harm and ensure the continuity and resilience of critical operations and services.

Table II illustrates the transformative impact of enhanced security measures on key security metrics within an organization. The significant reduction in the number of security incidents from 50 to 20 reflects the efficacy of strengthened security protocols and controls in mitigating risks and preventing unauthorized access or breaches. Moreover, the substantial improvement in the average time to detect security incidents, decreasing from 24 hours to 8 hours, highlights the enhanced responsiveness and efficiency of security monitoring and detection systems. Similarly, the decrease in the average time to respond from 48 hours to 12 hours signifies the organization's improved ability to swiftly address and mitigate security threats, minimizing the potential impact on operations and data integrity. Furthermore, the increase in the compliance score from 75% to 90% underscores the organization's commitment to adhering to regulatory requirements and industry standards, demonstrating its proactive approach to maintaining a robust security posture. Overall, the table showcases the tangible benefits of enhanced security measures in bolstering resilience, minimizing vulnerabilities, and safeguarding critical assets and information against emerging cyber threats and risks.

TABLE II. SECURITY

Metric	Current Value	Enhanced Value
Number of Security Incidents	50	20
Average Time to Detect	24 hours	8 hours
Average Time to Respond	48 hours	12 hours
Compliance Score	75%	90%

C. Cost Optimization

Cost optimization involves systematically evaluating cost drivers, identifying inefficiencies, and implementing targeted interventions to reduce costs while maintaining or enhancing value delivery. Cost optimization initiatives aim to achieve a balance between cost reduction and value creation, enabling organizations to streamline operations, optimize resource utilization, and improve profitability. By leveraging data-driven analysis, process optimization, technology adoption, and strategic sourcing strategies, organizations can identify opportunities for cost savings, mitigate financial risks, and enhance competitiveness in dynamic business environments. Cost optimization is essential for organizations to achieve sustainable growth, resilience, and long-term success by aligning costs with business objectives and optimizing return on investment.

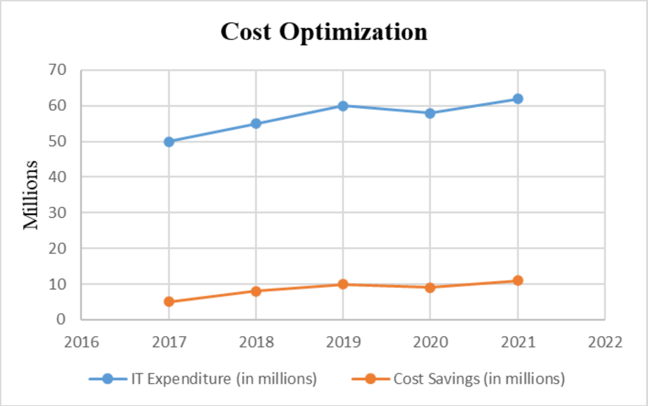

Fig. 4. Cost optimization.

Fig. 4 depicts the trend of IT expenditure and corresponding cost savings over a five-year period. The graph illustrates a consistent increase in IT expenditure from 2017 to 2021, indicating growing investment in IT resources and infrastructure. Despite the upward trend in IT spending, the graph also highlights a concurrent rise in cost savings during the same period, suggesting effective cost optimization measures implemented by the organization. This trend underscores the organization's ability to balance investment in technology with initiatives aimed at reducing operational costs and maximizing efficiency. Overall, Fig. 4 demonstrates the organization's commitment to strategic cost management and its success in achieving cost savings while maintaining a trajectory of IT investment and growth.

D. Strategic Planning

Organizations use strategic planning, a methodical and forward-thinking process, to identify their long-term goals, priorities, and objectives and to create strategies and action plans to reach them. Through strategic planning, organizations can anticipate challenges, capitalize on opportunities, allocate resources effectively, and adapt to changing environments, ultimately positioning themselves for success in a dynamic and uncertain future. It is depicted in Fig. 5.

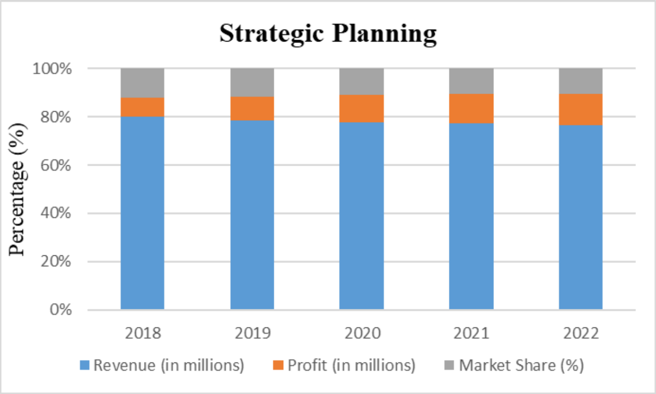

Fig. 5. Strategic planning.

E. Mean Absolute Error (MAE)

The average of the variations between the actual and anticipated values is known as MAE. Eq. (4), which describes it.

$$MAE = \frac{1}{n}\sum_{i=1}^{m}\left|X_i - \widehat{X_\iota}\right| \tag{4}$$

Where m is the number of datum, X_i is the ground truth and $\widehat{X_\iota}$ is the predicted values.

F. Mean Squared Error (MSE)

The average squared difference between the target value and the model's projected value in the dataset is measured by MSE. Eq. (5), which describes it.

$$MSE = \frac{1}{m}\sum_{i=1}^{m}\left(X_i - \widehat{X_\iota}\right)^2 \tag{5}$$

G. Root Mean Squared Error (RMSE)

RMSE is a measure of the average deviation between observed and predicted values, calculated by taking the square root of the average of the squared differences between observed (y) and predicted (ŷ) values:

$$\text{RMSE} = \sqrt{\frac{1}{n}\sum_{i=1}^{n}(y_i - \hat{y}_i)^2} \tag{6}$$

H. Mean Absolute Percentage Error (MAPE)

MAPE is a measure of the average percentage difference between observed and predicted values, calculated by taking the mean of the absolute differences between observed (y) and predicted (ŷ) values, divided by the observed values, and then multiplied by 100:

$$\text{MAPE} = \frac{1}{n}\sum_{i=1}^{n}\left|\frac{y_i - \hat{y}_i}{y_i}\right| \times 100 \tag{7}$$

TABLE III. COMPARISON OF ERROR METRICS

Methods	MAE	MSE	RMSE	MAPE
Exponential Smoothing [21]	1.45	3.20	1.78	0.098
Moving Average [22]	1.65	3.80	1.95	0.112
ARIMA	1.25	2.67	1.63	0.089

Table III provides a comprehensive comparison of error metrics for three different forecasting methods: Exponential Smoothing, Moving Average, and ARIMA. The metrics evaluated include MAE, MSE, RMSE, and MAPE. Across all metrics, the ARIMA method consistently outperforms both Exponential Smoothing and Moving Average, demonstrating its superior forecasting accuracy. With lower values of MAE, MSE, RMSE, and MAPE, the ARIMA model exhibits closer alignment between observed and predicted values, indicating its effectiveness in capturing underlying trends and patterns in the data. These results underscore the importance of employing sophisticated time-series forecasting techniques like ARIMA for improved decision-making and resource allocation in diverse domains. It is depicted in Fig. 6.

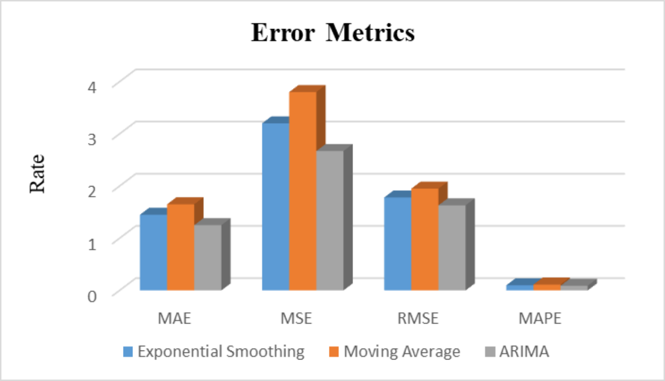

Fig. 6. Comparison of error metrics.

I. Discussion

The results obtained from the comparison of performance metrics among the three existing methods, Exponential Smoothing [21], Moving Average [22], and ARIMA, offer valuable insights into their respective forecasting capabilities. Exponential Smoothing exhibits moderate performance, with MAE, MSE, and RMSE values of 1.45, 3.20, and 1.78, respectively. However, it lags slightly behind ARIMA, as indicated by higher error metrics. Moving Average, while simple and easy to implement, demonstrates inferior performance compared to both Exponential Smoothing and ARIMA, with higher MAE, MSE, and RMSE values. These findings suggest that while Exponential Smoothing may suffice for basic forecasting needs, organizations seeking more accurate predictions should consider adopting ARIMA for enhanced forecasting accuracy and reliability.

Further analysis reveals that ARIMA outperforms both Exponential Smoothing and Moving Average across all metrics, with significantly lower MAE, MSE, and RMSE values, indicating its superior forecasting accuracy and predictive power. With MAPE values also considerably lower than those of Exponential Smoothing and Moving Average, ARIMA demonstrates its effectiveness in minimizing percentage errors between observed and predicted values. These results underscore the importance of leveraging advanced time-series forecasting techniques, such as ARIMA, for achieving more precise and reliable predictions, thereby empowering organizations to enhance strategic planning processes for sustainable growth and competitive advantage in dynamic business environments.

VI. Conclusion and Future Works

In summary, the application of ARIMA models to data-driven decision-making procedures in IT administration has shown a great deal of promise for raising organizational competitiveness, efficiency, and agility. Organizations may estimate resource consumption, predict future trends, and maximize operational efficiency in resource allocation and strategic planning thanks to ARIMA's predictive capabilities. ARIMA minimizes downtime and disturbances in important IT systems by facilitating predictive maintenance techniques through the use of historical data analysis. Additionally, by offering precise projections of future spending needs, ARIMA helps firms optimize their IT budgets by allowing them to strategically deploy funds and efficiently manage expenditures while increasing value delivery. Moving forward, future research could explore the application of ARIMA models in additional areas of IT management, such as capacity planning, risk management, and performance optimization. Additionally, the refinement and optimization of ARIMA models, including parameter tuning and model selection techniques, could further enhance their predictive accuracy and reliability. Moreover, combining ARIMA with other cutting-edge analytical techniques may open up new avenues for IT management decision-making, allowing businesses to glean more nuanced understanding from their data and spur creative thinking. Finally, in-depth analyses of the effects of ARIMA models on organizational performance and their practical use in actual IT settings would offer insightful information on the potential advantages and efficacy of these models. In the current quickly changing digital ecosystem, more study and innovation in ARIMA-based decision-making processes have the potential to propel further improvements in IT management and support organizational success.

***Abstract*—The secure sharing and privacy protection of medical data have become pain points for medical data management platforms. Therefore, a secure sharing electronic health record privacy protection method based on blockchain is proposed in the study, aiming to improve data security privacy and ensure absolute ownership of patients' medical data. Attribute encryption and blockchain computing are utilized to construct a data secure sharing model, and zero-knowledge proof and ElGamal encryption algorithms are introduced to further improve the construction of data privacy protection methods. Experimental verification showed that the data secure sharing method proposed in the study has more advantages in terms of production key size and time cost. Compared with other public recognition mechanisms, zero-knowledge proof reduced the average time cost of generating keys by 54.36%. The proposed data privacy protection method had an average increase of 7.73% in protection effectiveness compared to other methods. The results indicate that the data secure sharing and privacy protection methods proposed in the study can improve the overall performance and security of the system while fully ensuring the absolute ownership of patients' data. This method has positive application value in the privacy protection of medical data.**

***Keywords*—Blockchain; secure sharing; electronic health records; privacy protection; zero-knowledge proof; attribute encryption**

I. Introduction

With the continuous improvement of the national economic level, the process of medical intelligence and wireless technology is gradually improving. However, limited medical resources, uneven distribution of medical levels, and heterogeneity of system data based on different medical systems have led to the phenomenon of isolated medical data [1-2]. Meanwhile, the optimization and advancement of Internet of Things technology have led to threats to the privacy and security of data information. Issues such as hacker attacks, data information leakage, and patient privacy protection urgently need to be addressed [3]. Blockchain technology has achieved decentralization through distributed consensus, data encryption, economic incentives, and other methods, improving data privacy protection. It has been widely applied in research on data privacy protection in the Internet of Things. However, the current privacy protection methods for electronic health records still need further development and optimization. Based on this, a secure shared electronic health record privacy protection method is proposed on the basis of blockchain, aiming to improve the protection performance of medical data and enhance patients' sharing rights over their medical data. By putting patients at the center, we ensure the privacy and security of user Electronic Health Record (EHR) data while safeguarding patients' absolute rights to their own medical data. At the same time, zero knowledge proof (ZKP) was introduced in combination with ElGamal encryption algorithm to explore EHR data privacy protection.

The overall structure of the research includes six sections: Section I summarizes the research achievements and shortcomings of blockchain and medical data privacy protection at home and abroad; Section II studies and designs a privacy protection method for secure shared electronic health records based on blockchain technology; Section III conducted experiments and analysis on the proposed privacy protection method for secure shared electronic health records; Section IV summarizes the experimental results. Discussion and conclusion are given in Section V and Section VI respectively.

II. Related Works

With the continuous application and development of big data technology, how to effectively share medical data information and protect privacy has become a new focus in the current research field. Ortega Calvo and others proposed an artificial intelligence modern data platform to address the limitation of healthcare data management systems being unable to utilize the generated data. Based on big data, artificial intelligence management, and efficient data processing, different components were utilized to regulate data collection and heterogeneous data was analyzed. By constructing a security and data governance layer, the privacy and integrity of the system database were maintained [4]. Kumar et al. raised a secure and efficient data sharing framework based on blockchain and deep learning to address the issues of unreliable connection security and privacy in real-time monitoring of patients in public networks. By utilizing consensus mechanisms based on smart contracts to register and verify communication entities, and using stacked sparse mutation autoencoders for key verification, privacy protection for real-time transmission of healthcare data was improved [5]. Shuaib et al. proposed a medical data sharing system based on licensed blockchain technology (BCT) to address the limitation of BCT relying on centralized databases. By integrating BCT, threshold signatures for decentralized file systems, and using the Istanbul Byzantine consensus algorithm as key verification, the performance and security of the system were improved [6]. To improve privacy protection during medical data sharing, Liu et al. proposed combining

*Corresponding Author

federated learning with neural architecture search and developed a multi-objective convolutional interval type 2 fuzzy rough model based on neural architecture search. By combining convolutional neural networks with fuzzy rough sets, the interpretability of deep neural networks was effectively improved [7].

The development of BCT provides security and privacy protection for data transmission in the era of intelligent informatization [8]. To improve the resistance of e-government systems to malicious attacks, Elisa et al. proposed a decentralized peer-to-peer e-government system framework using BCT. By utilizing BCT to verify and store existing and new data, the information security and privacy of the system were enhanced [9]. Sharma et al. raised a distributed application that protects privacy in response to various security attacks on traditional healthcare solutions. By utilizing BCT to create and maintain healthcare integers, the security, privacy, and transparency of healthcare platforms were improved [10]. Awotunde et al. raised a network architecture based on blockchain, which combines a hybrid convolutional neural network and kernel principal component analysis, to protect the system from potential threats and ensure network traffic security. By extracting features through kernel principal component analysis and then using convolutional neural networks for classification and detection, the security, privacy, and maintainability of IoT smart cities were improved [11]. To address the data security and management issues between IoT edge nodes and massive heterogeneous devices, Zhonghua et al. proposed an IoT access control model combining BCT. By proving the workload of traditional consensus algorithms, the Proof of Work (PoW) mechanism was optimized to provide decentralized, fine-grained, and dynamic access control management for IoT environments [12]. Due to the difficulty in ensuring security and privacy in data management, information verification, and dissemination, Patil established a medical record security system based on BCT. By utilizing BCT to improve the access of medical data management systems to monitoring drugs, hospital assets, etc., the service efficiency of medical service systems was improved [13].

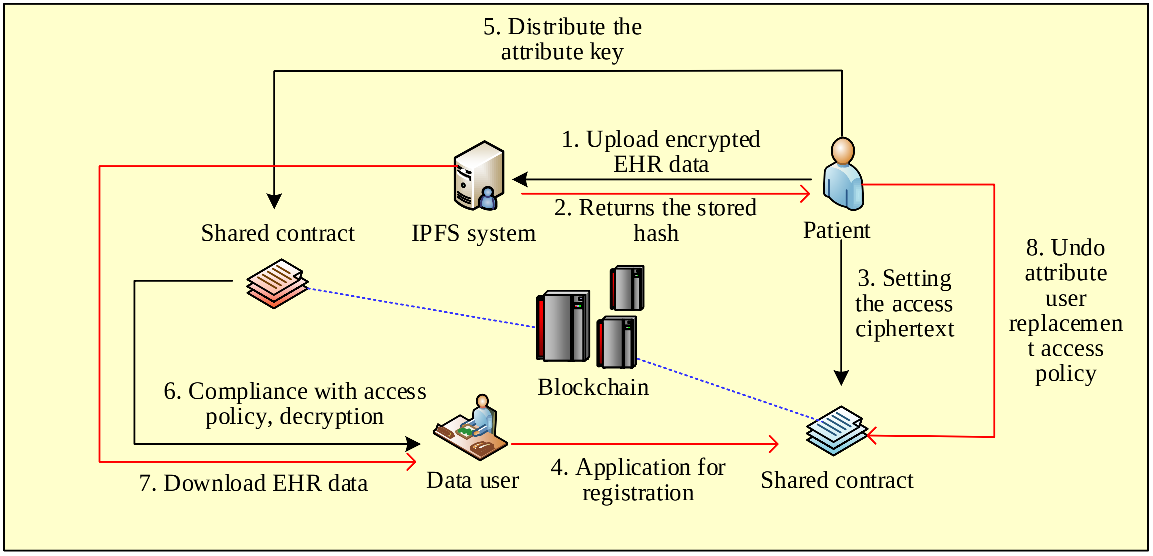
Based on the above, relevant experts and scholars have explored various aspects of privacy protection of medical data and the application of BCT, and have achieved good results. However, current medical data systems still have a high dependence on third-party service providers, and patients cannot have absolute ownership of their own medical data. Therefore, the study innovatively proposes a secure sharing Electronic Health Record (EHR) privacy protection method based on patient-centered blockchain, aiming to ensure the privacy and security of user EHR data while safeguarding the absolute right of patients to their own medical data. In addition, to improve the privacy and security of the system, Zero Knowledge Proof (ZKP) is introduced. The combination of ZKP and ElGamal encryption algorithm has been explored for EHR data privacy protection.

III. Methods and Materials

The study first designed an EHR Security Sharing (EHRSS) based on BCT. On this basis, the study further introduced ZKP based on blockchain for EHR Privacy Protection (EHRPP) method design.

A. Design of Secure Sharing Method Based on Blockchain

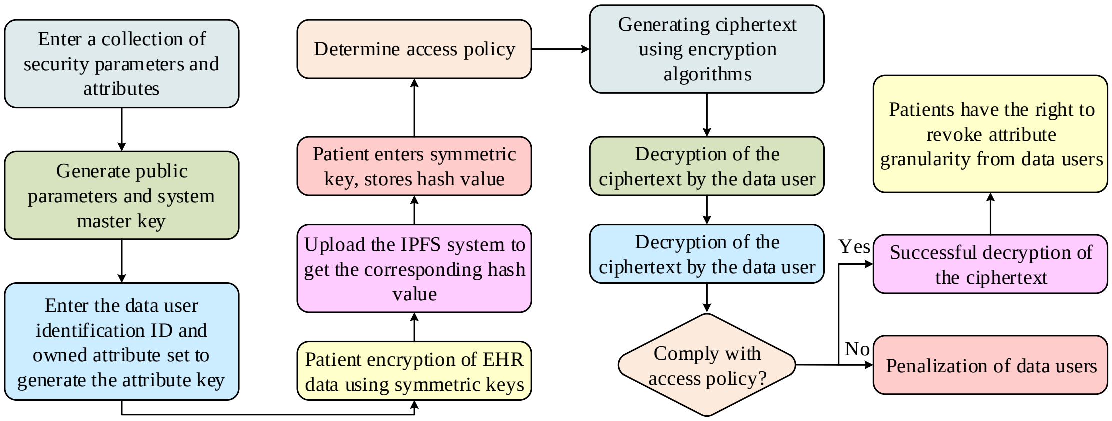
The processing and sharing of EHR data are mainly achieved by commonly used data sharing management platforms in medical systems, but during the platform sharing process, users need to upload the data to cloud storage themselves [14-15]. However, the security of this operation is extremely low, and it overly relies on third-party service providers, making it difficult for users to guarantee their absolute ownership of the uploaded data. Therefore, this study proposed an EHRSS method based on BCT. The specific architecture is shown in Fig. 1.



5. Distribute the attribute key
1. Upload encrypted EHR data
2. Returns the stored hash
Shared contract
IPFS system
Patient
8. Undo attribute user replacement access policy
3. Setting the access ciphertext
Blockchain
6. Compliance with access policy, decryption
7. Download EHR data
Data user
4. Application for registration
Shared contract

Fig. 1. Blockchain-based EHRSS model architecture.

In Fig. 1, the EHRSS model proposed in the study is mainly composed of the proprietary Inter Planetary File System (IPFS), blockchain, patients, and data users. Among them, the IPFS interstellar file system is responsible for storing the patient's EHR, and the blockchain is responsible for storing the public information and user operation records generated in the entire EHRSS model, while also considering the communication channel between patients and data users. The patient mainly refers to the owner of EHR, who creates and deploys smart contracts in the EHRSS model. The data users mainly refer to doctors, nurses, hospital administrators, and medical institutions. When the attributes of the data user comply with the strategy embedded in the ciphertext, the data sharing right is obtained based on the decryption address and key information. The execution process of the EHRSS model is denoted in Fig. 2.



Enter a collection of security parameters and attributes
Generate public parameters and system master key
Enter the data user identification ID and owned attribute set to generate the attribute key
Patient encryption of EHR data using symmetric keys
Upload the IPFS system to get the corresponding hash value
Patient enters symmetric key, stores hash value
Determine access policy
Generating ciphertext using encryption algorithms
Decryption of the ciphertext by the data user
Decryption of the ciphertext by the data user
Comply with access policy?
Yes
No
Successful decryption of the ciphertext
Patients have the right to revoke attribute granularity from data users
Penalization of data users

Fig. 2. Blockchain-based EHRSS model flowchart.

As shown in Fig. 2, The EHRSS model first determines the system's security parameters, attribute sets, random parameters, etc., and generates common parameters and the system's master key. The generation process is shown in Eq. (1).

$$\begin{cases} Pk = \left(N, e(g,g)^{b}, g, t = g^{c}, \{D_i = g^{d_i}, h_i = g^{\gamma_i}\}_{i\in I}\right) \\ Msk = (b, c, \{d_i\}_{i\in I}, Y) \end{cases} \quad (1)$$

In Eq. (1), Pk represents a common parameter. Msk represents the system master key. N represents the product of two prime numbers multiplied. g represents the generator. b and c represent random numbers. γ_i and h_i represent calculations related to attribute revocation. d_i and D_i represent attribute related calculations. t represents the calculation related to the identity of the data user. e represents bilinear mapping. I represents a set of attributes. Y represents the random private key of the data user. Based on the generated public parameters and system master key, the data user inputs their unique Identity Document (ID) and the corresponding attribute set, in order to obtain the exclusive attribute key for the data user. The specific calculation method is shown in Eq. (2).

$$\begin{cases} K_{i,1} = g^{b\gamma + d_i\gamma_i + c\gamma_i} Y_{i,1} \\ K_{i,2} = g^{\gamma_i} Y_{i,2} \\ K_{i,3} = (t^{ID} h_i)^{\gamma_i} Y_{i,3} \end{cases} \quad (2)$$

In Eq. (2), $K_{i,1}$, $K_{i,2}$, and $K_{i,3}$ represent the attribute private key information of the data user. t^{ID} represents the identity ID of the data user. On this basis, the patient encrypts the EHR using their symmetric key, uploads it to the IPFS system, obtains the corresponding storage hash value, and stores the ciphertext in a shared contract. Among them, the EHR expression is shown in Eq. (3).

$$M = (key \| hash_{ipfs}) \quad (3)$$

In Eq. (3), M represents HER data. $hash_{ipfs}$ represents the hash value of the storage address in the IPFS system. key represents symmetric key information. The ciphertext expression is shown in Eq. (4).

$$CT = (C_0, C_1, \{C_{x,0}, C_{x,1}, \{C_{x,y,1}, C_{x,y,2}\}_{y=\{1,\ldots,l_{\rho(x)}\}}\}_{x\in\{1,\ldots,l\}}) \quad (4)$$

In Eq. (4), CT represents ciphertext information. x and y represent rows and columns. $\rho(x)$ represents attributes. l represents the length of the access address. C represents encryption. Meanwhile, the data user decrypts the ciphertext information based on their own attribute private key. When the data user meets the set orientation strategy and is not included in the attribute revocation list, they can obtain the storage information and decryption key of patient EHR data in IPFS. The identity discrimination calculation method for data users is shown in Eq. (5).

$$\begin{cases} F_{x,1} = \prod_{y=1}^{l_{\rho(x)}} \left(\dfrac{e(K_{\rho(x),2}, C_{x,y,2})}{e(K_{\rho(x),3}, C_{x,y,1})}\right)^{1/ID - ID_y} \\ F_{x,2} = \dfrac{e(K_{\rho(x),1}, C_{x,0})}{e(K_{\rho(x),2}, C_{x,1})} \end{cases} \quad (5)$$

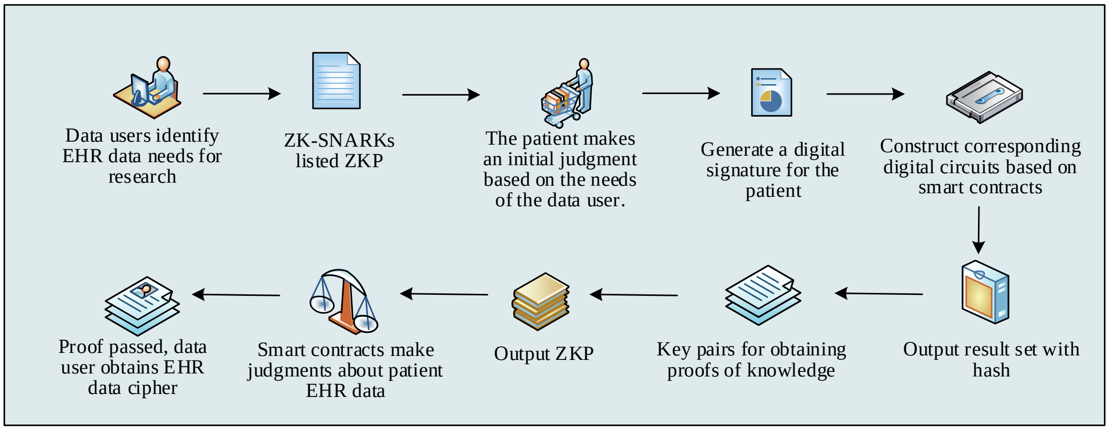
In Eq. (5), $F_{x,1}$ and $F_{x,2}$ represent the conditions that satisfy the data user being accessed. The expression for EHR data obtained by data users is shown in Eq. (6).

$$M=(key\|hash_{ipfs})=C_0\cdot\frac{1}{e(K_0,C_1)}\square\prod_{x\in L}(F_{x,1},F_{x,2})^{u_x} \quad (6)$$

In Eq. (6), u_x represents the recovery coefficient. In addition, in the EHRSS model, patients have the right to specify the users of their private data and perform fine-grained revocation of attribute sets, without updating the private key information of other data users associated with the ciphertext. Taking revoking a certain identification ID as an example, the patient needs to add the data user's ID to the revocation list corresponding to the attribute, and re encrypt and upload the electronic health record data to the IPFS system, replacing the access policy set in the shared contract.

B. *Design of Privacy Protection Methods Based on Blockchain*

In the process of EHR data sharing, relying solely on the security of the IPFS system and blockchain cannot fully guarantee the privacy of patient EHR data. Therefore, based on the proposed EHRSS model, further research was conducted on the privacy protection of EHR using ZKP and ElGamal encryption algorithms on the basis of BCT. ZKP can prove to other verifiers that a proposition is true without disclosing any actual information of the verifier [16-17]. Therefore, the proof process of ZKP in the proposed EHRPP method is shown in Fig. 3.



Data users identify EHR data needs for research
ZK-SNARKs listed ZKP
The patient makes an initial judgment based on the needs of the data user.
Generate a digital signature for the patient
Construct corresponding digital circuits based on smart contracts
Output result set with hash
Key pairs for obtaining proofs of knowledge
Output ZKP
Smart contracts make judgments about patient EHR data
Proof passed, data user obtains EHR data cipher

Fig. 3. ZKP's proof process in EHRPP.

In Fig. 3, data users use Zero-Knowledge Succinct Non-Interactive Argument of Knowledge (ZK-SNARKs) list the ZKP of patient EHR data required for their research, and publish the correlation results and hash values generated based on digital circuits into smart contracts. Secondly, patients make a preliminary judgment on whether they meet their expectations based on the data keywords disclosed by medical institutions. If so, continue to validate the patient's data to ensure that it meets the needs of the data user. The patient randomly selects a numerical value and combines it with information such as ID, timestamp, and EHR data to generate a digital signature. The specific expression is shown in Eq. (7).

$$q_z=AuthSign(x_p,H_1(ID_p,\tau,M,k)) \quad (7)$$

In Eq. (6), q_z represents digital signature. $AuthSign(*)$ represents authorized signature. x_p represents the patient's private key. ID_p represents the patient's identification information ID. τ represents timestamp. k represents a random number. H_1 represents a hash function that can resist collisions. At the same time, patients establish corresponding digital circuits based on smart contracts, and combine random values to obtain the EHR dataset, additional data, and common parameters of the system. The specific expression is shown in Eq. (8).

$$\begin{cases}M'=<m_1...,m_n,k>\\<ID_p,\tau>\\V(<m_1...,m_n,r>)\to(R,H)\end{cases} \quad (8)$$

In Eq. (8), M' represents the HER dataset obtained by selecting a random number k. m_n represents HER data. V represents the digital circuit constructed by the patient. R represents the result set. H represents the hash value. r represents the output result. Based on the above parameters, it inputs and calculates the result set and hash value of EHR to prove the authenticity and availability of the obtained EHR data. After inputting system security parameters and digital circuits, it can obtain the key pair information of ZKP. The specific expression is shown in Eq. (9).

$$ZKPkeygen(1^\eta,V)\to(Pk_V,Uk_V) \quad (9)$$

In Eq. (9), $ZKPkeygen(*)$ represents the ZK-SNARKs algorithm. Pk_V represents the key for listing ZKP. Uk_V represents the key for verifying ZKP. η represents system security parameters. Input the patient's EHR data, digital signature, and the key generated by ZKP, as well as the obtained result set and hash value, and then output ZKP. The specific expression formula is shown in Eq. (10).

$$Prove(M,q_z,Pk_V,R,H)\to\pi \quad (10)$$

In Eq. (10), $Prove(*)$ represents the output of patient related information. π represents ZKP. After the patient submits the ZKP, the EHR data of the patient is determined based on the smart contract to determine whether it meets the needs of the data user. The specific expression is shown in Eq. (11).

$$Verify(Uk_V, \pi, q_z, y_p, R, H) \to (true / false) \quad (11)$$

In Eq. (11), y_p represents the patient's public key. ZKP verifies the digital signature of EHR data using the patient's public key, and determines the ZKP, result set, hash value, ZKP generated by the data user, result set, and hash value. When all the above results meet the verification requirements, ZKP will output "true" to EHRPP, otherwise it will output "false". Therefore, the EHRPP model architecture based on the proposed ZKP is shown in Fig. 4.

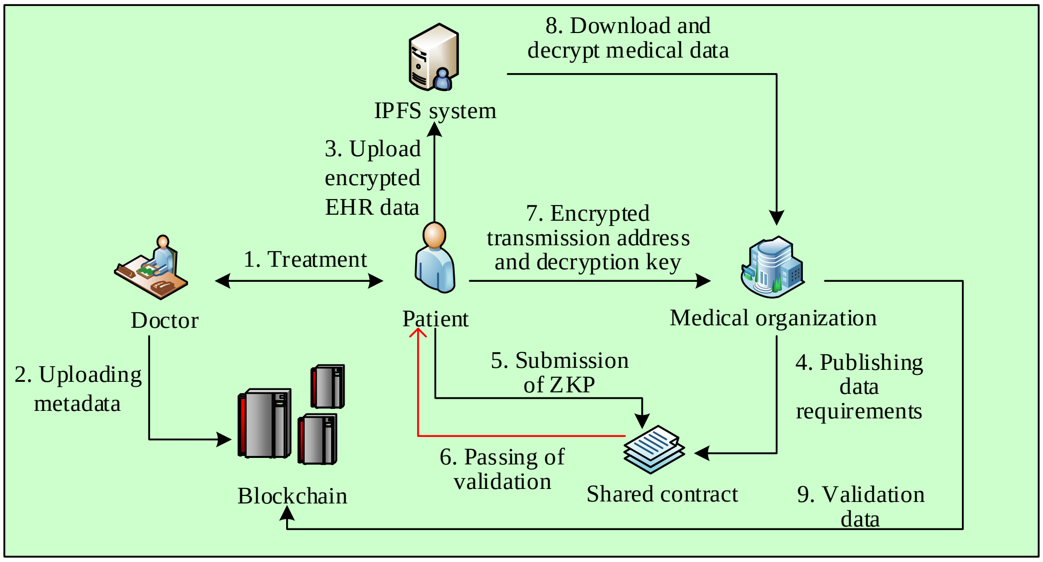


Fig. 4. Blockchain-based EHRPP model architecture.

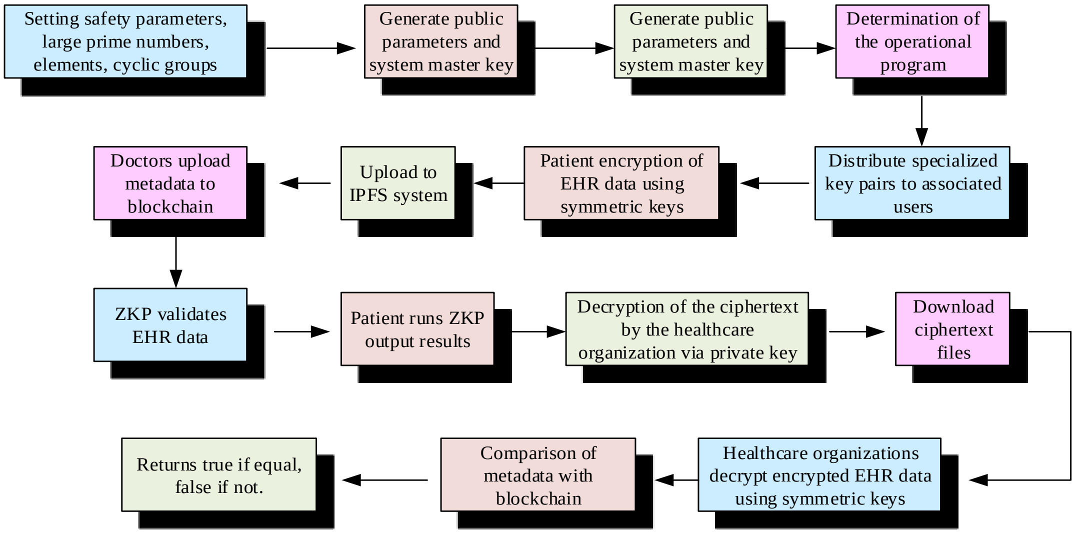
From Fig. 4, the EHRPP model proposed in the study differs from the EHRSS model in that it divides data users into doctors and medical institutions. This is because the study considers that on the basis of secure sharing of patient EHR data, medical institutions need to use EHR data for research or analysis to promote the recovery of medical diseases. Therefore, the study split the data users in the EHRPP model. Among them, doctors mainly generate EHR data for patients and are responsible for uploading patient metadata to blockchain for recording. Before using EHR data, medical institutions need to prove and define ZKP, and write the required keywords into smart contracts. Therefore, the process of the EHRPP model proposed in the study is shown in Fig. 5.

From Fig. 5, the EHRPP model first sets security parameters and parameters such as large prime numbers, meta groups, cyclic groups, priority over representation, hash functions, etc., to generate common parameters and system master keys. The specific expression is denoted in Eq. (12).



Setting safety parameters, large prime numbers, elements, cyclic groups
Generate public parameters and system master key
Generate public parameters and system master key
Determination of the operational program
Distribute specialized key pairs to associated users
Patient encryption of EHR data using symmetric keys
Upload to IPFS system
Doctors upload metadata to blockchain
ZKP validates EHR data
Patient runs ZKP output results
Decryption of the ciphertext by the healthcare organization via private key
Download ciphertext files
Healthcare organizations decrypt encrypted EHR data using symmetric keys
Comparison of metadata with blockchain
Returns true if equal, false if not.

Fig. 5. Blockchain-based EHRPP model flowchart.

$$Pk = (p, g, G_1, Z_p, H_1, H_2) \tag{12}$$

In Eq. (12), p represents large prime numbers. G_1 represents a cyclic group of order p. Z_p represents a finite field. H_2 represents an reversible hash function. The system conducts qualification review for patients, doctors, and medical institutions with requirements, and creates corresponding key pairs for them. The three obtain their respective public key calculation formulas as shown in Eq. (13).

$$\begin{cases} y_p = g^{x_p} modp \\ y_d = g^{x_d} modp \\ y_r = g^{x_r} modp \end{cases} \tag{13}$$

In Eq. (13), y_d and y_r respectively represent the public keys of doctors and medical institutions. x_d and x_r respectively represent the private keys of doctors and medical institutions. The patient encrypts EHR data using a symmetric key and uploads the ciphertext to the IPFS system to obtain the corresponding storage hash value. Meanwhile, doctors upload patient metadata to blockchain for recording and storage. Medical institutions provide ZKP certification based on the patient EHR data they need. After the ZKP verification is passed, the medical institution sends an application to the patient to obtain EHR data information. The patient randomly outputs the shared data and synchronously stores it in the system. The specific expression is shown in Eq. (14).

$$\begin{cases} key' = H_2(key \| hash_{ipfs}) \\ s_1 = g^{\gamma_1} \\ s_2 = y_r^{\gamma_1} key' \\ s_3 = H_2(key \| hash_{ipfs}) \cdot y_r \end{cases} \tag{14}$$

In Eq. (14), s_1, s_2, and s_3 represent the results obtained by calculating the application information of medical institutions. key' represents the symmetric key of the medical institution. Medical institutions obtain IPFS information and symmetric keys for stored HER data based on the key. At this point, the system checks the medical institution based on the hash value and identification ID, as shown in Eq. (15).

$$\begin{cases} k_s = s_1 s_2{}^{-x_r} \\ k_s{}' = H_2{}^{-1}(k_s) = key \| hash_{ipfs} \\ check = H_1(key \| hash_{ipfs}) \cdot y_r \end{cases} \tag{15}$$

In Eq. (15), k_s and $k_s{}'$ represent the application information calculated by the patient and medical institution, respectively. The system compares the examination values of medical institutions with the medical institution information stored by patients in the system. When the two are equal, it indicates that the transaction is legal. At this point, medical institutions can obtain encrypted EHR data by downloading based on hash values. Conversely, the system determines that the medical institution is a malicious user and punishes them. After downloading EHR data, medical institutions can use symmetric keys to decrypt the data and obtain the original EHR data. At the same time, it compares the hash value of EHR data with the metadata of blockchain records to determine whether the data is EHR data required by medical institutions.

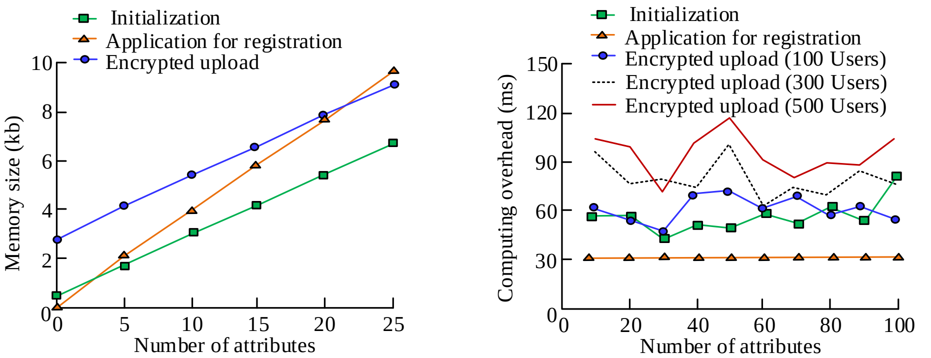
IV. RESULTS

To verify the effectiveness of the EHR data security sharing and privacy protection methods proposed on the basis of blockchain, the study first analyzed the properties and encryption efficiency of the EHRSS method during the encryption and upload stages. Secondly, performance validation and analysis were conducted on the proposed EHRPP method.

A. *Verification and Analysis of Security Sharing Methods Based on Blockchain*

To effectively validate the effectiveness of the EHRSS method, simulation experiments were conducted on the Java Pairing Based Cryptography (JPBC) library in the Java language. It assumed that the cyclic group and generator are both 1024 bits, the ID length is 64 bits, the account length is 160 bits, and the IPFS address length is 256 bits. In EHRSS, it interacted with blockchain during initialization, registration application, encryption, and upload stages. Therefore, the study first analyzed the changes in storage size, computational cost, and number of attributes in three stages, as shown in Fig. 6.

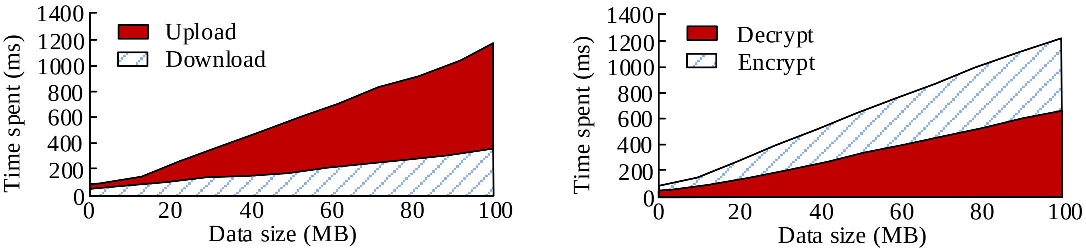
Fig. 6(a) showcases the relationship between the storage phases of the EHRSS model in three stages and the amount of attributes when the revocation list has 10 data users. As the amount of attributes increases, the storage overhead for the three stages of model initialization, application for registration, and encryption upload all increased. Based on the calculation cost of the three stages in Fig. 6(b), as the amount of attributes changes, the calculation cost of the initialization stage first increased and then decreased with the increase of the number of attributes, but the overall change is relatively small. The computational cost during the registration application stage remained generally stable as the amount of attributes increased. However, the computational cost of EHRSS encryption and uploading was not affected by the amount of attributes for different user numbers. This indicated that users can expand the attributes in the EHR data sharing project as needed, and the computational efficiency will not be reduced by the increase in the number of attributes. On this basis, the study further analyzed the impact of different sizes of EHR data on IPFS system upload and download, encryption and decryption, as shown in Fig. 7.



(a) Variation of storage size with the number of attributes for the three phases

(b) Variation of computational overhead with the number of attributes for the three phases

Fig. 6. Relationship between the three phases of EHRSS and changes in the number of attributes.



(a) Time overhead of uploading/downloading EHR data of different sizes to/from IPFS

(b) Time overhead of symmetric encryption and decryption of EHR data of different sizes

Fig. 7. Impact of different sizes of EHR data on uploading and downloading, encryption and decryption in IPFS systems.

From Fig. 7 (a), as the EHR data increased, the upload and download time overhead of the IPFS system also increased. When the EHR data size was 100MB, the upload time cost in the IPFS system was 1.17s, and the download time cost for h was 0.36s. Based on Fig. 7 (b), the proposed security sharing method had lower encryption and decryption time costs for EHRSS under different EHR data sizes, and had ideal efficiency in processing large-scale EHR data. Therefore, the study further compared the performance of medical data security sharing methods proposed by other scholars with EHRSS. The EHR data size was set to 2GB, and the specific comparison results are denoted in Table I.

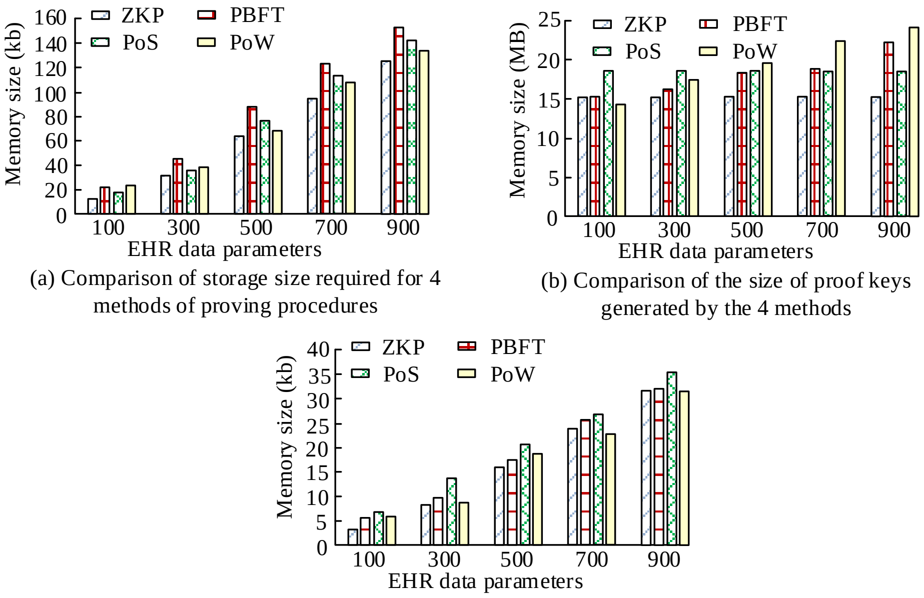
TABLE I. PERFORMANCE COMPARISON OF DIFFERENT SECURITY-SHARING METHODS

Methods of secure data sharing	Encryption overhead (s)	Generated key size (kb)	Decryption overhead (s)
Reference [6]	45.23	124.24	40.35
Reference [7]	42.54	150.00	34.62
Reference [18]	35.46	128.00	29.88
Reference [19]	22.43	89.75	15.87
EHRSS	19.23	54.32	6.63

From Table I, the EHRSS method proposed in the study required significantly less encryption and decryption time compared to other methods. The encryption time required for EHRSS was reduced by an average of 47.20% compared to other methods, while the decryption time was reduced by an average of 78.03%. This indicated that the introduction of attribute revocation lists on the basis of blockchain has improved the encryption and decryption efficiency of data security sharing. By comparing the key sizes generated by different algorithms, the proposed method reduced them by 56.28%, 63.79%, 57.56%, and 39.48%, respectively, compared to other methods. This indicated that the algorithm raised in the study not only improves the granularity of attribute revocation, but also enhances the convenience of ciphertext applications. Compared to other methods, EHRSS has superior computational efficiency and practicality.

B. Verification and Analysis of Privacy Protection Methods based on Blockchain

To further demonstrate the privacy and security of EHRPP in protecting patient EHR data, this study verified and analyzed the performance of the ZK-SNARKs algorithm in the EHRPP method, the required time for verifying keys, generating proofs, and the time cost for verifying proofs. The research set the security parameter to 128 bits, ZKP was defined by the libSNARK code library, and each experiment was repeated 10 times. The average of each indicator was taken for the experimental results. Meanwhile, the Practical Byzantine Fault Tolerance (PBFT) mechanism, Proof of Stake (PoS) mechanism, and PoW mechanism were introduced and compared with ZKP. The required storage sizes for the four mechanisms under different EHR data scales are shown in Fig. 8.



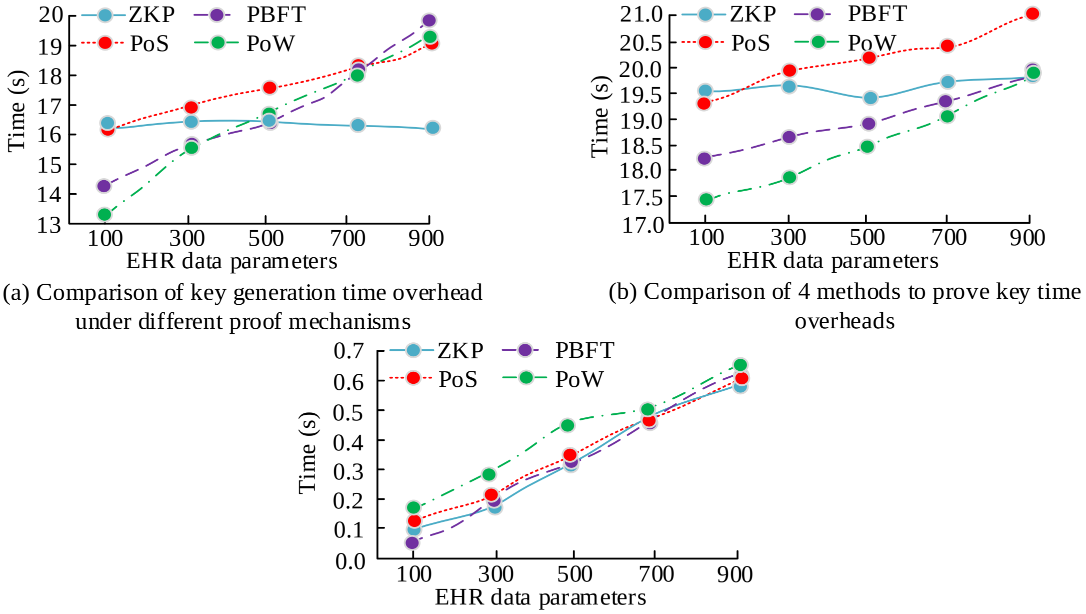
(a) Comparison of storage size required for 4 methods of proving procedures

(b) Comparison of the size of proof keys generated by the 4 methods

(c) Comparison of storage size of authentication keys generated by 4 methods

Fig. 8. Comparison of key generation and verification storage size under different proof mechanisms.

From Fig. 8(a), as the EHR data parameters increased, the storage size required for all four proof methods also increased. Compared to other methods, ZKP required smaller storage. Combining the four proof methods in Fig. 8(b), ZKP reduced the storage requirements for keys by an average of 5.18%, 13.14%, 19.45%, 24.00%, and 30.05% compared to the other three methods when the medical data parameters were 100, 300, 500, 700, and 900, respectively. The size of ZKP and PoS proof keys remained basically unchanged, while PoW's proof key size increased as the number of parameters increased, although the proof size was less than ZKP when the parameter was 100. This indicated that the proof process of ZKP is more stable. By comparing the verification key sizes of the four methods in Fig. 8(c), when the parameter was 900, the verification key size of ZKP was 31.80kb, which was 4.70% less than the other three methods. This indicated that the EHRPP based on the ZKP proposed in the study has superior performance in protecting patient privacy, balancing the security sharing and privacy protection issues of EHR data. Meanwhile, the study further compared the time overhead for generating keys, proving keys, and verifying keys using four methods, as shown in Fig. 9.



(a) Comparison of key generation time overhead under different proof mechanisms

(b) Comparison of 4 methods to prove key time overheads

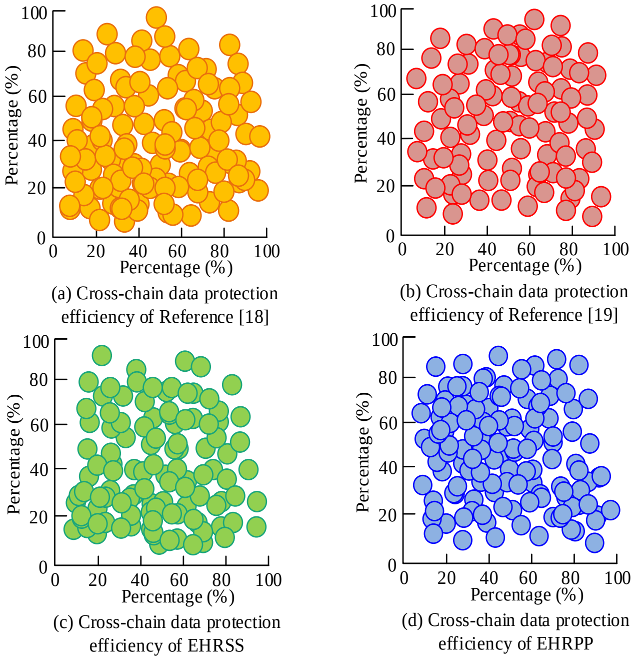
(c) Comparison of the time overhead of 4 methods of examining keys

Fig. 9. Comparison of the time overhead required for key generation and verification under different authentication mechanisms.

As shown in Fig. 9(a), the time overhead of generating keys for ZKP under different EHR data parameters showed no significant change, with an average time cost of 16.29 seconds. Compared with the other three methods, the average time overhead decreased by 3.93%, 7.39%, and 1.51%, respectively. From the comparison of the time cost required to prove the key using the four methods in Fig. 9(b), ZKP was least affected by the size of data parameters. The other three algorithms showed an upward trend with the increase of parameter size. This may be because during the key proof process, the storage capacity of the three algorithms for proving keys is relatively large, which requires more time for proof. Fig. 9(c) shows the time overhead for four algorithms to verify whether the key information is the data required by medical institutions. When the parameter quantity of EHR data was 900, the time overhead of ZKP was reduced by an average of 4.84% compared to the other three algorithms. The above verification indicates that the EHRPP proposed based on ZKP has superiority in overall performance. In addition, the study further compared the privacy protection effects of Study [18], study [19], EHRSS and EHRPP 4 methods on EHR data security sharing are shown in Fig. 10.

Fig. 10 (a), (b), (c), and (d) show the EHR data sharing protection effect of study [18], study [19], EHRSS, and EHRPP four schemes, respectively. The protection effect of study [18], study [19], EHRSS, and EHRPP was about 91%, 84%, 84%, and 93%, respectively. This may be because the method proposed in study [18] achieved data protection through secret sharing algorithms, which has less dependence on the IPFS system, while study [19], although storing data in an off chain database based on IPFS, still relied on the authorization verification of the Ethereum blockchain. However, overall, the EHRPP method raised in the study has better security than the other two methods. Compared with EHRSS, after introducing ZKP, its privacy protection effect on EHR data was significantly improved. The performance comparison results of EHRPP with study [18] and study [19] in EHR data with 500 input parameters are denoted in Table II.

From Table II, the size of the proof key generated by EHRPP was only 15.2MB, and the time overhead for generating the proof key was16.3s. Compared with the key sizes generated in studies [18] and study [19], EHRPP had an average reduction of 84.52%. This indicated that the EHRPP method proposed in the study had a faster speed in generating proof key pairs, while comparing the time overhead for verifying keys with the three methods, the time overhead required in study [18] was lower. This may be because both EHRPP and study [19] were IPFS systems, while study [18] defined a group secret sharing algorithm architecture. However, overall comparison shows that EHRPP still has significant advantages in overall performance and security privacy.



(a) Cross-chain data protection efficiency of Reference [18]

(b) Cross-chain data protection efficiency of Reference [19]

(c) Cross-chain data protection efficiency of EHRSS

(d) Cross-chain data protection efficiency of EHRPP

Fig. 10. Comparison of the effectiveness of cross-chain data protection.

TABLE II. PERFORMANCE COMPARISON OF DIFFERENT METHODS

Method	Key generation process (s)	Proof key (s)	Authentication key (s)	Proof key size (MB)	Authentication key size (KB)
EHRPP	16.3	19.5	0.32	15.2	16.2
Reference [18]	15.9	21.2	0.04	165.4	16.2
Reference [19]	21.5	24.6	0.45	31.0	16.2

V. DISCUSSION

The study proposes a blockchain based EHR secure sharing and privacy protection method aimed at improving the security and privacy protection of medical data, ensuring that patients have absolute ownership of their medical data. Through experimental verification, the proposed method has significant advantages in generating key size and time cost. Compared with existing recognized mechanisms, ZKP reduces the average key generation time cost by 54.36%. In addition, this method has an average improvement of 7.73% in data protection effectiveness compared to other methods. This is consistent with the results obtained by Konkin A et al. in their study of ZKP [20]. By combining attribute encryption and blockchain computing to construct a data security sharing model, as well as introducing zero knowledge proof and ElGamal encryption algorithm, the research has successfully improved the construction of data privacy protection. The proposed method shows high efficiency in generating key size and time cost. Especially, compared with studies [18] and [19], the reduction in key generation time of ZKP indicates its potential advantages in handling large-scale data. Through smart contracts and attribute based encryption, patients can have more precise control over access and sharing of their EHR data, ensuring their absolute rights to their data. It can be considered that the introduction of ZKP and ElGamal algorithms on the basis of existing blockchain technology is an innovative attempt to improve the security and privacy of data sharing. Compared with other proposed data sharing frameworks, the research method shows lower time overhead and smaller key size in key generation, proof generation, and verification.

VI. Conclusion

To improve the security sharing and privacy protection performance of medical data systems, research explored security sharing EHR data privacy protection methods based on blockchain. Firstly, an EHRSS method based on BCT was proposed to improve the security of EHR data through attribute encryption algorithms. Secondly, the EHRPP model was constructed by introducing ZKP and ElGamal encryption algorithms. Experimental verification showed that compared to the other four methods, the key sizes generated by EHRSS decreased by 56.28%, 63.79%, 57.56%, and 39.48%, respectively. When the parameter was 900, the verification key size of ZKP was 31.80kb, which is 4.70% less than the other three methods. The data protection effect of EHRPP obtained by introducing ZKP on the basis of EHRSS increased by 10.71% compared to EHRSS. Compared to other methods, the key generated by EHRPP was only 15.2MB, and the time overhead for generating the proof key was 16.3s, resulting in an average reduction of 84.52% in key size. The outcomes indicated that the EHR data security sharing and privacy protection method proposed in the study can improve the overall performance and security of the system, and has positive application significance in medical data security and privacy protection. However, the study only conducted theoretical exploration and experimental analysis of security sharing and privacy protection methods. In the future, it will consider further optimizing ZKP technology, compressing its scale and generation time, and improving the security of data privacy protection.

Ensemble Machine Learning for Enhanced Breast Cancer Prediction: A Comparative Study

Md. Mijanur Rahman[1]*, Khandoker Humayoun Kobir[2], Sanjana Akther[3], Md. Abul Hasnat Kallol[4]
Assistant Professor, Department of Computer Science and Engineering, Southeast University, Dhaka, Bangladesh[1]
Student, Department of Computer Science and Engineering, Southeast University, Dhaka, Bangladesh[2, 3, 4]

***Abstract*—Breast cancer poses a significant threat to women's health, affecting one in every eight women globally and often leading to fatal outcomes due to delayed detection in advanced stages. Recent advancements in machine learning have opened doors to early detection possibilities. This study explores various machine learning algorithms, including K- Nearest Neighbor (KNN), Support Vector Machine (SVM), Multi- Layer Perceptron (MLP), Decision Tree (DT), Logistic Regression (LR), Naive Bayes (NB), Random Forest (RF), Ada Boost (AB), Gradient Boosting (GB), and XGboost (XGB). The employed algorithms, along with nested ensembles of Bagging, Boosting, Stacking, and Voting, predicted whether a cell is benign or malignant using the Wisconsin Diagnostic Breast Cancer (WDBC) dataset. Utilizing the Chi-square feature selection technique, this study identified 21 essential features to enhance prediction accuracy. Results of this study indicate that MLP LR achieved the highest accuracy of 98.25%, closely followed by SVM with 97.08% accuracy. Notably, the Voting classifier yielded the highest accuracy of 99.42% among the ensemble methods. These findings suggest that the research model holds promise for accurate breast cancer prediction, thus contributing to increased awareness and early intervention.**

Keywords—Breast cancer; detection; machine learning; bagging; boosting; stacking; voting; chi square; ensemble; hybrid ensemble; bioinformatics

I. Introduction

This Breast cancer is one of the alarming signs of female health, as many patients are added to the breast cancer queue every year globally. Mortality rate and late detection problems confirm that early detection is a must. According to the WHO report of July 2023, about two and nearly half million women were diagnosed, and 685,000 died in 2020 globally. On the other hand, in the last five years, only 7.8 million women survived after being diagnosed with breast cancer, ensuring it is the world's most prevalent cancer [1]. Similarly, as per the Daily Star report, more than 12 thousand women and seven hundred are diagnosed with breast cancer every year in Bangladesh, and about 6,844 of them don't make it [2]. Despite significant advancements in medical science, early detection remains the primary obstacle in effectively treating breast cancer. Timely detection is crucial, as failure to do so can result in fatal outcomes for patients [3].

Cancer occurs when healthy tissues undergo uncontrolled growth, forming masses or clusters of cells called tumors. Tumor cells can be of two types: Cancerous (called Malignant) and non-cancerous (named Benign) [4]. Malignant is harmful because this cell can grow and spread to other body parts, whereas Benign does not spread but grows. Cancer is detectable through physical examination, biopsy, or mammograms. These ways are effective but time-consuming, costly, and painful.

The primary challenge in breast cancer diagnosis lies in distinguishing between cancerous (malignant) and non-cancerous (benign) cells. Machine learning algorithms have emerged as a solution to this problem, leveraging previous patient data to develop various models. Over the past few decades, these algorithms, particularly Artificial Neural Networks and Support Vector Machines (SVM), have consistently demonstrated high accuracy and effectiveness. Their reliability makes them valuable tools for achieving better diagnostic outcomes [3].

Ensemble machine learning algorithms have long been employed to improve detection accuracy. In a recent study by R. Murtirawat et al. [3], an update on Ensemble Learning techniques involving five machine learning algorithms (LR, KNN, LDA (Linear Discriminant Analysis), SVM, RF) was presented. The study achieved an impressive accuracy of 99.30% using a 75% training and 25% testing dataset. Therefore, this paper represents a significant milestone by achieving even higher accuracy with a 70:30 training-testing data ratio.

In a study conducted by E. Strelcenia et al. [5], the accuracy of several machine learning methods, including LR, DT, RF, KNN, MLP, and XGB Classifier, was evaluated. Their findings revealed accuracies of 96%, 98%, 97%, 89%, 92%, and 94%, respectively, based on their dataset. Machine learning techniques consistently demonstrate notable accuracy percentages across various applications. In the context of breast cancer predictions, these algorithms proved to be particularly effective, yielding higher accuracy rates. For instance, both MLP and LR achieved an accuracy of 98%. Additionally, SVM, KNN, and XGboost demonstrated performances with 97% accuracy.

The aim of this research is to use ten different computer programs to guess if someone has breast cancer, using a dataset of 21 features. The goal is to accurately differentiate between benign and malignant cases using a range of algorithms, including KNN, SVM, DT, RF, MLP, NB, LR, ADB, GB, and XGB, along with other ensemble techniques such as Bagging, Voting, and Stacking. Ensemble techniques play a crucial role in breast cancer prediction and diagnosis, offering enhanced accuracy, particularly in the early stages. The proposed study utilizes proper statistical feature selection techniques to effectively detect breast cancer by distinguishing between benign and malignant cases. Furthermore, the research model holds promise for advancing developments in breast cancer research and improving patient care and treatment.

This study is structured into several sections. Firstly, it serves as a literature review, providing relevant information and discussion. Following this, the methodology section outlines the techniques and algorithms used in the model. Subsequently, the results section presents outcomes in terms of matrices and parameters. Discussions ensue, where the findings are analyzed and compared with existing works. Finally, the conclusion summarizes the study's key insights.

II. Literature Review

Ensemble methods have been used in breast cancer detection for quite some time now, mainly because they've been proven to boost accuracy. With the continuous advancements in medical science and machine learning algorithms, the impact on breast cancer research is becoming increasingly evident, attracting more researchers to the field each day. Many have focused their efforts on the WBCD dataset due to its extensive statistical data, allowing for more thorough experimentation.

In a recent study conducted by R. Shafique et al. [6], the significance of feature selection techniques was highlighted by comparing the performance of PCA, chi-square, and SVD on specific datasets. Models constructed using RF, SVM, GBM, LR, MLP, and KNN algorithms demonstrated enhanced accuracy with all three techniques. Notably, KNN achieved the highest accuracy of 95% on the WDBC dataset across the three feature selections. Following this, the study addressed dataset imbalance by employing upsampling, which involves adding extra samples to test the model's performance. This approach aimed to mitigate potential inaccuracies resulting from neglecting the minor class, ultimately improving accuracy. The following study displayed that Chi2 offered more impactful results than PCA comparatively in different models on statistical datasets, especially WDBC.

A study by M. Kumar et al. [7] introduced the OSEL (Optimized Stacked Ensemble Learning) model, which combines various algorithms such as KNN, RF, LR, SVM, DT, ADBM1, GB, SGB (Stochastic Gradient Boosting), and Cat Boost. This model achieved impressive metrics, including 99.4% accuracy, 99% precision, 98% recall, and 99% F-measure. As an effective heterogeneous ensemble method, Stacking demonstrated superior performance compared to other Boosting classifiers, resulting in higher accuracy, precision, recall, and F1-measure. This makes the combined model particularly relevant in the current research landscape. Another notable ensemble model for diagnosis was established by U. Naseem et al. [8], utilizing a combination of four classification methods (SVM, LR, NB, DT) as base learners and artificial neural networks (ANN) as the meta-learner. This model achieved an accuracy of 97.6% without sampling and 98.83% with sampling. In the prognosis case, the ensemble model performed best with SVM, LR, and RF as base learners and ANN as the meta-learner, achieving an accuracy of 83.15% without sampling and 88.33% with sampling. Notably, SVM consistently outperformed other classification models across both diagnosis and prognosis datasets when used individually.

The study by R. Murtirawat et al. [3] garnered attention for showcasing remarkable accuracy through the Voting ensemble technique. Their updated Ensemble Model (LR, KNN, LDA, SVM, and RF) achieved an impressive accuracy of 99.42% with a 75% training dataset and 25% testing dataset. However, this notion was challenged by another report from A. Assiri et al. [9], whose Voting ensemble boasted even higher accuracy of 99.42%, achieved solely through majority Voting. This majority-based algorithm was constructed using the top three algorithms (logistic learning, SVM with SGD, and multilayer perceptron) from the initial eight classification techniques, which then determined the final result through a voting mechanism. Interestingly, this study revealed that the majority-based ensemble model outperforms the soft voting accuracy (98.83%), showcasing its comparative effectiveness.

V. Nemade et al. [10] presented a model comprising two sections: standard ML algorithms and ensemble techniques. Achieving an accuracy of 97% with XGboost, the evaluation was based on the confusion matrix labels, including True Negative (TN), False Negative (FN), True Positive (TP), and False Positive (FP). Notably, this model utilized AUC as a metric, distinguishing itself from others that typically rely on accuracy, precision, recall, and AUC-ROC.

M. Ramakrishna et al. [11] proposed an AdaBoost ensemble model that leveraged recognized feature patterns. Notably, Adaboost-RF and Adaboost-NB took 8.52s and 18.32s, respectively, to develop the model. Impressively, Adaboost-RF achieved an accuracy of 97.95%, demonstrating commendable performance. Further evidence of the effectiveness of the AdaBoost algorithm was provided by N. Mashudi et al. [12], who implemented it on the WBCD dataset and achieved an accuracy of 98.77%. Through various cross-validation techniques such as 2-fold, 3-fold, and 5-fold, AdaBoost demonstrated consistent high accuracy, with scores of 98.41% and 98.24% for 2-fold and 3-fold cross-validation, respectively. Additionally, SVM displayed a notable accuracy of 98.60% in 5-fold cross-validation.

In a study by M. Momtahen et al. [13], a DOB-Scan probe was introduced to classify breast tissues as healthy or unhealthy. They devised a technique utilizing bagging and boosting on machine learning classifiers, achieving 100% accuracy in classifying 68 tissue-mimicking liquid phantom samples. Similarly, the effectiveness of the voting classifier was demonstrated in a paper by Q. Nguyen et al. [14]. In their research, the Ensemble-voting classifier, SVM tuning, and logistics regression achieved an accuracy of 98.83%. The study utilized PCA for feature extraction and implemented a 90:10 training-testing ratio with 10-fold cross-validation to mitigate the risk of overfitting.

III. Methodology

For early detection, it's crucial to determine whether the affected cell is cancerous (Malignant) or not (Benign). The process discussed in this research involves several phases, including data analysis, model preparation, training, and ensemble techniques. During data analysis, researchers of this study conducted data description, collection processing, and feature selection. The prepared data is then used for model preparation, implementing various ML algorithms. This includes individual machine training, ensemble approaches, and evaluation metrics.

In Fig. 1, the primary task was to pre-process the data. After selecting the WBCD dataset and dividing it into training (70%) and testing (30%) sets, this study applied standard scaling to standardize features. Ensemble and machine learning models of this research aim to detect cancer cells (Benign or Malignant), incorporating the effectiveness of all algorithms and ensemble models with differences in their performance.

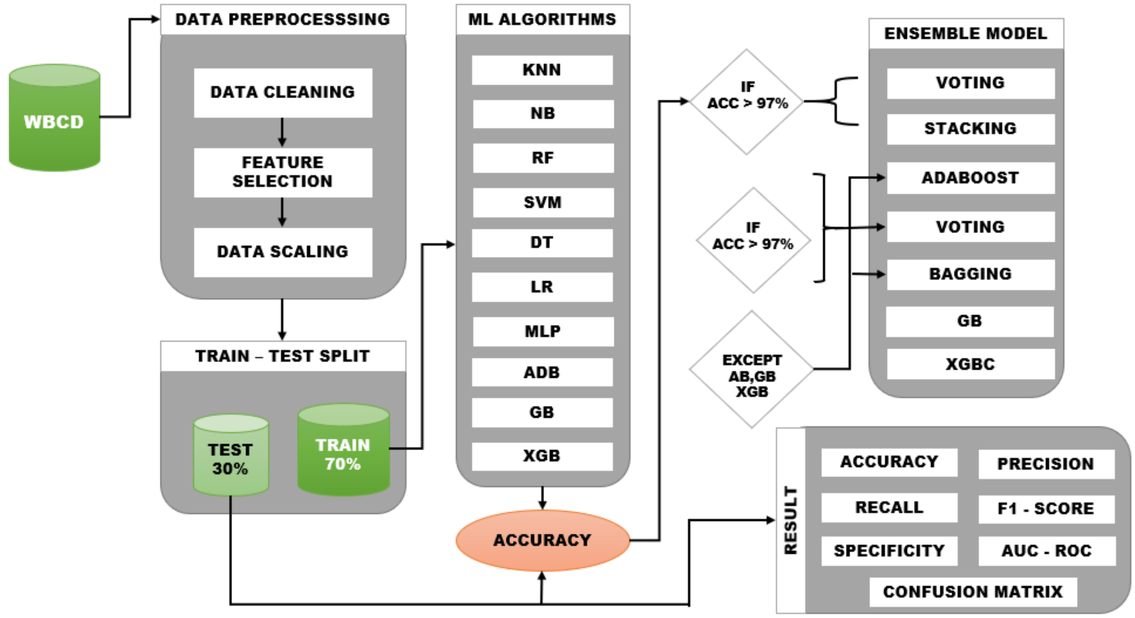

Fig. 1. Diagram of proposed methodology.

A. Dataset Description

The 'WBCD' dataset, curated by Dr. William H. Wolberg from the University of Wisconsin Hospital in Madison, comprises 569 rows and 33 columns. For each cell nucleus, ten actual valued features are computed, including radius (mean of distances from the center to points on the perimeter), texture (standard deviation of gray-scale values), perimeter, area, smoothness (local variation in radius lengths), compactness (perimeter^2 / area-1.0), concavity (severity of concave portions of the contour), concave points (number of concave portions of the contour), symmetry, and fractal dimension ("coastline approximation" - 1). Additionally, attributes such as ID Number and Diagnosis (M=malignant, B=benign) are included, with 357 instances classified as Benign and 212 as Malignant.

B. Data Collection and Pre-processing

1) Data collection: Collected this 'WBCD' dataset from Kaggle (a renowned platform for dataset collection). This dataset contains many features related to breast cancer, which helps in determining whether it's Benign or Malignant.

2) Data exploration: Providing a comprehensive explanation of the dataset is crucial for a proper understanding of the data. To achieve this, this research conducted descriptive statistics, checked for missing values, and visualized distributions using box plots, heat maps, histograms, and correlation matrices. These techniques are invaluable for gaining insight into the dataset and effectively addressing any issues that may arise.

3) Cleaning: For cleaning purposes, the researches of this study removed the 'ID' and 'unnamed' columns as they are not necessary for cancer detection or prediction. After removing them, the dataset became more significant and accurate, leading to easy working processes for proper detection.

4) Feature selection: The feature selection method of this model is Chi-square(chi2). It helped to find 21 features to detect whether the actual cell is benign or malignant. Of the 569 records, 37% were classified as Malignant, accounting for 212 records. Conversely, 63% of the cells were classified as Benign, resulting in 357 records. This approach focuses on extracting features that are both informative and straightforward for cell determination. Fig. 2 shows percentage of patients.

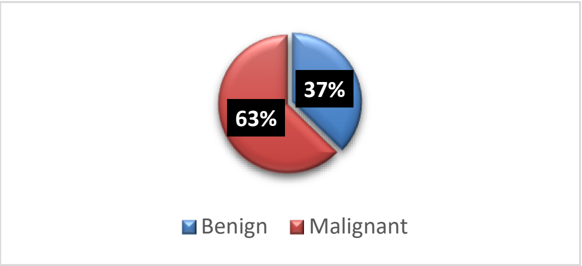

Fig. 2. Percentage of patients.

5) Train-test split: The dataset was divided into two parts: (1) Training and (2) Testing. 70% of the data is allocated for training, as this portion teaches the model and determines the actual results. The remaining 30% of the dataset was reserved for testing, providing insights into the model's performance and evaluating the training process's effectiveness.

6) Scaling: Scaling method uses data transform technique to fit within a specific scale. In this case, the research used standardization as the scaling method, which involves converting data to have a mean of zero and a standard deviation of 1 so that all features can be expressed in a comparable way.

7) Encoding: For encoding, we've used data labeling. This approach assigns a unique number to label each class inside a definite feature. It expresses records by changing them into a numerical layout, ensuring compatibility with the algorithms' requirement for numerical inputs, and even maintaining the specific feature's information.

8) Final data set: This is the final dataset resulting from an exhaustive study. With 569 samples and numerous features, the model can effectively detect whether a cell is Benign or Malignant. The main approach involved selecting 21 features using the chi-square method, which proved instrumental in identifying cancer cells. Through various techniques and methods, this research successfully achieved accurate cancer detection and more.

C. Algorithms

1) Chi-square: It is [6] a feature selection technique to select the best correlational feature from independent variables. It is a well-performed method for feature selection in statistical datasets. Chi-square performs to determine the GOF (Goodness of it), which measures the closeness of the prediction from a hypothesis [6]. The formula of chi-square is:

$$x^2 = \sum(f_0 - f_e)/f_e \tag{1}$$

Where,

f_0= observed frequency

f_e =expected frequency when no relation existed between variables.

In Fig. 3, also shows the visualization of the importance of 30 features through chi2, among which we select the top 21 features for our model prediction.

2) K-nearest neighbor: In short, KNN is a non-parametric, supervised learning algorithm that works to classify similar points near one another and make an individual group of them. To measure the new Knearest point, the researchers of this study calculated with Euclidean distance. It's a distance measurement to deal with big datasets. [7] The equation is:

$$d(x, y) = \sqrt{\sum_{i=1}^{n}(x_i - y_i)^2} \tag{2}$$

3) Logistic regression: A binary classification process to work with a linear function. Here, the sigmoid function is used as it refers to the assumption or probability [5]. The equation of this is:

$$P(Y = 1|x_i) = \sigma(x_i^T W) = \frac{1}{1+e^{-(w_0+w_1x_1,1+w_2x_2,2+\cdots+w_dx_i,d)}} \tag{3}$$

4) Multilayer perceptron: MLP is a supervised, feed-forward back-propagation network comprising multiple layers: input, output, and hidden layers. These layers play a crucial role in extracting essential information during learning and adjusting weights accordingly [5]. MLP employs a stimulation function across all neurons, calculated using the following formula [25]:

$$f(x_i) = \text{b} + \sum_{i=1}^{n} x_i\, w_i \tag{4}$$

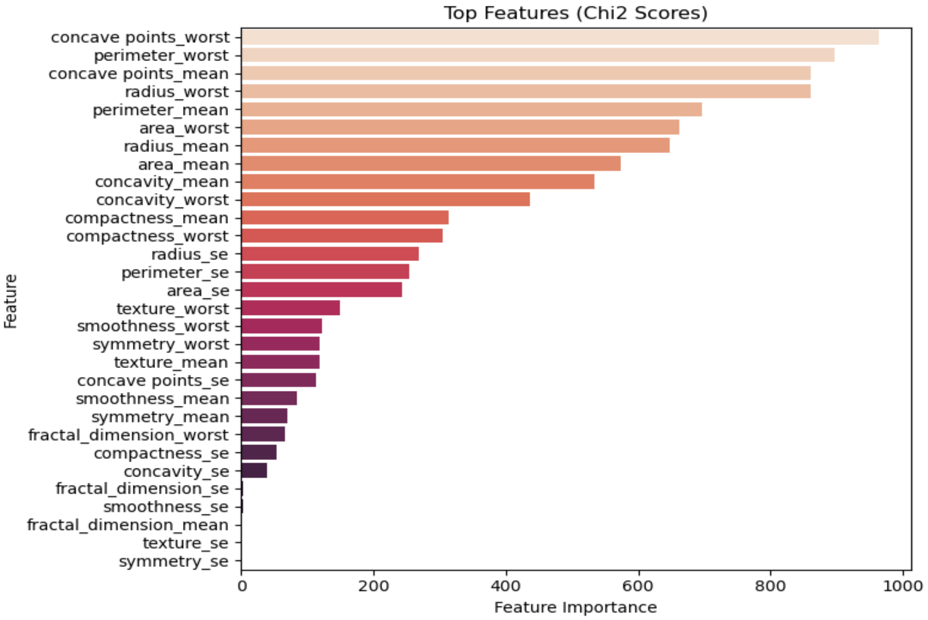

Fig. 3. Important features representation.

where,

x_i = inputs of incoming layers.

w_i = weights of hidden layers neurons.

b = initial weight.

5) Random forest: It is another type of supervised learning algorithm with a building block of machine learning, a way of making new data predictions based on previous data. RF is built with a set of decision trees of randomly chosen features, which gives the best prediction from the voting of every tree [25].

6) Adaboost: AdaBoost is an ensemble method that utilizes boosting, combining numerous "weak classifiers" to form a "strong classifier" by updating their weights iteratively. Training continues until a minimized error is achieved [11]. AdaBoost is a boosted classifier of the form:

$$F_T(\text{x}) = \sum_{t=1}^{T} f_t\, x \quad (5)$$

Where each f_t is a weak learner that takes an object as input and returns a value indicating the class of the object [26].

7) Gradient boosting: GB is a numerical optimization technique that addresses classification and regression problems [26]. It operates sequentially, gradually improving weak learners by focusing on high-value data points. It can be defined as:

$$\text{Y} = \text{ax} + \text{b} + \text{e} \quad (6)$$

Where e represents the error and shows the inexplicable data [6].

8) XGboost: The XGB is a high-scalability decision tree that minimizes the loss function to get an additive expansion of the function [5]. XGB uses extensive and complex datasets to classify objects [7].

9) Bagging: Bagging is a way of reducing variance from noisy datasets by converting some random subsets into decision trees. It trains multiple instances of weak learners and finally predicts by averaging on regression and voting for classification, which tends to reduce overfitting and makes it more sustainable [27].

10)Boosting: Boosting is a sequential process of reducing errors in a predicted model. In this method, the base classifier allocates updated weight to the occurrences of misclassification, which improves the performance of the model sequentially [27].

11)Voting: Voting is a method of combining the prediction of multiple independent models. It could either be Soft voting or Majority Voting. It is useful when the base model shaves multiple predictions, like high or low, but can have the majority or average performance percentages [27].

12)Stacking: Stacking is a technique of taking outputs from multiple base models and passing them as an input of a Meta model for final prediction. It takes base predictions optimally and leads to better performance [27].

IV. Result

The proposed model of this study is a combination of machine learning algorithms, including ensemble methods. To preprocess the WDBC dataset, this study applied standardization and then used the Chi-square method for univariate feature selection, resulting in 21 effective features for classification. Initially, the dataset was divided into two parts: 70% for training and 30% for testing, using the train_test_split function from the Sklearn model selection package. The random state number 42 was used for this function. The researchers of this study developed the model using Python (version 3.11) and Anaconda (Anaconda Inc., Austin, TX, USA) as the software platform. Built-in functions such as Sklearn, Numpy, Pandas, Matplotlib, and Seaborn were utilized to conduct experiments and evaluate results. After splitting the dataset, ten different ML classification and regression algorithms were applied —KNN, SVM, MLP, NB, RF, DT, LR, XGB, AB, and GB—to train all the ML models on 70% of the training data. Subsequently, the remaining 30% of the data allowed the prediction of cancer cell types, assessing the research model's performance on unknown data. The Chi-square method significantly contributed to achieving an accuracy of over 98%, compared to PCA [6] [28], which yielded an accuracy of only 94%.

To determine the supremacy of any model, researches need to measure the performance via metrics. ROC can help to represent its performance; the higher the curve, the better performance is provided by the model [29].

1) Confusion matrix: A confusion matrix is a table describing the performance of a classification model based on test data whose original valid values are known before. Though it is simply stable, other parameters are slightly confusing (see Fig. 4).

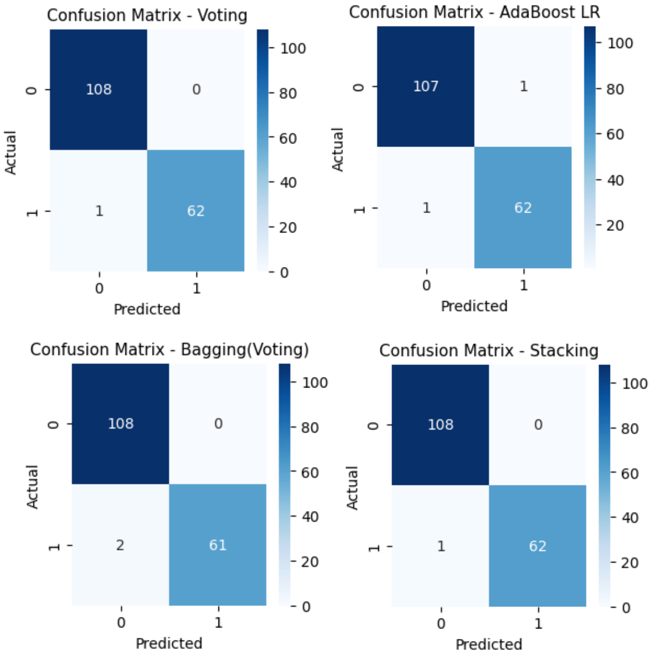

Fig. 4. Confusion matrix of ensemble techniques.

2) Accuracy: Accuracy measures the number of correctly detected Breast tumors [27]. It describes the model's correct output prediction and measures how accurately a model works so that the model can prove (see Fig. 6) itself more effective. High accuracy produces high success of models. The formula is given below:

$$\text{Accuracy} = \frac{TP+TN}{TP+FP+FN+TN} \tag{7}$$

3) Precision: It evaluates the accurate classification of positive samples and the true positive rate. This paper presents the valid Malignant rate, indicating the perfect positive output correctly identified by the model. This can be calculated using the formula below:

$$\text{Precision} = \frac{TP}{TP+FP} \tag{8}$$

4) Recall: It is an output of total positive classes that confirms the correct prediction of a model. The recall is as preferable as higher. The formula for the recall is:

$$\text{Recall} = \frac{TP}{TP+FN} \tag{9}$$

5) Specificity: It measures the correct negative sample classification. It can be mentioned as the actual negative rate. The formula of it:

$$\text{Specificity} = \frac{TN}{TN+FP} \tag{10}$$

6) F1 score: When two models exhibit significant differences between precision and recall points—such as high precision and low recall, or vice versa—comparing them becomes challenging. This is where the F-score comes into play, as it aims to balance recall and precision simultaneously. The F-score reaches its maximum value when recall is equal to precision. The formula below can be used to calculate it:

$$\text{F1} - \text{Score} = \mathbf{2} \times \frac{Recall \times Precision}{(Recall + Precision)} \tag{11}$$

7) AUC-ROC: AUC mainly measures the ranking of good prediction; on the other hand, ROC is a graph showing the performance of all classification models (see Fig. 5).

Table II presents the accuracy, precision, recall, f1, f2, f3 scores, and AUC-ROC. MLP and LR achieved the highest accuracy prediction of 98.25%, followed by KNN, SVM, XGB, and RF with 97.08% accuracy. AB and GB both attained 95.91% accuracy, while DT and NB achieved 94.15% and 93.57% accuracy, respectively. The highest precision score of 0.9839 was obtained from MLP and LR. Additionally, recall, f1, f2, and f3 scores, and AUC-ROC yielded the highest values of 96.83%, 97.60%, 97.13%, 96.98%, and 97.95%, respectively. It is evident that when considering all parameters, MLP and LR performed the best as individual algorithms.

Following that, the ensemble algorithm is presented in Table III, showcasing the results of the research model after applying the Ensemble Technique. Once the top algorithms have been identified, they are utilized for the ensemble technique (shown in Table II). As SVM, LR, MLP, and XGBC worked well (shown in Table I), this study chose them for Voting and Stacking, which gave the highest accuracy of 99.42% as well as precision, recall, F1, and F2 scores of 1.0, 0.9841, 0.9920, and 0.9873, respectively. Despite having the lowest accuracy of NB and DT (shown in Table III), they performed much better after applying Bagging. So, it is evident that ensemble techniques are always more effective in performance. Fig. 7 shows performance of different EML algorithms.

V. Discussion

Table IV below provides a comprehensive comparison between existing models and the model created within this study, all applied to the same ‘WBCD’ dataset. Despite the numerous proposals on breast cancer, these represent some recent works by various researchers. The research model outperforms many of these in multiple aspects. This comparison is organized based on accuracy, precision, recall, specificity, F1 score, AUC-ROC, and train-test performance of the existing models, allowing for an overall performance contrast.

The effectiveness of the stacking algorithm has been demonstrated by author A. Abdar et al. [30], achieving over 98% performance in accuracy, precision, and recall. Another model, SELF by A. Jakhar et al. [26], attained 98.80% accuracy using this technique, along with high precision, recall, F1-score, and AUC-ROC scores exceeding 99% on an 80:20 training-testing ratio. On the other hand, the recent model OSEL by author M. Kumar et al. [7] garnered attention with the highest accuracy of 99.45%. However, the precision, recall, and F1-score scores were 99%, 98%, and 94%, respectively, leading to somewhat less satisfaction. In terms of the research model, stacking achieved an accuracy of 99.42%, with 100% precision, 98.41% recall, 100% specificity, 99.2% F1-score, and AUC-ROC scores on a 70% training dataset and 30% testing dataset, showcasing the highest overall performance among the models

A voting classifier is another technique aimed at enhancing performance, as described by Q. Nguyen et al. [14], achieving an accuracy of 98.83% and nearly 99% in other scores. However, this performance was surpassed by another model by M. Murtirawat et al. [3], utilizing the same classifier and achieving 99.30% accuracy, along with 100% precision, 97.8% recall, and 98.87% F1-score on a 75:25 train-test ratio. A recent paper by A. Assiri et al. [9] provided a remarkable accuracy of 99.42%, including more than 99% precision, recall, and F1-score with a complex voting ensemble technique, which was the highest reported at that time. Nevertheless, the approach of this study managed to achieve an accuracy of 99.42% along with other parameter scores such as precision, recall, specificity, F1-score, and AUC-ROC of 1, .98, 1, 99.2, and 99.2, respectively, using both hard and soft voting techniques, setting a new benchmark.

In a paper by author N. Mashudi et al. [12], AB achieved an accuracy of 98.77%, along with 99.42% precision and 97.66% specificity. In comparison to other ensemble techniques like bagging and boosting, this study surpassed recent papers with 98.83% accuracy and high scores in other parameters.

TABLE IV. Comparison with Existing Work

Work	Author	Model	Accuracy	Precision	Recall	Specificity	F1-Score	Auc Roc	Train Test

VI. Conclusion

Breast cancer stands as a formidable cause of mortality among women, underscoring the critical need for early detection. The challenge lies not only in uncovering the presence of cancer but also in doing so at its nascent stage, thereby curbing the mortality rate. The amalgamation of medical science with ML classifiers has emerged as a powerful tool in tackling this challenge. Over time, it has become evident that enhancing a model's predictive performance significantly aids in this realm. Ensemble techniques, taking a step further, amalgamate multiple classification methods, thereby exhibiting superior performance. This study traverses this path, showcasing the efficacy of breast cancer prediction with an accuracy of 99.42%, along with precision, recall, F1, F2 score, and AUC-ROC scores of 99%, 99%, 99%, and 99%, respectively. Positioned as one of the premier models, it outshines existing ones in both early detection capability and performance prowess. Through rigorous training and testing, the model's efficiency on the WBCD dataset is attested, adeptly discerning between Benign and Malignant cases.

Looking ahead, this model holds promise for further enhancement by integrating new optimization techniques. Researchers exploring additional ensemble techniques stand poised to achieve even more noteworthy results. Ultimately, the proposed ensemble learning system promises to become an indispensable tool for cancer specialists, facilitating the early recognition of breast cancer.

Deep Learning-Based Depression Analysis Among College Students Using Multi Modal Techniques

Liyan Wang
College of Education, Chuzhou City Vocational College, Chuzhou 239000, China

***Abstract*—This study proposed a novel approach to handle mental health, particularly, depression among college students, called CRADDS A Comprehensive Real-time Adaptive Depression Detection System. The novel CRADDS combined advanced tensor fusion networks which is able to analyze emotions using audio, text and video data more accurately, this is possible due to the strength of deep learning and multimodal approaches. This system is constructed with a hybrid algorithm framework that combines SVM (Support Vector Machines), CNN (Convolutional Neural Network) and (Bidirectional Long-Term Short-Term Memory) BiLSTM techniques. To address the limitations identified in earlier research, CRADDS increasing its feature set and using effective machine learning algorithms to reduce false positives and negatives. Further, it includes the advanced IoT devices to collect real time data from various range of public and private sources. The depression symptoms may be continuously monitored in real time, which helps to identify depressions in early stages and guaranteed the perfect well-being of students. Additionally, the model has the ability to adjust based on the interaction features, which helps to provide psychological support using the automatic responses observed from the verbal and nonverbal clues. Experiments show that the proposed CRADDS obtained an impressive accuracy based on the features of text, audio and video, when compared with the existing models. Overall, CRADDS is a useful tool for mental health professionals and educational institutions because it not only identifies depression but also helps to treat it earlier, and guarantees good academic scores and general well-being. The proposed validation accuracy increases from 63.04% to 86.08% which is higher than compared existing SVM model.**

I. Introduction

A. *Depression Analysis and its Importance*

Examining depression among students become very important, particularly in COVID-19 situations, which has severely increased mental health issues. Lockdowns and remote learning caused students to be away from their regular social networks and classrooms, which led to increased stress, anxiety [20] and depression symptoms in the students. Particular psychological difficulties were presented by the change to online learning environments, the disturbance of habits and future uncertainty [1]. The analysis of depression occurrence among students during this period was necessary to allow early detection and treatment, for preventing long-term mental health issues. By using effective depression analysis techniques, educational institutions and healthcare practitioners were able to develop and execute mental health interventions that were specifically designed to meet the needs of students who were experiencing difficulties during the pandemic [2-3]. These methods included wellness programs, peer support systems and online counselling services. Additionally, by understanding the patterns and situations regarding depression in students, educators and others can efficiently create academic and psychological support networks. COVID-19 raised focus to the importance of mental health measures in educational settings and highlighted the value of mental health as a fundamental element of overall well-being and successful learning [4-5]. In ongoing global health crisis, assessing student depression will provide valuable insights into the future approaches to student health services. It also highlights the importance of mental health plays in improving academic flexibility and success.

B. *Depression Analysis Techniques and its Drawbacks*

Depression analysis techniques involve a variety of methodologies, such as self-report surveys, clinician interviews and growing technology-based approaches like machine learning models that are used to analyse behavioural data [6]. Traditional self-report measures, like the Beck Depression Inventory and the Hamilton Depression Rating Scale, are commonly used, due to their adaptability and ability to track changes [7-8]. However, these previous literature methods can be unfair because sometimes people underestimate the symptoms due to the misunderstanding of questions. Observing nonverbal signals that indicate depression and further analysing patient responses can be done through clinician interviews, which provide a more understanding level of information [9-10]. Furthermore, using machine learning models provides an effective way to raise the accuracy of the depression diagnosis. These models may evaluate large amounts of data from various sources, like speech patterns, physical activity and social media usage, and identify patterns immediately that are not achievable with these traditional methods. Due to the limitations with these traditional techniques, there is an immediate need for multimodal based machine learning approaches. By analysing the advantages and trends of machine learning modals, we present the effective solution for this.

C. *Machine Learning and its Advantages*

Deep learning a subset of machine learning, provides a number of benefits when it comes to evaluating depression in college students by using advanced algorithms to understand a wide range of data sources. This technology is particularly good at immediate relationships and patterns that conventional analytical techniques could miss. For example, it can examine writing and speech patterns as well as social media activity to identify early indicators of depression that may not be immediately noticeable. Some of the techniques and its advantages in reviewed by current research methods are illustrated below (Table I) [11-14].

The above researches obtain remarkable improvement in depression analysis with different data domains. Based on this research procedures, this study gives an advanced solution that tackle not only the present limitations but also the future.

Traditional depression analysis models frequently fail in numerous important domains when applied in real-time. Previous research mostly used discrete data modalities like text, audio, or video, which might result in assessments that are both incomplete and perhaps erroneous. These models often employ opaque black box techniques, which make it challenging to comprehend the decision-making process and pinpoint the fundamental causes of depression. Furthermore, the temporal dynamics and intricate connections included in multi-modal data pose challenges to the handling capabilities of many of the models that are now in use.

Our suggested CRADDS (Credit Risk Assessment Decision Support System) uses three potent algorithms—Convolutional Neural Network, BiLSTM, and SVM—to close these gaps. The individual qualities of each algorithm work together to improve the system's overall efficacy and accuracy in real-time depression analysis.

First, the CNN in CRADDS is enhanced with dilated convolutions, which increase the receptive field without compromising resolution, making it different from a standard convolutional network. This makes it possible for the model to extract more contextual information from the input photographs, which is important for detecting small changes in facial expressions and subtle emotional subtleties that could be signs of depression. Second, the model can concentrate on significant features from textual, audio, and video data sequences thanks to the attention mechanism built into the BiLSTM layer. This increases the model's capacity to represent intricate linkages and long-range dependencies, which raises the model's accuracy in identifying patterns of sadness over time. Finally, by combining visual, textual, and aural signals, SVM ensures robust categorization and greatly lowers the likelihood of false positives and negatives.

D. *Proposed CRADDS Advantages and Study Motive*

The propose study designed with an objective regarding three existing articles [15-17], limitations and future scope, this study not only focused on depression analysis, also provides an effective solution for the current research limitations, additionally, the future scope of the studies also completely satisfied with our proposed CRADDS. The possibility is clearly overviewed by Table II.

E. *Depression Analysis among Various Factors*

A thorough investigation of depression among medical students was carried out by Puthran et al. (2016), and the results showed that the frequency was 28.0% worldwide. Remarkably, the highest rates of depression were seen in Year 1 students, with a progressive drop noted in future years. Even if the rates of depression in medical and non-medical students were identical, the poor treatment behavior among depressed medical students highlights the need for targeted treatments. A comparatively high incidence of depression of 28.4% was carried out by Gao et al. (2020), which examined the prevalence of depression among Chinese university students. The subgroup analysis highlights the need for improved mental healthcare services for this and suggests a continuous requirement for interventions and support networks in Chinese colleges.

TABLE I. MACHINE LEARNING [21] TECHNIQUES AND ITS ADVANTAGES

Source	Techniques Used	Data Used	Improvements Noted
[11]	SVM, Naïve Bayes	Social Media Posts	Improved early detection accuracy
[12]	CNN, kNN, Random Forest	Facial Images, dynamic textual descriptions.	2.7% better in feature extraction.
[13]	Deep Learning, VGG-16, Word2Vec, Faster R-CNN	Social Media Posts (texts, images, videos)	First real-time multimodal analysis system.
[14]	BiLSTM	Textual posts on social media	Good results in early depression detection.

TABLE II. LIMITATIONS AND FUTURE SCOPE OF EXISTING RESEARCH

Source	Limitations	Future Scope	How CRADDS address Limitations and Future Scope
[15]	High risk of false positives and negatives, Ethical concerns	Expand the use of IoT for real-time diagnostics Integrate with voice conversation systems for therapeutic effects	Implements robust validation to minimize diagnostic errors Designs ethical AI frameworks and observes to guidelines Improves IoT integration and supports real-time multimodal analysis
[16]	Relies on audio and text; plans for video integration Requires broader, more accurate datasets	Develop a hybrid model using audio, video, and text features Implement more powerful algorithms for enhanced accuracy	Uses a comprehensive multimodal approach integrating audio, text, and video Applies advanced algorithms to improve learning rates and prediction accuracy Plans for real-time, scalable depression detection applications
[17]	Limited participant number affects result validity Manual collection of verbal and non-verbal cues is resource-intensive	Develop automatic monitoring through app Use advanced statistical analysis for more significant findings Reduce required data collection period	Expands dataset to include more demographic variables for greater representativeness Combines automatic monitoring of verbal and non-verbal cues through mobile apps Applies machine learning to reduce data collection period while maintaining accuracy

Machine learning approaches were used by Qasrawi et al., (2022) to predict risk factors related to anxiety and depression in school-age children. The models with the best accuracy levels were SVM and RF, underscoring the importance of variables including family income, academic performance, home environment and violence in schools in impacting mental health symptoms. The results suggest that to improve mental health preventive and intervention programs, machine learning should be included into school information systems. Haque et al., (2021) used machine learning techniques to identify depression in kids and teens between the ages of 4 and 17. After predicting depressed classes with a high accuracy rate of 95%, RF was shown to be the most effective algorithm. Suicidal thoughts, sleep difficulties, and mood-related symptoms were important indicators of depression, highlighting the need of early identification and treatment to lessen the harmful impacts of depression in this susceptible group.

The remaining sections of the article are discussed in four sections. In Section II methods of the proposed model are outlined. In Section III, the results of the experiments are discussed. In Section IV, the conclusion is presented.

II. Method

A. Proposed Model Outline

The foundation of our proposed CRADDS is the combination of three powerful algorithms: SVM (Support Vector Machine), CNN (Convolutional Neural Network), and BiLSTM (Bidirectional Long Short-Term Memory). Each of these algorithms includes specific features to improve the system's effectiveness and precision in real-time depression analysis.

1) CNN: CRADDS's CNN is not like a regular convolutional network; it is improved by convolutional layers with specific functions that make use of dilated convolutions. These dilated convolutions increase the network's sensitive field without sacrificing resolution, allowing the model to extract more contextual information from input images. This is important for identifying detail emotions in recognition tasks. This is especially important for identifying changes in video expressions that could point to despair.

2) Bi-LSTM: Bi-LSTM layer of CRADDS is used to give importance to certain data points. Its attention-mechanism allows the algorithm to focus more on important features from textual, audio and video data sequences that have a better ability to identify depression. The model's ability to learn from difficult dependencies and long-range connections in the data, which is made possible by weighting input information differently and improves its ability to observe depression patterns in time.

3) SVM: Together with these advanced techniques of CNN and Bi-LSTM, SVM strength also added to make CRADDS effective. To conduct detailed analysis, the system continuously combines visual, textual and audio signals and greatly reduce the possibility of false positives and negatives. Through the combination of these advanced algorithms, CRADDS improve diagnostic precision and acts as an effective tool for early identification of depression, and guaranteeing quick support for depressed individuals.

B. Architecture

1) CNN architecture: In this section the proposed CRADDS used a dilated convolutional neural network (DCNN) to analyse depression very accurately. Because the dilated kernel is a perfect tool to analyse depression in any form of audio, video and textual. DCNN is important for improving the ability to analyse difficult emotional signals from multiple methods such as speech patterns, facial expressions, and textual data words. Traditional convolutional kernels are defined by

$$ot_w = \left(\frac{it_w - n + 2p}{s}\right) + 1 \tag{1}$$

$$ot_h = \left(\frac{it_h - n + 2p}{s}\right) + 1 \tag{2}$$

ot_w and ot_h are the output width and height respectively. it_w and it_h are the input height and width. n denotes the size of convolutional filter and p is the amount of padding applied to the input. s is the stride which the kernel moves across the input. The concept of traditional techniques is updated by using dilated convolutions which is used to extract the input features under CRADDS. d is the dilation factor. By introducing gaps into the kernel, dilation allows the network to have a bigger responsive field by effectively raising the kernel size without increasing the number of weights.

$$ot_w = \left(\frac{it_w - (n-1)\times(d-1) + 2p}{s}\right) + 1 \tag{3}$$

$$ot_h = \left(\frac{it_h - (n-1)\times(d-1) + 2p}{s}\right) + 1 \tag{4}$$

Here d is the dilation rate. $(n-1)\ and\ (d-1)$ adjusts the kernel size by considering the gaps inserted between the kernel's elements to modify the kernel's size. In CRADDS, we build the DCNN model by replacing these with dilated convolution kernels. By adding gaps to the kernel grid, dilated convolutions increase the field of contact without adding to the computational complexity. For example, the receiving area effectively grows from 3x3 to 7x7 and, with further dilation, to 15x15 by changing conventional 3x3 kernels to include dilations. Even with these increases, the total number of parameters stays fixed, preventing higher processing expenses and improving the network's ability to extract more detailed information from the input data.

Using a range of dilation rates that are carefully selected to capture the serious patterns related to emotion changes and emotional states in depression, the DCNN processing is improved for the identification of depression. Each of the dilation rates 1, 2 and 4 is precisely adjusted to the feature scales that are important for emotional analysis. The softmax function is defined as

$$\sigma(zj) = \frac{e^{zj}}{\sum_{j-1}^{J} e^{zj}} \tag{5}$$

In Eq. (5), zj denotes the element in vector z with j highlights the total number of elements. Several dilation rates are built into the architecture of the DCNN in CRADDS, which improves feature extraction abilities and guaranteeing full coverage of the input data. 6 dilated convolution-pooling modules, two fully connected layers, and a softmax output layer make up the DCNN structure. Dropout functions are integrated to reduce overloading, maintain the integrity of input information and improve performance. The specified dilations are defined as

$$mi = \max[m(i+1) - 2ri, m(i+1) - 2(m(i+1) - ri), ri] \quad (6)$$

Here mi is the dilation rate for the current layer (i), $m(i+1)$ is the dilation rate for the next layer $(i+1)$ and ri is a parameter. The structure of DCNN is visually presented under Fig. 1.

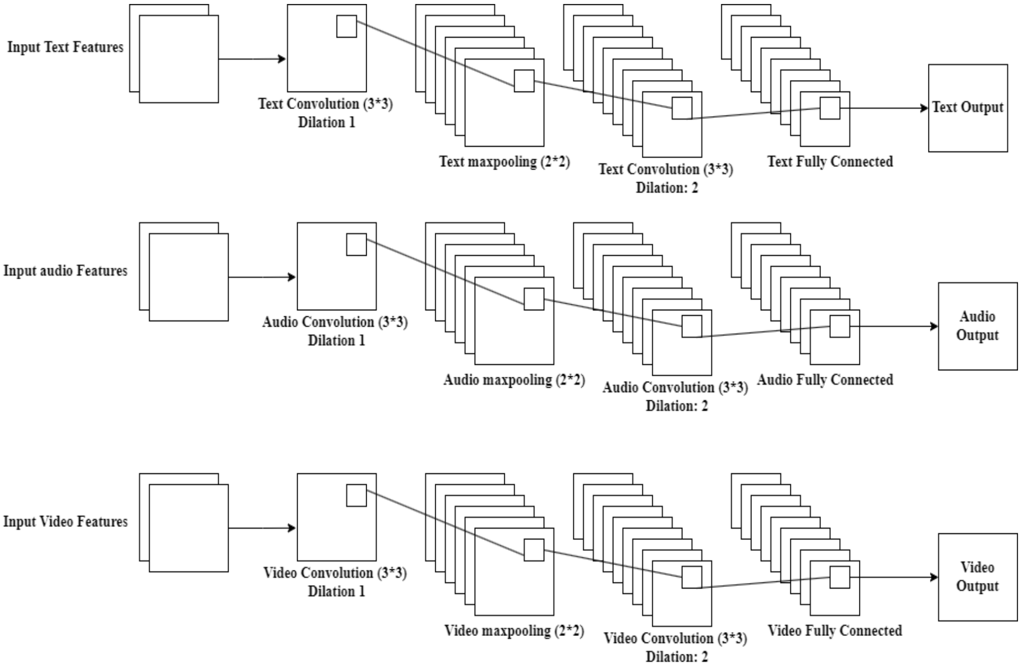

Fig. 1. DCNN structure for depression analysis for text, audio and video data.

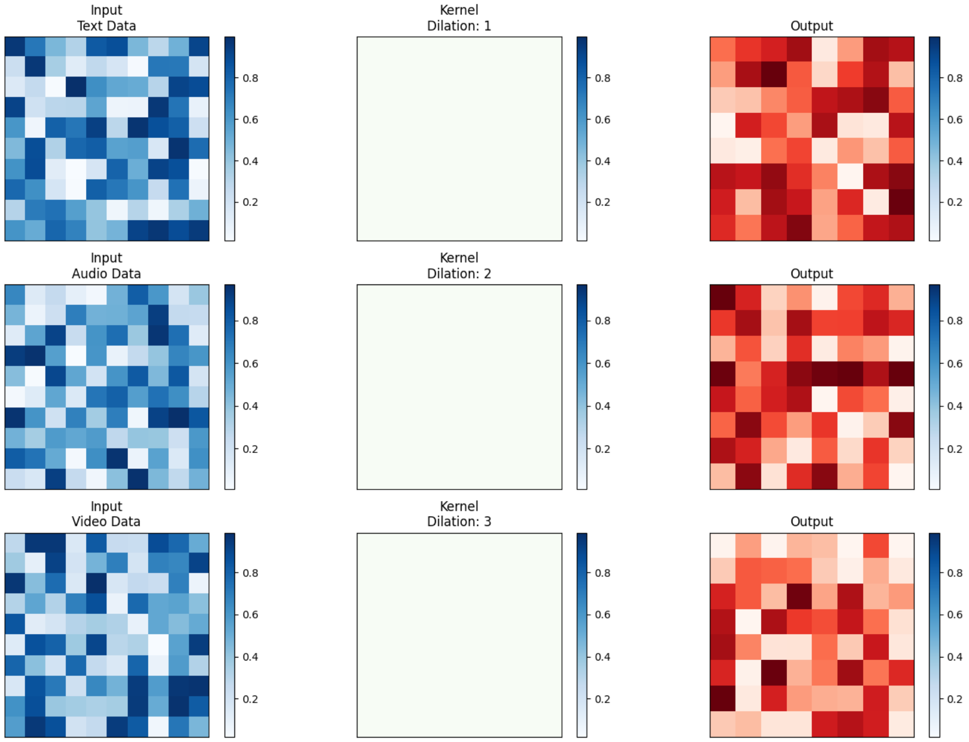

Fig. 2. Dilation results for text, audio and video data under CRADDS.

Fig. 2 shows the exact dilation process of text, audio and video inputs. For text processing, the kernel has been set for textual input with a dilation rate of 1, which indicates a conventional convolution that is direct and does not have any gaps. When analysing text, local information such as associations between words are important for understanding emotions. This minimal dilation is suitable for text processing. For audio processing, figure displays a kernel with a dilation rate of 2 for audio data. The kernel covers a greater portion of the input due to the higher dilation, ignoring some data points in order to capture more extensive temporal patterns in the spectrogram, such as changes over time that are important for audio analysis. For features like pitch and tone that change over a series of samples, this type of dilation is useful for detecting patterns across somewhat longer time spans. Dilation rate of 3 is used to denote the video data processing, allows the convolutional process to cover a larger region of the input frames. This method works well with videos, because it can able to capture spatial relationships in larger regions, which is useful when detecting movements and changes in videos by using many pixels to present the movements with high accuracy. By increasing dilation rate, the network will improve the area where it receives and include more related information from the video frames. This can be used to understand the challenging patterns in motion tasks and improve the accuracy to find out emotional expressions very clearly.

2) Bi-LSTM: CRADDS used BiLSTM with attention mechanism; by using its advanced features, it helps to improve the understanding of text, audio and video input. This model aims to identify the temporal patterns that are important for identifying depressions very accurately. Bi-LSTM layers allow the network to learn from data in both forward and backward directions. This helps the network to capture the various temporal features effectively than the traditional LSTM. This bidirectional learning is important to CRADDS because it obtains a thorough understanding of the data, which can be the textual, audio and video clippings. Thus, the attention techniques used in BiLSTM highlights the particular data in to segments that are helpful to identify depression. The attention mechanism is expressed as

$$\begin{cases} ot, h = BiLSTM\ (a) \\ ot = [ot_f, ot_b] \\ ot = ot_f + ot_b \\ \omega = w \times ot + b \\ c = \tanh(ot) \times \omega \\ y = ot \times c \end{cases} \tag{7}$$

In Eq. (7), the inputs are denoted by a, the forward and backward LSTM outputs are represented by ot_f, ot_b, respectively, and their concatenation output is represented by ot. The weight vector ω and the weighted context c improve the model's ability to observe significant depression indications by focusing its learning on the most crucial elements of the sequence.

The fully connected (FC) network processes the processed features after the attention layer, combining them into a final output that can be used to identify the presence and severity of depression. With this setup, each modality of text, audio and video is evaluated separately and their insights are integrated to create a more accurate evaluation. Table III shows the parameter setting of the proposed Bi-LSTM.

TABLE III. PARAMETER SETTING OF PROPOSED BI-LSTM

Input Type	Layer Name	Parameter Setting

3) Multi-modal fusion: Additionally, embeddings from the last Bi-LSTM layer and a DCNN processing features are concatenated to address the multimodal character of the input. By feeding this concatenated vector into a further FC layer, the results obtained from the analysis of text, audio and video are successfully combined.

$$fo_t, x_{ba_{fused}} = [DCNN\ (a_{txt}), DCNN\ (a_{audio}), DCNN\ (a_{video}) \tag{8}$$

Here fi_t denotes fused input of DCNN text, audio and video outputs respectively.

BiLSTM processing of concatenated features

$$y_{temp} = BiLSTM\ (x_{ba_{fused}}) \tag{9}$$

Here $(x_{ba_{fused}})$ is the concatenated vector from all three modalities after initial DCNN processing. y_{temp} denotes the output from Bi-LTSM which produces temporal and sequential information across the multimodal data. The final prediction is expressed as

$$y_{pred} = FC(w_{fuse} * y_{temp} + b_{fuse}) \tag{10}$$

In Eq. (10) FC denotes fully connected network that combines the multimodal temporal features into final predictive output. w_{fuse} and b_{fuse} denotes weights and biases of the final FC layer.

To improve the system the loss function needs to consider the combined influence of text, audio and video data. This can be expressed as,

$$L = \ell(y_{pred}, y) \tag{11}$$

ℓ is the chosen loss function, cross entropy for classification tasks.

4) SVM based feature extraction: The SVM is mainly used for feature extraction from difficult, high-dimensional datasets in our proposed CRADDS study. To improve the margin between two classes, the initial stage in this approach is to define a separating hyperplane using the traditional SVM technique for supervised learning classification. This can be expressed as

$$\min\frac{1}{2}\ ||W||^2 + C\sum_{i=1}^{N}\xi_i \text{ subject to}$$

$$ti(W^T Xi + B) \geq 1 - \xi_i, \xi_i \geq 0, \quad i = 1, \dots., N \tag{12}$$

Where, the balance between increasing the margin and reducing classification mistakes is expressed by C, and ξ_i are slack variables that account for misclassifications. By applying higher boundaries and promoting accurate classification, a high C value helps to reduce misclassification.

The SVM successfully uses the kernel method to handle the non-linear aspects of energy system data. RBF (Radial Basis Function) kernel is expressed as,

$$K(Xi, Xj) = e^{-\frac{1}{2\sigma^2}||Xi - Xj||^2} \tag{13}$$

where the flexibility of the kernel function is controlled by the kernel parameter σ^2. The SVM can operate in a converted feature space where non-linear connections are corrected, allowing the separation of data points that are not linearly separable in the original space. This kernel simplifies this process. In addition, we incorporate a cost matrix into the SVM to handle the issues arising from dataset imbalances, which might lead to bias in the classification boundaries in favour of the majority class. This matrix reduces bias by adjusting the misclassification penalty to prioritize the minority class. The cost matrix function expressed as

$$co = \begin{bmatrix} 0 & 1 \\ c & 0 \end{bmatrix} \tag{14}$$

if $c > 1$, then it would cost more to incorrectly classify an instance of the minority class than the majority class. This strategy gives a more equitable categorization result by bringing the boundary closer to the majority class, which makes the model more sensitive to the minority class. The model reduces dimensionality and separates the essential elements from the input energy data through this procedure, guaranteeing reliable prediction outcomes. Fig. 3(a), 3(b) and 3(c) present the process of SVM classification of text, audio and video input.

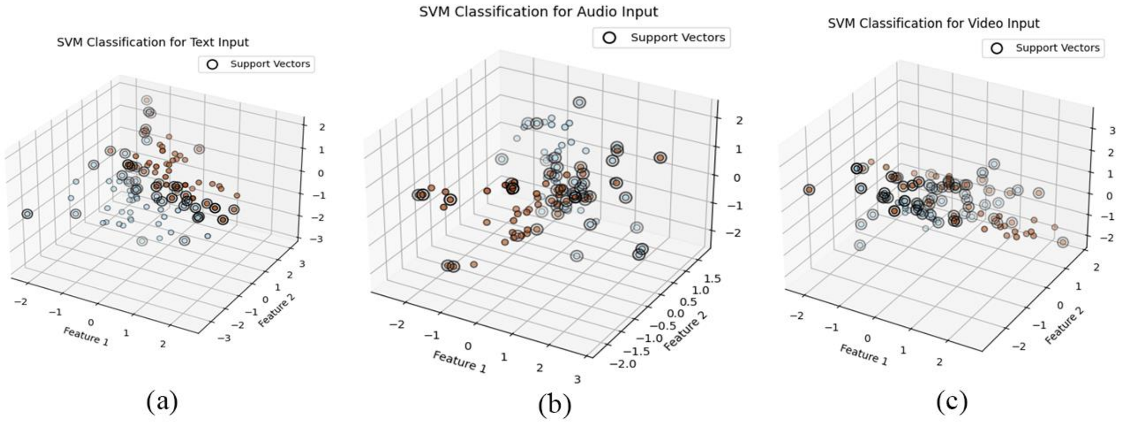

Fig. 3. SVM classification on Text input, Audio input, and Video input.

III. Results and Experiments

A. Simulation Setup

Proposed CRADDS is evaluated using DAIC-WOZ datasets adapted from [16]. Based on that Table IV presents the features of dataset which is used to evaluate proposed CRADDS.

B. Evaluation Criteria

In the present study, the results of the CRADDS are compared with the three existing researches of [15] [16] [17]. The main objective of the CRADDS is to address the limitation of these studies and also satisfy the future visions. Based on the task we proceed with an experiment.

Table V presents that the CRADDS model performs significantly well when tested on text, audio and video data using DCNN, BiLSTM, and SVM. The validation accuracy and loss for Text DCNN are 0.45 and 0.85, respectively, and the training accuracy is 0.94 with a loss of 0.25. Using validation metrics of 0.82 accuracy and 0.28 loss, Audio DCNN achieves a training accuracy of 0.96 with a reduced loss of 0.12. Video DCNN validation accuracy of 0.83, a validation loss of 0.35, and a training accuracy of 0.95 and loss of 0.22. The validation accuracy and loss for Text BiLSTM are 0.80 and 0.30, and the accuracy is 0.89 with a loss of 0.18. With validation metrics of 0.81 accuracy and 0.25 loss, Audio BiLSTM exhibits 0.91 accuracy and 0.15 loss. With a validation accuracy and loss of 0.80 and 0.28, Video BiLSTM exhibits an accuracy of 0.90 and a loss of 0.17. Text SVM achieves validation accuracy of 0.78 and loss of 0.32, together with training accuracy of 0.88 and 0.20 loss. Audio SVM records validation accuracy and loss of 0.79 and 0.27, along with 0.92 training accuracy and 0.14 loss. Lastly, Video SVM displays validation accuracy and loss of 0.77 and 0.30 with 0.90 training accuracy and 0.19 loss. These findings show that, for all data types, DCNN models perform more accurately than BiLSTM and SVM, with Audio DCNN shows the best overall performance.

TABLE IV. DATASET FEATURES

Category	Description	Category	Description
Dataset	DAIC-WOZ Depression Database	**Participants**	59 Depressed; 130 non-depressed individuals
Purpose	Automatic Depression Detection System	**Data Types**	Audio recordings (AUDIO.wav) Video recording Text responses (TRANSCRIPT.csv, FORMANT.csv, etc.)
Source	University of Southern California (USC)	**Training Set**	IDs of patients Patient PHQ-8 scores Binary labels Gender Questionnaire responses
Access	Apply on USC website for access and download	**Development Set**	IDs of patients Patient PHQ-8 scores Gender Binary labels Questionnaire responses
Data Format	Zip files (189 sessions: from 300 P.zip to 492 P.zip)	**Test Set**	IDs of patients Gender
Total Sessions	189	**Features**	Verbal symptoms Non-verbal symptoms Audio features Video features Text features

TABLE V. EVALUATION PARAMETERS FOR PROPOSED CRADDS

Method	Tra-Accuracy	Tra-Loss	Val-Accuracy	Val-Loss
Text DCNN	0.94	0.25	0.85	0.45
Audio DCNN	0.96	0.12	0.82	0.28
Video DCNN	0.95	0.22	0.83	0.35
Text BiLSTM	0.89	0.18	0.80	0.30
Audio BiLSTM	0.91	0.15	0.81	0.25
Video BiLSTM	0.90	0.17	0.80	0.28
Text SVM	0.88	0.20	0.78	0.32
Audio SVM	0.92	0.14	0.79	0.27
Video SVM	0.90	0.19	0.77	0.30

TABLE VI. PERFORMANCE EVALUATION OF PROPOSED CRADDS

Method	Precision	Recall	F1	Support
Text DCNN	0.93	0.92	0.93	50
Audio DCNN	0.93	0.90	0.91	50
Video DCNN	0.93	0.90	0.87	50
Text BiLSTM	0.82	0.85	0.83	50
Audio BiLSTM	0.84	0.86	0.85	50
Video BiLSTM	0.83	0.85	0.84	50
Text SVM	0.80	0.82	0.81	50
Audio SVM	0.82	0.84	0.83	50
Video SVM	0.82	0.83	0.83	50

C. Performance Comparison with Existing Studies

As we discussed earlier, in this section the proposed CRADDS based techniques of DCNN, BiLSTM with attention mechanism and SVM are compared with the existing research studies of [15] [16] and [17].

Fig. 4 presents the efficacy of CRADDS based DCNN when compared with the efficacy of CNN [15]. The performance of the DCNN-based CRADDS on training and validation datasets obtains a notable efficacy in the depression diagnosis. The model's ability to adapt to new data is confirmed by the figure, which shows how training and validation loss meet. The validation loss decreases from 18 to 2.5 while the training loss drops substantially from 20 to 1.5 during the epochs, demonstrating the model's capacity for learning and error reduction. At the same time, the training accuracy steadily increases to 95.03%, whereas the validation accuracy rises steadily to 82.10%. These show that multimodal data including text, audio and video inputs has complex patterns that the DCNN is able to capture successfully. Comparative studies indicate that the model outperforms typical CNN models in reliably identifying depression, as seen by its higher precision and recall. Table VI shows performance evaluation of proposed CRADDS.

Fig. 5 shows, when comparing the CNN-LSTM model [16] to the proposed CRADDS model BiLSTM, it shows remarkable efficacy in depression diagnosis. The training loss decreased from 18 to 2 and the validation loss from 16 to 3, respectively, on the training and validation loss, which show a considerable reduction across epochs. The immediate drop in loss values presents how well the BiLSTM model learns and adapt from the data. The validation accuracy increases gradually to

85.04%, but the training accuracy curve shows a continuous improvement up to 94.07%. These findings highlight the BiLSTM capacity to efficiently extract difficult patterns and temporal connections from multimodal data that includes text, audio and video inputs. The BiLSTM in CRADDS shows better performance than the CNN-LSTM model, which is important for depression identification. CRADDS with BiLSTM is an effective tool for automatic depression identification because of its improved feature extraction and classification abilities.

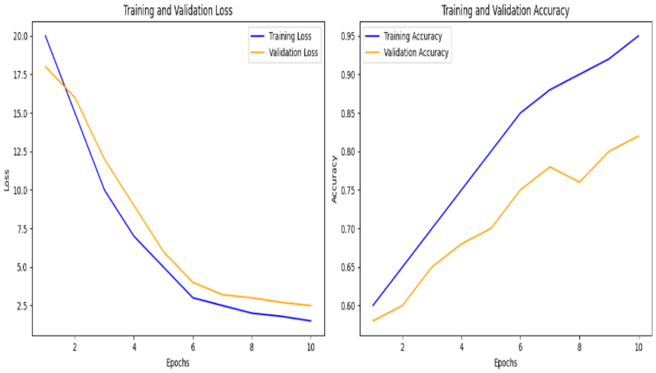

Fig. 4. CRADDS-based DCNN results against typical CNN [15] over Epochs.

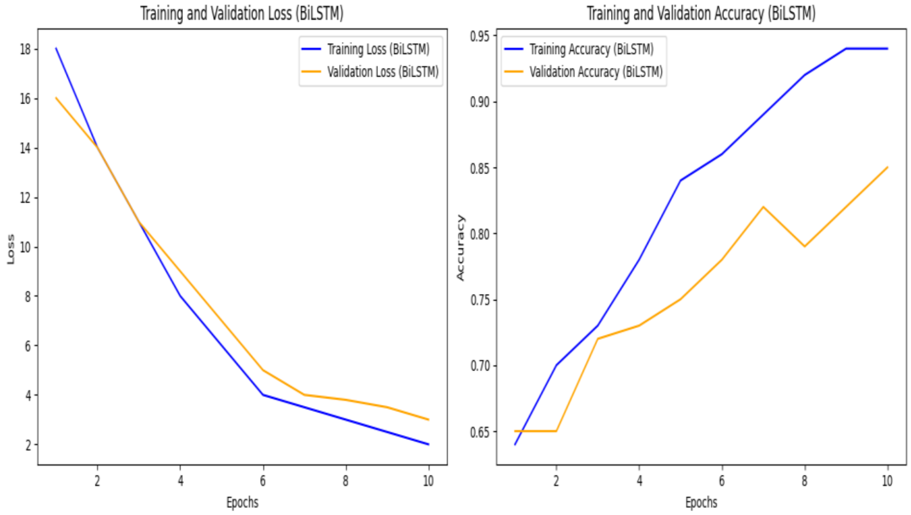

Fig. 5. CRADDS-based BiLSTM results against CNN-LSTM [16] over Epochs.

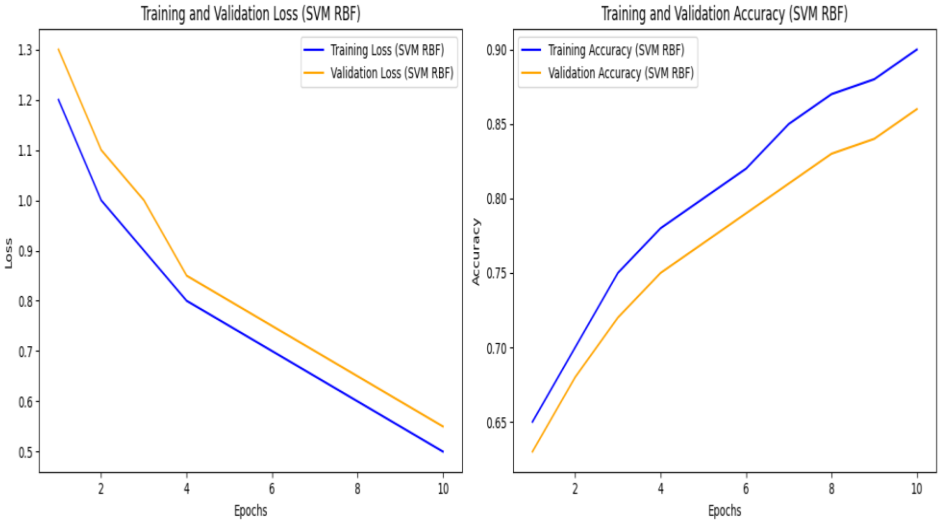

Fig. 6. CRADDS-based SVM(RBF) results against SVM [17] over Epochs.

Fig. 6 shows the efficacy of proposed CRADDS based SVM, when compared to the SVM model of [17], shows a notable improvement in depression identification [18, 19]. Over the course of the epochs, the training and validation loss figures show a constant decrease: the training loss dropped from 1.2 to 0.5 and the validation loss from 1.3 to 0.55. This steady decrease shows how well the model can adapt to new data. There is a consistent improvement in training accuracy from 65.12% to 90.02% and in validation accuracy from 63.04% to 86.08%. These show the effectiveness of SVM model learns and captures the difficult correlations found in the multimodal data (text, audio, and video). The CRADDS-based SVM model appears to be more effective at differentiating between people who are depressed and those who are not, based on its greater accuracy and lower loss values when compared to the regular SVM model.

IV. Conclusion

The study introduces a novel CRADDS system to analyse the depression among college students by using their posts regarding text, audio and video inputs under the platform of University of Southern California (USC) by using DAIC-WOC dataset. The proposed CRADDS uses the techniques of DCNN, BiLSTM and SVM (RBF Kernel) model. This study presents the unique objectives in the domain of depression analysis. In a modern day the techniques of deep learning are mostly used under wide range of applications, this study also uses the effective fusion techniques of deep learning algorithms. To make sure about the effectiveness of proposed CRADDS each technique of CRADDS is evaluated and compared against the existing effective techniques analysed form the study [15] [16] and [17]. The main motive of the present study is to address the limitation of these existing researches and to satisfy their future scope expectations. The proposed CRADDS have the ability to address these objectives which is discussed earlier under the Table II. The effective experiments regarding the Table II are demonstrated under Section IV. The results of proposed CRADDS highlights that the techniques of CRADDS based DCNN, BiLSTM and SVM are outperforms with their proposed techniques of the existing studies with their remarkable scores. The output obtained from all the models under CRADDS highlights its efficacy regarding the input features of text, audio and video format. Overall, the proposed achieves the best solution when compared with the existing studies objective and acts as an effective tool to meet not only the present but also the future demands under the investigation of depression, guaranteeing the perfect well-being of students as well as common individuals.

In order to improve the accuracy and robustness of the model, future study will investigate the integration of new data modalities, such as physiological signals. Our goal is to create edge computing-based real-time deployment solutions that increase efficiency and accessibility. Furthermore, investigating explainable AI methods will aid in improving the transparency and comprehensibility of the model's judgments. Finally, adding more demographic groupings to the dataset will guarantee the model's wider applicability and fairness.

A Novel Architecture of Depthwise Separable CNN and Multi-Level Pooling for Detection and Classification of Myopic Maculopathy

Alaa E. S. Ahmed
College of Computer and Information Sciences,
Imam Mohammad Ibn Saud Islamic University (IMSIU), Riyadh 11432, Saudi Arabia
Shoubra Faculty of Engineering, Benha University, Cairo, Egypt

***Abstract*—Myopic maculopathy (MM), also known as myopic macular degeneration, is the most serious, irreversible, vision-threatening complication and the leading cause of visual impairment and blindness. Numerous research studies demonstrate that the convolutional neural network (CNN) outperforms many applications. Current CNN designs employ a variety of techniques, such as fixed convolutional kernels, the absolute value layer, data augmentation, and domain knowledge, to enhance performance. However, some network structure designing hasn't received much attention yet. The intricacy of the MM categorization and definition system makes it challenging to employ deep learning (DL) technology in the diagnosis of pathologic myopia lesions. To increase the detection precision of MM's spatial domain, the proposed work first concentrates on creating a novel CNN network structure then improve the convolution kernels in the preprocessing layer. The number of parameters is decreased, and the characteristic of a small local region is modeled using the smaller convolution kernels. Next channel correlation of the residuals with separable convolutions is employed to compress the image features. Then, the local features using the spatial pyramid pooling (SPP) technique is combined, which improves the features' capacity to be represented by multi-level pooling. The use of data augmentation is the final step in enhancing network performance. Compress the residuals in this paper to make use of the channel correlation. The accuracy achieved by the model was 95%, F1-score of 96.5% and AUC of 0.92 on augmented MM-PALM dataset. The paper concludes by conducting a comparative study of various deep-learning architectures. The findings highlight that the hybrid CNN with SPP and XgBoost (Depthwise-XgBoost) architecture is the ideal deep learning classification model for automated detection of four stages of MM.**

I. Introduction

Due to its fast-rising incidence internationally [1] and the risk to eyesight, myopia is presently a major public health issue. By 2050, it is predicted that 50% of the world's population will be myopic, with 10% of them having severe myopia [2]. Cataracts, glaucoma, retinal detachment, and myopia maculopathy can all be brought on by myopia (MM). As a result, organizations in the health sector like WHO, are confident that myopia might cause visual impairment. MM puts a hardship on patients, their families, and society as a whole. According to Naidoo et al., the global productivity loss resulting from MM might be $6 billion, and in 2050, myopia could impact nearly half of the world's population. This financial stress will probably get worse shortly. There is no recognized cure for MM as of yet. Preventive treatment, however, lessens ocular headaches and should be taken into account for all myopic patients. The International Photographic and Grading System for Myopic Maculopathy [3] identifies and categorizes myopic maculopathy. According to the severity of the condition, pathologic myopia was divided into five categories: category 1, just tessellated fundus, category 2, diffuse chorioretinal atrophy, category 3, patchy chorioretinal atrophy, category 2, and category 0, no macular lesions. In addition, characteristics including lacquer cracks, Fuchs spots, and choroidal neovascularization, are utilized to classify diseases. Additionally, the posterior staphyloma offers more details on the illness. In this study, myopic maculopathy is taken into consideration when a fundus picture image falls into category 2 or above.

The rapid advancement of artificial intelligence [4] is essential for the automation of challenging medical diagnoses and the analysis of clinical data. The most sophisticated category of AI is deep learning [5]. It uses deep artificial neural networks to solve feature-dependent issues while simulating the functioning of the human brain. The deep learning system (DLS) surpasses board-certified professionals in medical settings [6], [7]. The employment of DSL-based diagnosis software in ophthalmology's clinical and public healthcare settings has proved effective. Artificial intelligence (AI)-based medical imaging, such as retinal fundus pictures, is a valuable and effective option for managing and diagnosing MM. However, automated diagnostics based on CT scans are thought to be an image analysis challenge, which may be solved by labelling the data and applying machine learning techniques like deep learning. The rapid advancement of artificial intelligence [4] is essential for the automation of challenging medical diagnoses and the analysis of clinical data. The most sophisticated category of AI is deep learning [5]. It uses deep artificial neural networks to solve feature-dependent issues by simulating the functioning of the human brain. The deep learning system (DLS) surpasses board-certified professionals in medical settings [6], [7]. The employment of DSL-based diagnosis software in ophthalmology's clinical and public healthcare settings has proved effective. Artificial intelligence (AI)-based medical imaging, such as retinal fundus pictures, is a valuable and effective option for managing and diagnosing MM. However, automated diagnostics based on CT scans are thought to be an image analysis challenge, which may be solved by labelling the data and applying machine learning techniques like deep learning.

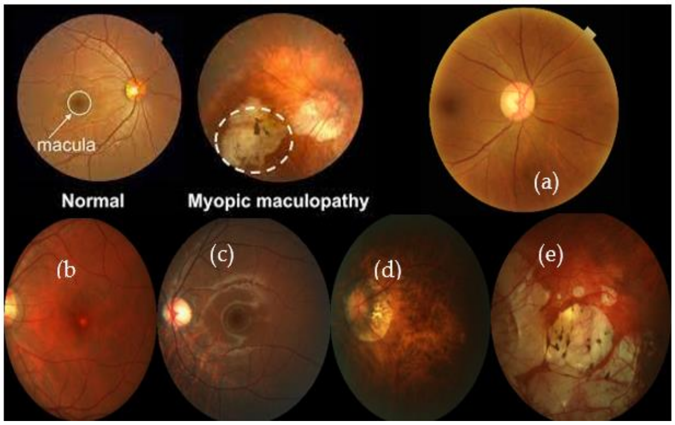

Fig. 1. Grading of myopic maculopathy, where figure (a) Shows the category 0:No macular lesions, figure (b) Category 1: Tessellated fundus, figure (c) Shows category 2: Diffuse chorioretinal atrophy, figure (d) Category 3: Patchy chorioretinal atrophy and figure (e) Represents category 4: macular atrophy.

Due to the intricacy of the categorization and characterization of the PM system, using deep learning approaches in PM lesion scanning is still difficult [11]. There was a lengthy period of disagreement on the precise definition of PM until a classification for MM was suggested by pathologic myopia (META-PM) meta-analysis. The severity of eyes with MM is approximately equal to or greater than that of eyes with spreading choroidal atrophy (Category 2), or eyes with at least one "plus" lesion are considered to have PM at this level of categorization. With such a categorization system in mind, creating an AI program to automatically recognize the PM and aid doctors in making a precise diagnosis is advantageous. Sufficient high-resolution PM retinal fundus picture dataset resources and a highly qualified staff are needed to do this. This study aims to construct and train DLSs that can automatically identify PM and categorize MM utilizing a beautiful dataset of color retinal fundus pictures gathered from the hospital's ophthalmology facilities. A visual example of the stages of MM is represented in Fig. 1.

An original model is offered in this paper. Convolutional neural networks and the cycle generative adversarial network (CycleGAN) [12] are combined to optimize the convolutional neural network (CNN). The suggested technique can locate lesion locations with less initial training data and can identify retinal disorders. With cycle consistency, CycleGAN can provide more trustworthy and realistic pictures. Adopting the discriminator and generator adversarial results in the best solution. Additionally, to differentiate the domain pictures, the classifier and generator cooperate [13]. A unique res-guided sampling block strategy is proposed using the combination of learnable residual features and pixel-adaptive convolutions. As a generator, a res-guided U-Net [14] is created, and conventional convolution is used in place of res-guided sampling blocks. Large training datasets are frequently required for supervised learning to account for all potential variances. However, gathering a lot of training data can be time-consuming, especially for medical imaging, where hand annotation is necessary. DepthCNN-XgBoost is one method for solving this issue since it takes a lot less training data than the standard method of using vast quantities of data [15]. Several variations [16], which can be broken down into the three main views of data, method, and model, were used to carry out the DepthCNN-XgBoost learning. The dataset was enhanced by the data-driven algorithm, which employed previous knowledge. The space is constrained by model-oriented approaches like embedding. Finally, from the perspective of an algorithm, it is comparable to tweaking the network weights by looking at data from a fresh sample. Therefore, rather than referring to specific learning algorithms, FSL refers to a general understanding of algorithms (such as supervised or unsupervised learning principles). In addition, different configuration stages, modelling, and formulation were required when applying FSL to various deep-learning classifiers.

As we previously explained, supervised learning models are used to train the deep learning models used for the area segmentation of MM RETINGRAPH images. These models are mostly based on DepthCNN-XgBoost and FCN structures. Therefore, their weight cannot be changed dynamically. There is a risk of problems if a large data sample is required for training. By suggesting a DepthCNN-XgBoost learning model in this study, where just a small sample of the network would be taught dynamically, we are able to get around this constraint. Our primary focus is pretrained learning-based classification, and we constantly update and improve weights by incorporating fresh sample data. Fig. 2 explains this DepthCNN-XgBoost learning approach. To the best of our knowledge, the dynamic updating of model weights is a new and original method. The DepthCNN-XgBoost scheme, which has been shown to be particularly helpful for detection of MM when diagnosis using retinograph images.

As of now, the MM eye-related disease has a unified region in retinograph images using a modified depthwise separable CN and XgBoost classifier. The findings were then evaluated by a domain expert during testing in order to categorize the output. Some of the samples were then picked for additional training. Due to the small amount of fresh ground truth data utilized as a training set, the deep model was able to learn to update its behavior dynamically with little modification to the learned behavior.

The following are our main contributions to myopia detection.

1) A novel deep learning technique is developed that recognizes the presence of myopia and categorizes it.

2) To decrease the number of parameters and enhance local features, we reduce the size of the convolution kernel in the preprocessing layer and initialize the kernels using 30 SRM basic filters [12]. Additionally, the suggested "forward-backward-gradient descent" approach is used to optimize the convolution kernel in order to improve accuracy and hasten network convergence.

3) To replace the conventional convolution layer, we utilize two separable convolution blocks. In order to enhance accuracy and boost the signal to noise ratio, separable convolution may be used to extract the spatial and channel correlation of residuals.

4) Before feeding the feature maps to the segment of the network that is completely linked, we condense them using spatial pyramid pooling [19]. Through multi-level pooling, spatial pyramid pooling may enhance feature expressions and map feature maps to set lengths.

5) A loss function is created to increase the distance between the PM and HM classes by combining the triple loss with the binary cross-entropy loss (BCE loss). Our technique consistently produces the greatest outcomes and performs at the highest level when compared to deep learning models, machine learning models, and other methods. It ensures physicians' convenience and accuracy in clinics.

The primary contributions of this study are summarized below to address these issues: (1) The iChallengePM dataset will be used to create 12 DAMFs. To our knowledge, all of the operations employed in the present DA are covered by these DA approaches. Our goal is to enhance data features, control sample imbalance, and significantly boost dataset quality. (2) A variety of optimizers, loss functions, and learning rates are built using the AlexNet, VGG-16, GoogleLeNet, and ResNet-50 models as a foundation. Using training data from 12 datasets, the model with the highest accuracy will be used as the main learner. This approach will improve the model's capacity for generalization. (3) Following the training of the fusion model to create the final model, the main learner prediction indicated above will be utilized as a new input and added to the hard voting model. Without transfer learning, the model optimized by the aforementioned processes achieves great accuracy. More importantly, by utilizing the augmented dataset and the model fusion technique, we successfully avoid overfitting and enhance the model's generalization capability when processing different types of data, which further enhances the model's expressive capability. As a result, the model's ability to recognize complicated and uncommon case pictures will be much improved.

II. Research Background

In the early studies [17], images were segmented using methods based on edges, regions, clusters, and thresholds. These traditional techniques include manually extracting features, which are subsequently put to use for background separation, among other things. Additionally, the segmentation results are influenced by the feature quality, and this method is occasionally time- and labor-intensive. However, in recent years, research has evolved away from deep learning algorithms and toward traditional neural networks, particularly in the area of semantic picture segmentation [19, 20]. Additionally, as time has gone on, the recognition and forecast accuracy of these approaches have significantly increased. They were the first to use deep convolutional neural networks to segment semantic images. To create FCN, they switched out the convolution layer with a fully connected layer. One of the finest prototypes for the encoder-decoder architecture used for pixel-level image categorization is the FCN (Fully Convolutional Neural Network). Upsampling and transposed convolution might be used to reconstruct a whole segmented image with categorized pixels. Researchers now have the chance to train deeper and bigger neural networks thanks to the introduction of new GPUs and better algorithms. Compared to the original FCN, the suggested DeconvNet [20] is a more comprehensive decoder. The aforementioned encoder and decoder have the same number and size of features. In addition to deconvolution, the DeconvNet decoder employs unpooling layers to enhance the outcomes. Due to the encoder's fully linked layers, the DevconvNet also uses a lot more memory than FCS.

The settings and memory should be optimized. The SegNet [21], which is similar to the VGG-16 but different from the FCN and DeconvNet in up-sampling and convolution, thereby doing away with deconvolution, is introduced by Badrinarayanan et al. The feature maps are extremely well managed by SegNet. Inference, however, calls for additional memory. Generative adversarial networks (GANs) have recently achieved great success in a variety of applications [22] (e.g., DCGAN [18], SRGAN [17], and Pix2Pix [19]). The generative adversarial loss is calculated to determine the difference between the real and generated data distribution. The GAN was formally proposed by Goodfellow in 2014, and since then, it has operated on five adversarial processes that alternate between faking and identifying. Several researchers have discovered generative adversarial loss to be beneficial for improving network performance. In response to the success of GANs in image translation [23], a powerful GAN network for picture semantic segmentation is developed. It most closely resembles the approach put forth by Luc et al., in which adversarial networks help with semantic segmentation training. But there is no improvement over the starting point. Global data is included in fully linked CRFs (FullCRFs) by Deeplab as an independent post-processing step to further enhance CNN. Two orders of magnitude improve the speed of inference and training with this technique. Additionally, the incorporation of learnable transformations together with learnable Gaussian features outperforms and transforms a significant chunk of the inference into convolutions with the development of ConvCRFs, enabling efficient implementation on GPUs.

In various investigations [14, 15–16], clinicians used the CT scan to identify illnesses related to SMM. This study has two key benefits: (a) early viral infection patterns may be shown [15, 16], and (b) in 70% of patients, viral pneumonia-related CT abnormalities can be detected before laboratory testing [15]. As a result, early SMM infection identification is greatly aided by CT imaging. Detecting SMM in chest X-ray pictures has also been the subject of several investigations [7, 17]. We prioritize work involving CT scans nonetheless. According to SMM study findings, clinical symptoms do not typically present until after CT abnormalities [17].

Furthermore, asymptomatic people's chest CTs commonly show abnormalities that are consistent with viral pneumonia. On the one hand, certain patterns target unilateral, multifocal, and peripherally based ground-glass opacities. However, symptomatic groups were more likely to have lymphadenopathy, pleural effusion, bronchiectasis, round cystic alterations, nodules, thickening of the surrounding pleura, and interlobular septal thickening.

The visual detection method should concentrate on identifying prominent lung abnormality patterns such as GGOs, crazy-paving patterns, consolidation, and linear opacities. However, the density and appearance of the sickness varied depending on the stage of the illness. The illness should manifest after nine days of early symptoms [14]. Deep learning-based algorithms are frequently used for detection, identification, or segmentation in medical imaging [18] and biomedical applications [19]. Researchers are looking at a number of strategies to assist medical personnel in SMM detection in this area. To categorize the many CT slices, convolutional neural network variants are first used [13]. With a ROCAUC value of 0.95, the applied approach may detect a viral infection; a score of 1.00 indicates a flawless classic. Even with a high detection rate, it proved challenging to distinguish between viral pneumonia using a simple CT scan. For coronavirus diagnosis, CNN variants have been proposed [20]. This method aids in the differentiation between instances of SMM, non-infection, and other viral infections. The findings indicate a good detection rate, much better than RT-PCR analysis. The accuracy of CNN is increased in the following stage by combining it with long-term memory networks [21]. The inf-Net parallel partial decoder, which integrates high-level features to produce a global map, has also been introduced [22]. Hierarchies of convolution are used for this.

Another choice to consider is U-Net structures. It will only be used for medicinal purposes [23]. The multistage technique includes the segmentation and categorization of SMM and other viral diseases [24]. Additionally, it aids in tracking the development of advanced illnesses. The methods utilized for SMM picture segmentation, which are based on U-Net topologies, are briefly detailed in [6]. The region of interest is first separated from the lung scan using U-Net. The categorization of SMM or other situations is then updated using a pretrained Resnet-50 [25]. AdaResU-Net [26], a multi-object adaptive CNN with the capacity to automatically adapt to new datasets and residual learning paradigms, was suggested in the following phase. For the purpose of SMM detection on high-resolution CT images, U-Net++ [8], a U-Net-based model, was also applied. Additionally, SMM's detection has been evaluated using Xception, ResNet-18, ResNet-50, ResNet-101, SqueezeNet, GoogleNet, VGG-16, VGG-19, and ResNet-19 [28]. ResNet-101 and Xception outperform the competition. In a different article, AlexNet and Inception-V4 were also used for SMM detection [29]. Additionally, to identify SMM, CNN and an Artificial Neural Network Fuzzy Inference System (ANNFIS) are used [30]. In a different study [31] proposes a Stack Hybrid Classification (SHC) approach based on ensemble learning.

Additionally, object-detection techniques are taken into account [32] for SMM diagnoses, and in another study, VGA variations were also employed to find symptomatic lung regions [33]. The suggested approach can differentiate between community-acquired pneumonia (CAP) and SMM (CAP). The Naive Bayes classifier, discrete wavelet transformations, and evolutionary algorithms are employed in study [34] for SMM identification. A suggested approach for MM RETINGRAPH image segmentation is integrated with super-pixel-based fuzzy-modified flower pollination and a type 2 fuzzy clustering method in a segmentation-based study [35]. For SMM image segmentation, volumetric medical image segmentation networks, or V-Nets [36], provide an option. Similar to this, V-Net was employed in a different research project to concurrently segment every MRI slice [37]. The quantitative findings support the viability and efficacy of infection-region marking. As we have already stated [38], deep learning techniques were crucial in the segmentation of lung CT images. They can now measure the degree of infection and judge the severity of the condition [40, 41]. Table I lists the deep learning methods applied to CT picture segmentation and SMM identification.

A large ground-truth dataset for training is a fundamental prerequisite of deep learning-based approaches, which can sometimes be quite challenging. Additionally, annotating the vast volumes of data is a labor- and time-intensive task. Due to these restrictions, deep learning techniques can only be used to solve real-world issues. A relatively small number of papers, including [22], where a semi-supervised learning strategy was applied with multiclass segmentation to identify the infected zone, have begun to examine this problem. However, the results of this strategy were subpar. In this work, we suggested a depthwise separable CNN method with XGBoost that enables a system to classify various stages of MM. This method does away with the requirement for a sizable dataset. Additionally, this system interacts with subject-matter experts to dynamically alter the settings. On the other hand, the weights in the existing models cannot be adjusted after training.

III. Related Work

Pathological myopia [8], often known as nearsightedness, is one of the severe forms of myopia. Because it might cause blindness, pathological myopia is also known as degenerative myopia. One might spot pathological myopia by looking at the diseases that develop in the posterior of the eye. Pathological myopia can cause several eye conditions, such as posterior staphyloma, vitreous opacities, Weiss' reflex, liquefaction, macular degeneration, cystoid degeneration, liquefaction, Foster-Fuchs' spot, etc. In this study, an automated method for the diagnosis of problematic myopia based on fundus pictures is constructed using a deep learning approach known as a convolutional neural network.

TABLE II. SUMMARY OF STATE-OF-THE-ART MACHINE LEARNING TECHNIQUES EMPLOYED FOR DETECTION OF PATHOLOGIC MYOPIA IN RETINAL FUNDUS IMAGES

Reference	Image Processing	Techniques/Models	Results	Advantage
Rauf et al. [8]	Grayscale, histogram, Red channel, Shuffle	The preprocessed images are then fed to the designed CNN model. The CNN model automatically extracts the features from the input images and classifies the images, i.e., normal image or pathological myopia.	AUC: 0.9845	Detect different stages of PM.
Li et al. [9]	Color histogram distribution	A dual-stream DCNN (DCNN-DS) model that perceives features from both original images and corresponding processed images.	sensitivities of 90.8% and 97.9% and specificities of 99.1% and 94.0% for detecting PM	Detect PM and TF
Devda et al. [10]	Morphological edge detection	A deep learning model with convolutional neural networks (CNN) is employed for classification, and the U-net model does image segmentation.	ACC of 97.8%	Detect PM
Hemelings et al. [24]	CNN and Semantic Segmentation	CNN is combined with lesion segmentation. Furthermore, domain knowledge is incorporated by using Optic Nerve Head (ONH)-based prediction to improve the segmentation of atrophy and fovea.	AUC of 0.9867 for PM detection, Euclidean distance of 58.77 pixels for fovea localization	Detect PM and fovea localization
Li Lu et al. [25]	NA	The author proposed a series of deep learning systems to detect myopic macular lesions and PM in accordance with the international photographic classification system (META-PM) using color fundus images.	AUC of 0.989	
Du et al. [26]		Deep Learning (DL) algorithms are proposed to identify the key features.	AUC values were 0.970, 0.978, 0.982, and 0.881	diffuse atrophy, 87.22% for patchy atrophy, 85.10% for macular atrophy, and 37.07% for choroidal neovascularization
Zhang et al. [27]		In [27], using ultra-wide field of view (UWF) fundus color imaging, a screening system named DeepUWF was developed, which can diagnose three kinds of fundus diseases (diabetic retinopathy, retinal tear, retinal detachment, and pathological myopia). This system is composed of CNN and two customer classifiers.		three kinds of fundus diseases (retinal tear & retinal detachment, diabetic retinopathy and pathological myopia)
Shi et al. [28]		A Myopia Detection Network (MDNet) is proposed that combines the advantages of dense connection and Residual Squeeze-and-Excitation attention to detect myopia in optos fundus images.	Mean Absolute Error of the Spherical Equivalent detected by this network can reach 1.1150 D	
Freire et al. [29]		First, different Deep Learning techniques are applied on fundus images, and, then transfer learning is applied on all tasks using Xception.		algorithms to diagnosis Pathological Myopia (PM) and detection of retinal structures and lesions such asOptic Disc (OD), Fovea, Atrophy and Detachment

The CNN was invented by Spyder. The characteristics are automatically extracted from the photos and categorized for pathological myopia. The metrics AUC = 0.9845 and validation loss = 0.1457 show the CNN model's excellent performance. The identification of pathological myopia from fundus pictures is therefore possible in the medical field using CNN.

MM, pathologic myopia (PM), and tessellated fundus were classified using a dual-stream DCNN (DCNN DS) model in [9]. (TF). It functions by taking characteristics out of the original image and applying them to an image that has been color histogram. The DCNN-DS model achieved sensitivities of 93.3% and 91.0%, specificities of 99.6% and 98.7%, and an AUC of 0.988 and 0.994 for identifying PM. According to the author's claims in [10], the suggested algorithm is trustworthy and has high sensitivity, specificity, and AUC to discriminate against various levels of MM on fundus images. A deep learning model using convolutional neural networks (CNN) is used for classification, and a DepthCNN-XgBoost model handles image segmentation. Devda et al. concentrate on segmenting lesions (atrophy and detachment), classifying nonpathological and pathological myopia images, detecting the fovea, and localizing the optical disc. Positive outcomes are produced by combining CNN with DepthCNN-XgBoost.

CNN and lesion segmentation are integrated in [24]. The segmentation of atrophy and fovea is further enhanced by applying optic nerve head (ONH)-based prediction, which incorporates domain knowledge. Segmentation, as opposed to detection or regression models, is used in this work to locate the fovea. Euclidean distance for fovea localization, AUC for PM detection, and F1 and Dice for semantic segmentation are some of the metrics that are used to evaluate the outcomes (optic disc, retinal atrophy, and retinal detachment). The model successfully localizes the fovea at a distance of 58.77 Euclidean pixels and detects PMs with an AUC of 0.9867. The optic disc lesion, retinal detachment lesion, and retinal atrophy lesion F1 and Dice metrics for semantic segmentation of lesions are observed at .9303 and 0.9869, 0.8073 and 0.7059, and 0.8001 and 0.9135, respectively. To identify myopic macular lesions and PM in line with the worldwide photographic classification system (META-PM) using color fundus photos, the author of [25] presented a number of deep learning algorithms. Both the test and external validation.

Datasets are said to have robust performance. The identification of the relevant traits is presented using deep learning (DL) methods in [26]. Additionally, these models are used to create a meta-analysis for pathologic myopia (META-PM) classifying system (CS) by adding a specific layer. The DL models' sensitivity to choroidal neovascularization was 37.07%, 87.22%, 84.44%, and 85.10%, respectively, as were their sensitivity to patchy atrophy, diffuse atrophy, and macular atrophy. These are the relevant AUC values: 0.970, 0.978, 0.982, and 0.881. The META-PM study CS had an overall accuracy of 87.53%, with rates of 90.18%, 95.28%, 97.50%, and 91.14% for each kind of lesion, respectively.

A screening technique known as DeepUWF was created in [27], utilizing ultra-wide field of view (UWF) fundus color imaging, and it can diagnose three different fundus disorders (diabetic retinopathy, retinal tear, retinal detachment, and pathological myopia). This system is built using CNN and two customer classifiers. Six different image preparation approaches are also used to fix the low contrast problem with UAF photos. These preprocessing steps improve the networks' ability to learn and help them achieve high levels of sensitivity and specificity. The benefits of dense connection and residual squeeze-and-excite attention are combined in [28] to present a myopia detection network (MDNet) that can identify myopia in a fundus image. Following the extraction of the region of interest using the optical disc identification approach, the dataset is expanded using the data augmentation method. This network's capacity to recognize spherical equivalents with a mean absolute error of 1.1150 D (diopters) demonstrates the utility of this approach. In [29], transfer learning is used to complete all tasks using Xception after various deep learning algorithms are initially applied to fundus pictures. The optical disc segmentation algorithm pipeline also employs the YOLO design. The model is assessed using the following metrics: AUC-ROC, F1-Score, Mean Dice Score, and Mean Euclidean Distance. The approach has so far shown positive outcomes.

IV. Research Methodology

1) *Data acquisition:* The training dataset for this study was acquired from the event hosted by the International Symposium on Biomedical Imaging (ISBI-2019) in Italy. It contains 400 labelled funds images. The dataset consists of 239 pathological myopic eye images and 161 normal eye images. The image size is 1444×1444×3 (RGB image). The database is available at https://palm.grand-challenge.org/. Fig. 2 shows the preprocessing step.

2) *Proposed method:* The initial step involves preprocessing the image (as illustrated in subsection A) to emphasize particular patterns, which aids in effectively training Deep Learning models for classification purposes. Overall steps of proposed system is described in Algorithm 1. This algorithm outlines the steps for extracting features using Depthwise Separable CNN and Multi-Level Pooling. It applies depthwise separable convolution to capture spatial features efficiently and then performs multi-level pooling to reduce dimensionality and retain important information. The extracted features are then used to train a CNN model for classification.

The proposed framework for steganography based on a convolutional neural network (CNN) is illustrated in Fig. 3. The proposed CNN architecture consists of several layers that take a 256 x 256 input image and generate two class labels, namely "Normal" and "Pathological Myopia". The network includes an image preprocessing layer, two separable convolutions (sepconv) blocks, four fundamental feature extraction blocks, a spatial pyramid pooling (SPP) module, and two fully connected layers followed by a softmax function. The convolutional blocks consist of four blocks known as "Basic Blocks 1" to "Basic Blocks 4," which perform operations to capture the spatial relationships between feature maps and transmit this information to the fully connected layer for classification using the XgBoost classifier. Each Basic Block carries out a set of actions to achieve this.

A. Image Preprocessing

In the initial stage of processing, we adjust the size of the convolution kernel and employ 30 fundamental SRM filters [12] to set the kernels to minimize parameters and enhance local features. We also use the "forward-backward-gradient descent" approach to optimize the convolution kernel, thereby improving accuracy and speeding up the network's convergence.

B. Convolution Layer

Instead of using bigger convolution kernels like 55, employed in earlier publications [18], [20], we use compact convolution kernels like 33 in our CNN design to limit the number of parameters. The number of parameters is decreased while the extraction of local characteristics is made effective by the use of small convolution kernels. As a result, we decided to use a convolutional kernel size of 3 with 32 channels for each of the first four Basic Blocks. The performance of the network and computational complexity are carefully analyzed to determine the number of channels for each fundamental block.

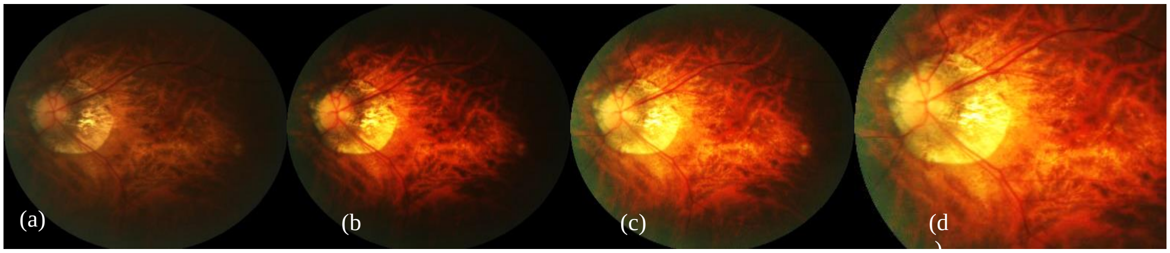

Fig. 2. A preprocessing step to enhance the contrast while adjusting the light illumination, where figure (a) shows input image, (b) enhance the contrast, and (c) light adjustment. Also, the figure (d) shows the region-of-interest (ROI).

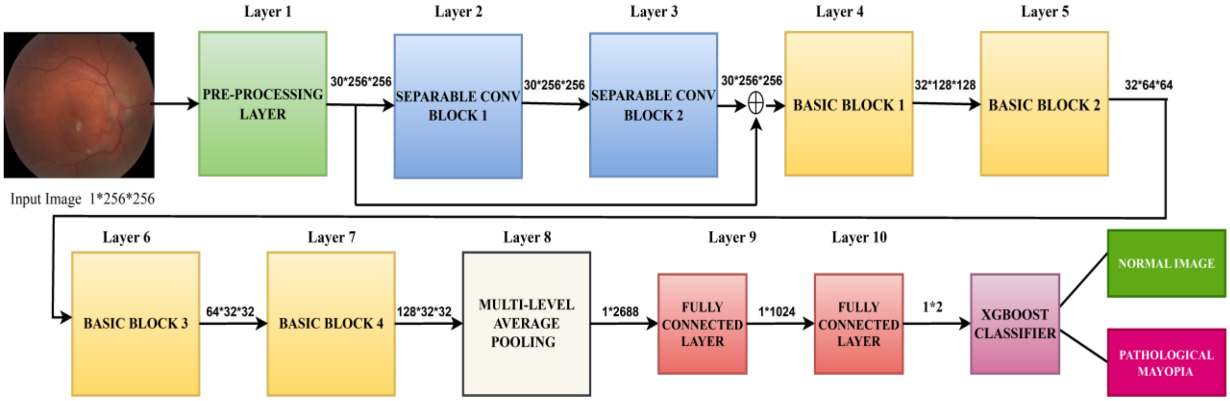

Fig. 3. The systematic flow diagram of proposed system.

C. *Batch Normalization (BN) Layer*

Batch normalization [25] is a technique commonly employed during training to normalize the distribution of each mini batch, typically resulting in a zero mean and unit variance. According to study [25], incorporating a BN layer in deep neural networks can prevent the issues of gradient vanishing or explosion and overfitting. Moreover, it allows for a reasonably high learning rate, which helps in achieving faster convergence. After conducting experiments, we observed that networks similar to Ye-Net that do not have BN are highly vulnerable to inadequate parameter initialization and may not reach convergence. These findings were noted in the study [20]. Therefore, BN is utilized in the proposed approach.

D. *Non-Linear Activation Function*

We use the traditional rectifying linear unit (ReLU) as the activation function for each block in the Zhu-Net to avoid gradient vanishing or exploding issues, hasten network convergence, and achieve several additional aims. Utilizing ReLU on neurons during training can teach them to respond exclusively to inputs that carry significant signals, which can enhance the creation of more efficient features. The ReLU function is useful and makes computing back-propagation gradients easier. In our research, we made use of the network shown in Figure to assess the performance of other activation functions, including the truncated linear unit (TLU) suggested in Ye-Net, for purposes alongside ReLU. ReLU is used as the activation function to train the entire model, comprising all of its layers and building components. The utilization of ReLU results in enhanced performance and accelerated convergence.

E. Average Pooling Layer

Average pooling layers, which can improve receptive fields, shrink feature maps, and improve image feature abstraction, are included in the first three essential building blocks. Moreover, average pooling improves the network's generalization capacity. To prevent information loss, the network's first block does not use pooling. Furthermore, we utilize separable convolution blocks (Sepconv Blocks 1 and 2) to enhance the SNR (the ratio of the signal-to-noise in the stereo signal and the resultant image) and efficiently manage spatial and channel correlations. In the last stage, we utilize an SPP module to improve the extraction of features. Through the application of multi-level pooling, the SPP module enhances the representation of features. At the conclusion of the suggested approach, a trio of fully connected layers are implemented, consisting of 2688, 1024, and 2 neurons in each layer. The ultimate layer with complete connectivity employs a softmax activation function to establish scores for the two class labels.

1) Separable convolution architecture: Recent achievements in computer vision projects like Inception [29], Xception [30], and other architectures have been made possible by separable convolution. In Fig. 5, we can observe Xception, which is a modified version of the Inception module (a). In this particular Inception variation, known for its extreme approach, the interdependence between channels is entirely eliminated, resulting in a boost in model expressiveness and storage efficiency. When the layer has been preprocessed, we create the relevant sepconv blocks using two separable convolution blocks made up of a 1x1 and a 3x3 convolution. This is done in order to use the leftover information from the normal and pathological myopia images more efficiently (as shown in Fig. 1). In our configuration, we presume that the residual correlations in the spatial and channel domains are independent of one another. Each feature map produced by the high-pass filter can be subjected to group convolution using the sepconv block. Fig. 4 depicts the structure of sepconv blocks. A sepconv block consists of three repetitions of both a 1x1 pointwise convolution and a 3x3 depthwise convolution.

In order to extract spatial correlations, a convolution operation with a depth of 3 x 3 is first carried out, employing a total of 30 groups. Pytorch uses the "groups" argument to implement separable convolution. After that, a pointwise convolution is performed in a sepconv block to get rid of any remaining channel correlations. After the initial 1-1 convolutional layer of sepconv block 1, we add an ABS layer [26] to help our model recognize the symmetry present in the noise residual. The two sepconv blocks integrate residual connections to improve classification performance and prevent gradient vanishing or explosion. Fig. 5 represents the visual architecture example used in our proposed model. It's important to note that the second SepConv block lacks an activation mechanism. We chose to employ the ABS layer in the first sepconv block even though depthwise separable convolutions are typically applied without nonlinearities. It somehow boosts the network performance. The optimized kernel and the hyper parameter description are as follows:

F. Optimizing Kernels

Modeling the residuals rather than the pixel values will produce more robust characteristics. The convolution kernels in the preprocessing layer are constant during training for the Yedroudj-Net and Xu-Net architectures. We built a preprocessing method termed "forward-backward-gradient descent" to improve the SRM feature sets that were manually created using domain-specific expertise.

To determine the residual, we follow this method: Firstly, we take each image X = Xij and compute the residual R = Rij as

$$\mathrm{Rij} = \mathrm{X\,pred\,(Nij)} - \mathrm{cXij}, \tag{1}$$

In this equation, c is an integer that represents the residual order, Nij denotes the neighboring pixels of Xij, and X pred (.) is a predictor of cXij based on the values of Nij. Generally, we utilize high-pass filters to obtain X pred ()

Algorithm 1: An algorithm for feature extraction using Depthwise Separable CNN and Multi-Level Pooling

```
Input:
- Images dataset (X) with corresponding labels (Y)
- Hyperparameters: number of layers (L), filter sizes (F), pool sizes (P), depthwise separable convolution parameters (D)
- Number of classes (C)
Output:
- Extracted features (X_features)
- Updated labels (Y)
Algorithm:
1. Initialize an empty list X_features.
2. Initialize an empty list Y.
3. For each image x and its corresponding label y in the dataset:
    - Perform depthwise separable convolution on x with parameters D, resulting in feature maps.
    - Perform multi-level pooling on the feature maps with pool sizes P, resulting in pooled feature maps.
    - Flatten the pooled feature maps to obtain a 1D feature vector.
    - Add the feature vector to X_features.
    - Add the label y to Y.
Convert X_features and Y to numpy arrays.
Split X_features and Y into training and testing sets.
Initialize a depthwise separable CNN model.
Add L convolutional layers to the model, each with filter size F.
Add a fully connected layer with C neurons for classification.
Compile the model with an appropriate loss function and optimizer.
Train the model using X_features_train and Y_train, and validate it using X_features_test and Y_test using XGBoost classifier as described in section 4.4.
Evaluate the model's performance metrics such as accuracy, precision, recall, etc.
Return the trained model for future predictions.
```

During the backpropagation step of each iteration, we utilize the stochastic gradient descent (SGD) algorithm to update filter weights. Earlier studies have demonstrated that a Convolutional Neural Network (CNN) with weights initialized randomly typically fails to converge. To address this, previous research has often utilized SRM kernels to initialize the weights of the initial layers in order to generate a group of prediction errors based on pixel values, which can enhance the performance of the CNN.

G. Hyper-Parameters

We utilize mini-batch stochastic gradient descent (SGD) as the training approach for the CNN networks, while setting the momentum and weight degradation values to 0.9 and 0.0005, respectively. Due to limitations in GPU memory, the training mini-batch size has been established as 16, comprising 8 Normal/Myopia pairs. After that, the networks undergo training to reduce the cross-entropy loss using the variables mentioned earlier. During training, we modified the learning rate, which was initially set to 0.005. At certain predetermined steps throughout the training process, this modification entails dividing the learning rate by five. Specifically, during the 400-epoch training of a CNN, the learning rate will decline during epochs 50, 150, and 250. In the final phases of training, using a slower learning rate can significantly decrease training loss and boost accuracy. To prevent over-fitting, stopping training before reaching 400 epochs is common. This means that training is stopped when the cross-entropy loss on the training set continues to decrease, but the accuracy on the validation set begins to decrease. Specifically, during the 400-epoch training of a CNN, the learning rate will decline during epochs 50, 150, and 250. In the final phases of training, using a slower learning rate can significantly decrease training loss and boost accuracy. The testing accuracy was used to evaluate the performance. The proposed DSC-XGBOOST structure for identifying myopia anomalies is shown in Fig. 3.

2) *Classification:* The XGBoost algorithm has become the preferred tool for many data scientists, as it is a highly sophisticated algorithm capable of managing any kind of data abnormalities. Crafting a model using XGBoost is effortless, but enhancing it with XGBoost is arduous, at least in my experience. There are several things to take into account when using this strategy. To improve the performance of the model, it is essential to modify certain parameters. Nonetheless, it can be challenging to come up with a satisfying response to practical queries such "What is the perfect parameter setup for optimal results?"

3) *Regularization:* While XGBoost is known as a "regularized boosting" method, standard GBM lacks regularization, which helps to avoid overfitting. Moreover, XGBoost uses parallel processing, which accelerates performance compared to GBM. Yet, because the boosting process is sequential, it begs the question of how parallelization is even conceivable. What prevents us from building a tree employing all cores at once if each tree can only be formed after the one before it?

The XGBoost algorithm tries multiple approaches to handle missing data in each node while the user inputs a unique value as a parameter. In GBM, the tree pruning strategy is employed to prevent further division of that node if split results in a loss. In comparison to GBM, the XGBoost algorithm is more greedy because it prunes the tree backward and eliminates splits that don't offer any additional benefits. Moreover, XGBoost allows positive loss splits even after negative loss splits, something that GBM does not. For instance, XGBoost would continue and preserve both divides if they resulted in a total effect of +8, while GBM would stop at a split of -2.

Built-in Cross-Validation: XGBoost simplifies the process of obtaining the perfect number of boosting iterations by enabling users to perform cross-validation at every stage of boosting. This is different from GBM, which requires a grid search and only permits a limited number of variables to be analyzed. Using the latest iteration of an XgBoost model as the starting point for training can be extremely advantageous in specific contexts. The GBM implementation in sklearn includes the same capability, so both XgBoost and GBM are equally equipped. However, XgBoost may produce unstable models due to overfitting on the training set. To avoid this, regularization techniques can be employed to consider the model's complexity and prevent overfitting. In XgBoost, including a term that measures the model's complexity can modify the cost function. The two parameters used for regularization in XgBoost are alpha and lambda, which correspond to L1 regularization (Manhattan distance) and L2 regularization (squared Euclidean distance), respectively [1]. In order to implement L2 regularization, we need to assign a value to the reg lambda parameter in XgBoost.

The term "extreme gradient boosting," abbreviated as "XgBoost," refers to a method of gradient boosting that has been rigorously analyzed and parallelized to minimize the training time of the entire boosting procedure drastically. Instead of the traditional approach of creating the best possible model based on the data and then selecting it, we train numerous models on various subsets of the training dataset and choose the one that performs the best by gathering the results from all the models. XGBoost is often superior to standard gradient-boosting techniques in various scenarios. A vast array of key parameters can be adjusted for improved precision and accuracy by utilizing the Python implementation.

Consider a function or an approximation, and then generate a sequence of values based on the gradients of the function. The subsequent formula models a particular form of gradient descent. The loss function indicates the direction of the function's descent, which needs to be minimized. The fitted change rate is equivalent to the learning rate used in gradient descent. It is expected to match the behavior of the loss function accurately.

$$F_{x_i} = F_{x_i} + \alpha_{x_i} \frac{\partial}{\partial x}(x_t) \tag{2}$$

To find the best definition of the model, we need to describe the formula as a sequence and find a function that efficiently converges to its minimum. This function will be used as an error metric to help us reduce loss and maintain performance over time. Eventually, the sequence will reach the minimum of the function. This notation defines the error function for assessing a gradient boosting regressor.

$$f(x, \theta) = \sum l(f(x_i, \theta), y_i) \tag{3}$$

The following are the steps involved in the XgBoost algorithm:

XgBoost algorithm classifier for severity level of Myopic Maculopathy.	
Steps	Given training data from the instance space
1	Space S_1= $\{(x_1,y_1)\}$, where $S = \{S_1, S_2, S_3, \ldots, S_n\}$
2	[Initialize], $D_1(i) = \frac{1}{m}$
3	Repeat: For i= 1,2,3,…, n do
4	Train a weak leaner $h_i: x \rightarrow R$ using distribution D_i
5	Update the distribution over the training set:
6	$D_{i+1}(k) = \frac{D_i(k)e^{-\alpha_i}}{Z_i}$ (4)
7	Where Z_i is a normalization factor D_{i+1} chosen so that D_{i+1} will be a distribution
8	[end for]
9	$f(x) = \sum_{i=0}^{n} \alpha_t h_t(x)\ and\ H(x) = sign\ (f(x)$ (5)

V. Experimental Results

A. Data Augmentation

The augmentation approach is used to make the balance among classes of MM. The network becomes resistant to certain alterations in this way. The integration of spatial information, which is essential for image segmentation tasks, is a strength of CNNs and DepthCNN-XgBoost in particular, although they are not equally resilient to transformations like scaling and rotation. The network may get the necessary invariance and resilience properties through the use of rotations and flips, two data augmentation techniques. The data augmentation also included shears, a derivation of elastic deformations recommended as a general best practice for convolutional neural networks and flips and rotations. The ImageDataGenerator function of Keras is used to implement the augmentation. Fig. 6 is visually displayed the distribution after performing data augmentation.

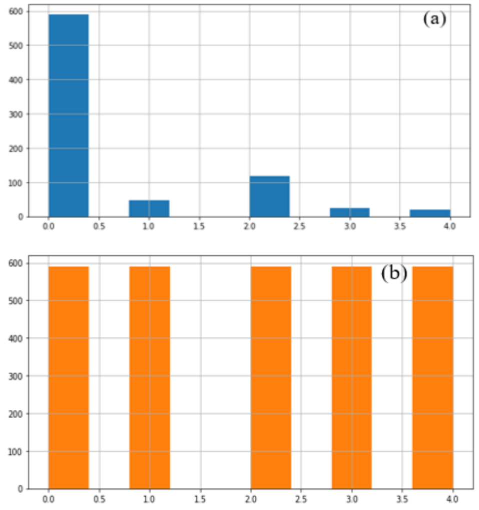

Fig. 6. Sample distribution of PALM dataset, where figure (a) shows the original images, whereas figure (b) shows the number of images after data augmentation.

B. Experimental Setup

All networks were developed in Python using the Keras and TensorFlow packages. The models were trained on an NVIDIA Tesla P4 GPU supplied by Google Colab. The test was run on a computer with an 8-core AMD FX-8320 CPU running at 3.5 GHz and 8 GB of RAM.

C. Assessment Criteria

The false positive rate (FPR) is the proportion of times a biometric system incorrectly accepts a fake subject. The false negative rate (FNR) is a biometric system that wrongly rejects the percentage of times a legitimate subject. Finally, the proportion at which FPR and FNR are identical is referred to as the equal error rate (EER). The binary classification error rates are shown graphically by the detection error trade-off (DET) curve. The FPR is on the x-axis, and the corresponding FNR is on the y-axis in this curve. The system's effectiveness is evaluated using a verification system comprising EER and DET curves. Since it tries to match the biometrics provided by a person with the precise biometrics already enrolled, it is sometimes referred to as a "1-to-1 matching system."

The identification system is represented as a 1-to-n matching system, in contrast to verification systems, where n is the total number of records in the database. Here, rank-1 IR and the CMC curve are used to evaluate the framework's performance. The rank-k identification rate is the proportion of times the true subject's match score appears in the top k matches (IR). A 1:1 identification system may have its performance evaluated using the cumulative match curve (CC). Plotting a curve between rank-k IR on the y-axis and rank-k on the x-axis illustrates it. Using a number of other assessment metrics, such as specificity, sensitivity, F1-score, accuracy, recall, and precision, the effectiveness of the suggested approach is measured in numbers.

Accuracy (ACC) is one of the most frequent and fundamental performance indicators. It is simply the likelihood that a randomly chosen example (positive or negative) will be true. In this measure, the diagnostic test shows how likely it is that the correct result will happen or how likely it is that the diagnosis is correct.

$$Accuracy\ (ACC) = \frac{TP+TN}{FP+FN+TP+TN} \quad (6)$$

The ability to properly identify positive categories within whole expected positive classes is referred to as precision, and it is stated as a ratio of all successfully predicted positive categories to all correctly expected positive categories:

$$Precision\ (PR) = \frac{TP}{TP+FP} \quad (7)$$

Sensitivity (SEN), Recall, True Positive Rate, Hit Rate: It is a measure of a model's capability to detect all positive instances and is represented as:

$$Recall(RE) = \frac{TP}{TP+FN} \quad (8)$$

It's worth noting that the above equation implies that a low false-negative rate almost always accompanies a high recall.

Specificity (SPE): Ratio of true negatives to total negatives in the data. Mathematically can be represented as follows:

$$Specificity = \frac{TN}{TN+FP} \quad (9)$$

F1-score: It is not as straightforward as accuracy, but this metric is useful in determining the classifier's exact and robustness. The F1 score, which is a key metric that considers both recall and precision for performance testing, it could be represented as follow:

$$F1 - score = 2.\frac{Precision \times Recall}{Precision \times Recall} \times 100\% \quad (10)$$

Where TN (true negative) and TP (true positive) are accurately predicted negative and positive outcomes, respectively. FN (false negative) and FP (false positive) do not predict negative and positive human identification cases correctly.

AUC: This stands for area under the receiver operating characteristics (AUC). The AUC is a graphical representation or plotting the diagnostic ability of any machine learning classifier using all thresholds.

D. Hyper-parameters Fine-tune

To determine the optimal hyper-parameter values for the optimizer and initial learning rate, a grid search was conducted. This search involved considering five different optimizers: stochastic gradient descent (SGD), SGD-Momentum, Nesterov Accelerated GD, RMSProp, and ADAM. The initial learning rate was varied within the range of 10^-1 to 10^-4. The training process involved each benchmark CNN being initially trained with the hyper-parameter values specified in their respective papers. However, due to factors such as the relatively small size of the training dataset compared to the larger datasets they were originally trained on ImageNet and the differences in discriminative features among classes, these initial attempts resulted in poor learning.

For each combination of optimizer and initial learning rate in the grid, the CNN models were trained for 20 epochs using the modified EyePACS train-set. Specific parameter values were set for each optimizer: a momentum of 0.9 for SGD and Nesterov Accelerated GD, a discounting factor (ρ) of 0.9 and a stability factor (ε) of 0.1 for RMSProp, and exponential decay rates β1 and β2 of 0.9 and 0.999 respectively, along with a stability factor (ε) of 1e-7 for ADAM. The best-performing optimizer and initial learning rate pair, which resulted in the highest training accuracy within the 40 epochs, was selected as the optimal combination of hyper-parameters for each benchmark CNN.

E. Result Analysis

The experimental results took numerous classification-related performance metrics into account, including the identification skills and the average computational time required by a trained network to fully annotate a CT image. Five performance metrics are typically considered when assessing a classifier: accuracy, precision, recall, F1-score, and AUC. The DepthCNN-XgBoost model beat the other deep learning models in terms of classification accuracy for detecting the MM-infected regions. It has been found that class imbalance may be used to explain the difference in accuracy, F1-score, and AUC. The majority class (no detections) was almost always classified properly. On the edges of infected regions in photos, false-negative detections were discovered when MM symptoms were plainly discernible. Nevertheless, the minority class (MM symptomatic regions) was discernible because the F1-score and AUC were both reasonably high. Model loss and accuracy curves are visually displayed in Fig. 7.

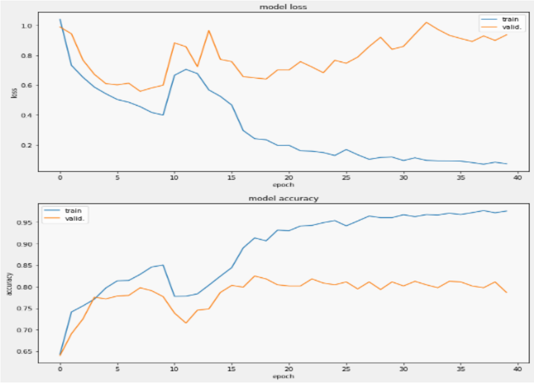

Fig. 7. Accuracy and validation loss curve for the proposed architecture.

The DepthCNN-XgBoost model's higher generalization capabilities when compared to the CNN, LSTM and CNN-LSTM. The current work aimed to decrease false positives since erroneous detections in medical imaging applications are crucial (normal areas are diagnosed as symptomatic). Additionally, the pandemic has raised the need for chest CT scan interpretation. With this in mind, we concentrated on minimizing radiologists' burden by striving for a high proportion of true positives (symptomatic areas diagnosed as symptomatic). In this situation, it is important to investigate the techniques that may result in extremely high accuracy and appropriate recall scores. DepthCNN-XgBoost and CNN-LSTM occasionally outperformed the traditional CNN because of their high-precision scores, which included both FP and TP values, even though all three models produced the same results for the F1-score, AUC, and accuracy. The result of AUC curve in Fig. 8 shows that the higher AUC value of 0.92 achieved by the proposed Depthwise-XgBoost with data augmentation compared other classifiers. Similarly, Fig. 9 shows the confusion matrix of the proposed system without data augmentation.

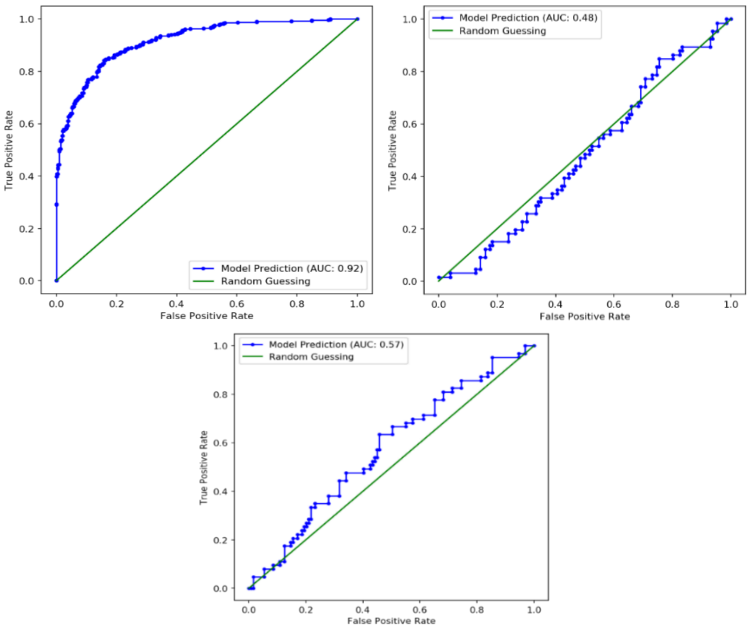

Fig. 8. Three AUC curves for figure (a) Proposed depthwise-XgBoost with data augmentation, (b) Original depthwise separable CNN, and (c) XgBoost classifier.

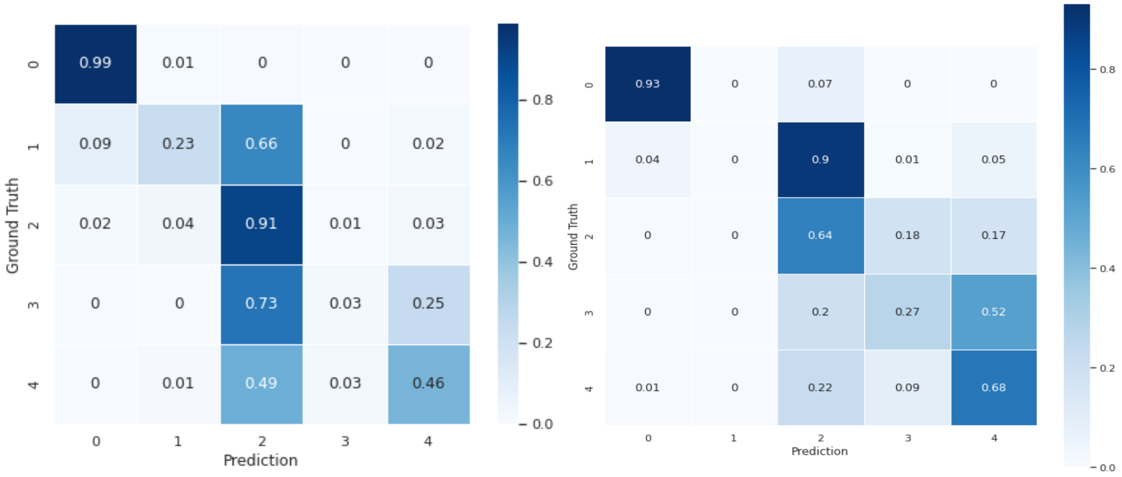

Fig. 9. Confusion matrix of proposed model for recognition of each class of MM.

Here we include a detailed comparison of various machine learning classifiers' performance in detecting and classifying stages of Myopic Maculopathy, using three different train-test partition strategies, Table II, Table III and Table IV. Each table assesses the classifiers based on Accuracy (ACC), Precision (PR), Recall (RE), and F1-Score. In the 70%-30% train-test partition strategy, the classifiers including CNN, LSTM, CNN-LSTM, Depthwise Separable, and the proposed Depthwise-XgBoost, all showcase high performance with the metrics mostly in the mid-90s percentile. The proposed Depthwise-XgBoost model exhibits a competitive edge with a 96.5% F1-Score. When the partition strategy shifts to 80%-20%, the classifiers show similar or slightly improved performance. Notably, the Depthwise-XgBoost stands out with the highest precision of 98% and maintains a robust F1-Score of 96.5%.

This indicates a consistency in the model's performance even as the data partitioning varies. The 90%-10% partition further underscores this consistency and, in some cases, an increase in accuracy and other metrics for all classifiers. The CNN-LSTM model achieves the highest accuracy at 97%, while the Depthwise-XgBoost maintains its high precision and F1-Score, emphasizing its reliability and effectiveness across different data distributions. Overall, the comparisons indicate that the advanced machine learning techniques, particularly the proposed Depthwise-XgBoost, are highly effective in diagnosing Myopic Maculopathy. The consistent performance of the Depthwise-XgBoost across various partition strategies highlights its potential as a robust and reliable model for medical diagnostic purposes. Each classifier demonstrates strengths in different metrics, but collectively they underscore the capability of deep learning architectures in enhancing the accuracy and reliability of medical diagnoses in ophthalmology.

TABLE III. CLASSIFICATION PERFORMANCE OF THE PROPOSED METHOD WITH OTHER MACHINE LEARNING CLASSIFIERS USING 70%-30% TRAIN-TEST PARTITION STRATEGY

Classifier	ACC	PR	RE	F1-Score
CNN	95%	95%	95%	96%
LSTM	94%	93%	96%	95%
CNN-LSTM	96%	94%	97%	96%
Depthwise Separable	95%	94%	97%	96%
Proposed Depthwise-XgBoost	95%	96%	97%	96.5%

TABLE IV. CLASSIFICATION PERFORMANCE OF THE PROPOSED METHOD WITH OTHER MACHINE LEARNING CLASSIFIERS USING 80%-20% TRAIN-TEST PARTITION STRATEGY

Classifier	ACC	PR	RE	F1-Score
CNN	95%	96%	94%	95%
LSTM	94%	95%	94%	95%
CNN-LSTM	96%	95%	96%	96%
Depthwise Separable	95%	95%	95%	95%
Proposed Depthwise-XgBoost	95%	98%	97%	96.5%

TABLE V. CLASSIFICATION PERFORMANCE OF THE PROPOSED METHOD WITH OTHER MACHINE LEARNING CLASSIFIERS USING 90%-10% TRAIN-TEST PARTITION STRATEGY

Classifier	ACC	PR	RE	F1-Score
CNN	96%	94%	96%	96%
LSTM	95%	95%	95%	95%
CNN-LSTM	97%	96%	96%	97%
Depthwise Separable	96%	96%	96%	96%
Proposed Depthwise-XgBoost	95%	98%	97%	96.5%

In addition to comparing various machine learning classifiers, the article presents Table V, which contrasts the performance of the proposed method with other existing studies in the field of Myopic Maculopathy detection and classification. The comparison is based on four key metrics: Recall, Precision, F1-score, and Accuracy. The table lists several methods from different researchers, including Rauf et al., Li et al., Devda et al., Li Lu et al., Du et al., Zhang et al., along with the proposed method. Each method's performance is quantified, demonstrating a range of effectiveness in diagnosing Myopic Maculopathy. For instance, Rauf et al. show balanced performance across all metrics at 94%. Li et al. have a notably high precision of 97% but lower accuracy at 88%. Other methods like Devda et al. and Li Lu et al. present a balanced mix of recall, precision, and accuracy, reflecting the diversity in effectiveness and approach among different studies. The proposed method distinguishes itself at the end of the table, demonstrating superior recall (97%), precision (98%), and an F1-score of 96.5% with an accuracy of 95%. These numbers indicate a high level of reliability and precision in detecting and classifying Myopic Maculopathy, surpassing the other methods listed. This comparison not only underscores the proposed method's robust performance but also contextualizes it within the broader landscape of existing research, highlighting its potential as a significant advancement in the field. A visual result of the proposed system is also displayed in Fig. 10 to detect different classes of MM.

VI. DISCUSSION

This work suggests the identification and classification of myopia maculopathy (MM) from retinograph pictures, utilizing multi-layer deep learning and pretrained learning techniques. In reality, a number of conditions, such as myopia maculopathy, can be followed by cataracts, glaucoma, retinal detachment, and other conditions (MM) as described in Table VI.

The World Health Organization consequently recognizes myopia as a significant factor in visual impairment if it is not completely treated. On patients, their families, and society as a whole, MM imposes a heavy cost. For MM, there is presently no effective therapy. For all myopic individuals, preventive treatment can lessen ocular problems. According to the International Photographic Classification and Grading System for Myopic Maculopathy [3], myopic maculopathy was identified and categorized. Myopia is classified according to its severity. In this study, identifying myopic maculopathy for fundus pictures in categories 2 and above is explored. Deep learning algorithms have lately been the subject of several academic studies aimed at segmenting MM-infected areas. In pixel-based segmentation for medical pictures, fully convolutional networks and U-shaped convolutional networks perform exceptionally well. So, when separating the MM-infected part of the retinal fundus picture, both are given top priority.

The adoption of deep learning (DL) technologies in identifying pathologic myopia (PM) lesions remains a difficulty due to the complexity of the PM classification and definition system. However, enough resources can achieve objectives, such as high-quality PM retinal fundus picture collections and high-caliber expert teams. This study aims to create and train DLs to recognize PM as well as the categories. In this article, we used a novel deep learning model based on depthwise separable convolution layer for the detection of MM using fundus images. Motivated by the DSC model's outstanding results in various research disciplines. They perform well on small number of samples and allow.

In this instance, we employed the idea of depth-wise separable. A small number of training examples are used at a time in this online learning process. According to this process, new fundus pictures are fed to the model with the approval of subject-matter experts, and the model outputs are also assessed by experts throughout the testing phase to detect findings that were incorrectly categorized. Despite the fact that this technique improved segmentation performance and provided a foundation for online learning, Nevertheless, it required expert input throughout the algorithm's testing stage. As a result, human participation is required throughout the learning process with this technique. Although unlikely, errors in judgment made by the medical experts would have led to a decline in network performance. The same problem arises when an incorrectly labeled dataset is introduced to the network in the supervised learning paradigm. But because the supervised learning ground truth data were generated offline, there was plenty of time to evaluate the accuracy of the annotation. The dynamic weight adjustments in the recommended learning technique prevent the expert from having time to reconsider their choice. In order to condense the training dataset and accommodate fresh training examples, a forgetting mechanism is used. The image is carefully examined at every level, from coarse to fine, in order to grasp its features. In the first stage, classification will be done, and an image's MM infection will be looked at.

The FCN model, on the other hand, initially performs multi-scale image processing, in which feature maps are created at several sizes. As the name suggests, an FCN model is built using locally linked layers, including convolution, pooling, and up-sampling [42]. Fig. 4, which contrasts FCN processing with conventional CNN structure processing, serves as an illustration of this. A down-sampling path is in charge of obtaining semantic and contextual data, and an up-sampling path is in charge of extracting spatial data. Together, these two components make up an FCN's topology. Due to the absence of a thick layer in this architecture, the number of parameters required and the associated computational expense are reduced [44, 45]. Implementing a skip connection action, which bypasses at least one layer, can minimize any downsides related to information loss due to pooling or down-sampling layers. An FCN model is compelled by this structure to operate inside a global-local data processing architecture.

It is clear that global-local analysis, as opposed to local-based ones like CNN, offers a superior classification framework for MM RETINGRAPH image segmentation. DepthCNN-XgBoosts is another design that may maintain the local-data features during the upsampling process and is similar to FCNs [23]. As a result, in this work, the MM segmentation of CT images is performed using the DepthCNN-XgBoost model. Ranneberger et al. (2015) demonstrated extremely strong performance when segmenting arterial brain arteries in a patient with cerebrovascular disease using a modified version of DepthCNN-XgBoost. This achievement motivates the development of vessel segmentation techniques for computer-aided diagnosis of cerebrovascular illness. Deep learning-based networks do not require unique feature engineering or selection, in contrast to earlier "rule-based" non-neural network techniques. While DepthCNN-XgBoost outperforms the traditional graph-cut-based segmentation approach by effectively extracting the pertinent features during training.In the second phase, the MM region is localized and labeled, and a bound box is created around the area of interest. This will help specialists focus on the diagnosis. However, for many purposes, bounding boxes are inadequate (for example, precise tumor diagnosis). In such cases, we need extremely detailed "pixel-based segmentation," or information at the pixel level. Semantic segmentation is aimed at achieving this. In this case, each pixel in a picture is assigned to a certain class. But due to time restraints, computational limitations, and low false-negative detection limits, semantic segmentation is restricted.

[41]	CNN bundles lesion segmentation and PM classification	PALM	AUC of 0.9867	No multiclass categorization of different types of MM and so limited capability

[42]	four convolutional neural network (CNN) architectures, namely DenseNet201, ResNet50, VGG16, and Xception. The CNN architectures were evaluated in the test dataset and their performances were compared. Xception had the best metrics compared with the other architectures in all three tasks	META-PM	--	Multiclass MM classification but without preprocessing and data augmentation.
[43]	DL models were able to recognize the lesions of myopic maculopathy	META-PM	AUC of 0.970	No multiclass recognition of MM and no generalize tool. No preprocessing to adjust the pixels.
[44]	Combination of dense connection and Residual Squeeze-and-Excitation attention is proposed in this paper to detect myopia automatically	Private	--	No multiclass recognition of MM and no generalize tool. No preprocessing to adjust the pixels.
[45]	three five-classification models based on Vision Outlooker for Visual Recognition (VOLO), EfficientNetV2, and ResNet50 for detecting myopic maculopathy were trained with data-augmented images	Meta-PM	SE of 96.43	No generalize tool. No preprocessing to adjust the pixels.
[46]	The efficientNet model was utilized to recognize multi-classes of MM.		AUC of 0.98	No preprocessing to adjust the pixels.
[47]	Image Processing and feature fusion approach were developed.	PALM	AUC of 0.9981	No multiclass recognition of MM and no generalize tool. No preprocessing to adjust the pixels.

A medical expert can evaluate the segmentation quality in addition to a quantitative evaluation. U-Visual Net's analysis performance was therefore shown to be much better. However, compared to smaller arteries, huge vessels can be seen very well, which can be enhanced in the future. As a result, it demonstrates the excellent performance of the DepthCNN-XgBoost architecture in the clinical area. Utilizing more recent segmentation topologies, such as the MS-net (Shah et al., 2018), can result in even greater performance. We should examine the problem's constraints before beginning any implementation technique. Two key criteria in deep learning methods are data availability and data imbalance, which both affect the choice of classification model and topological complexity. The fundus samples' positive-to-negative ratio (492:447) is reasonable; however, the pixel ratio between MM and non-MM is unbalanced. This is because the infected eye part is smaller than the healthy one (see Fig. 3 and Fig. 6). As a result, the first step was to implement a training data balancing strategy that included undersampling the majority class (non-MM regions) [48]. To do this, 492 photographs with a positive annotation ratio of 0.01 to 59% of the total pixels are supplied to deep networks for training, while the 447 images with negatively annotated pixels are excluded from the training process. A visual example of heatmaps show in Fig. 11 about the success of classifying different patterns in MM retinograph images.

4) *Limitations of current study:* The study acknowledges the significance of proper hyper-parameter tuning and the size and quality of the training dataset in achieving successful learning of a CNN model. In the context of this research, the focus was on evaluating various benchmark CNNs for MM classification tasks specifically using retinal fundus images. For future investigations, it is suggested that hybrid variations of the architectural concepts from the best-performing benchmark models, combined with attention mechanisms and spatial pooling, could be explored. This approach aims to synthesize a robust and accurate MM classification model by leveraging the strengths of different architectures and incorporating attention mechanisms to enhance the model's ability to focus on important regions or features in the images.

VII. Conclusion and Future Directions

This study presents a pretrained learning technique for segmenting SMM-infected regions. The DepthCNN-XgBoost framework was used to construct this model. Based on a small number of newly received samples, it modifies the network dynamically. This retraining method reduced the loss of existing knowledge while allowing the model to trust the approaching new incoming data to the greatest extent possible. The recommended solution differs from conventional methods in that it employs an online learning paradigm using spatial pyramid pooling technique. This novel approach, called "few-shot powered DepthCNN-XgBoost," is reportedly effective and persuasive in the segmentation of SMM-infected areas. Experimental results show the effectiveness of the suggested few-shot learning strategy in combination with a DepthCNN-XgBoost model for finding and characterizing infectious SMM regions. The few-shot powered DepthCNN-XgBoost is a possible artificial intelligence (AI) framework for medical imaging, particularly beneficial for locating pathogenic SMM regions when compared to deep learning models like convolutional neural networks, fully convolutional networks, and traditional DepthCNN-XgBoost structures. The proposed few-shot DepthCNN-XgBoost model exhibited an IoU increase of 5.388% (3.046% for all test data utilizing 4-fold cross-validation results from the various classifiers) compared to a regular DepthCNN-XgBoost. The F1-Score also increases by 5.394, or 3.015%. We found increases in accuracy and recall of 1.162, 2.137%, and 4.409, 4.790%, respectively. The Kruskal-Wallis test p-value on the F1-score and IoU values between the proposed few-shot DepthCNN-XgBoost model and the traditional model was 0.026 (below 0.05). This indicates that there is a significant difference between the metrics of the two techniques, with a 95% confidence level. The recommended model needed around eight photos and a small number of new incoming samples in order to change its behavior effectively. Due to the fact that new data was combined with older samples to improve the network's generalization skills, the suggested few-shot DepthCNN-XgBoost model has a similar level of computational complexity to the traditional DepthCNN-XgBoost model. The combination of few-shot learning with other deep models and learning techniques like transformers [48] is quite appealing for future development. According to a recent study, transformer-based models beat other types of networks, such as recurrent and convolutional structures, in a variety of benchmarks for visual information.

Towards a Framework for Optimized Microservices Placement in Cloud Native Environments

Riane Driss, Ettazi Widad, Ettalbi Ahmed
IMS Team-ADMIR Laboratory ENSIAS-Rabat IT Center, Mohammed V University in Rabat, Rabat, Morocco

***Abstract*—In recent times, cloud-native technologies have increasingly enabled the design and deployment of applications using a microservice architecture, enhancing modularity, scalability, and management efficiency. These advancements are specifically tailored for the creation and orchestration of containerized applications, marking a significant leap forward in the industry. Emerging cloud-native applications employ container-based virtualization instead of the traditional virtual machine approach. However, adopting this new cloud-native approach requires a shift in vision, particularly in addressing the challenges of microservices placement. Ensuring optimal resource utilization, maintaining service availability, and managing the complexity of distributed deployments are critical considerations that necessitate advanced orchestration and automation strategies. We introduce a new framework for optimized microservices placement that optimizes application performance based on resource requirements. This approach aims to efficiently allocate infrastructural resources while ensuring high service availability and adherence to service level agreements. The implementation and experimental results of our method validate the feasibility of the proposed approach.**

Keywords—Cloud native architecture; Service placement; containerization; Cloud resource allocation; microservices architecture

I. Introduction

Cloud computing revolutionizes IT infrastructure by offering on-demand access to a shared pool of configurable computing resources, such as servers, storage, and applications, over the internet. This model enhances flexibility, scalability, and cost efficiency, making it ideal for businesses of all sizes. Cloud-native development takes full advantage of cloud computing by building and deploying applications specifically designed to operate in a cloud environment. These applications leverage microservice architecture, which breaks down a monolithic application into smaller, independent services that communicate through APIs. This approach enhances agility, scalability, and resilience, as each microservice can be developed, deployed, and scaled independently. Containers further support this architecture by encapsulating microservices and their dependencies into lightweight, portable units, ensuring consistency across different environments. Technologies like Docker [1] and Kubernetes [2] facilitate container orchestration, automating deployment, scaling, and management, thereby streamlining the development and operational processes in a cloud-native landscape.

Deploying cloud-native applications involves leveraging containerization and container orchestration to achieve seamless scalability, flexibility, and resilience. Containers, which package applications with their dependencies, ensure consistency across different environments, from development to production. This approach simplifies the deployment process and enhances the portability of applications. Container orchestration, with Kubernetes being the most widely used platform, automates critical functions such as deployment, management, scaling, and networking of containers. Kubernetes manages containerized applications across a cluster of machines, ensuring optimal resource utilization and availability. It handles load balancing, scales applications based on demand, and provides self-healing capabilities by automatically restarting failed containers.

The deployment process of cloud-native applications typically begins with defining application components in declarative configuration files, which Kubernetes uses to create and maintain the desired state of the application. Integration with continuous integration and continuous deployment (CI/CD) pipelines further streamlines the process, allowing for rapid and reliable updates. CI/CD pipelines automate the building, testing, and deployment of code changes, reducing manual intervention and minimizing the risk of errors. This automation not only improves operational efficiency but also enhances the application's ability to adapt to changing workloads and recover from failures. By adhering to cloud-native principles, organizations can achieve greater agility, scalability, and resilience in their application deployments, ensuring they are well-prepared to meet evolving business demands.

The challenge of optimal microservices placement over multiple resources is a critical aspect of managing cloud-native applications, particularly in a dynamic and distributed cloud environment. As applications are decomposed into numerous microservices, each with distinct resource requirements and performance characteristics, determining the most efficient placement of these microservices becomes increasingly complex. This challenge is compounded by the need to balance multiple factors such as resource utilization, latency, service availability, and compliance with service level agreements (SLAs).

Effective microservices placement requires sophisticated algorithms that can analyze and predict resource demands, identify potential bottlenecks, and dynamically allocate resources to maintain optimal performance. These algorithms must also account for the heterogeneity of resources across different cloud environments, including various types of compute, storage, and networking resources. Furthermore, they must be resilient to changes in workload patterns and capable of quickly adapting to failures or unexpected spikes in demand.

Addressing these challenges is essential for maximizing infrastructural efficiency, reducing operational costs, and ensuring the high availability and reliability of cloud-native applications.

This article presents a new approach to optimizing the placement of microservices across multiple resources in cloud-native environments. By using PSO-based algorithm, our method strategically deploys microservices to enhance resource utilization and service performance. The proposed solution incorporates continuous monitoring to anticipate resource demands and mitigate bottlenecks, ensuring efficient distribution of workloads. This approach also employs container orchestration platforms, to automate the dynamic scaling and management of microservices, thereby maintaining high availability and resilience. Evaluation through comprehensive simulations highlights the efficacy of our method in optimizing the placement of microservices based on monitored data.

The following sections of this paper take a systematic approach to examine the optimal placement of microservices in cloud native environment. Section II reviews related work, identifying gaps and opportunities in existing methodologies. Section III details our proposed framework, including its design and implementation. In Section IV, we present the Sock Shop application as a use case for microservices deployment. Section V introduces our proposed algorithm for microservices placement using Particle Swarm Optimization (PSO), along with performance evaluations that highlight the results of our simulations and the advantages of our approach. Finally, Section VI provides a conclusive summary of our findings, discussing their implications for future research and practical applications in cloud-native environments.

II. Related Work

The placement of microservices in cloud-native environments is crucial for enhancing performance, scalability, and resource utilization. Numerous techniques and frameworks have been proposed to address microservices placement challenges. This section reviews existing work, categorized into heuristic approaches, optimization-based techniques, and frameworks. Heuristic approaches are popular for their simplicity and efficiency, offering sub-optimal solutions quickly, making them ideal for large-scale deployments. Greedy algorithms [8, 18], for instance, place microservices by iteratively selecting the best local option, such as prioritizing resource-intensive microservices to ensure adequate resource allocation.

Optimization-based techniques use mathematical models and algorithms to find near-optimal or optimal placement solutions, offering superior results in resource utilization and performance despite their higher computational demands. Methods like Linear and nonlinear Programming (LP) [3, 6] and Mixed-Integer Linear Programming (MILP) [5, 7] model the placement problem with linear constraints, providing powerful solutions but often at a high computational cost for large-scale problems. Metaheuristic algorithms, including Genetic Algorithms (GA) [4, 10, 13], and Particle Swarm Optimization (PSO) [14, 9], are also widely used. These algorithms are designed to escape local optima and thoroughly explore the solution space, making them well-suited for complex placement problems.

Various frameworks and tools streamline microservices placement in cloud-native settings by integrating placement algorithms with container orchestration platforms like Kubernetes, automating deployment. Kubernetes-native solutions [11, 19, 22] leverage features like node affinity/anti-affinity, taints and tolerations, and custom schedulers [12, 15], empowering developers to guide placement decisions based on resource needs and workload traits [16]. Additionally, service meshes such as Istio [21] and Linkerd [24] enhance placement strategies by dynamically altering request routing according to real-time performance metrics [17], bolstering traffic management [23] and observability capabilities.

However, there is a lack of continuous monitoring and real-time service redeployment in these approaches, which are critical for maintaining optimal performance and resource utilization in dynamic cloud environments. In our work, we focus on integrating these capabilities to ensure that microservices placement can adapt to changing workloads and cloud native infrastructure conditions in real-time.

III. Framework for Optimsed Microservices Placement

This section initially outlines the criteria necessary to meet microservices placement key points aligned with workload characteristics obtained from continuous monitoring. Following this, we introduce a design and implementation of our framework.

A. Key Points

In order to guarantee the performance of deployed applications on cloud native environment, we consider the following requirements:

1) Continuous monitoring for deployed microservices applications in a cloud-native environment is crucial for maintaining optimal performance, security, and reliability. By constantly tracking metrics such as CPU usage, memory consumption, network traffic, and response times, continuous monitoring provides real-time insights into the health and behavior of each microservice. This proactive approach allows for the rapid detection and resolution of issues, minimizing downtime and ensuring seamless user experiences. Furthermore, continuous monitoring supports scalability by identifying performance bottlenecks and guiding resource allocation decisions, ultimately enhancing the efficiency and resilience of cloud-native applications.

2) Collecting and analyzing workload data involves gathering detailed metrics on system performance and resource utilization under actual usage conditions. This process provides critical insights into how different workloads impact the system, revealing patterns and trends that are not apparent through continuous monitoring alone. For microservice applications in cloud-native environments, this data is invaluable. It helps developers and administrators optimize resource allocation, design better scaling strategies, and enhance overall performance. By understanding real-world usage patterns, teams can make informed decisions that improve the efficiency and reliability of their microservices deployments.

3) Placement strategies for microservices deployment based on heuristics that consider continuous monitoring and workload data collection are essential for optimizing performance in cloud-native environments. These strategies use real-time monitoring to track system health and resource usage, while data analysis provides insights into actual workload patterns. By combining these approaches, heuristic algorithm can make informed decisions about the optimal placement of microservices, ensuring efficient resource utilization, minimizing latency, and enhancing overall application resilience and scalability.

B. Optimised Microservices Placement Framework Design

Based on the key points presented in the previous section, we design the framework for optimized microservices placement as shown in Fig. 1 and Fig. 2. Our framework includes the following components: i) Workload continuous monitoring, ii) workload analysis, iii) Microservices Placement, iv) cloud-native infrastructure Management. The proposed framework handles cloud-native application requirements that include resource parameters and microservices inter-communication for efficient application deployment in cloud-native infrastructure such as Kubernetes platform.

The workload continuous monitoring provides real-time visibility into the performance and health of microservices by tracking key metrics. It measures CPU usage to detect overutilization or underutilization, monitors memory consumption to prevent leaks and ensure efficient usage, tracks network traffic to identify bottlenecks and optimize communication, and measures response times to ensure low latency and high performance. This comprehensive monitoring is crucial for maintaining optimal functionality and reliability of microservices in a cloud-native environment.

The workload analysis collects and processes detailed metrics on system performance and resource utilization under actual usage conditions. Key functions include:

- Data Collection: Aggregates performance data over time, providing a historical view of system behaviour.
- Pattern Identification: Analyzes data to identify trends, peak usage times, and typical workload patterns.
- Impact Assessment: Evaluate how different workloads affect system components, enabling resource allocation optimization.

The Microservices placement uses heuristic algorithm to make decision about where to deploy microservices. Key features include:

- Resource Allocation: Determines the optimal distribution of resources based on continuous monitoring and workload analysis.
- Scalability Management: Adjusts the number of instances of each microservice to match current demand, ensuring efficient resource usage.
- Latency Minimization: Places microservices in locations that reduce communication delays, enhancing overall system responsiveness.

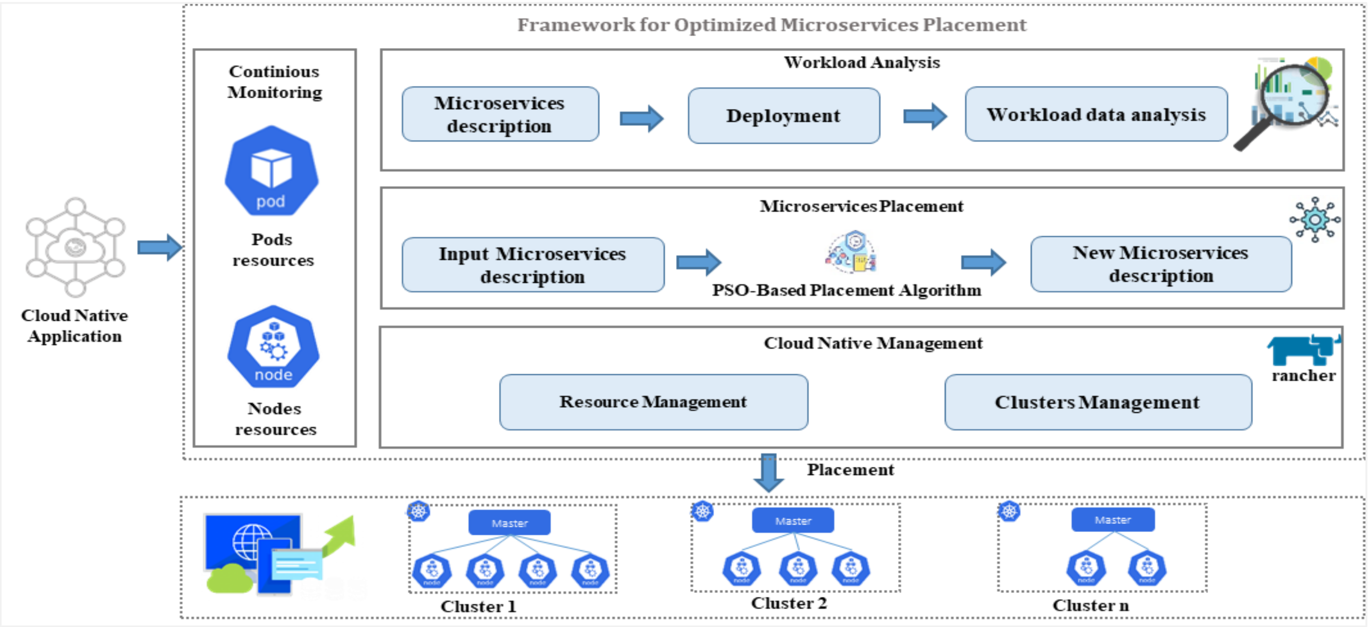

Fig. 1. Overview of optimised microservices placement framework design.

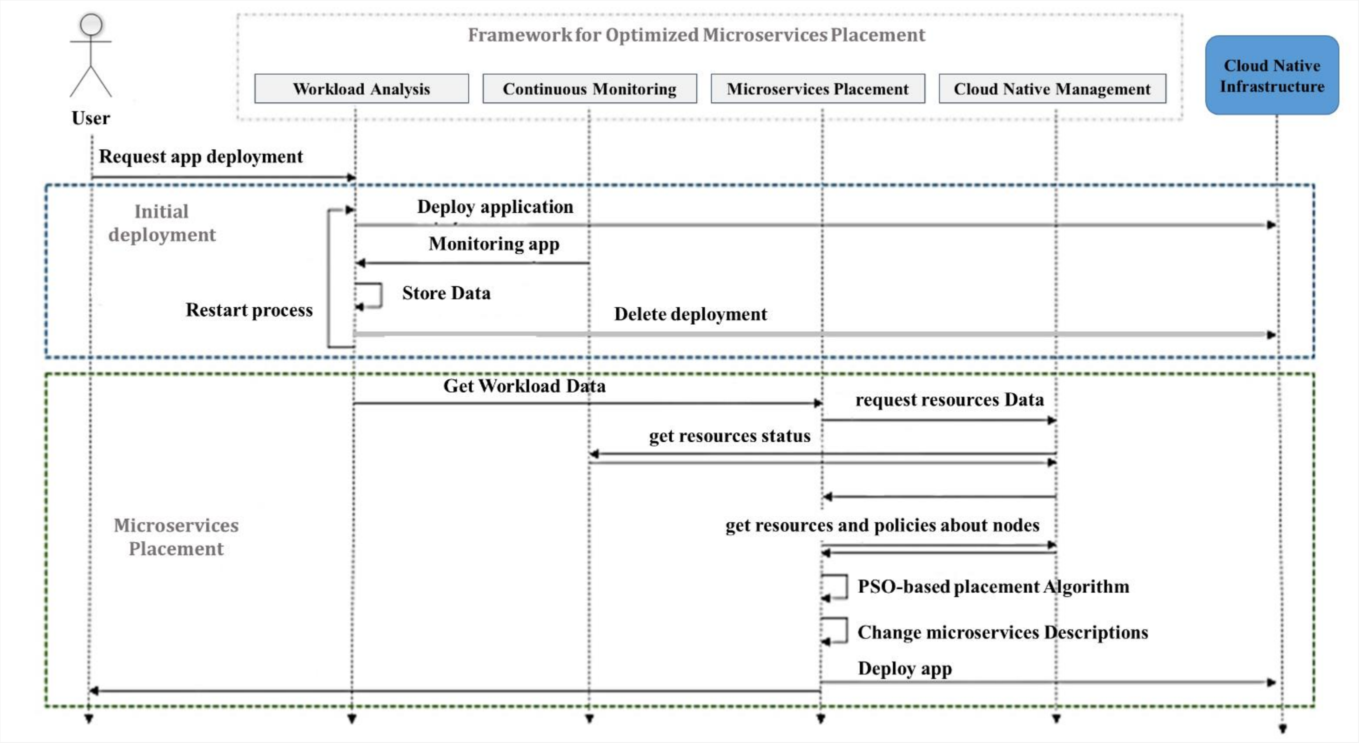

Fig. 2. Workflow diagram of optimised microservices placement framework.

The cloud-native management, such as a Kubernetes platform, provides the environment for deploying and managing microservices. Key capabilities include:

- Container Orchestration: Manages the deployment, scaling, and operation of containerized applications, ensuring consistent and reliable performance.
- Self-Healing: Automatically restarts failed containers, ensuring high availability and resilience.
- Load Balancing: Distributes incoming traffic across multiple instances of a service to optimize resource usage and prevent overloads.
- Resource Management: Dynamically allocates computing resources to meet the needs of deployed microservices based on real-time data.

Fig. 2 illustrates the workflow diagram of our framework. The process begins with users submitting requests to the framework, providing a YAML description (which includes specifying all the necessary components, such as microservices, their dependencies, resource requirements, environment variables, and network configurations), of the cloud-native application along with workload parameters, such as CPU and memory limits, replica counts, and other resource requirements.

The second steps consists of deploying the application the cloud native platform (e.g. kubernetes), monitoring and collecting workload data (i.e. resource usage for pods and nodes).

The third step focuses on microservices placement within cloud native platform. Based on the stored data from previous step, including resource status. This stage performs the placement Algorithm, quantifies each microservice's description and returns the placement results.

IV. Use Case: Sockshop Application

A. Microservice Demo

The Sock-Shop application [20], also known as the Microservices Demo, is a widely recognized reference application designed to illustrate microservices architecture in practice. It serves as a tool for demonstrating and testing microservice and cloud-native technologies. Simulating an e-commerce platform that sells socks, it provides developers and architects with a practical example to explore, learn, and experiment with microservices concepts, technologies, and best practices.

It is built using Spring Boot, Go kit, and Node.js, and is packaged within Docker containers. We use Locust [25] as a testing tool that allows defining user behavior and simulating traffic to create workloads for the application. This helps in evaluating how well your application handles different levels of user load. Fig. 3 provides more details about its overall architecture.

B. Testbed Cloud Native Environment

As illustrated in Fig. 4, we set up cloud-native environment using multiple Kubernetes clusters. We created two different Kubernetes clusters to test and experiment with the Sock-Shop cloud-native application. The first cluster consists of one master node and three worker nodes. The second cluster includes master node and two worker nodes.

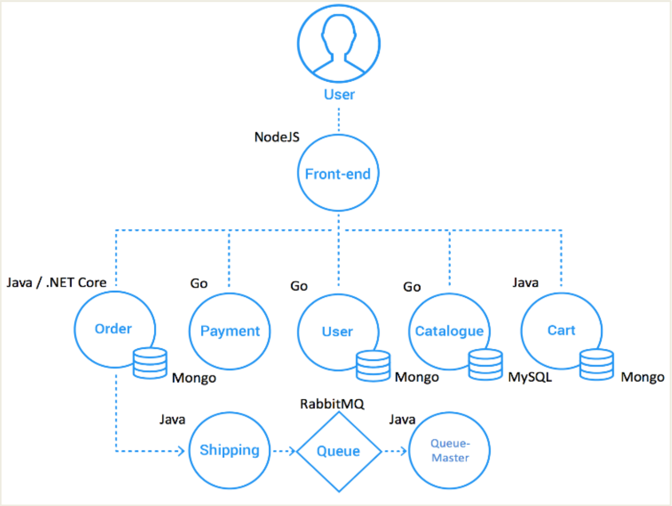

Fig. 3. Sock-Shop application architecture.

We use Rancher [26] tool that offers built-in monitoring capabilities through its integrated monitoring stack, which includes Prometheus for metrics collection and Grafana for visualization. Rancher allows monitoring resource usage, CPU and memory utilization, as well as workload data across multiple Kubernetes clusters.

After the application has been deployed, Rancher actively monitors the health status of Kubernetes pods to ensure optimal performance. Leveraging its robust automation capabilities, Rancher dynamically introduces various workloads tailored to the specific requirements of the application type. These workloads, meticulously crafted within a shell script and utilizing benchmarking tools, aim to emulate real-world scenarios and stress test the application's resilience. Following the injection process, Rancher diligently gathers resource utilization data from all microservices constituting the application, meticulously assessing CPU, memory, and network usage. Subsequently, this monitored data is securely stored in a dedicated profiling datastore, facilitating comprehensive analysis and enabling informed decision-making regarding resource allocation and performance optimization strategies.

Upon reaching the specified duration parameter, if the elapsed time of application deployment matches, Rancher initiates the termination process, dismantling the application infrastructure. This cyclic operation persists automatically until the desired number of iterations is achieved, ensuring thorough profiling and assessment of the application's performance under varying conditions. As the profiling process concludes, Rancher leverages its visualization capabilities to render the stored profiling data into a comprehensive graph format, typically presented as a scatter plot. This graphical representation provides stakeholders with valuable insights into the application's behavior, enabling informed decision-making regarding optimization strategies and resource allocation.

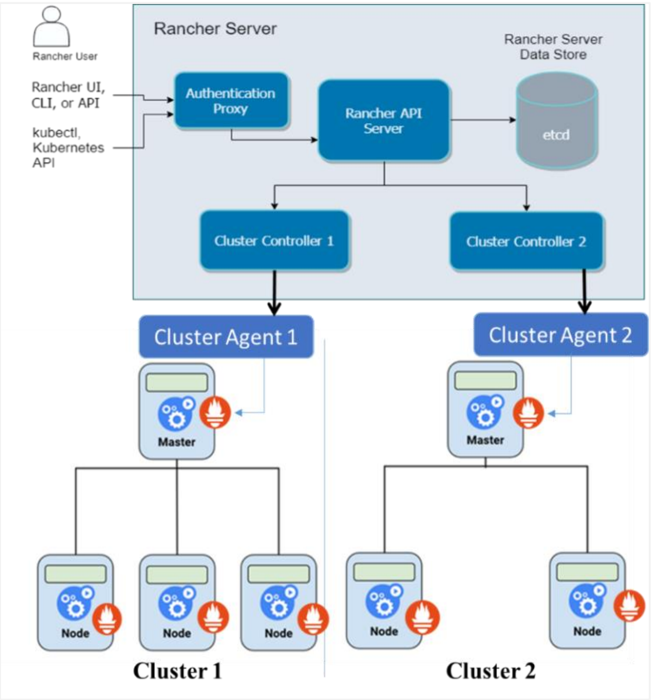

Fig. 4. Multiple Kubernetes cluster management with Rancher.

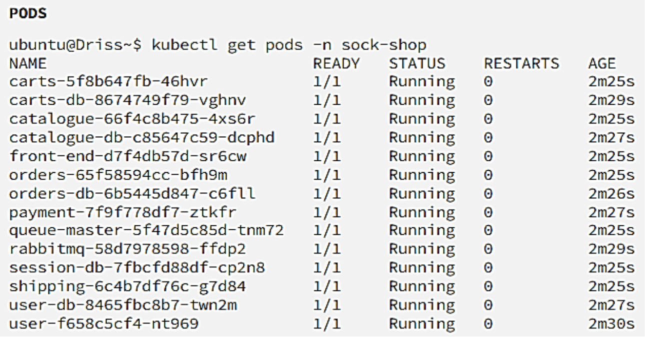
C. Sock Shop Performance

Fig. 5 shows the output of the command `kubectl get pods -n sock-shop` which lists the pods running in the "sock-shop" namespace. This indicates a healthy and stable deployment of the sock-shop microservices application in Kubernetes.



```
PODS

ubuntu@Driss~$ kubectl get pods -n sock-shop

```

Fig. 5. Running Pods for sock shopp application.

The performance analysis of the Sock Shop services after 15 iterations, as depicted in Fig. 6, reveals distinct patterns in resource utilization across various services. The front-end service exhibits the highest CPU usage at 1.2 cores, which indicates it is a critical component in terms of processing power. Similarly, the queue-master service shows a significant memory consumption of 2.7 GB, suggesting it handles substantial data throughput. In contrast, services like carts-db, orders-db, payment, and user-db have minimal CPU and memory usage, implying they are lightweight and less demanding on infrastructure resources.

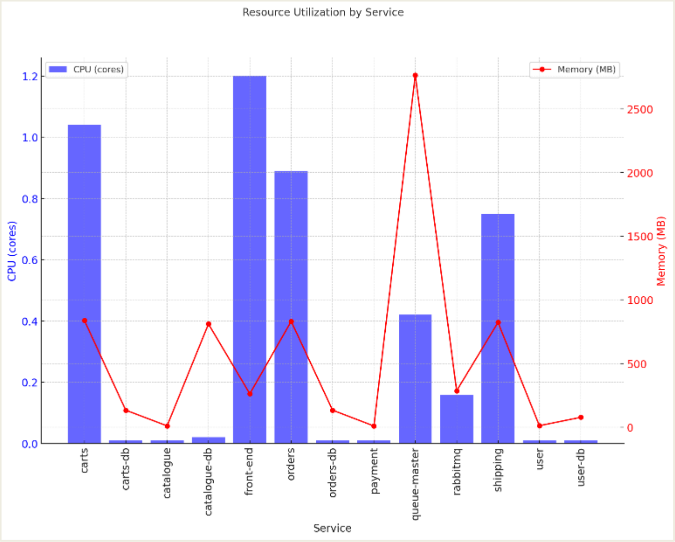

Fig. 6. Resources utilisation by services.

V. PSO-Based Placement Algorithm

This section presents PSO PSO-based placement algorithm used in our framework in order to deploy microservices in the cloud native infrastructure. Then we evaluate the performances of algorithm and the results analysis.

A. PSO-Based Microservices Placement Algorithm

In this section, we present a model for microservices placement based on Particle Swarm Optimization (PSO), an optimization technique inspired by the social behavior of particles in nature. PSO has been adapted to address the microservices placement problem by effectively exploring the solution space to find optimal placement configurations.

In the context of microservices placement, the variables and notations used includes: *C* represents the set of available clusters where microservices can be deployed in the cloud-native infrastructure. H_n denotes the set of hosts within the nth cluster, which serves as the infrastructure for hosting microservices. *MS* signifies the set of microservices that need to be placed within the cloud-native environment. P_i refers to the position of particle i within the search space, where each particle represents a potential solution for microservices placement. V_i represents the velocity of particle i within the search space, indicating the rate and direction of movement as the algorithm progresses.

The update of particle positions and velocities in the PSO algorithm is performed using the following equations:

$$V_i(t+1) = w * V_i(t) + c_1 * rand() * \left(BestPos_i(t) - CurrentPos_i(t)\right) + c_2 * rand() * \left(GlobalBestPos_i(t) - CurrentPos_i(t)\right) \quad (1)$$

$$P_i(t+1) = CurrentPos_i(t) + V_i(t+1) \quad (2)$$

Where, w is the inertia weight, c_1 and c_2 are the acceleration coefficients, and $rand()$ is a function that generates a random number between 0 and 1.

Fitness of microservices placement solutions is evaluated based on resource (CPU and Memory) utilization. A placement solution is considered better if it minimizes resource usage while meeting performance and availability constraints.

Algorithm 1 outlines the steps for implementing the PSO algorithm to optimize microservices placement in a cloud-native environment. It includes the initialization of particles, updating their positions and velocities, and evaluating fitness based on resource utilization (CPU and memory) to find the best placement solution.

Algorithm 1: PSO-Based Microservices Placement

```
    Input:
    - C: Set of clusters
    - H_n: Set of hosts in cluster n
    - MS: Set of microservices
    - MaxIterations: Maximum number of iterations
    - PopulationSize: Number of particles in the swarm
    - w: the weight
    - c1, c2: Acceleration coefficients
    Output:
    - BestPlacement: Optimal microservices placement solution
-Initialize a population of particles with random positions and velocities.
-Initialize the best position found by each particle and the global best position.
for iteration = 1 to MaxIterations do
    for each particle do
        -Evaluate the fitness of the particle's current position based on resource utilization (cpu and memory).
        -Update the best position found by the particle and the global best position if necessary.
        -Update the particle's velocity using the velocity update equation (1).
        -Update the particle's position using the position update equation (2).
    end for
end for
-Select the placement corresponding to the global best position as the optimized microservices placement solution.
```

B. Performance Evaluation for PSO-Based Microservices Placement Algorithm

In this section, we evaluate the performance of the PSO-based microservices placement algorithm by using the Sock Shop microservices demo as a test case. The Sock Shop demo is a widely recognized benchmark for demonstrating microservices architectures, consisting of various services that simulate an e-commerce application for selling socks. This demo provides a realistic and complex environment for testing and validating the efficiency and effectiveness of our placement algorithm.

1) Experimental setup: The experimental setup involves multiple components, including the configuration of Kubernetes clusters, the deployment of the Sock Shop microservices, and the definition of key parameters for the Particle Swarm Optimization algorithm. By creating a controlled environment that mirrors real-world conditions, we can systematically measure the impact of the PSO algorithm on resource utilization, load balancing, service latency, and overall system fitness.

Table I details the specific configurations and parameters used in the experiment, and the metrics employed for performance evaluation.

TABLE I. EXPERIMENTAL PARAMETERS

	Parameter	Detail
Workload	Kubernetes Clusters (C)	Multiple clusters set up to host the Sock Shop microservices.
	Hosts (H_n)	Each cluster consists of multiple hosts with random capacities of CPU and memory resources.
	Microservices (MS)	The Sock Shop application includes user, catalog, cart, order, payment, and shipping services.
PSO Parameters	w	0.5
	c_1	1.5
	c_2	1.5
	Poupulation size	30
	Max iterations	100
Microservices resource requirments	user	Cpu=1 , Memory =512
	catalog	Cpu=2 , Memory =1024
	orders	Cpu=2 , Memory =512
	Payment	Cpu=2 , Memory =1024
	Shipping	Cpu=1 , Memory =512
	Cart	Cpu=1 , Memory =512

2) Experimental result: To evaluate the efficiency of the PSO-based microservices placement algorithm, we conducted an analysis of resource utilization, specifically focusing on CPU and memory usage across all hosts. The assessment was performed before and after applying the PSO algorithm, and the results are depicted in Fig. 7 and Fig. 8.

The results demonstrate that the PSO-based placement algorithm significantly enhances resource utilization. By balancing the CPU and memory usage, the algorithm ensures that no single host becomes a bottleneck, thereby improving the overall performance and reliability of the microservices deployment. The reduction in resource hotspots contributes to a more efficient and resilient cloud-native environment, capable of handling varying workloads with greater stability.

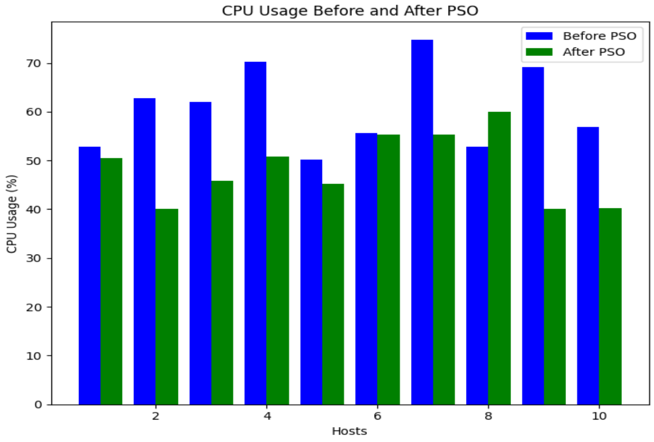

Fig. 7. CPU utilisation before and after PSO.

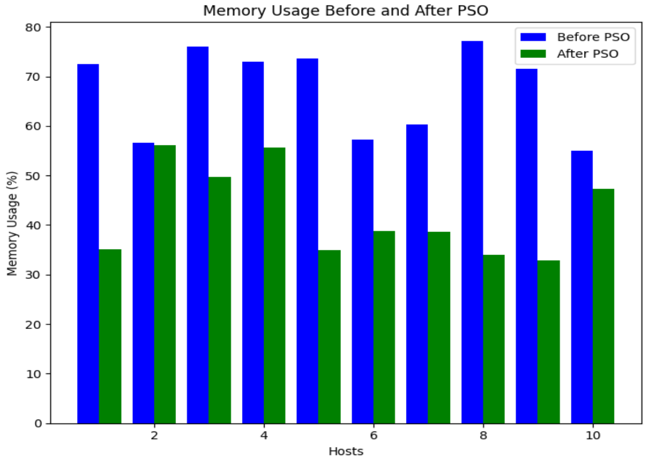

Fig. 8. Memory utilisation before and after PSO.

VI. CONCLUSION

In conclusion, this paper has explored the significant advancements enabled by cloud-native technologies in the design and deployment of applications utilizing a microservice architecture. These technologies enhance modularity, scalability, and management efficiency, facilitating a shift from traditional virtual machine-based approaches to container-based virtualization. The adoption of this cloud-native paradigm introduces new challenges, particularly in the optimal placement of microservices, which is crucial for maximizing resource utilization, ensuring service availability, and managing the complexity of distributed systems.

We proposed a new framework for optimized microservices placement, focusing on efficient resource allocation while maintaining high service availability and compliance with service level agreements. By leveraging Particle Swarm Optimization (PSO), our approach effectively addresses the challenges associated with microservices placement in cloud-native environments. The experimental results obtained from the Sock Shop application use case demonstrate the feasibility and effectiveness of our proposed method.

This work not only highlights the potential benefits of advanced orchestration and automation strategies but also paves the way for future research to further enhance microservices placement techniques. The implications of our findings suggest that continued innovation in this area will be essential for improving the performance and scalability of cloud-native applications, ultimately driving more efficient and resilient cloud infrastructures.

Advances in Consortium Chain Scalability: A Review of the Practical Byzantine Fault Tolerance Consensus Algorithm

Nur Haliza Abdul Wahab[1], Zhang Dayong[2], Juniardi Nur Fadila[3], Keng Yinn Wong[4]
Faculty of Computing, Universiti Teknologi Malaysia, Johor Bahru, Malaysia[1, 2, 3]
Faculty of Mechanical, Universiti Teknologi Malaysia, Johor Bahru, Malaysia[4]

***Abstract*—Blockchain technology, renowned for its decentralized, immutable, and transparent features, offers a reliable framework for trust in distributed systems. The growing popularity of consortium blockchains, which include public, private, hybrid, and consortium chains, stems from their balance of privacy and collaboration. A significant challenge in these systems is the scalability of consensus mechanisms, particularly when employing the Practical Byzantine Fault Tolerance (PBFT) algorithm. This review focuses on enhancing PBFT's scalability, a critical factor in the effectiveness of consortium chains. Innovations such as Boneh–Lynn–Shacham (BLS) signatures and Verifiable Random Functions (VRF) are highlighted for their ability to reduce algorithmic complexity and increase transaction throughput. The discussion extends to real-world applications, particularly in platforms like Hyperledger Fabric, showcasing the practical benefits of these advancements. This paper provides a concise overview of the latest methodologies that enhance the performance scalability of PBFT-based consortium chains, serving as a valuable resource for researchers and practitioners aiming to optimize these systems for high-performance demands.**

Keywords—Blockchain; Practical Byzantine Fault Tolerance (PBFT); consensus algorithm; cryptography

I. Introduction

A major worry in both academic and industrial circles in the Big Data era brought about by 5G, Artificial Intelligence (AI), and Internet of Things (IoT) breakthroughs is safeguarding human privacy and data security [1]. Traditional centralized data management solutions frequently fail, especially when it comes to large-scale applications because of flaws including data tampering concerns, single points of failure, and vulnerability to denial-of-service assaults [2].

Blockchain technology offers a novel approach to data security and privacy protection because of its decentralization, non-tamper ability, and openness, transparency, and traceability features. Public chains, private chains, hybrid, and consortium chains are some of its variants. Of these, consortium chains are becoming more and more popular since they are appropriate for enterprise-level applications and provide systems for identity management and controlled access [3].

Consensus is the foundation of blockchain technology and is essential to maintaining data consistency and integrity over a distributed network. In addition to being the cornerstone of blockchain design, the consensus mechanism plays a crucial role in defining the network's ability to handle transactions and grow efficiently [4]. Due to its higher performance and energy efficiency, the Practical Byzantine Fault Tolerance (PBFT) consensus algorithm is frequently chosen in consortium chains, which are being adopted more and more for their industry-specific applications over the more energy-intensive Proof of Work (PoW) used in public chains.

Even while PBFT is advantageous in consortium chains, there are several drawbacks, especially with regard to performance scalability [5]. The system experiences a decrease in performance as the network grows and the number of blocks rises. This is because creating new blocks takes longer and puts more strain on node storage capacity [6]. Although there are many facets to these difficulties, including network, storage, and performance scalability, this research focuses on the crucial component of performance scalability, which is essential for consortium chain throughput and responsiveness [7].

This paper summarizes and evaluates the literature on the performance scalability of PBFT-based consortium chains, with a focus on novel approaches that have been developed to overcome the bottlenecks in performance. In particular, we investigate the use of Boneh–Lynn–Shacham (BLS) signatures and Verifiable Random Functions (VRF) [8], [9], which are noteworthy developments in lowering algorithmic complexity and speeding up transaction processing [10].

In order to gain a thorough understanding of the scalability solution landscape, this review will conduct a systematic literature review (SLR) of relevant research, focusing on papers that overlap VRF, PBFT, BLS cryptography, and consortium blockchains. Prominent databases such as IEEE Xplore, SpringerLink, and Elsevier's ScienceDirect will be searched by the SLR in order to compile and analyze research that has been published between 2018 and 2023 [11]. This temporal window provides a current snapshot of the state of performance scalability in consortium chains by capturing the latest developments and conversations in the area.

Through the examination of various sources, the review seeks to condense a clear picture of the approaches, difficulties, and innovations that are now being faced in the field of consortium blockchain scalability [12]. The goal is to provide a condensed body of knowledge that will help practitioners and researchers comprehend the evolution of scalability optimizations and their useful applications in the context of PBFT.

II. Literature Review

The development and introduction of Bitcoin, which was first made public in 2008 by an individual or group going by the pseudonym Satoshi Nakamoto, is credited with the invention of blockchain technology [13]. The first decentralized digital currency, Bitcoin, was launched in Nakamoto's whitepaper, "Bitcoin: A Peer-to-Peer Electronic Cash System," which also established the framework for blockchain technology [14].

The Origin of Bitcoin and the Underlying Blockchain Idea start by using a peer-to-peer network. Bitcoin offered the first workable solution to the issue of double-spending in digital money [15], [16]. Its distributed ledger, or blockchain, which records every transaction over a network of computers without the need for a central authority, is the main innovation [17], [18]. The decentralized structure of blockchain guaranteed data security, integrity, and transparency [19].

The next big development in blockchain technology, commonly known as Blockchain 2.0, was launched in 2015 with the introduction of Ethereum by Vitalik Buterin and associates [20], [21]. Ethereum extended the usage of blockchain technology to incorporate "smart contracts," which are self-executing contracts with the contents of the agreement between the buyer and seller explicitly encoded into code, in contrast to Bitcoin's focus on financial transactions[22], [23]. This breakthrough made it possible for blockchain to be used for purposes other than cryptocurrency, allowing for the development of decentralized application (DApp)[24], [25], [26]. The third development in blockchain technology is the division of the technology into four primary categories: public, private, hybrid and consortium chains [27].

Following the introduction of Ethereum and smart contracts, the focus in the blockchain community shifted to consensus mechanism optimization for various network architectures [28], [29]. Of them, PBFT has become a prominent algorithm for consortium chains networks that are more open than private networks but still need a more regulated environment than public blockchains[30], [31], [32].

Consensus algorithm development in blockchain technology is essential to maintaining dependability and confidence in decentralized systems [4], [33], [34]. There are two types of these algorithms: non-Byzantine fault-tolerant and Byzantine fault-tolerant (BFT). Byzantine defects, or hostile components present in the system, do not prevent consensus in BFT algorithms [35].

Fig. 1 in this research shows the evolution and relationships between various algorithms in a chronological order. An arrow from algorithm A to algorithm B, for example, indicates that algorithm A influences algorithm B. Arrows from both point to an algorithm like C, which is a hybrid algorithm inspired by both A and B.

The inception of consensus algorithms can be traced back to non-BFT protocols such as Viewstamped Replication and Paxos. The Proof of Work (PoW) algorithm, which was first established with the introduction of Bitcoin, completely changed the way consensus was reached in a trustless setting. But because PoW requires a lot of energy, substitutes like Proof of Stake (PoS) and its variations were created in an effort to find consensus procedures that use less energy [36].

The Practical Byzantine Fault Tolerance (PBFT) algorithm has had a major impact on the Byzantine fault-tolerant category. It has sparked additional innovations like Tendermint and Honey Badger, which provide enhanced efficiency and adaptability in a range of network conditions.

PBFT is advantageous to consortium chains because of its low latency and finality of transactions, which are critical for business applications where immutability and transaction speed are crucial. Since PBFT presupposes that a certain amount of trust is built between nodes, a feature intrinsic to the consortium model, consortium chains, as opposed to public chains, might use it to expedite their consensus process [37].

Although PBFT offers consortium chains a dependable consensus method, as the network expands, its scalability becomes problematic. A variety of PBFT improvements are suggested in the literature in order to address these scaling issues. These include lowering the overhead necessary to obtain consensus, strengthening the algorithm's resistance to node failure, and optimizing the communication complexity [7].

The focus of current scientific debate on PBFT is on enhancing its performance scalability in order to accommodate consortium chains' growing requirements. A number of changes and implementations have been suggested in recent research to address the shortcomings of PBFT. These include the use of sharding strategies, sophisticated cryptographic techniques like BLS signatures and VRF, and the utilization of trusted execution environments to improve the consensus process's throughput and effectiveness [38].

Essentially, PBFT has proven to be the best consensus method for consortium chains, fitting their requirement for a well-balanced approach to efficiency and trust. By showcasing the advancements that are propelling this subject forward, this section of the literature review lays the groundwork for a more in-depth analysis of the performance scalability of PBFT within consortium chains [6].

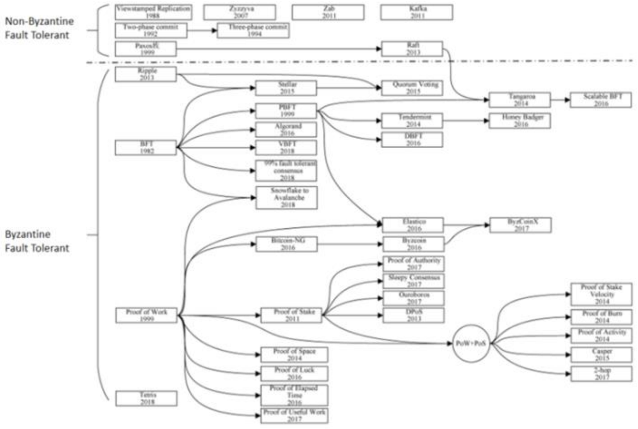

Fig. 1. Summary of consensus mechanism.

A. Fundamentals of Consortium Chains

Consortium chains are an example of a hybrid blockchain technology that combines public blockchain transparency with the controlled governance of private networks. These networks, which are run by a coalition of organizations, provide a collaborative setting where a limited number of pre-approved nodes are in charge of governance. The customized governance provided by this arrangement satisfies the unique requirements of the involved companies.

Consortium chains, which are ideal for sectors needing compliance and secrecy, combine data protection and integrity in a way that is selectively transparent [39]. Because there are fewer nodes, consensus and transaction processes proceed more quickly, improving scalability and making these chains perfect for industry-specific applications [40].

Consortium chains, while more centralized than public blockchains, provide security by reducing the possibility of single points of failure through the distribution of trust across verified members. Usually, they use energy-efficient consensus algorithms like PBFT, which give fast consensus at a lower cost than Proof of Work [31].

Consortium chains, a growing trend in industries like finance, healthcare, and supply chain management, combine privacy, trust, and cooperative efficiency. Their architecture demonstrates a dedication to establishing safe, expandable blockchain networks for inter-organizational cooperation.

As depicted in Fig. 2, the volume of research pertaining to consortium chains has seen a significant increase from 2020 to 2023. This upward trend continues into 2024, with early access articles on the subject already available. This suggests that the field of consortium chain research remains ripe with opportunities for exploration and innovation.

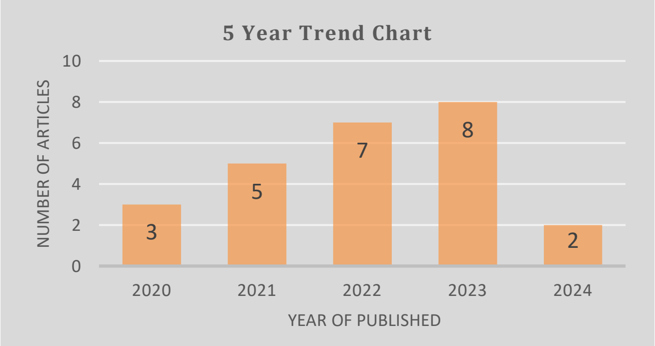

Fig. 2. Latest five years article trends of consortium chains topic studies.

This surge in research activity aligns with the publishing trends observed among researchers. As elucidated in Fig. 3, the Institute of Electrical and Electronics Engineers (IEEE) remains the most popular publisher among researchers in this field. Elsevier follows closely, contributing a substantial number of articles over the past five years.

Despite their efforts, Taylor & Francis and Wiley have yet to surpass Springer in terms of the number of published articles. This indicates a competitive landscape among publishers, with Springer maintaining a strong presence in the dissemination of consortium chain research. This dynamic interplay between researchers and publishers underscores the vibrancy and ongoing evolution of the field.

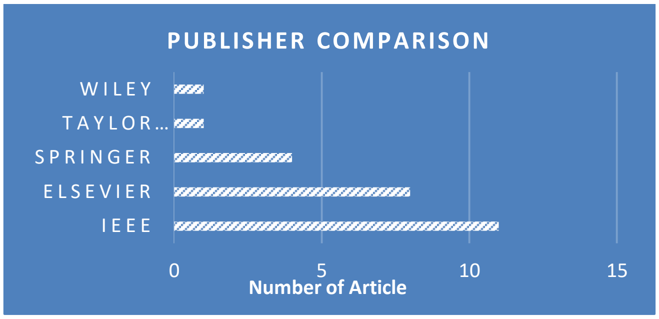

Fig. 3. Publisher destination for consortium chain topic studies.

Upon further analysis, TABLE Iprovides a comparative study of the articles across all databases, categorized into three main criteria: consensus, security, and improvement. The distribution of articles is shown in the matrix, with 41 articles focusing on consensus, 59 on security, and 54 on improvement. Additionally, there are overlaps where articles address multiple criteria, such as 19 articles covering both consensus and security, 12 articles on consensus and improvement, and 24 articles on security and improvement. This matrix highlights the diverse focus areas and intersections within the research landscape.

TABLE I. MATRIX TABLE OF RECORD FINDING BASED ON TOPIC

	Consensus	Security	Improvement
Consensus	41		
Security	19	59	
Improvement	12	24	54

Moreover, on the TABLE IIoutlines several methods for managing consortium chains, highlighting their respective advantages and disadvantages. These methods include consensus algorithms, encryption mechanisms, access control techniques, and trust incentive models. Each method offers unique benefits, such as reducing consensus delays, improving encryption efficiency, and enhancing trust in federated learning. However, they also come with specific challenges, such as low consensus efficiency, lack of fine-grained access control, and high energy consumption. This comparative analysis provides a comprehensive overview of the strengths and limitations of each approach, aiding in the selection of the most suitable method for managing consortium chains.

There's a focus on advanced consensus algorithms for improved blockchain network efficiency, as seen in the work of [41]. Enhanced encryption mechanisms and access control methods are being utilized for better data security, as demonstrated by study [39]. The importance of decentralization and fairness in the consensus process is highlighted by [42] research. Trust incentive consensus methods, like the one proposed by [43], are gaining traction to boost trust in federated learning. Lastly, the emergence of cross-chain communication mechanisms, as proposed by study [40], simplifies node topology for dynamic interaction, facilitating safe and autonomous sharing of patient records.

TABLE II. METHODS ON CONSORTIUM CHAIN ARTICLES

Method	Advantages	Disadvantages	Category
Consensus algorithm based on PBFT [41]	Reduces consensus delay and communication times between nodes.	Inability to dynamically join nodes, low consensus efficiency, primary master node selection challenges.	Consensus
Improved Paillier homomorphic encryption [39]	Reduces overall encryption and decryption time.	Lack of data ownership and fine-grained access control, lack of transparency and auditability.	Encryption
CP-ABE for access control [39]	Adaptive for storing massive data.	Time-consuming decryption (about 2 seconds).	Decryption
Voting-based decentralized consensus algorithm [42]	Faster consensus process, better user fairness, negligible energy cost, adequate security.	Ultrahigh energy consumption, time inefficiency, low transaction throughput.	Consensus
Trust rewards and punishments method [43]	Improves trust perception in federated learning.	Limitations in main node's misbehavior or fault tolerance.	Consensus
Cross-chain communication mechanism [40]	Safe and autonomous sharing of patient records within milliseconds.	No specific limitations mentioned.	Sharing

The comparative analysis reveals that while each method offers unique advantages, they also come with specific limitations that need to be addressed. For instance, consensus algorithms like PBFT and voting-based methods improve efficiency and fairness but face scalability and energy consumption issues. Encryption methods like Improved Paillier and CP-ABE enhance performance but lack fine-grained control and transparency. Trust-based methods and cross-chain mechanisms show promise in improving trust and interoperability but may face challenges in fault tolerance and integration.

B. *PBFT Consensus Mechanism and its Evolution*

Miguel Castro and Barbara Liskov created the PBFT consensus algorithm in 1999, and it is a key component of consortium blockchain networks' consensus procedures. PBFT is a distributed system reliability technique that tackles the problem of Byzantine faults, which are caused by some nodes in the network acting in an unpredictable manner [32]. It uses a multi-phase communication protocol that involves multiple rounds of node contact to achieve system consistency. The request, pre-prepare, prepare, and commit phases of this procedure enable the network to come to a consensus even when there are malicious or malfunctioning nodes present—as long as they make up no more than one-third of the total.

When compared to the PoW algorithm, PBFT is more efficient and uses less resources, which is why consortium chains prefer it. Because of its deterministic structure, transactions are completed quickly after a single consensus round, obviating the need for several probabilistic rounds that are common to other algorithms [44].

RBFT and BFT-SMaRt are two examples of the many improvements made to PBFT over time that have improved its resource management and scalability. These improvements are designed to support the growing complexity and scale of contemporary distributed networks while preserving the robustness of PBFT [45].

Scalability, node selection optimization, communication efficiency, and data management have all been continuously prioritized in PBFT's evolution in order to better support larger and more complicated consortium chain applications. Since its inception, this algorithm has developed into a commonly used mechanism in consortium chains because of its ability to balance performance, efficiency, and fault tolerance. This section examines the development of PBFT from theory to application, highlighting its vital role in consortium chains' expansion and success [32].

Fig. 4 depicts a clear upward trend in the research on this topic over the past five years. This suggests a growing interest in PBFT within the academic community, reflecting its increasing relevance in the field of distributed systems. The sustained growth in research output underscores the importance and potential of PBFT in advancing our understanding of Byzantine fault tolerance in practical applications. This trend is expected to continue, fostering further innovation and exploration in this area.

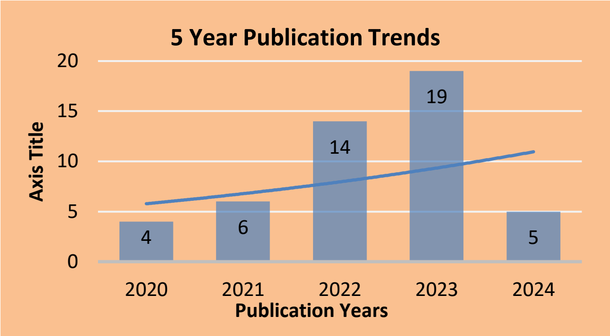

Fig. 4. Latest five years article trends of PBFT topic studies.

Furthermore, as illustrated in Fig. 5, the distribution of studies on PBFT is predominantly concentrated among three major publishers: IEEE, Elsevier, and Springer. These publishers have been instrumental in disseminating a significant volume of research on this topic. Interestingly, there appears to be a conspicuous absence of PBFT studies in both Wiley and Taylor & Francis, indicating a potential gap in their publication portfolio.

Further analysis on the PBFT articles which is lead to comparison TABLE III, we find diverse methods being explored. [7] and [41] both focus on PBFT consensus mechanisms, with the former targeting large systems and the latter aiming to reduce consensus delay. [46] integrate cryptographic primitives with Byzantine fault tolerance, while [47] use a PoQF consensus algorithm for VEC networks. The research in [48] propose a blockchain-based method for medication traceability. Each study has its unique advantages and challenges, contributing to the evolving research landscape. The upward trend in research output suggests a promising future for these methods in practical applications.

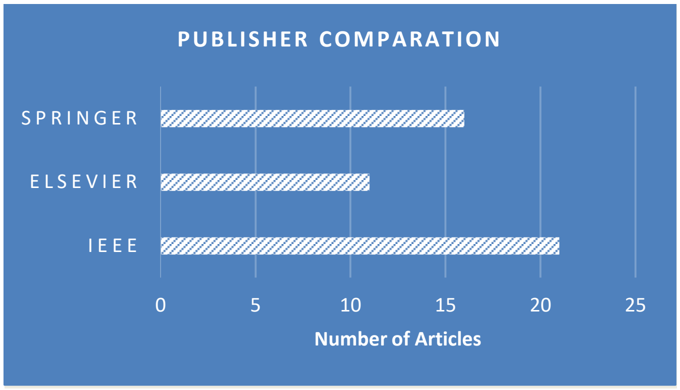

Fig. 5. Publisher destination spreads for PBFT studies.

TABLE III. STUDIES COMPARISON IN PBFT TOPIC

Method	Advantages	Disadvantages
Scalable multi-layer PBFT [7]	Validated security threshold, effective in simulations.	Poor node scalability, suitable for small networks.
Consensus algorithm based on PBFT [41]	Reduces consensus delay and communication times.	Inability to dynamically join nodes, low consensus efficiency, primary master node selection challenges.
Integration of cryptographic primitives and PBFT [46]	Removes transaction fees and mining rewards for better performance.	Lacks conflicting properties like anonymity and regulation.
PoQF consensus for VEC networks [47]	Reduces validation failure by 11%, faster message validation.	PoS favors nodes with higher stakes, PoET lacks security against malicious nodes.
Blockchain-based medication anti-counterfeiting [48]	Ensures transparency, openness, and full record of medication circulation.	No specific limitations mentioned.

Regarding to the study comparison, the Scalable multi-layer PBFT method demonstrates a validated security threshold and effectiveness in simulations, making it a reliable choice for small networks. However, its poor node scalability limits its applicability in larger systems, highlighting a significant drawback for broader adoption. The Consensus algorithm based on PBFT effectively reduces consensus delay and communication times, which is crucial for enhancing network efficiency. Nevertheless, its inability to dynamically join nodes, coupled with low consensus efficiency and challenges in primary master node selection, restricts its flexibility and scalability in dynamic environments.

The Integration of cryptographic primitives and PBFT offers improved performance by eliminating transaction fees and mining rewards. This integration enhances the overall efficiency of the blockchain system. However, it lacks conflicting properties such as anonymity and regulation, which are essential for certain applications requiring privacy and compliance. The PoQF consensus for VEC networks method stands out by reducing validation failure by 11% and providing faster message validation compared to other consensus algorithms like PoS and PoET. Despite these advantages, it faces challenges such as PoS favoring nodes with higher stakes and PoET's vulnerability to malicious nodes, which can compromise the network's security and fairness.

Lastly, the Blockchain-based medication anti-counterfeiting method ensures transparency, openness, and a comprehensive record of medication circulation, which is vital for maintaining trust and integrity in the pharmaceutical supply chain. However, the absence of specific limitations in the provided context suggests that further scrutiny is needed to identify potential challenges in practical implementation. Overall, while each method offers unique strengths, they also come with specific limitations that need to be addressed. Future research should focus on developing hybrid approaches that combine the strengths of these methods while mitigating their weaknesses to create more robust, scalable, and secure blockchain systems.

III. PERFORMANCE SCALABILITY

Consortium chains, which provide a sophisticated architecture al solution that balances completely private and fully public networks, have becoming increasingly popular in the blockchain space. Nevertheless, a crucial and urgent issue facing these consortium networks is performance scalability, particularly for those depending on the PBFT consensus algorithm[11], [32].

The way consortium chains handle transactions is at the core of the problem. Their use of conventional transaction processing techniques, which are mainly defined by serial verification and transaction storing, is intrinsically constrained. These traditional methods place fundamental limitations on the blockchain system's ability to effectively manage an increasing number of transactions[49]. These restrictions represent a major bottleneck in the context of PBFT-based consortium chains, which priorities fast and dependable consensus.

As the need for high-performance applications keeps growing, the performance scalability issue gets worse. Consortium chains are used in a number of sectors, including supply chain management, healthcare, and banking, where effective transaction processing is critical. These industries need blockchain systems that can process a large number of transactions efficiently and rapidly[45].

The emphasis is now being placed on more sophisticated and creative approaches rather than the traditional block scaling methods, which have drawbacks. Improving consensus algorithms has been a vital path to improving consortium chain performance. Throughput and scalability have grown as a result of the PBFT consensus process being streamlined by innovations like Tendermint and Honey Badger BFT.

Moreover, using cryptography methods like VRF and BLS signatures is another interesting way to address the performance scalability issue. These cryptographic techniques provide a workable way to increase transaction throughput while preserving the required degree of privacy and confidentiality, in addition to strengthening the security and integrity of consortium chains. Several related research on performance scalability optimization schemes is shown in Table IV.

TABLE IV. SUMMARY OF PERFORMANCE SCALABILITY OPTIMISATION SCHEMES

Optimization Scheme	Description	Application	Advantages	Disadvantages
Traditional Block Scaling Methods	Serial verification and transaction storing.	Initial stages of consortium chains.	Simple to implement and understand.	Limited scalability; ineffective for increasing transactions.
Consensus Algorithm Improvements	Enhancements like Tendermint and Honey Badger BFT.	Modern consortium chains.	Improved performance and scalability; handles larger transaction volumes.	Complex to implement; higher computational resources needed.
Cryptography Methods (VRF and BLS signatures)	Techniques to increase throughput while preserving privacy.	Various sectors using consortium chains.	Increases transaction throughput; maintains privacy and confidentiality.	Requires advanced cryptographic knowledge; potential speed-security trade-off.

Regarding to that comparison table, Traditional block scaling methods, while simple to implement and understand, suffer from limited scalability and inefficiency in handling increasing transaction volumes. In contrast, consensus algorithm improvements, such as Tendermint and Honey Badger BFT, offer enhanced performance and scalability, making them suitable for modern consortium chains. However, these improvements come with increased complexity and higher computational resource requirements. Cryptographic methods, including VRF and BLS signatures, provide significant advantages in transaction throughput and privacy preservation, making them valuable in various sectors. Nevertheless, these methods demand advanced cryptographic knowledge and may involve trade-offs between speed and security. Overall, while each optimization scheme offers unique benefits, their limitations must be carefully considered to ensure effective and scalable consortium chain management.

This chapter is essentially an in-depth investigation of the various performance scalability problems that consortium chains, particularly ones that depend on PBFT face. It explores a number of potential solutions, such as improvements in consensus algorithms and the thoughtful fusion of cryptographic methods like as VRF and BLS. The ultimate goal is to give a thorough overview of the strategies used to solve the crucial performance scalability issue, opening the door for the creation of consortium blockchain networks that are both highly scalable and effective, satisfying the requirements of contemporary high-performance applications.

A. PBFT-Based Performance Scalability in Consortium Chains

One major difficulty in the field of blockchain technology is the performance scalability of consortium chains, especially those that use the Practical Byzantine Fault Tolerance (PBFT) consensus method [32]. Consortium chains present a promising hybrid solution that combines the openness of public blockchains with the regulatory advantages of private networks; nevertheless, their performance scalability is severely constrained [50], [51]. The main issue with performance scalability in consortium chains is presented in this section, with particular attention paid to the application of the PBFT consensus algorithm.

1) The challenge of performance scalability: Consortium chains are well-suited for various applications, including supply chain management, finance, and healthcare, due to their collaborative nature among a limited number of organizations. However, as the demand for high-performance and scalable solutions grows, the scalability of consortium chains becomes a significant challenge. This issue is particularly pronounced in systems relying on PBFT consensus mechanisms. The core issue lies in the traditional techniques for transaction processing used by blockchain systems. The process of serial verification and storage of transactions inherently limits transaction throughput. This bottleneck is especially problematic for PBFT-based consortium chains, where achieving quick and reliable consensus is crucial. As the number of nodes increases, the communication overhead and consensus delay also rise, leading to decreased performance and scalability.

2) How consortium chains are affected?: Consortium chains are perfect for a variety of use cases, such as supply chain management, finance, and healthcare, since they are made to encourage collaboration among a small number of organizations, unfortunately, the consequences of performance scalability limits for consortium chains are extensive.

a) Transaction throughput: Consortium chains' ability to effectively handle a large number of transactions is limited by the traditional transaction processing techniques. The inability to meet the expectations of industries seeking simultaneous and speedy transaction validation is caused by this bottleneck.

b) Latency: Prolonged delays in transaction processing lead to higher latency, which affects consortium chains' ability to respond quickly. This is especially important for industries where instantaneous decision-making and data accessibility are crucial.

c) Limitations on scalability: The extensive use of consortium chains depends critically on scalability. Consortium chains run the danger of being unsuitable for large-scale enterprise applications if performance scalability is not addressed.

3) How to Address the Issues?: To address the scalability challenges in consortium chains, several improvements and alternative approaches have been proposed. Enhanced versions of PBFT, such as tPBFT and CBFT, introduce mechanisms like trust-based scoring and grouping of nodes to reduce communication overhead and improve consensus efficiency. These methods show promise in increasing the scalability of PBFT-based systems by dynamically adjusting the list of consensus nodes and simplifying the consensus process. Another approach involves integrating cryptographic primitives and other consensus algorithms to balance performance and security. For instance, combining PBFT with techniques like sharding or layer-2 solutions can help distribute the consensus workload and improve scalability without compromising security.

While PBFT offers robust fault tolerance and deterministic finality, its scalability limitations pose significant challenges for consortium chains. Addressing these challenges requires innovative approaches that enhance the consensus process and reduce communication overhead. By adopting hybrid consensus mechanisms and advanced cryptographic techniques, it is possible to develop more scalable and efficient consortium chains that meet the growing demands of various applications. This comprehensive approach will ensure that the strengths of each method are maximized while mitigating their limitations, leading to more efficient and secure blockchain applications.

Creative solutions are essential for overcoming the performance scalability difficulties in consortium chains. This analysis examines numerous strategies and developments aimed at mitigating these restrictions. The goal of the review is to illuminate the path towards more effective and scalable consortium blockchain networks by examining advancements in consensus algorithms, the incorporation of cryptographic techniques such as Verifiable Random Function (VRF) and Boneh-Lynn-Shacham (BLS) signatures, and other cutting-edge tactics. In the following sections, we explore these approaches and how they can improve performance scalability in consortium chains. By conducting a thorough assessment of pertinent studies published between 2018 and 2023, we aim to shed light on the evolving scalability of consortium chains and its implications for the blockchain sector.

B. Utilizing Boney-Lynn-Shacham (BLS) Signatures for Enhanced Consensus Efficiency

In the field of blockchain technology, BLS signatures have become a potent cryptographic tool with a wide range of uses. BLS signatures, which were first proposed by Boneh, Lynn, and Shacham in 2004 and then substantially improved in 2018, provide a unique method for aggregating signatures and improve the security and efficiency of consensus algorithms in consortium blockchains [12], [52], [53].

Although consortium blockchains are renowned for their tightly managed governance, they have scalability issues with the effectiveness of their consensus processes. Although reliable, the conventional PBFT consensus mechanism can be computationally and communication-intensive, which limits its scalability as blockchain networks get bigger and more complicated [54].

When it comes to consensus algorithms like PBFT, researchers and developers have realized that BLS signatures can help solve some of the efficiency issues that consortium blockchains face. The literature has examined the following crucial elements:

1) Simplifying Consensus via BLS: In order to streamline the consensus process and lower computational overhead and communication complexity, BLS signatures are used. By using signature aggregation techniques, nodes can reduce the number of messages they exchange with one another during consensus by combining many individual signatures into a single aggregated signature.

2) Improved scalability: Convergence algorithms become more scalable when BLS signatures are integrated. Consortium blockchain technology facilitates the processing of transactions more efficiently and may support larger networks due to the decrease in computer resources and communication overhead.

3) Security points to remember: The security ramifications of using BLS signatures are also covered in the literature. The resilience of BLS signature methods against different types of attacks and their capacity to preserve the validity and integrity of transactions are examined.

4) Uses not limited to consensus: Beyond consensus methods, BLS signatures are used in a variety of consortium blockchain network applications, including as identity management, access control, and privacy-preserving transactions. Scholars have investigated how BLS signatures might be used to improve consortium blockchain security and functionality in general.

Particularly in the context of PBFT, the literature on BLS signatures in consortium blockchains emphasizes their potential to solve efficiency issues and enhance the scalability of consensus algorithms. More investigation into sophisticated cryptographic methods and their incorporation into consortium blockchains is anticipated as blockchain technology develops, opening the door to more effective and secure decentralized networks. A promising first step towards accomplishing these goals and enhancing consortium blockchain capabilities is the implementation of BLS signatures.

Several articles found on the database that related to utilize of BLS Signature can be seen on TABLE V

TABLE V. RELATED TO HIGH-CITED STUDIES BASED ON BLS SIGNATURE KEYWORD

References	Key Findings	Advantages	Disadvantages
[55]	The paper introduces the notion of outsourced proofs of retrievability (OPOR), where users can task an external auditor to perform and verify proofs of retrievability (POR) with the cloud provider.	The OPOR setting provides a solution to security risks not covered by existing POR security models.	The paper does not provide a comprehensive analysis of potential attacks or countermeasures.
[56], [57]	The paper presents LDuAP, a lightweight dual auditing protocol that verifies data integrity in cloud storage servers. It combines public and private auditing schemes to improve the authenticity of the integrity results.	LDuAP reduces the size of the signature by 50% and subsequently reduces the overhead of the entire auditing scheme.	The paper does not discuss the potential impact of compromised auditors.

[8], [54], [58], [59], [60]	The paper presents a chain-based unique signature scheme where each unique signature is composed of n BLS signatures computed sequentially like a blockchain.	The proposed scheme achieves optimal tightness and significantly improves on previous reduction loss.	The paper does not discuss potential attacks or countermeasures.
[8], [54], [57]	The paper presents a dynamic provable data possession scheme for secure cloud data auditing. The scheme leverages BLS signatures and RMHT to support batch auditing and then optimizes batch auditing scenarios with four algorithms to support efficient batch updates.	The proposed scheme supports efficient batch updates and reduces the overhead of the entire auditing scheme.	The paper does not discuss the potential impact of compromised auditors.
[21], [61]	The paper presents a novel robust solution for key management, message encryption, and authentication, offering enhanced security for 5G-V2X communication.	The protocol achieves a high level of security and incorporates bilinear pairing, and AES encryption.	The paper does not discuss potential attacks or countermeasures.
[8], [58], [62]	The paper proposes a modification of BLS signatures with an additive key split augmented with a refresh technique.	The proposed scheme protects against a powerful adversary that can control distinct HSMs in different signing sessions.	The paper does not discuss potential attacks or countermeasures.
[21], [60]	The paper proposes an authentication mechanism that allows a Seed OppNet to process pieces of information effectively and efficiently.	The proposed scheme is secure against the rogue pubic key, tapping, forgery, replay, and man-in-the-middle attacks.	The paper does not discuss potential attacks or countermeasures.

C. Verifiable Random Function (VRF) for Enhancing Consortium Chain Performance

Performance scalability in consortium chains is still a major concern. These blockchain networks, which are overseen by a small number of institutions, put efficiency, security, and trust first. Because of its effectiveness and speed at reaching consensus, the Practical Byzantine Fault Tolerance (PBFT) consensus method is frequently chosen in consortium chains. Nevertheless, despite these benefits, consortium chains—PBFT-based included face constraints in their performance that limit their capacity to manage an increasing number of players and transactions [32], [63].

The blockchain's transaction processing is at the centre of the performance scalability problem for consortium chains. Conventional methods for storing and verifying transactions restrict these systems' capabilities. This problem is more apparent in PBFT-based consortium chains, where prompt and trustworthy node agreement is crucial. Researchers and developers have turned away from traditional block scaling techniques in favour of creative approaches meant to improve performance in order to overcome these constraints [63].

Consensus algorithm optimization is one of the key areas to increase consortium chain performance. Tendermint and Honey Badger BFT are two examples of notable inventions that simplify the PBFT consensus procedure. These developments improve consortium chains' overall scalability in addition to increasing their throughput. These optimizations assist consortium chains satisfy the requirements of high-performance applications by lowering the computational cost of the consensus procedure.

Still, more than only consensus algorithms are involved in better performance. The efficiency of consortium chains has been significantly improved by the application of cryptographic techniques [11]. Verifiable Random Functions (VRF) are one of these methods that stands out as a potentially useful approach.

Fundamentally, VRF presents a new way to confirm the leader node in the PBFT consensus procedure. It accomplishes this by using a predetermined set of criteria to start the VRF process, which produces a cryptographic proof and a random integer. This number is then compared to a predefined threshold, which is ensured to be unique and unchangeable [32], [64], [65].

The value of VRF is found in its capacity to improve leader node election in a way that is both highly secure and unpredictable. Using VRF, the top nodes in the consortium chain with the highest trust value calculate random numbers, and the node with the highest value is named the leader. This strategy guarantees equity and lessens the possibility of manipulation or collaboration.

Using VRF in consortium chains has a number of noteworthy benefits. Above all, it strengthens the overall reliability of the PBFT consensus process by improving the security and randomness of leader node selection. Moreover, it adds a level of unpredictability that reduces the possibility of predictability, which bad actors could take advantage of.

In summary, Verifiable Random Functions (VRFs) present a promising avenue for enhancing the speed of consortium chains, especially those employing the Practical Byzantine Fault Tolerance (PBFT) consensus algorithm. By introducing an additional layer of security and randomization to the consensus process, VRFs alter the selection mechanism for leader nodes, thereby better catering to the demands of high-performance applications. This discussion delves into the role of VRFs in augmenting the scalability and efficiency of consortium chains, a critical aspect of performance scalability within this blockchain architecture. TABLE VIprovides a comprehensive overview of several studies that have incorporated VRFs as their foundational methodology.

TABLE VI. TOP FIVE HIGH CITED ARTICLE ABOUT VRF

Author(s)	Article Title	Key Findings	Results
[66]	A Lightweight and Attack-Proof Bidirectional Blockchain Paradigm for Internet of Things	The paper introduces a novel bidirectional-linked blockchain (BLB) using chameleon hash functions to defeat double-spend attacks, long-range attacks, and eclipse attacks1.	The proposed blockchain consensus algorithm utilizes a verifiable random function (VRF) to select the third-party auditor committee (TPAC) which performs contract verification1.
[42]	Voting-Based Decentralized Consensus Design for Improving the Efficiency and Security of Consortium Blockchain	The paper introduces a voting-based decentralized consensus (VDC) algorithm for consortium blockchain to enhance the performance of blockchain platforms2.	The proposed blockchain consensus algorithm utilizes a verifiable random function (VRF) to select the third-party auditor committee (TPAC) which performs contract verification2.
[67]	Deep Video Prediction Network-based Inter-Frame Coding in HEVC	The paper proposes a novel Convolutional Neural Network (CNN) based video coding technique using a video prediction network (VPN) to support enhanced motion prediction in High Efficiency Video Coding (HEVC)3.	The proposed VPN uses two sub-VPN architectures in cascade to predict the current frame in the same time instance3.
[68]	Blockchain-based random auditor committee for integrity verification	The paper proposes a blockchain-based random auditor committee to replace the fixed TPAs for the integrity verification4.	The proposed blockchain consensus algorithm utilizes a verifiable random function (VRF) to select the third-party auditor committee (TPAC) which performs contract verification4.
[69]	A modified teaching learning metaheuristic algorithm with opposite-based learning for permutation flow-shop scheduling problem	The paper proposes a modified Teaching-Learning-Based Optimization with Opposite-Based-Learning algorithm to solve the Permutation Flow-Shop-Scheduling Problem with the purpose of minimizing the makespan5.	The proposed algorithm outperformed over five well-known datasets such as Carlier, Reeves, Heller, Taillards and VRF benchmark test functions, compared to other metaheuristic algorithms5.

IV. METHODOLOGY

In order to give a clear framework for the examination of scalability solutions inside consortium chains, this review paper outlines the scope of its research. It focuses on pertinent advances that have occurred between 2018 and 2023. The scope includes important areas of interest such as the use of BLS cryptography, the Practical Byzantine Fault Tolerance (PBFT) consensus algorithm, and the Verifiable Random Function (VRF), especially in relation to consortium blockchains. Consortium chains are a unique architectural paradigm in the blockchain space, and this review's comprehension of their scaling issues and remedies is crucial. The review guarantees that it includes the most recent developments and conversations in the area by defining a temporal window that runs from 2018 to 2023. This gives readers an understanding of the state of scalability solutions inside consortium chains at the moment. This method helps to provide a thorough and current analysis by bringing the evaluation into line with the changing field of consortium chain scalability research.

A. Data Sources

The use of relevant data sources is crucial for this in-depth analysis of consortium chains' scaling solutions in order to guarantee the accuracy and breadth of the study. In order to do this, reputable scholarly databases have been carefully selected to serve as the main sources for research articles. Notably, databases covering a wide range of academic articles related to consortium chains and blockchain technology, including IEEE Xplore, SpringerLink, and Elsevier's ScienceDirect, have been selected.

The assortment of research articles available in these well-chosen databases guarantees that the review will have access to a broad spectrum of scholarly sources. The choice to concentrate on reputable academic databases highlights the dedication to ensuring that the review is founded on reliable, authoritative, and peer-reviewed research. The robustness and dependability of the results offered in this journal paper are improved by this method.

With a focus on VRF, PBFT consensus algorithm, BLS cryptography, and their intersections, the review seeks to provide a thorough overview of the most recent advancements and discussions in the field of scalability solutions within consortium chains by utilizing these reliable data sources. The use of these databases strengthens the research's intellectual rigour and enhances its academic reputation.

B. Search Strategy

The idea behind this search method is to be broad but targeted at the same time. The search makes sure that publications that are directly connected to the main consensus mechanism under examination are included by using keywords like "PBFT consensus algorithm" and "Practical Byzantine Fault Tolerance."

Furthermore, adding terms like "Verifiable Random Function (VRF)" and "BLS cryptography" will help you find research on advancements and approaches in cryptography, which are crucial for improving consortium chains' security and efficiency.

The crucial term "consortium blockchains" ensures that the consensus algorithm and scalability solutions are thoroughly investigated by extending the search to include all facets of consortium chains.

Last but not least, the term "scalability solutions" is a catch-all for studies that specifically tackle the scalability issues consortium chains encounter. This guarantees that the assessment takes into consideration the most recent advancements and conversations in this important field.

Boolean operators are used to make the search approach more adaptive and versatile. It enables the retrieval of research papers that precisely address the intersections of these keywords by allowing for precise keyword combinations. This methodical technique to finding significant literature guarantees that the evaluation is thorough, balanced, and includes the most relevant studies that are available in the chosen databases.

C. Inclusion and Exclusion Criteria

To guarantee that the chosen research papers are in line with the main goals and parameters of the investigation, this evaluation utilizes a set of precisely outlined inclusion criteria. The following are included in the inclusion criteria:

- Pertinence to Scalability Solutions in Consortium Chains: Studies that specifically tackle scalability solutions in the framework of consortium chains are given careful consideration for publication. Verifiable Random Function (VRF), BLS cryptography, and the Practical Byzantine Fault Tolerance (PBFT) consensus algorithm are the main areas of interest. Research papers that examine the connections between these subjects are especially appreciated.
- Publication Period: This study specifically takes into account research papers published between 2018 and 2023 in order to capture the most recent advancements and discussions in the field. This temporal window guarantees that the evaluation includes the most recent developments and discussions regarding the scalability of performance in consortium chains.

Exclusion criteria are used to weed out research papers that don't fit inside the designated chronological window or don't correspond with the listed research subjects in order to preserve the accuracy and significance of the review. The following are the exclusion requirements:

- Irrelevance to Specified Research Topics: Papers that are not relevant to the specified research topics—such as BLS cryptography, PBFT, VRF, and scalability solutions in consortium chains—will not be accepted. The review seeks to concentrate only on studies that directly advance our knowledge of performance scalability in this particular setting.
- Publication outside the Specified Time Frame: Studies released before 2018 or after 2023 are not included. This temporal restriction makes that the review is up to date and covers research done in the chosen period of time.

A thorough examination of the chosen literature is made possible by the rigorous use of these inclusion and exclusion criteria, which ensure that the review keeps a clear and focused focus on relevant research.

D. Screening and Selection

The process of conducting a systematic literature review, or SLR, is designed to include stringent screening and selection phases. These steps are carefully crafted to find and select research articles that closely fit the specified parameters of the study. The following steps are sequential in the screening and selection process:

1) First screening: Review of Titles and Abstracts: Research paper titles and abstracts get a thorough examination at the first screening stage. The purpose of this preliminary evaluation is to determine how each publication relates to the defined scope of the research. Papers that demonstrate a strong fit with the research goals and thematic areas advance to the following phase.

2) Whole-Text examination: Detailed Evaluation: Selected papers move on to the full-text screening phase after the first screening. Here, every manuscript is carefully assessed in-depth to ensure that it is appropriate for inclusion in the review. This extensive evaluation includes a close look at the paper's methods, conclusions, and applicability to the designated study fields. Papers that fulfil the specified requirements for inclusion move on to the next round.

3) Evaluation of quality: Evaluating Credibility and Scholarliness: The chosen articles are subjected to a comprehensive analysis of their quality and rigour during the quality assessment step. The purpose of this evaluation is to guarantee that reliable, academic sources are included in the review. This grading takes into account various factors, including study technique, data integrity, citation sources, and general academic rigour. Merely those documents exhibiting an exceptional calibre of academic writing are kept for the thorough examination.

A careful and methodical approach characterizes the screening and selection procedure used in this SLR. This method is intended to preserve the review's integrity by making sure that the final selection of research papers closely follows the goals and scope of the study as defined. The study attempts to offer a thorough and academic analysis of the chosen literature by utilising these stringent screening and selection phases.

E. Data Extraction and Analysis

The methodical extraction of pertinent data is the following step after the selection of research articles is complete. This procedure is essential to extracting important data, conclusions, and insights from the chosen papers. The following are the essential phases in data extraction and analysis:

Data Extraction: Careful data extraction is applied to a selection of research papers. Research methods, empirical results, theoretical contributions, and noteworthy insights into the scalability of consortium chains are collected in a systematic manner, together with other pertinent material.

The gathered data is then rigorously subjected to thematic analysis. It is possible to identify recurring themes, new trends, and significant contributions in the field of consortium chain scalability with this analytical technique. A thorough grasp of the study landscape is attained by classifying and arranging the retrieved material into relevant themes.

F. Synthesis and Review Composition

The review article's composition is carefully organized to provide a logical summary of the chosen research publications. This synthesis is structured around a number of important components, such as:

The review article's thematic organization is based on topics that were found during the examination of a few research publications. Every subject is associated with a particular facet of consortium chain scalability, allowing readers to effortlessly peruse related content.

Methodological Insights: This page offers an analysis of the approaches taken in the chosen studies. Offering a thorough overview of the research landscape, it emphasizes the different study approaches and methodologies utilized by academics to investigate consortium chain scalability.

Presenting the major conclusions and ramifications drawn from the chosen research publications is a primary goal of the review. The paper provides insightful information about the present status of performance scalability in consortium chains by summarizing important research findings.

G. Conclusion

The evaluation concludes with a strong summary of the main lessons learned from the examined research publications. The following goals are fulfilled by the conclusion:

1) *Key takeaways synopsis:* It offers a succinct synopsis of the major discoveries and contributions that were emphasized during the evaluation. Readers can grasp the ideas obtained from the chosen research by reading this summary.

2) *Future implications:* The concluding section delves into the more extensive consequences of the examined studies for the scalability of consortium chains in the future. It explores possible ramifications for scholars, politicians, and industry practitioners.

3) *Future research directions:* The review indicates possible directions for further study and advancement in the area of consortium chain scalability. It advances the body of knowledge in the topic by highlighting areas that need more research.

With an emphasis on the PBFT consensus algorithm, the review paper seeks to offer a thorough and enlightening investigation of consortium chain scalability by adhering to this systematic methodology for data extraction, analysis, synthesis, and conclusion.

V. Result and Discussion

Upon conducting an in-depth analysis of articles from various databases, several findings emerged concerning research topics in the consortium and chain area. As illustrated in Fig. 6, the discovered articles were predominantly disseminated as conference articles or proceedings (41%) and technical journal articles (59%).

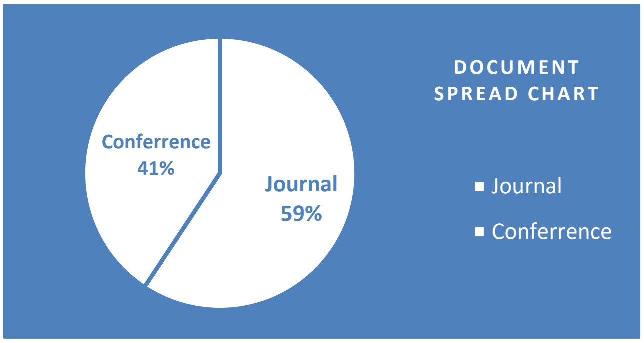

Fig. 6. Document type spreads of consortium + PBFT + VRF chain research.

These articles were distributed across a range of publisher databases as shown in Fig. 7, with IEEE being the most prominent publisher. Following IEEE, Elsevier and Springer occupy the middle tier. While Wiley and Taylor & Francis publishers constitute a smaller portion, they nonetheless contribute to the body of published articles on consortium and chain topics.

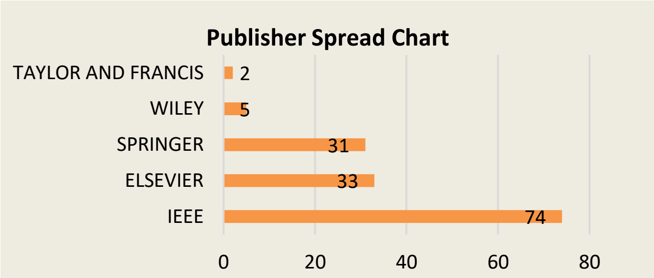

Fig. 7. Publisher spread of consortium + PBFT + VRF chain research.

The trend over the past decade reveals a consistent and significant increase in research related to consortium chains. Starting from 2014, there has been a steady rise in the number of studies published each year. The bar graph Fig. 8 underscores this growth, with the number of articles peaking at 313 in 2023. This surge not only highlights the escalating interest in consortium chains but also indicates a substantial investment in its research and development.

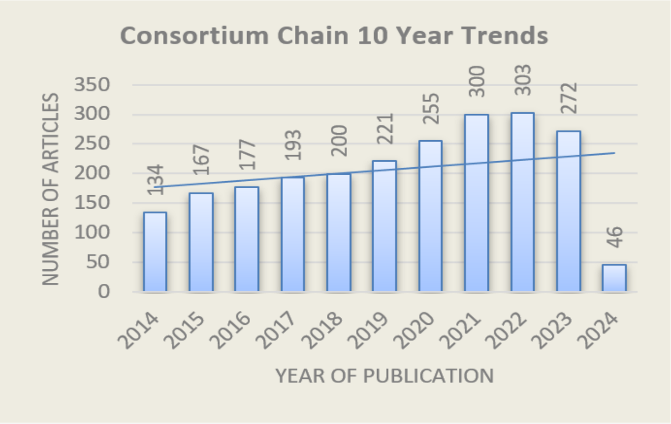

Fig. 8. Ten years trend of blockchain published articles.

The increasing trend suggests that consortium chains have become a significant area of focus in the contemporary technological landscape, particularly in the realm of blockchain technology. The continuous growth in research output also implies advancements in performance scalability and consensus algorithms, such as PBFT and BLS signatures, which are critical to the development and application of consortium chains. This trend is expected to continue as more technological innovations and applications emerge in the field.

The chart further illustrates in Fig. 9 that the research on this topic is not confined to a single domain but spans across multiple areas, reflecting its interdisciplinary nature. The areas include Engineering, Telecommunication, Automation and Control, Medical, Education, and Business. Engineering emerges as a dominant field in this distribution, signifying its substantial role and contribution. Telecommunication and Automation & Control follow closely, emphasizing the integration of advanced technologies and automated systems in the research landscape. The presence of Medical and Education sectors in the chart highlights the cross-disciplinary impact of the research, where innovations and findings are influencing healthcare and learning environments. The inclusion of Business underscores the commercial potential and economic implications associated with advancements in this field. This diverse spread of research areas indicates the broad applicability and transformative potential of this topic in various sectors.

Based on a comprehensive analysis of consortium blockchains, TABLE VIIhighlights the advantages, challenges, and implications of three key technologies: PBFT, BLS Signatures, and VRF. Each technology offers unique benefits and faces distinct challenges, shaping their suitability and impact on consortium blockchain environments. PBFT excels in low latency and immediate finality but struggles with scalability in larger networks. BLS Signatures enhance security and reduce communication load but demand high computational power [30], [31], [70]. VRF introduces unpredictability and fairness in leader selection, though its implementation can be complex. These insights provide a nuanced understanding of how these technologies can be leveraged to optimize consortium blockchain performance [11].

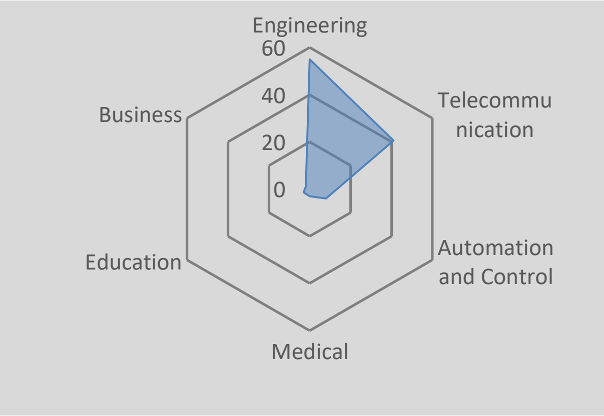

Fig. 9. Research area spreads of the chain studies.

TABLE VII. COMPARISON OF METHOD BASED ON RECORDED ARTICLES

Technology	Advantages	Challenges	Implications for Consortium Blockchains
PBFT (Practical Byzantine Fault Tolerance)	▪ Low latency and immediate finality ▪ Resilient to up to 1/3 faulty nodes. ▪ Well-suited for permissioned environments with known participants.	▪ Scalability issues with large networks due to high communication overhead. ▪ Performance degrades as the number of nodes increases.	Ideal for smaller, trust-based consortium environments where high throughput and quick consensus are required. Needs scalability enhancements for larger networks. [12], [32], [52], [53], [63], [70]
BLS (Boneh-Lynn-Shacham) Signatures	▪ Enables signature aggregation, reducing the number of transmissions required for consensus. ▪ Enhances security and integrity with cryptographic proof.	▪ Computational overhead for signature verification is high. ▪ Requires nodes to manage complex cryptographic operations.	Useful in reducing the communication load in PBFT systems, making them more scalable and efficient. However, demands high computational power and advanced cryptographic understanding. [8], [58]
VRF (Verifiable Random Functions)	▪ Provides unpredictability in leader selection, enhancing security. ▪ Ensures fairness and reduces risks of manipulation in the consensus process.	▪ Implementation complexity. ▪ May not be universally supported across all blockchain platforms.	Enhances the robustness of the consensus mechanism in PBFT by randomizing the proposer selection, thus preventing targeted attacks and promoting equitable node participation. [9], [10], [71]

VI. Conclusion

This review has systematically explored the enhancements in scalability of the Practical Byzantine Fault Tolerance (PBFT) consensus algorithm within consortium chains, highlighting pivotal research contributions and their practical implications. Our findings reveal that innovations such as Boneh–Lynn–Shacham (BLS) signatures and Verifiable Random Functions (VRF) significantly improve algorithmic efficiency, thereby enhancing transaction throughput while maintaining the requisite security and reliability in distributed systems. The integration of these technologies marks a substantial contribution to blockchain scalability, offering robust solutions for sectors that demand efficient, large-scale transaction processing such as finance, healthcare, and supply chain management.

While these advancements facilitate the handling of increased workloads without compromising speed or security, challenges persist. The complexity of implementing advanced cryptographic techniques may inhibit wider adoption and potentially introduce new security vulnerabilities that must be thoroughly addressed to prevent exploitation. Future research should therefore focus on optimizing cryptographic protocols within the PBFT framework to enhance both security and operational performance. Exploring hybrid consensus mechanisms that integrate multiple algorithms could provide a balanced approach to scalability and security.

Additionally, investigating the impact of network size on consensus efficiency could yield crucial insights, guiding the design of more adaptive blockchain networks. In conclusion, while the current progress in PBFT scalability is promising, ongoing efforts are necessary to refine these solutions and address emerging challenges. By deepening our understanding and overcoming these limitations, the full potential of PBFT in consortium blockchains can be realized, leading to more robust and scalable blockchain architectures.

Acknowledgment

This research was supported by the Ministry of Higher Education (MOHE) through Fundamental Research Grant Scheme (FRGS/1/2021/ICT10/UTM/02/3). We also want to thank the Government of Malaysia which provides the MyBrain15 program for sponsoring this work under the self-fund research grant and L0022 from the Ministry of Science, Technology and Innovation (MOSTI). This research was supported by a UTM Fundamental Research Grant Q.J130000.3828.23H38.

The Low-Cost Transition Towards Smart Grids in Low-Income Countries: The Case Study of Togo

Mohamed BARATE[1], Eyouléki Tcheyi Gnadi PALANGA[2], Ayité Sénah Akoda AJAVON[3], Kodjo AGBOSSOU[4]
Electrical Sciences-Centre d’Excellence Régional Pour La Maîtrise De L’Electricité (CERME),
University of Lome, Lome, Togo[1, 2, 3]
Electrical and Computer Engineering Department, Université Du Québec à Trois-Rivières, Quebec, Canada[4]

***Abstract*—Power grids must integrate information and communication technologies to become intelligent. This integration will enable power grids to be reliable, resilient, and environmentally friendly. The smart grid would help low-income countries to have a more stable power system to boost their development. However, implementing a smart grid is costly and requires specialized skills. This article aims to outline a low-cost transition from conventional power grids to smart grids in low-income countries. It examines the possibility of telecommunications networks participating in implementing smart grids in these countries, to minimize costs. A combination of quantitative and qualitative methods was used. Using Togo as an example, a conceptual scheme for a low-cost smart grid is proposed, with Togo's telecom operators as the telecoms network support. A transition plan to the smart grid is proposed, based on feedback from developed countries.**

Keywords—Smart grid; telecommunications network; low cost; low-income countries

I. Introduction

The smart grid encompasses ICT tools for more efficient management of the electrical grid, extensive integration of renewable sources, bidirectional management of the grid, and enhanced reliability of the entire electrical system [1], [2]. According to the European Union (EU) technological platform, a smart grid is an electrical grid capable of intelligently integrating actions from all connected users-producers, consumers, and prosumers. It incorporates intelligent technologies for monitoring, communication control, and self-healing to efficiently supply electrical energy [3]. Household appliances will communicate with smart meters and network equipment to ensure efficient infrastructure usage, responsive demand, and energy management.

Implementing smart grids contributes to improving the reliability, stability, and resilience of electrical systems, fostering economic and ecological benefits [4]. However, the deployment poses technical challenges, security concerns, interoperability issues, and significant costs [5], [6]. Technically, communication technologies for smart grids also present challenges but are surmountable.

To harness the advantages of the smart grid, numerous countries are pursuing this advanced network. As indicated in study [7] several key factors have driven most countries towards adopting a smart grid: energy efficiency, the integration of renewable energies such as solar, the reliability issues of the existing electrical grid, financial incentives from governments, policy mandates, environmental concerns, increasing demand, energy security, reduction of energy theft, and management control. Each country worldwide has a specific plan for its implementation. The development of a smart grid in developed countries often begins with the creation of a decision-making body to establish rules, hold meetings, and accelerate progress [7]. Nevertheless, the initial investment remains high [8]. For example, implementing a Smart City in India cost $7.4 billion in 2020 [9]. Unfortunately, private investment remains low, limiting the capacity of low-income countries to transition to a smart grid, as shown in study [10]. The authors present a global overview of the transition from conventional to smart electrical grids, highlighting issues such as the lack of private investment enthusiasm, cybersecurity, the low market penetration of electric vehicles with vehicle-to-grid functionality, and technical challenges in implementing microgrids.

In low-income countries, the state of the art on smart grid implementation shows conceptual proposals and incentives from stakeholders in the energy sector to transition to smart grids. In study [11], it has been shown that in Nepal's current electrical system, the fragility of the transmission and distribution network, aging infrastructure, high transmission and distribution losses, electricity theft, low renewable energy penetration, and heavy reliance on fossil fuels are significant concerns that need to be addressed promptly. Therefore, even with smart meters installed in the network, transitioning to a smart grid is necessary to solve Nepal's electrical system issues. According to [12], the reasons compelling Gulf countries to transition to smart grids include aging assets, lack of network coverage, and the need for new construction, network stability maintenance, network security, and the necessity of conserving petroleum resources. In study [13], the current and potential capacities of technologies, regulations, and policies for smart grid implementation in Brazil are evaluated. These capacities include significant renewable energy potential (hydropower), existing national laws, and tariff regulations, identified as potential sources for smart grid development in Brazil. In Nigeria, the potential improvements in reliability and efficiency that the Nigerian electrical grid could achieve through smart grid adoption are examined in study [14]. In Uzbekistan, [15] developed smart grid development concepts based on five essential points: developing new solutions and technologies, establishing interaction and control systems, regulatory reform, creating and implementing pilot projects, and finally, replicating results, though the implementation method is not specified.

In recent years, Information and Communication Technologies (ICT) have rapidly evolved in developing countries [16]. Given that smart grid technology is costly and not matured in developing countries, a thorough feasibility study is essential before implementation [17]. Therefore, an analysis of energy and telecommunication resources in low-income countries would provide valuable insights for smart grid deployment. However, no study has explored telecommunications network operators in these countries as a cost-effective avenue for smart grid implementation. It is believed that cost-minimization strategies for smart grid deployment would encourage stakeholders in the electrical field of low-income countries to transition. This article evaluates this approach, using Togo as a case study.

Togo, a low-income country in West Africa, imports 44% of its electrical energy. The remainder comprises 45% from thermal power plants and 11% from renewable sources such as solar and a hydroelectric dam. With primary renewable sources, the country could meet its growing energy demand and achieve energy independence through green energies. However, existing installations suffer from reliability and resilience issues [18]. Despite efforts including network expansions and integrating renewable sources, the grid faces reliability challenges exacerbated by intermittent sources. The solution for an efficient and sustainable electrical grid lies in implementing a smart grid. Yet, initial implementation costs in Togo are high, estimated at $1,054,167,660 for 2,919,000 users [19]. At lower costs, a gradual transition from conventional to smart grid infrastructure would enable Togo to attain reliable and resilient electrical energy.

Transitioning from conventional to smart grids, leveraging the energy potential and telecommunications networks of Togo's operators, and drawing on the experiences of other countries are central to this article. This study aims to serve as a benchmark, encouraging developing countries to transition their electrical grids towards smart grids.

Section II describes the method used in this article. It describes the data source and data processing. Section III shows the results obtained, Discussion is given in Section IV and finally, Section V concludes the paper.

II. Method

This study employed a mixed-methods approach combining quantitative and qualitative methods.

A. Quantitative Method

A comprehensive literature review was conducted using search engines such as Google Scholar and IEEE Explore. Key search indicators included "communication networks in smart grids,"; "smart grid development,"; "transition from conventional grid to smart grid," and "electric grid and Togo." Information specific to Togo was gathered from energy and telecommunication regulatory bodies' websites. The quantitative analysis focused on identifying communication network technologies in smart grids and drawing insights from successful smart grid implementation projects in developed countries.

B. Qualitative Method

The study data were collected from Togo's electric power distribution operator. They cover the periods from January 2014 to November 2019. Two days, corresponding to working days, weekends and, public holidays in 2019, were identified. Electricity consumption profiles for these days were plotted. To obtain the trend in the evolution of electrical energy consumption and imports, hourly consumption and imports are summed to find their annual values. Consumption from 2014 to 2018 was then represented. A consumption trend generated in Microsoft Excel 2019.

The overall objective of this methodology was to address the following research questions:

- Can telecommunication networks serve as a foundation for implementing smart grids in low-income countries at lower costs?
- How was the smart grid implemented in developed countries?
- What are the challenges and opportunities for low-income countries in integrating smart grids?

This methodological approach allowed for a comprehensive analysis combining theoretical insights from literature with practical data from Togo, aiming to provide valuable insights for smart grid implementation strategies in similar contexts.

III. Results

A. Communication Network Technologies in Smart Grids

In the development of smart grids, various communication network technologies have been proposed in the literature for smart grid management. Different types of networks such as home area networks (HAN), Neighborhood Area Networks (NAN), and Field Area Networks (FAN) have been identified. Technologies like ZigBee, Wifi, Z-wave, Power Line Communication (PLC), Bluetooth, and Ethernet are suitable for short-range networks like Home Area Network (HAN) and market networks.

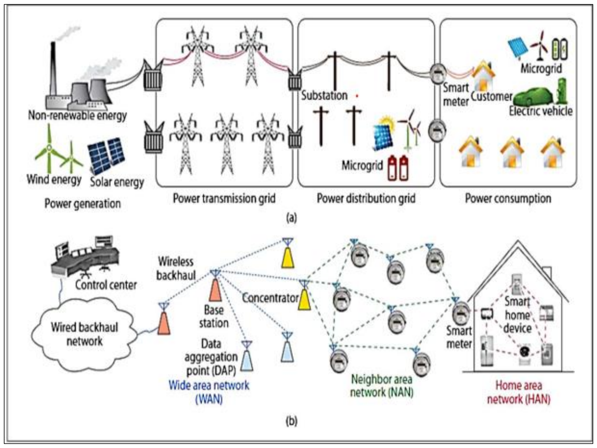

Fig. 1. Telecommunication technologies in smart grid [24].

For connecting smart meters to distribution networks (NAN/FAN), technologies such as ZigBee, WiFi, WiMax, cellular networks (LTE, GSM, 2G, 3G, 4G, and 5G), DSL, and coaxial cable are commonly used. For managing wide area networks (WAN) including transmission and distribution networks, cellular technologies, WiMax, and fiber optics are viable options [20], [21], [22], [23], [24], [25]. Fig. 1 illustrates the architecture integrating communication technologies in the smart grid.

B. *Retrospective on the Implementation of Smart Grids in Developed Countries*

Pilot projects have been implemented by private entities or state bodies to gain experience in smart grid implementation [26]. This section provides a retrospective on the implementation of smart grids in some developed countries.

1) Smart grid in Canada: The government launched a national law mandating the deployment of smart meters for businesses and households in Ontario from 2006 to 2010 as a pilot project to promote the integration of smart meters nationwide. Renewable energy management was a key concern for the government, leading to a $32 million investment in research for innovative solutions in this area. Additional funds were allocated for clean energy and eco-energy innovation initiatives. Furthermore, think tanks comprising universities and stakeholders were initiated to conduct research and develop policies related to smart grid development [19], [27].

2) Smart grid in China: China prioritizes energy independence. Efforts focus on storage, energy efficiency in transportation, and integration of renewable sources to minimize the carbon impact of the electrical energy sector [19], [28]. As early as 2011, a comprehensive project was launched to integrate Phasor Measurement Units (PMU) across power plants exceeding 300 MW and substations exceeding 500 kV. In 2009, China initiated a framework for smart grids focused on the transmission network [28].

3) Smart grid in Portugal: Portugal's distribution network is managed by a single enterprise. Renewable penetration in primary energy consumption is 21%, with renewables comprising 44% of the country's electricity mix. This high penetration is largely due to incentivized feed-in tariffs, encouraging efficiency through programs such as solar thermal sensor incentives. In 2011, thermal contributions were twice those of photovoltaic sources. Portugal uses a policy of price regulation ceilings to protect consumers from supplier losses due to operational quality issues. The regulator encourages the distribution operator to implement smart grids, allowing customer participation in innovative solutions to ensure energy quality. Conversely, gains from these innovations must benefit customer billing. Network expansion is not considered an innovation policy. These policies encourage the distribution operator to collaborate with entities including universities, technology firms, and metering equipment suppliers to create the InovGrid project. In 2009, InovGrid's initial investment enabled the implementation of a distribution transformer controller. In 2008, a project was initiated for integrating electric vehicles with over 1300 standard charging stations and 50 fast charging stations across 25 cities in the country. Many other projects have been implemented for the evolution of InovGrid [29].

4) Smart grid in India: Power outages in 2006 in India were the precursor to the beginning of smart grid implementation. A phasor measurement unit (PMU)--based monitoring system for network stability control was developed [30]. Smart grid implementation in India has been a state priority with the introduction of pilot projects. The investment cost was $7.4 billion in 2020, primarily driven by the Smart City initiative. A total of $480 billion has been allocated for Smart City development. Improvement of existing electrical network infrastructure has also been accomplished through projects. These include electrification projects, large-scale integration of renewable energies into the country's energy mix, and energy storage projects [31], [9].

C. *Case Study of Togo*

1) Electrical energy demand: Electrification rates are predominantly dominated by urban areas and their peripheries with access to 88.8% compared to only 8% for rural areas. However, thanks to electrification policies, access rates increased from 17% in 2000 to 45% in 2018 [32]. Between 2014 and 2018, there was a 29.51% growth rate in consumption, with a slight decline of 0.1% in imports, indicating the impact of energy source construction projects in Togo. This evolution is shown in Fig. 2.

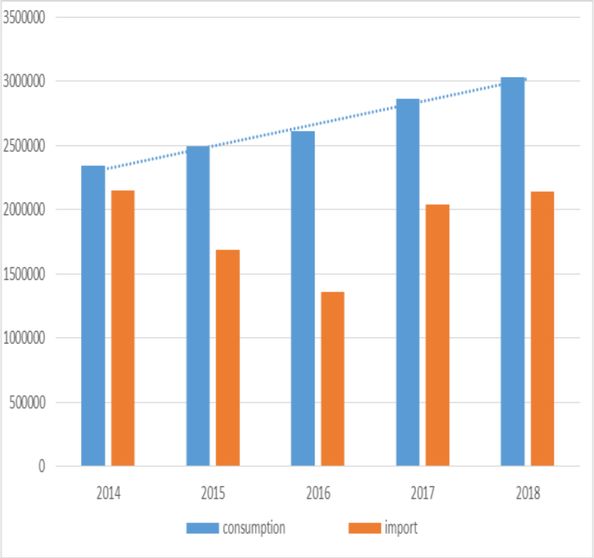

Fig. 2. Electricity consumption evolution.

The analysis of daily consumption, taking random dates (two holidays, two weekdays, and two weekends) as examples, reveals three major levels of electricity consumption in Togo, as indicated in Fig. 3.

- From 0 to 7 AM, consumption drops significantly, reflecting the sleeping hours of the population and the gradual shutdown of certain businesses whose activities are primarily or exclusively at night.

- From 7 AM to 6 PM, there is a bell-shaped consumption pattern, with peaks around 11 AM and noon, indicating increased usage due to rising temperatures. There is a slight relaxation between 12 PM and 2:30 PM, considered as break hours in Togo's services sector. During this time range, weekdays show higher consumption followed by weekends and holidays. It can be noted that consumption on weekdays is higher than on other days during this period.

- From 6:30 PM to 12 PM, consumption increases again, reaching peak levels for all days studied. This timeframe records the highest energy consumption in the country, as it corresponds to the time when almost the entire population is at home, using various electrical appliances.

This consumption pattern illustrates the daily fluctuations in electricity demand in Togo, influenced by societal and economic activities throughout the day.

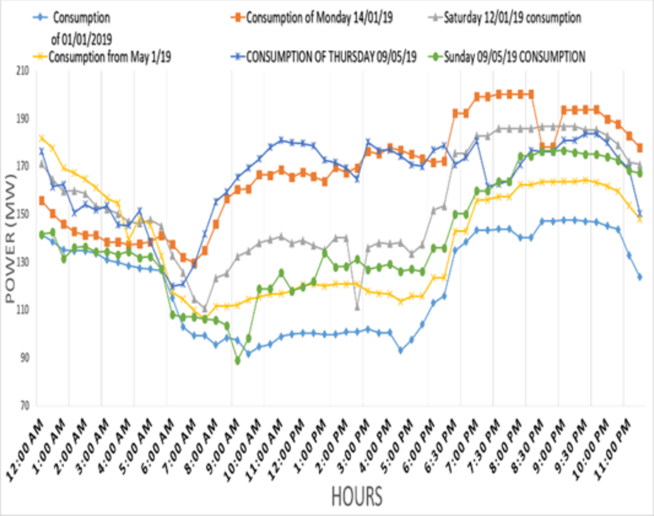

Fig. 3. Daily electricity consumption.

2) Regulatory framework: The energy sector in Togo is under the supervision of the Ministry delegated to the President of the Republic, responsible for energy and mines. This ministry implements state policy in the fields of mining, hydrocarbons, and energy, ensuring its follow-up. Within this ministry are the following entities:

- The General Directorate of Energy (DGE): It proposes development policies for the sector, particularly in research and the development of renewable energies. It drafts and proposes legislation, regulations, and standards related to energy. This directorate aims to stimulate public and private initiatives to promote the sector, ensure resource reliability, and guarantee security across the entire supply chain.

- The Energy Sector Regulatory Authority (ARSE): It oversees regulatory activities in the electricity sub-sector and potable water and sanitation.

- The Togolese Agency for Rural Electrification and Renewable Energies (AT2ER): This agency is responsible for implementing the country's rural electrification policy and promoting and valorizing renewable energies.

- The Togolese Agency for Standardization (ATN): It aims to achieve the objectives of harmonization and mutual recognition of technical standards and approval procedures in force within member states as stipulated by community treaties.

3) Electrical energy situation in the country:

a) Energy challenges: The total energy consumption was evaluated at 2042 Ktep in 2019, with electricity accounting for only 5% of this consumption [33]. Consequently, the country's electrification rate has continuously increased, rising from 44.6% in 2015 to 54% in 2020, marking a 9.4% increase in just five years [34].

The National Renewable Energy Action Plan (PANER) aims to increase the total capacity of renewable energies connected to the grid from 41% in 2010 to 41.9% in 2020 and 43.3% in 2030. This translates to capacities of 66.6 GWh in 2010, 131.635 GWh in 2020, and 131.635 GWh in 2030. This growth pertains to hydroelectric and intermittent renewable sources, particularly solar energy [35].

The integration of new sources into the grid and the increased load will exacerbate the issues currently faced by dispatching. These include synchronization problems, managing intermittent renewable sources, network failures, and load management.

The year 2030 is set as the target for universal access to electricity in Togo [36]. Achieving this will require $142 million annually, four times the national budget for electrification [37]. One of the strategic plans involves providing electricity access to over 300 households, requiring an investment of $251 million. Additionally, 555,000 solar kits need to be installed, and the electric grid needs expansion, including:

- Installing at least 108 MW of additional production capacity,

- Connecting 960 new localities to the grid,

- Electrifying 400,000 homes currently on the grid but not yet electrified.

4) Electrical grid: The electrical grid comprises the transmission network shared between Togo and Benin, transporting electrical energy from imports to each country's distribution networks [18]. This network integrates SCADA/EMS for supervision and operation and includes protection tools. However, it faces reliability issues that significantly impact the socio-economic and technical plans of both countries. The distribution of electrical energy in Togo is managed by Electric Power Company of Togo (CEET), under ARSEE's regulatory authority. CEET lacks supervision tools for its network. Regarding customers, there are two types of meters: post-paid meters with an analog display and pre-paid meters with an electronic display. The meters are not smart, contributing to energy loss problems due to theft and management, estimated at 16.04% in 2020 [38].

a) The architecture of Togo's electrical grid: Since 2006, Togo's energy situation has led to the revision of the energy policies of both countries. Consequently, CEET is now the sole entity authorized to purchase and sell electricity in Togo. Only projects like Nangbeto and Adjrala are shared by both countries. The Electrical Community of Benin (CEB) serves as the transmission network for both countries, with progressive integration into the ECOWAS transmission network. An independent transmission network regulatory body, separate from the policies of both countries, will be established. Each High Voltage and Medium Voltage customer can choose their supplier [39]. The current electrical grid architecture of both countries is shown in Fig. 4.

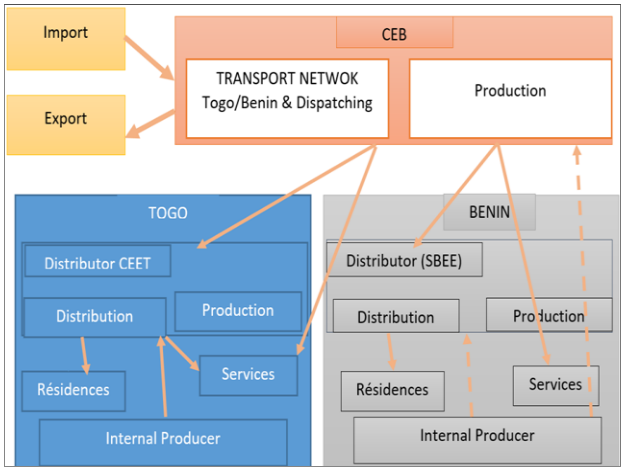

Fig. 4. Electricity grid distribution in Togo and Benin.

5) Milestones for the development of smart grids in Togo: The aim is to conduct an energy assessment to highlight the requirements that make a smart grid a viable energy solution for Togo. It is necessary to outline pathways for an affordable smart grid in Togo.

a) Togo's Energy Potential: Without oil and uranium resources, Togo's electrical energy potential is largely focused on renewable sources such as hydroelectricity, wind, and solar energy.

- Solar Potential: The average daily solar photovoltaic energy potential between 1994 and 2018 ranges from 3.8 kWh to 4.4 kWh from the south to the north of Togo. Annual totals range from 1387 kWh to 1607 kWh [40]. The average global irradiance of the country is around 4.4 kWh/m²/day for Lomé, 4.3 kWh/m²/day in Atakpamé, and 4.5 kWh/m²/day in Mango. During the dry season with clear skies, the irradiance can exceed 700 W/m². Studies by [35] confirm that Togo has renewable energy potential in hydroelectric and solar power. Regarding solar energy, studies by [41] have shown a variation in solar irradiation across the country depending on the month and altitude, proving the intermittent nature of solar energy in Togo. Climate change effects are expected to make solar energy a predominant source of renewable energy production by 2050 due to rising temperatures across the territory. Climate scenarios with projections for 2025, 2050, 2075, and 2100 reveal a trend of increasing rainfall concurrent with global warming. Simulations for 2025 and 2100 show an increase in maximum temperatures ranging from 0.63 to 4.5°C [42]. Fig. 5 illustrates Togo's solar potential.

Fig. 5. Togo photovoltaîc potential.

- Hydroelectric Potential: The currently installed hydroelectric capacity in Togo includes the Nangbeto Dam with a capacity of 2x32.8 MW and the Kpimé Dam with a capacity of 1.6 MW. Studies conducted in 1984 by Tractionnel Cabinet identified a hydroelectric potential at approximately forty sites on the Mono and Oti rivers, with 23 sites expected to generate more than 2 MW each. The total anticipated production from these sites is estimated at nearly 850,000 MWh, with an installed capacity of 224 MW [43]. It is important to note that this potential may be affected by climate change around 2050 and 2100. Besides this national potential, the presence of rivers throughout the territory could facilitate the establishment of micro-grids for local electrification.

- Wind Potential: According to the latest studies, the wind potential in Togo is relatively low. Wind potential is primarily around the coast and in the mountains, with the wind resource estimated at 20 MW [42]. Given that an average wind speed of 4.5 m/s can operate a small wind turbine, turbines can be installed on the coasts where average wind speeds are 4 m/s at a height of 10 meters. A planned wind energy project, awarded to Delta Wind Togo, the wind energy subsidiary of the ECO DELTA group, covers the Zio floodplain around Kagomé-Abobo and Djagblé-Agbata, spanning approximately 42 km² for the installation of a wind farm to produce electricity for Lomé. According to Global Atlas, wind speeds can peak at 5.5 m/s in the Oti plain and along the coasts, with an average of around 4 m/s. Fig. 6 illustrates the wind potential of Togo. Research by [44] indicates that using the E-53 turbine, an average annual energy output of 77.53 MW can be achieved at an altitude of 73 meters, 65.67 MW for the E-48 model at 76 meters, and 49.69 MW for the E-44 at 60 meters.

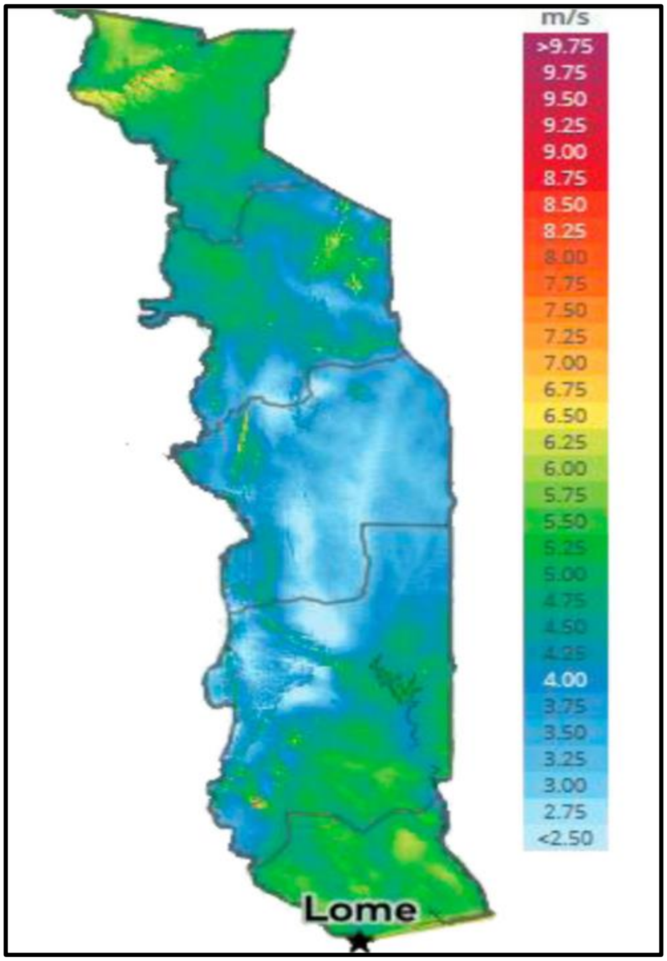

Fig. 6. Togo wind energy potential.

6) ICT in Togo: A foundation for smart grid development: In this section, an overview of Togo's communication networks will be conducted first. This assessment will highlight the strengths needed for a successful transition to a smart grid in Togo. Togo has several internet service providers, mobile phone operators, a data center, and an internet exchange point. Togocom, the state-owned operator, holds the rights to provide internet services and manage both fixed and mobile networks. This makes it a potential key player in the development of the smart grid in Togo through a public-public partnership.

a) Fixed Operators: Togocom is the leading operator with the most comprehensive and efficient core network. Its core network primarily consists of fiber optics covering the entire length of the country. This network is connected to the WACS (West Africa Cable System) submarine cable, of which the operator is the owner. It provides Internet through DSL, WiMAX, Specialized Line (RTC), and Fiber Optic Link (LFH) technologies. Thanks to the provision of aerial fiber optic Internet, Togocom has reached all neighborhoods of the Togolese capital. Its backbone is present in all Togolese cities with available fiber optic strands, allowing for the interconnection of intelligent elements from any part of the country.

There are other operators such as "Technologies Operations Liberté Services" (TEOLIS), "Centre d’Assistance, de Formation et d’Etude" (CAFE), which offer Internet through microwave links, and "Group Vivendi Africa" (GVA), which provides Internet to its subscribers through aerial fiber optics. These latter three are widely represented in the capital of Togo.

b) Mobile network operators: These are operators whose distribution network is a mobile phone network that provides access to the Internet. There are two historical operators: Togocom and Atlantique Télécom (Moov Africa).

Togocom has a network covering almost the entire Togolese national territory. Using Base Transceiver Stations (BTS), Base Station Controllers (BSC), and Mobile Switching Centers (MSC) as distribution points, it offers its subscribers technologies ranging from the first to the fifth generation of mobile telephony (2G, 3G, 4G, and 5G). Fig. 7 represents the network architecture of Togo Cellulaire, the mobile network entity of Togocom. It has a national backbone consisting of a fiber optic network and microwave links with a bandwidth of up to 10 Gbps [45]. The core network of Togo Cellulaire spans the entire territory. Its cellular network covers almost the entire country. The Togocom group has more than four million subscribers.

The Atlantique Télécom group announced a 400 km fiber network between Lomé and Kara by the end of July 2016 [46]. It has a network ranging from the first to the fourth generation, thus utilizing BTS, BSC, and MSC towers. For international connectivity, the Atlantique Télécom group subscribes to the WACS and satellites, enabling communication with other offices in Africa. Like its competitor, it has a fiber optic and microwave link backbone with a capacity of up to 10 Gbps. The installed fibers have up to 96 strands available, offering the possibility of smart grid interconnection throughout the Togolese territory. It has more than 3 million subscribers.

c) *Government network (e-Gov):* Inaugurated in 2017, the e-government network consists of a 250 km fiber optic network. It connects approximately 560 public buildings (university hospitals, health centers, more than one-third of public high schools, universities, all Republic institutions, and all ministries) in the Togolese capital, Lomé. The e-Gov network provides the entire public administration, university centers, and public university hospitals with high-speed Internet at 100 Mbps per building. An Internet bandwidth of 2 Gbps is available to it on the international WACS band. It offers an operations center allowing data storage and management with servers capable of processing approximately 2 terabytes [47]. This network can significantly contribute to local traffic development. It would be a crucial asset in the implementation of a smart grid in Togo, allowing for the connection of all entities and services in the electrical energy sector and housing smart grid data for intelligent analysis.

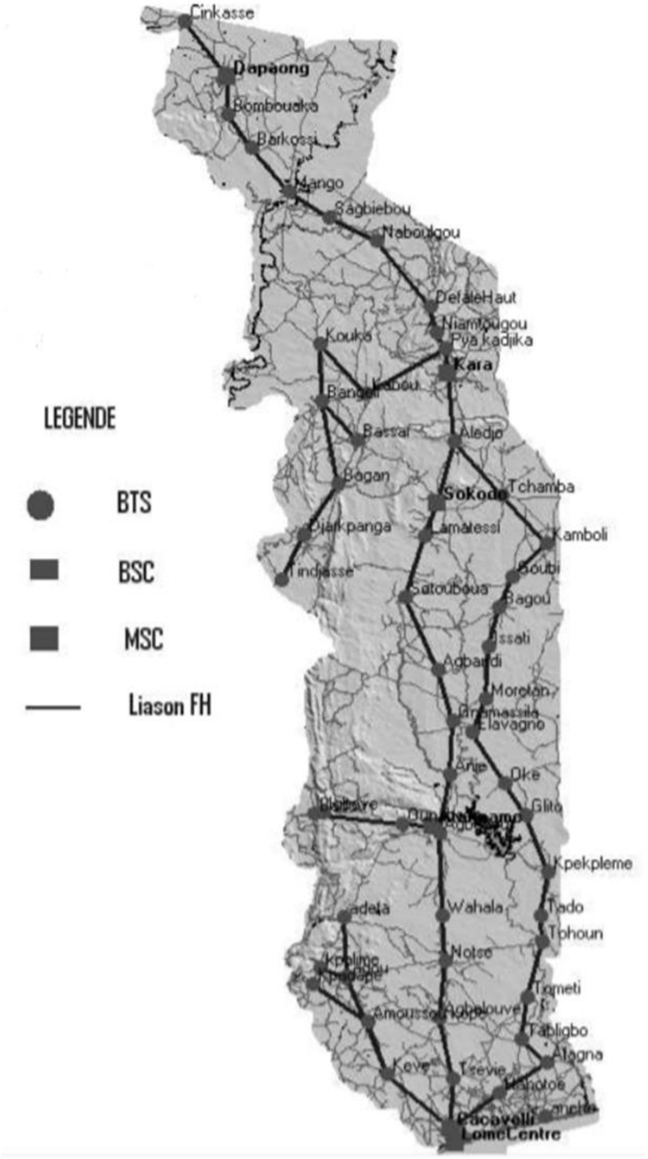

Fig. 7. Togocom network.

d) National education and research network (TogoRER): Connecting the University of Kara, the University of Lomé, and other public and private higher education institutions, the TogoRER network enables interconnected institutions to exchange information in real-time. This network, being connected to the regional WACREN network via a fiber optic link from Lomé to Accra and Lomé to Lagos, offers an opportunity to connect the Togolese grid to those of other countries in the sub-region within the framework of the WAPP project. The Togolese smart grid could, in real-time, analyze the price of electricity on the West African Power Pool (WAPP) and decide whether to sell or buy. This would help reduce the cost of electricity sales in Togo.

IV. Discussion

The literature review on communication technologies for smart grids shows they often rely on existing telecommunication networks. Considering the high initial cost of smart grid implementation, exploring the use of communication networks can minimize expenses and foster cooperation between the electric grid and telecommunication operators in low-income countries. In developed countries, smart grids aim to enhance operational efficiency, integrate renewable sources, or reduce carbon footprints. However, the initial investment, technical expertise, and state decision-making remain challenges, as noted by [26], [7] and [8]. In low-income countries, the focus is on studies and concepts, with imported electric networks facing similar issues as in developed nations. Implementing a smart grid could help low-income countries manage growing demand and establish a reliable, resilient, and economically and ecologically sound electric grid. The high initial cost remains a barrier for these countries.

Analyzing Togo's energy demand reveals a growing need, for renewable energy potential in hydroelectric, solar, and wind sources. Daily consumption profiles indicate that photovoltaic systems would require batteries, increasing the smart grid's cost. Therefore, solar thermal energy could be a more cost-effective option. Telecommunication operators with nationwide coverage are crucial for smart grid implementation in Togo. Since the state is represented in both the electric grid and telecommunication networks, agreements could be facilitated in a win-win framework. The National Cybersecurity Agency (ANCy) would be vital for securing the smart grid.

The smart grid is not a one-day solution; existing issues need to be addressed first. This includes securing the transport network, making the distribution network intelligent with bidirectional management, integrating renewable sources and micro-grids, implementing monitoring systems, and integrating smart meters and customer management systems. Progressive implementation is illustrated in Fig. 8, with the conceptual smart grid architecture incorporating telecommunication networks shown in Fig. 9. Telecommunication networks will primarily be used for consumption and management, connecting smart meters to the distribution network, and allowing consumers to manage electricity costs. Electric energy distributors can manage and monitor Virtual Power Pant (VPP) formed by microgrids in real-time through these networks.

Fig. 8. Concepts for smart grid in Togo.

The government network offers an opportunity to interconnect Togo's energy sector institutions (CEB Dispatching, DGE, ARSEE, and CEET Dispatching). Microgrids and a SCADA/EMS based on the CEET power distribution network will be managed with telecom operator networks. The TogoRER network, part of WACREN, provides an opportunity to connect Togo's grid to the regional WAPP grid. The national data center will save data at each level for real-time and future use, enabling quick analysis with advanced algorithms for reliable and resilient grid management. According to Fig. 8, three priority levels are essential. First, make the power transport network reliable, second, make the distribution network smart and finally integrate the customers.

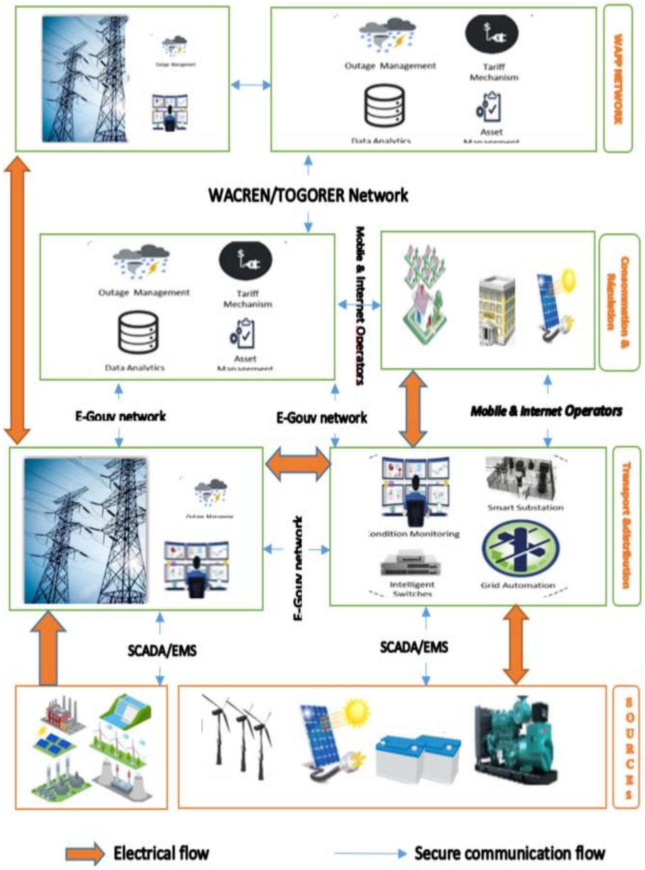

Fig. 9. Architecture of smart grid conceptual in Togo.

V. Conclusion

The implementation of smart grids will enable the electrical network to be reliable, resilient, economical, and ecological. This requires information and communication technologies (ICT). The implementation demands high investment costs, which marginalizes developing countries from these technologies that could boost their development. Togo, with its potential for renewable energy, struggles to implement smart grids due to high investment costs. This article has identified notable avenues for the implementation of smart grids in Togo, based on the experiences of other countries. The process of setting up tools to make the electricity transmission network reliable, the method and national policy for implementing smart meters and managing the distribution network are the notable feedback options used. Telecommunications operators' networks have been leveraged to reduce the cost of implementing smart grids. It is noteworthy that this approach can be applied in other low-income countries for effective smart grid implementation. The proposed architecture remains conceptual. So, to enable the smart grid to be implemented in Togo, an evaluation of the proposed architecture using a simulator will make it possible to assess its feasibility in low-income countries.

ACKNOWLEDGMENT

We would like to thank the World Bank and the Togolese government for their financial support of the "Centre d'Excellence Régional pour la Maîtrise de 'électricité" of the University of Lomé. This support contributed to the realization of this work. We would also like to thank our colleagues in the Department of Electrical Engineering at the University of Quebec, for their support in the realization of this work. Thanks to the scientific community for the efforts made for the development of the smart grid.

Graduate Students, University of Information Technology, Vietnam National University, Ho Chi Minh City, Vietnam[3]

Abstract—**Insect monitoring is vital for agricultural management and environmental conservation, but traditional methods are labor-intensive and time-consuming. This paper introduces a novel smart system utilizing NVIDIA's Jetson Nano technology combined with object detection models for remote insect monitoring. The system automates the processes of detection, identification, and monitoring, thereby significantly improving the efficiency and accuracy of insect population assessments. The implementation of the YOLOv7 model on a dataset containing 10 insect species achieved a mAP@0.5 accuracy of 77.2%. This enables farmers to take timely and appropriate measures to prevent pests and diseases, reducing production costs and protecting the environment.**

Keywords—NVIDIA Jetson Nano; insect monitoring; YOLOv7

I. Introduction

Insects are crucial to ecological health and agricultural ecosystems, pollinating crops and managing pest populations. Traditional monitoring of these insects is labor-intensive and resource-heavy. However, recent technological advances offer a solution through automation and real-time data processing. Innovations in sensor technology, machine learning, and computer vision enable precise and continuous monitoring of insect populations. These automated systems enhance data collection efficiency and provide valuable insights into insect behavior, aiding researchers and farmers in making informed decisions. This leads to better crop protection and ecological balance, supporting sustainable agriculture and environmental conservation.

The Jetson Nano, with its powerful GPU capabilities and compact size, offers a promising platform for developing a remote insect monitoring system. The literature cited presents a comprehensive overview of research endeavors aimed at revolutionizing insect monitoring and detection through innovative technological solutions. The authors in study [1] delve into the realm of computer vision techniques tailored specifically for automated insect monitoring and detection, a domain ripe for the development of cutting-edge image processing algorithms on platforms like the Jetson Nano. Expanding on this foundation, article [2] meticulously scrutinizes deep learning methodologies designed for insect detection and classification. Such insights not only enrich our understanding but also pave the way for implementing on-device machine learning models seamlessly integrated with Jetson Nano's capabilities.

Moreover, the discourse in study [3] sheds light on the integration of wireless sensor networks in environmental monitoring applications, offering invaluable insights into the design and deployment of sensor nodes for remote insect monitoring, a critical aspect of effective surveillance. These insights are crucial for ensuring that the sensor nodes are not only strategically placed but also robust and reliable in various environmental conditions. Additionally, researchers in study [4] review energy-efficient communication protocols tailored for IoT applications, a knowledge pool essential for optimizing communication between Jetson Nano devices and remote servers, ensuring seamless data exchange. This optimization is pivotal for maintaining long-term operation and minimizing energy consumption, which is vital for remote monitoring systems that often rely on limited power sources. By leveraging these protocols, the efficiency and reliability of remote insect monitoring systems can be significantly enhanced, leading to more accurate and timely data collection and analysis.

Furthermore, the authors in study [5] elucidate various data fusion techniques essential for integrating information from diverse sensors in environmental monitoring systems, a pivotal step towards enhancing the accuracy and reliability of insect monitoring data. The challenges and opportunities associated with deploying IoT systems in remote environments are thoroughly explored by researchers in study [6], offering pragmatic insights crucial for implementing smart systems for remote insect monitoring. Moreover, the researchers in study [7] explore the myriad applications of the NVIDIA Jetson Nano in edge computing, providing inspiring examples and case studies that could catalyze the development of innovative smart systems for remote insect monitoring.

Deep learning's prominence is reaffirmed in study [8], where the authors explore its effectiveness in automated insect pest detection for precision agriculture using image-based data. In [9], a real-time insect detection and classification system using convolutional neural networks (CNNs) on image data is proposed, offering a pioneering and practical approach. The authors in study [10] provide a detailed overview of image-based insect identification techniques employing deep learning, enhancing our knowledge of advanced methodologies. Article [11] presents a sophisticated framework integrating image-based and sensor-based data for real-time insect pest monitoring in greenhouse crops, highlighting the synergy between different data modalities. In study [12], a fusion approach combining data from multiple sensors for improved insect pest detection in precision agriculture is proposed, emphasizing the value of diverse data sources for thorough analysis. Finally, the authors in study [13] underscore the real-time processing capabilities of Jetson Nano for deep learning-based insect detection, demonstrating its potential as a key device for future advancements in this field.

As a result, this paper proposes a novel smart system with Jetson Nano for remote insect monitoring that is low in cost, efficient, has a fast response time, and is simple to install and implement in practice using hardware devices with limited configuration. The total cost of our proposed system is detailed in Table I. The main contributions of the paper include:

- A novel system utilizing the NVIDIA Jetson Nano and object detection models for real-time detection and classification of pest insects. This system significantly enhances the efficiency and accuracy of insect population assessments.
- The implementation of the YOLOv7 model on a dataset of 10 insect species resulted in a mAP@0.5 accuracy of 77.2%. This demonstrates the system's capability to identify and distinguish between 10 common insect groups with high precision.
- The system is designed to be low-cost, efficient, and easy to install and implement using hardware devices with limited configuration, making it accessible for practical agricultural applications.
- Leverages deep learning methodologies, image processing algorithms, and wireless sensor networks to create an integrated solution for remote insect monitoring.

The rest of the article is arranged as follows. Section II describes the materials and methods used to describe overview of our system, general system design and setup, NVIDIA Jetson Nano Developer Kit, insect trap, insect detection model. The experimental results and discussion are reported in Section III. Section IV presents the conclusions, limitations, and recommendations for future research.

TABLE I. THE DETAIL COST OF OUR SYSTEM

Device	Price in USD
NVIDIA Jetson Nano	224.32
Insect traps	62.97
UV Lights Attract Insects	4.72
Sticky insect trap	1.57
YOLO test fee	20
128GB memory card	25.58
Total cost	**339.16**

II. MATERIALS AND METHODS

A. System Overview

In the initial stage, we collected and labeled image data of pest insects for training and evaluating the CNN model. Next, YOLO object detection models were trained on the insect dataset. We evaluated the model parameters based on the trained models. From the evaluation, the best model with the appropriate parameters is selected for object recognition on the Jetson Nano device. Then, the trained model is deployed on the Jetson Nano device. Finally, we implemented the real-time pest insect recognition system in the fields. Overview of our real-time insect detection system is illustrated in Fig. 1.

B. Equipment Setup

1) Jetson Nano developer kit: The Jetson Nano Developer Kit [15] is a compact computer developed by NVIDIA for use in artificial intelligence (AI) applications, particularly in the field of real-time image and video processing. It allows users to run multiple neural networks in parallel for image processing applications. It delivers the performance to run modern AI workloads in a small, energy-efficient (consuming as little as 5W), and cost-effective form factor. The NVIDIA Jetson Nano consists of nine basic components, as illustrated in Fig. 3.

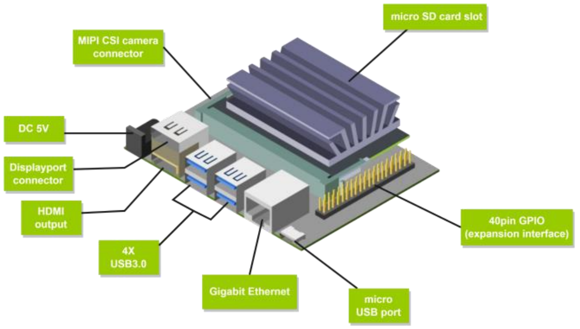

Fig. 3. NVIDIA Jetson Nano hardware overview.

The NVIDIA Jetson Nano Developer Kit is the smallest member of the Jetson product family, designed for portability and powered by a backup battery when mains power is unavailable. This makes it ideal for use outside of the office or on the go. The kit features a powerful GPU-supported system that includes a 64-bit quad-core ARM Cortex-A57 CPU, 4GB of RAM, and a video processor capable of 4K 30fps encoding and 4K 60fps decoding, as shown in Table II.

TABLE II. NVIDIA JETSON NANO DEVELOPER KIT B01 SPECIFICATIONS

Items	Technical Specifications
Model	NVIDIA Jetson Nano Developer Kit B01 (upgrade version with 2 cameras)
GPU	128-core Maxwell
CPU	Quad-core ARM A57 @1.43 GHz
Memory	4 GB 64-bit LPDDR4 25.6 GB/s
Model	NVIDIA Jetson Nano Developer Kit B01 (Upgraded version with dual cameras)
Storage	microSD
Video Encode	4K @ 30 | 4x 1080p @ 30 | 9x 720p @ 30
Video Decode	4K @ 60 | 2x 4K @ 30 | 8x 1080p @ 30 | 18x 720p @ 30
Mechanical	69.6 mm × 45 mm, 260-pin edge connector
Entire set	100mm × 80mm × 29mm
Camera	2x MIPI CSI-2 DPHY lanes
Connectivity	Gigabit Ethernet, M.2 Key E
Display	HDMI and display port
USB	4x USB 3.0, USB 2.0 Micro-B
Others	GPIO, I2C, I2S, SPI, UART

Additionally, it supports PCIe and USB 3.0 slots. The Jetson Nano delivers 472 GFLOPS for accelerated execution of modern AI algorithms. With a quad-core ARM 64-bit CPU, an integrated 128-core NVIDIA GPU, and 4GB of LPDDR4 memory, it can simultaneously run multiple neural networks and process high-resolution sensors.

Utilizing two cameras on NVIDIA Jetson Nano B01 offers several significant advantages. Firstly, it allows for image capture from two different angles, enhancing observational capabilities and covering a wider area. Secondly, with stereoscopic vision capabilities, the two cameras can create 3D images from different viewpoints, aiding in depth and distance determination, which is crucial for autonomous robots, object recognition, and navigation. Thirdly, the dual image sources enable the system to compare and eliminate errors or noise, increasing data accuracy and reliability. Fourthly, this setup optimizes performance and simplifies connections, removing the need for external adapters or USB ports. Fifthly, the Jetson Nano B01's design includes two CSI connectors, allowing for the simultaneous connection of multiple cameras, making it ideal for multi-channel applications. Lastly, NVIDIA provides robust software support for CSI cameras through Gstreamer and supporting libraries, making it easy to use commands like nvgstcapture to test and capture images from the cameras.

2) *Remote monitoring insect trap:* Weather is crucial to agricultural production, significantly impacting crops, livestock, and the environment, even with minor fluctuations. The outbreak and spread of pests and diseases are also highly dependent on weather conditions. Research has shown that temperature, humidity, rainfall, wind, and microclimate all influence the growth, reproduction, and population density of brown rice planthoppers. To address this, we propose a remote monitoring insect trap featuring an innovative model of integrated light traps that operate automatically based on sensor data, as shown in Fig. 5. These automatic light traps will continuously collect, analyze, store, and, if necessary, alert data, transmitting it to a network system. The newly trained model is eventually deployed to the Jetson Nano camera, as illustrated in Fig. 4.

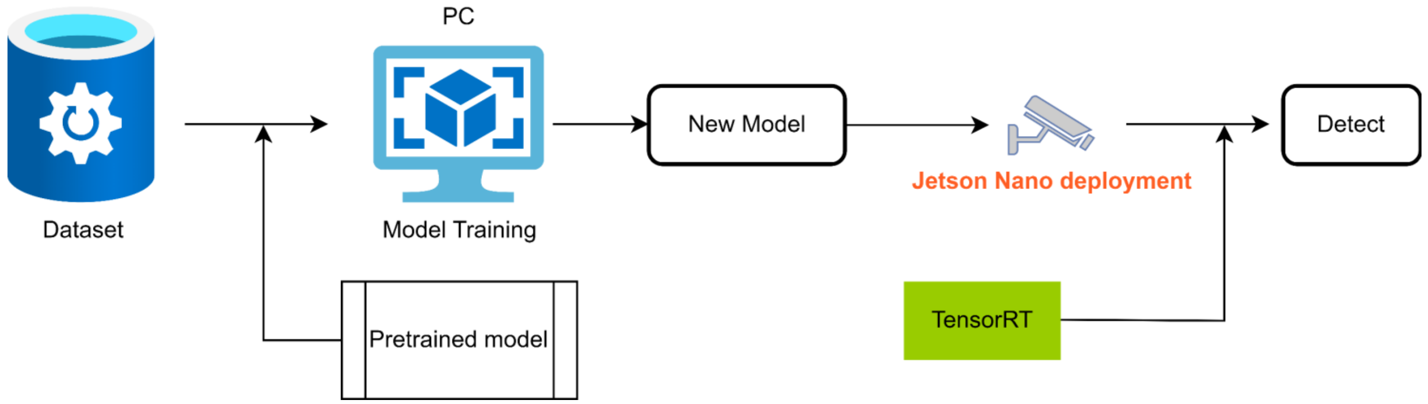

Fig. 4. Real-time insect identification system with Jetson Nano.

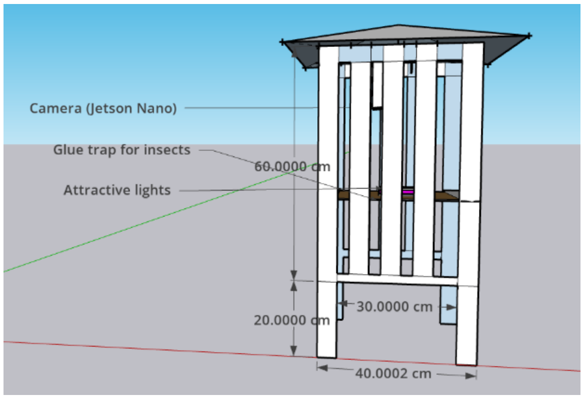

Fig. 5. Remote monitoring insect trap.

Based on the biological characteristics and behavior of certain harmful insects, insect traps can serve as an effective alternative to directly spraying pesticides onto plants, reducing the use of potentially harmful chemicals. By integrating multiple trapping methods, we can enhance overall effectiveness. Some possible methods to combine include:

- Attracting insects using sex pheromones.
- Attracting insects using bio-based traps (e.g., sweet sticky traps).
- Attracting insects using blue or yellow sticky traps.
- Attracting insects using light traps.

The study introduces a design for a light-induced insect trap with a modular design that enables straightforward assembly and disassembly of trap components. Detailed images illustrating the placement of devices within insect traps are depicted in Fig. 6. This design allows for easy relocation of the trap, operates effectively under various weather conditions, ensures high durability, and uses materials that are safe for both humans and the environment. Additionally, the modular nature of the trap makes it adaptable to different pest management needs and scalable for larger agricultural applications. This approach not only targets pest reduction but also promotes sustainable farming practices by minimizing the reliance on chemical pesticides, thereby protecting the ecosystem and promoting biodiversity.

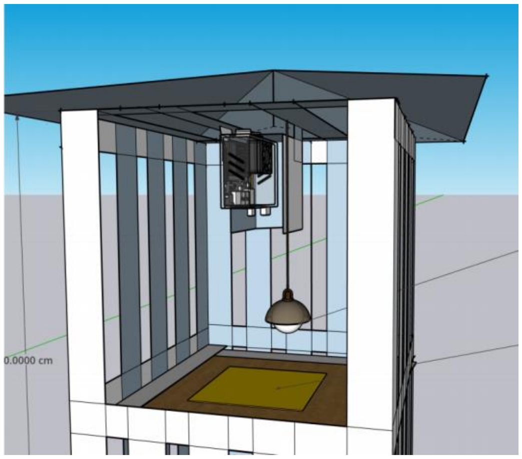

Fig. 6. Detailed images of device placement in insect traps.

3) Light attracts insects: Light is crucial for attracting insects to traps, with blue and ultraviolet (UV) light being particularly effective [21], [22]. Mosquitoes, flies, and moths are especially drawn to these wavelengths. Additionally, white light, which includes both blue and UV components, can also serve as an attractant. Using light to lure insects into traps is an effective, safe, and eco-friendly method for managing insect populations.

Examining the attractiveness of different light components enhances our understanding of their efficacy in insect attraction. Blue and UV light, with shorter wavelengths, are highly attractive to insects due to their eyes' sensitivity to these wavelengths. In contrast, red light has the lowest attraction capability, drawing only about 2% of insects in nature. Yellow light, with a slightly shorter wavelength and higher energy than red light, attracts approximately 4–5% of insects. Green light, being neutral and abundant in natural light, has average attraction capabilities, drawing around 7–8% of insects. The blue light spectrum, characterized by its short wavelength and high energy, is particularly enticing to insects, attracting roughly 20–23% of those present in nature. UV light, though not visible to the human eye, surpasses even blue light in energy and attractiveness, enticing approximately 40–50% of insects. Understanding these nuances in light spectra helps identify the most effective options for insect control.

As demonstrated by the list of light types and their respective insect attraction capabilities, UV lights exhibit exceptional ability to attract insects, drawing in approximately 40–50% of insect populations in nature. This remarkable effectiveness prompted our decision to use UV lights as the primary insect attractant in this research endeavor. The specifications of the UV insect attractant lamp are shown in Table III. The Conopery UV black light lamp, emitting purple light, operates on a convenient 220V power source, allowing for easy electrical plug-in. Its compact dimensions (5.2 cm by 17.5 cm) facilitate easy setup for insect trapping, as shown in Fig. 7.

TABLE III. THE SPECIFICATIONS OF THE UV INSECT ATTRACTANT LAMP

Product Name	**Conopery UV Black Light Lamp (Purple Light)**
Power Source	220V
Wavelength Range	300 ~ 400 nm
Peak Wavelength	365nm
Lifespan	8000 hours
Dimensions	5.2cm x 17.5cm
Type of Lamp	3U/36W Spiral

Fig. 7. UV lights attract insects

The choice of UV light in this study is also supported by its wide application in various ecological and agricultural settings. UV lights are known for their ability to attract a broad spectrum of insect species, making them highly versatile in different environments. The high attraction rates of UV lights not only enhance the efficiency of insect traps but also contribute to more accurate population assessments and monitoring in ecological studies.

Moreover, UV light traps have been shown to reduce the need for chemical insecticides, thus promoting environmental sustainability. By minimizing chemical usage, these traps help maintain ecological balance and reduce the risk of pesticide resistance among insect populations. This aligns with integrated pest management (IPM) strategies that emphasize sustainable and environmentally friendly pest control methods.

In practical applications, the Conopery UV black light lamp has been selected for its durability and ease of use in field conditions. Its design allows for seamless integration into various trapping setups, ensuring reliable operation even in remote or challenging environments. The lamp's specifications, including its wavelength emission, power requirements, and physical dimensions, have been carefully considered to maximize its effectiveness in attracting target insect species.

Overall, the deployment of UV light as an insect attractant in this study exemplifies the integration of scientific understanding and practical application. By leveraging the unique properties of UV light, this research aims to contribute valuable insights into insect behavior and improve pest management practices. The findings from this study could inform future developments in trapping technology and enhance the effectiveness of insect control strategies across diverse settings.

4) Insect sticky trap: This is a flat surface used to trap insects. One challenge is to maintain the shape of the insect when it is caught in the trap and when it dies, so that the camera can recognize it. The solution in this study is to use an insect sticky trap, as illustrated in Fig. 8.

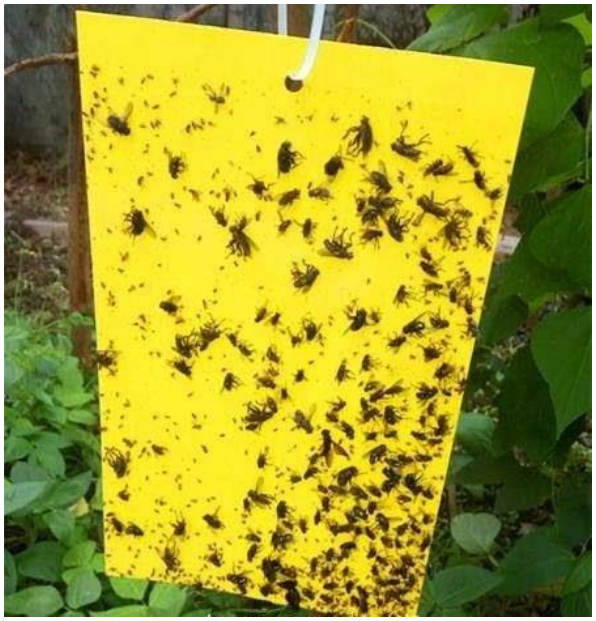

Fig. 8. Insect sticky trap.

C. Insect Image Dataset

Creating a dataset requires thorough planning and execution to ensure its quality and relevance for the intended task. Initially, the scope and purpose of the dataset are defined, specifying criteria such as data types, sources, and required volume. Potential sources like public repositories, APIs, or manual data collection methods are then identified. Data collection protocols are implemented with ethical guidelines and privacy considerations in mind, ensuring proper consent and anonymization where necessary. Techniques such as web scraping, surveys, or crowd-sourcing are employed to gather diverse and representative samples.

The dataset is iteratively refined through processes like data cleaning, validation, and augmentation to enhance usability and reliability. Thorough documentation including metadata and usage guidelines is provided to facilitate accessibility and reproducibility for researchers and practitioners.

To evaluate the effectiveness of a new pest insect recognition system, insect images collected from the internet were utilized to train convolutional neural network (CNN) models. The primary objective was to develop a system capable of identifying and distinguishing 10 common insect groups. The dataset used, Insect10_Bbox [14], consisted of 2,335 images categorized into 10 classes.

To ensure effective learning and accurate evaluation of the models, the Insect10_BBox dataset was divided into three sets: training, validation, and testing, in a ratio of 7:2:1. This division ensures sufficient representative images for each insect class in every subset of the dataset.

Specifically, the training set comprises 1,633 images, the validation set contains 467 images, and the testing set includes 235 images. This balanced split enables the model to encounter various examples of each insect type, thereby enhancing its ability to accurately recognize and distinguish them.

D. YOLO

1) YOLO algorithm: The You Only Look Once (YOLO) algorithm is an object detection method. YOLO utilizes a unified model to simultaneously predict bounding boxes and the probabilities of classes within these boxes [16]. This method operates by applying a single convolutional neural network across the entire input image, thereby quickly providing predictions. Compared to traditional classification methods, YOLO is trained on a loss function directly related to detection performance, allowing the model to learn the best way to comprehensively detect objects, as illustrated in Fig. 9.

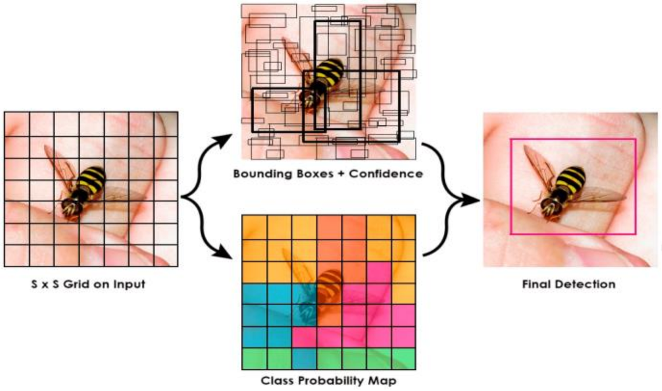

Fig. 9. YOLO algorithm for detecting insects.

In general, during classification, we determine labels from the data being tested. However, in YOLO, classification is combined with localization by providing additional information about the object's location in the form of bounding boxes. Each bounding box B consists of five predictions: x, w, y, h, and confidence score. The coordinates (x, y) represent the center of the box, determined by grid cells. Meanwhile, w (width) and h (height) predict the size of the object in the overall image [17]. The confidence score is typically used to represent the Intersection Over Union (IOU), a measure of the correlation between the predicted box and the actual object's box.

2) YOLOv7: YOLOv7 is a highly impactful algorithm in the computer vision and machine learning communities, surpassing previous object detection models and YOLO versions in both speed and accuracy [18]. It requires cheaper hardware and can be trained quickly on small datasets without pre-trained weights. Key features include an efficient backbone network, advanced optimization strategies, and novel loss functions, making it suitable for real-time applications.

YOLOv7's versatility allows it to be effectively used in domains like autonomous driving, surveillance, and medical imaging. It is easy to deploy, compatible with common machine learning frameworks, and adaptable for specific tasks, such as agricultural technology and retail. Additionally, YOLOv7 supports edge computing solutions, enabling real-time detection on devices with limited processing power. Overall, YOLOv7 sets new standards for performance and efficiency in object detection, driving innovation across various fields. The architecture of YOLOv7 is shown in Fig. 10.

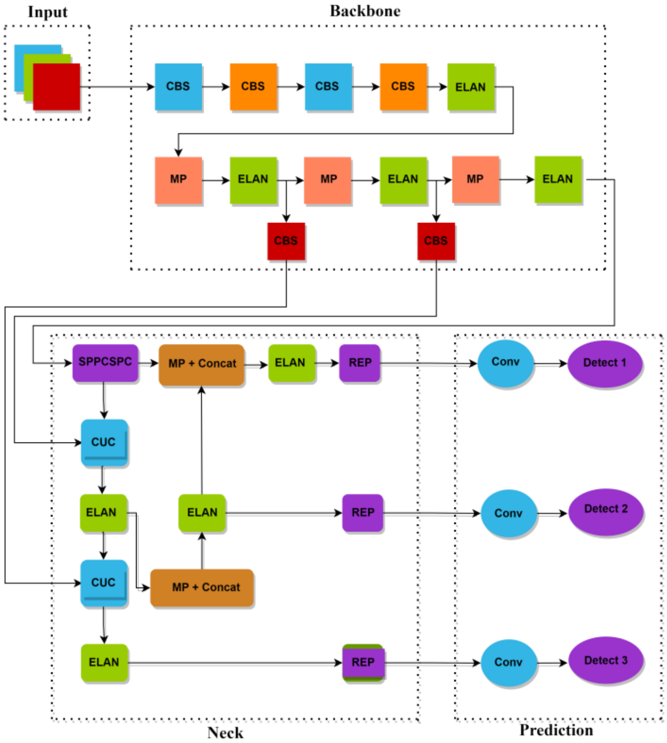

Fig. 10. YOLOv7 architecture. (Different colors represent the various functions performed within a single block).

E. Training Model

The dataset used for training the model is the Insect10_BBox of the authors in [14]. This dataset includes 10 insect classes including 'Acalymma_vittatum', 'Achatina_fulica', 'Alticini', 'Asparagus_beetles', 'Aulacophora_similis', 'Cerotoma_trifurcata', 'Dermaptera', 'Leptinotarsa_decemlineata', 'Mantodea', and 'Squash_bug'. The number of images for each insect class in the dataset used for training, validation, and testing the model is presented in Table IV.

TABLE IV. TABLE OF INSECT QUANTITIES IN THE INSECT10_BBOX DATASET

STT	Insect Name	Train	Val	Test
1	Acalymma_vittatum	115	33	17
2	Achatina_fulica	258	74	36
3	Alticini	193	55	28
4	Asparagus_beetles	89	25	13
5	Aulacophora_similis	113	32	17
6	Cerotoma_trifurcata	86	25	17
7	Dermaptera	111	32	16
8	Leptinotarsa_decemlineata	234	67	34
9	Mantodea	185	53	26
10	Squash_Bug	249	71	36
Total		**1633**	**467**	**235**

The training process for the YOLOv7 model is carried out using Google Colab, a free cloud computing service that provides a powerful Jupyter Notebook environment. Google Colab also offers access to GPUs to accelerate the model's training speed.

The first step begins by downloading the source code of YOLOv7 from GitHub and installing other necessary supporting libraries to run YOLOv7 on Google Colab in the requirement.txt file. Then, we proceed to pretrain the YOLOv7 model to evaluate its detection performance. Next, we upload the Insect10_BBox dataset to Google Drive and connect it to Google Colab. Additionally, we modify the data configuration file and YOLOv7 cfg file according to the number of object classes in the dataset.

Start training with the YOLOv7 model on the Insect10_BBox dataset. The configuration of the data.yaml file includes class names as the names of insect objects in the Insect_10BBox dataset; the content of dataset yaml file is shown in Table V.

TABLE V. DATASET YAML FILE

Item	Value
path	'/content/gdrive/My Drive/QL/Insect10_BBox'
train	'/content/gdrive/My Drive/QL/Insect10_BBox/images/train'
val	'/content/gdrive/My Drive/QL/Insect10_BBox/images/val'
test	'/content/gdrive/My Drive/QL/Insect10_BBox/images/test'
nc	10
names	['acalymma', 'alticini', 'Squash_Bug', 'asparagus', 'aulacophora', 'dermaptera', 'leptinotarsa', 'mantodea', 'Achatina_fulica', 'Cerotoma_trifurcata']

Finally, the YOLOv7 model was trained using the prepared training dataset. The training process will iterate through batches of images and update the model parameters based on the dataset used. During training, researchers can monitor evaluation metrics such as loss rate, accuracy, or mAP (mean average precision) to assess the model's performance. These evaluations can be conducted on validation or test datasets. Once the training process is complete, the model will be saved in an appropriate format. The model will undergo testing, and if the obtained results do not meet the requirements, the model will continue training until it fits the predefined parameters.

F. Evaluation Metrics

In our study evaluating the performance of an insect detection system, we employed a confusion matrix to provide a thorough understanding of its classification capabilities [19]. This matrix, a fundamental tool in classification model assessment, tabulates the counts of true positive (TP), true negative (TN), false positive (FP), and false negative (FN) predictions. Here, we elucidate these components:

- True Positives (TP): Insects correctly identified by the system.
- True Negatives (TN): Non-insects correctly identified as such.
- False Positives (FP): Non-insects erroneously identified as insects (Type I error).
- False Negatives (FN): Insects erroneously identified as non-insects (Type II error).

Leveraging these values, we computed several performance metrics: Accuracy, Precision, and Recall. Accuracy measures the ratio of correctly identified insects to the total number of insects in the test dataset. Precision, a critical metric, delineates the ratio of true positive detections to the sum of true positive and false positive detections. Similarly, recall assesses the ratio of true positive detections to the sum of true positive and false negative detections. Additionally, we employed the F1-score, serving as the harmonic mean of precision and recall, to provide a balanced evaluation of the system's performance. These performance metrics were calculated using the following equations:

$$\text{Accuracy} = \frac{TP+TN}{TP+FP+TN+FN} \times 100\% \quad (1)$$

$$\text{Precision} = \frac{TP}{TP+FP} \times 100\% \quad (2)$$

$$\text{Recall} = \frac{TP}{TP+FN} \times 100\% \quad (3)$$

To assess robustness, we tested the system across various environmental conditions, such as different lighting and backgrounds, to ensure consistent performance. The evaluation process should also include computational efficiency, assessing the system's processing speed and resource utilization. Finally, user feedback and field testing provide practical insights into the system's usability and real-world effectiveness, enabling further refinements.

G. Deployment on NVIDIA Jetson Nano

1) Preparation for Installation: To proceed with the installation of the Jetson Nano device, the following items have been prepared:

- Jetson Nano Developer Kit equipment box, including: NVIDIA Jetson module and reference carrier board.
- MicroSD card (recommended minimum 32GB UHS-1).
- MicroSD card reader to USB port.
- USB keyboard and mouse.
- Computer monitor (HDMI or DP).
- 5V-4A power supply.
- Pre-trained YOLO model.
- NVIDIA Jetpack.
- BalennaEtcher software for booting the drive onto the microSD card.
- SDCardFormatter software for formatting the microSD card.

2) Device setup: Initially, the microSD card undergoes formatting using SDCardFormatter. Subsequently, the Jetpack, obtained via download, is to be flashed onto the microSD card utilizing BalenaEtcher. Upon completion, the microSD card is to be inserted into the Jetson Nano.

The Jetson Nano operates efficiently with a 5V-4A power supply, facilitating easy connection for powering and booting up. It supports HDMI connectivity to a monitor, enabling users to visualize the interface and outcomes of AI applications. Additionally, it features a Gigabit Ethernet port for network access, facilitating internet connection and LAN device connectivity. With four USB 3.0 ports and one Micro-B USB 2.0 port, the Jetson Nano offers versatile connectivity options. The Micro-B USB 2.0 port serves dual purposes for power supply or device mode.

Integrated with two cameras, the Jetson Nano enables direct connection for recognition tasks. Furthermore, it offers various interfaces including GPIO, I2C, I2S, SPI, and UART, facilitating connection of peripheral devices such as sensors, motors, and expansion modules. Fig. 11 presents description of these device connections. The actual configuration of external devices connected to the Jetson Nano is depicted in Fig. 12.

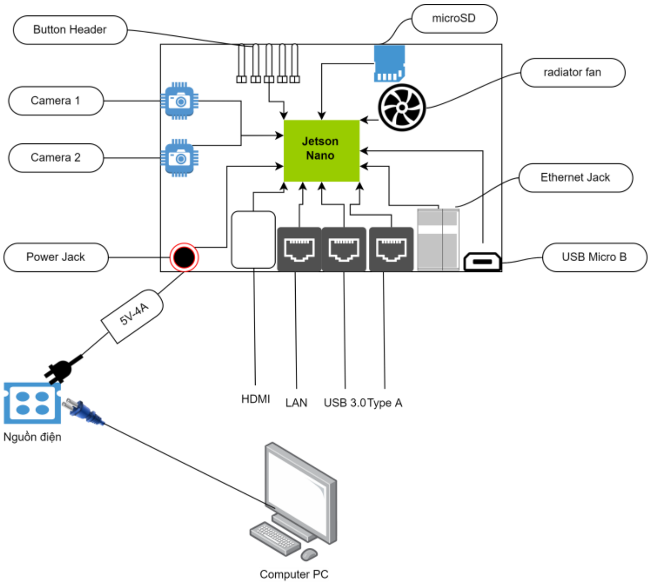

Fig. 11. Description of device connections.

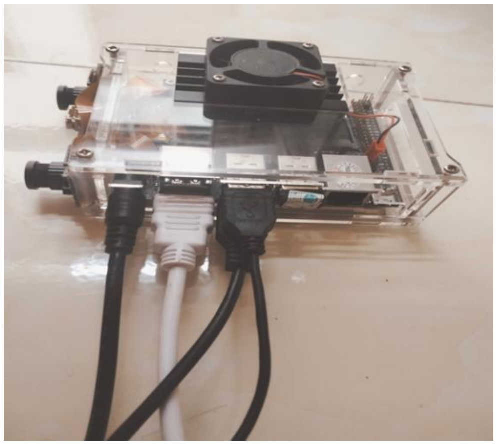

Fig. 12. The actual configuration of external devices connected to the Jetson Nano.

The green LED next to the MicroUSB connector will light up. During the initial boot, the tool will guide users through the setup process, which includes:

- Reviewing and accepting the NVIDIA Jetson EULA software.
- Selecting the system language, keyboard layout, and time zone.
- Creating a username, password, and computer name.

For the APP partition size, we use the maximum recommended size. The setup process will take approximately one minute. After completion, the computer screen will boot up as shown in Fig. 13.

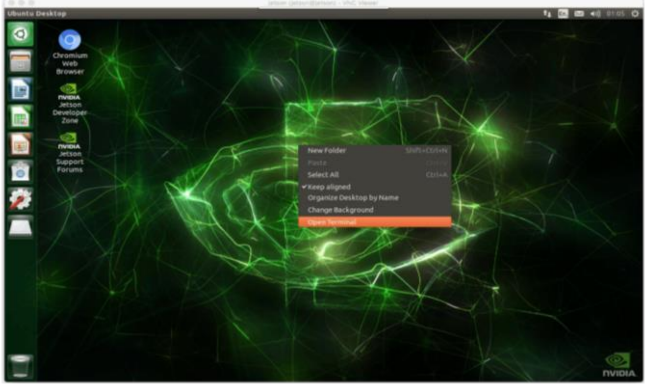

Fig. 13. The screen after configuration completion for Jetson Nano.

3) *Library setup:*

a) PyTorch: PyTorch offers a powerful and versatile deep learning framework built for Python. Backed by a thriving community and a rich ecosystem of tools, PyTorch excels in both research and production settings. It delivers seamless interoperability and optimized performance for your machine-learning projects.

b) *TorchVision:* TorchVision is your one-stop shop for computer vision projects using PyTorch. It streamlines development by providing pre-trained models and image transformation tools. This powerful library bridges the gap between cutting-edge research and real-world applications on your Jetson Nano.

c) CUDA: CUDA, the de facto standard for GPU acceleration, empowers you with high-performance computing tools. This comprehensive toolkit accelerates application development and unleashes the full potential of your deep learning PC or Jetson Nano.

III. RESULTS AND DISCUSSION

A. Model Training

This study proposes a novel model utilizing the YOLOv7 algorithm for real-time detection of harmful insects. The model is trained for 100 epochs with a batch size of 8, demonstrating high efficiency in identifying and classifying various insect species. Feature extraction and object detection training were conducted using different YOLOv7 models: YOLOv7, YOLOv7-X, and YOLOv7-W6. The comprehensive training results, including metrics such as FPS, model size, precision, and recall, are detailed in Table VI, showcasing the effectiveness of the proposed approach in diverse environmental conditions.

TABLE VI. YOLOv7 TRAINING RESULTS

Dataset	Models	FPS	Model size (MB)	Precision (%)	Recall (%)
Insect10_Bbox	YOLOv7	161	74.9	74.7	73.4
	YOLOv7-X	114	142.2	84.2	80.3
	YOLOv7-W6	84	162.7	89.6	82.5

The corresponding confusion matrix for the trained YOLOv7 model was obtained and is presented in Fig. 14. This confusion matrix reflects the performance of the classifier when evaluated on the test set. The diagonal elements indicate the number of samples correctly predicted for each insect class. As illustrated in Fig. 14, the leptinotarsa class achieved the highest accuracy at 89%, whereas the acalymma class exhibited the lowest accuracy at 63%.

To enhance the model's performance, attention should be directed towards improving the prediction results for the acalymma class. The misclassification rate for this class is 13%, as indicated by the sum of the values in the white box of column 1, representing incorrect predictions into other classes. Additionally, there is a 24% false negative rate, where the model fails to detect the presence of an insect when one is actually present. This rate is the highest among all classes. Consequently, the accuracy in predicting the acalymma class is limited to 63%.

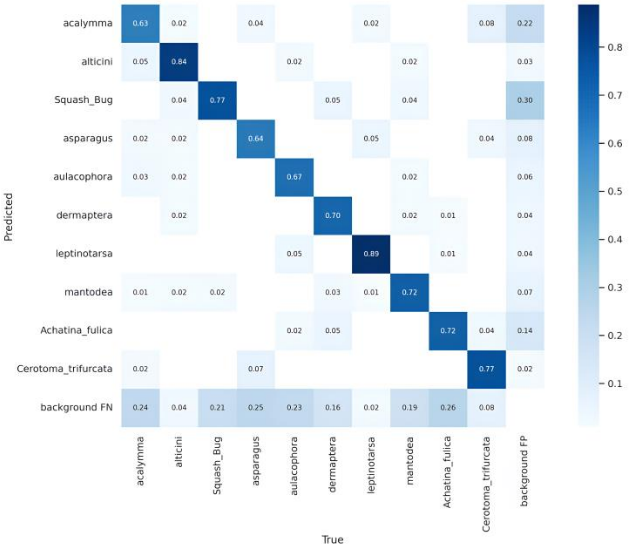

Fig. 14. Confusion matrix for training the YOLOv7 model.

The disparity in accuracy for the acalymma class can be attributed to a limited or lower quality dataset and high visual similarity with other classes, which confuses the model. To address this, several strategies are recommended: applying data augmentation techniques to increase the diversity of training samples, collecting more high-quality images of acalymma, fine-tuning the YOLOv7 model specifically for acalymma, implementing class rebalancing with weighted loss functions, and conducting feature analysis to highlight distinctive characteristics of acalymma. These approaches aim to improve the model's accuracy in predicting the acalymma class and enhance overall performance in insect classification tasks, with further experiments and validations needed for optimal results.

B. *Detect on NVIDIA Jetson Nano*

Upon completion of the training process, the YOLOv7 model is employed for object detection in images and videos, as referenced in study [20]. The detection outcomes for single-class insect identification are either displayed on the screen or saved to a file, as illustrated in Fig. 15. This procedure involves the model analyzing each frame or image to identify and classify insects based on the training it received. The results are then rendered visually on the screen with bounding boxes around detected insects, or alternatively, the data can be stored in a file for subsequent analysis. This dual approach allows for both immediate visual verification and detailed post-processing, enhancing the versatility and applicability of the detection system in various operational contexts.

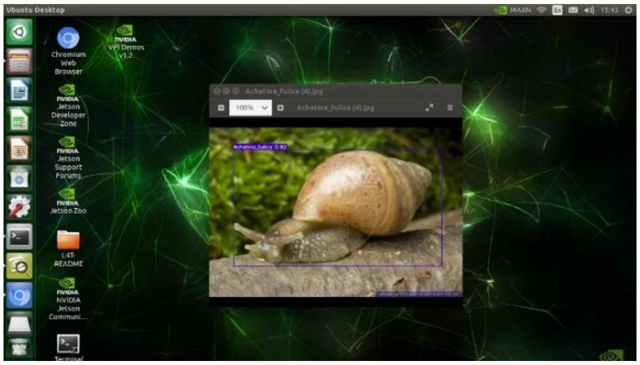

Fig. 15. Single-class insect detection.

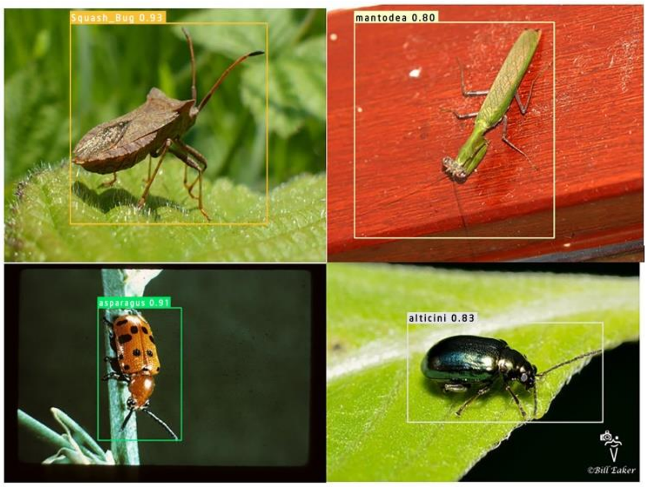

Fig. 16. Multiclass insect detection.

Fig. 15 and Fig. 16 present examples of insect object detection performed on the Jetson Nano, demonstrating both single-class and multiclass detection capabilities using images from the test dataset. These figures highlight the accuracy and efficiency of the model in identifying various insect species under different conditions. Table VII provides comprehensive details on the system's performance metrics, including frames per second (FPS) and precision, offering insights into the computational efficiency and detection accuracy of the YOLOv7 model on the Jetson Nano platform. This performance evaluation is critical for understanding the model's applicability in real-time insect monitoring and detection scenarios, ensuring reliable and efficient operation in practical applications.

TABLE VII. INSECT RECOGNITION TEST RESULTS ON NVIDIA JETSON NANO

Insect name		Detection result	FPS	Precision (%)
Single-class object detection	Acalymma_vittatum	1 Acalymma	5,543	67%
	Achatina_fulica	1 Achatina_fulica	5,735	66%
	Alticini	1 alticini	4,999	76%
Multiclass object detection	Alticini, Squash_Bug, Mantodea, Asparagus_bee	1 alticicni, 1 Squash_Bug, 1 mantodea, 1 asparagus	4,890	Alticini 83%, Squash_Bug 93%, mantodea 80%, asparagus 91%

We conducted real-time insect detection experiments using NVIDIA Jetson Nano. The results indicate an approximate frame rate of 4 frames per second (FPS), as illustrated in Fig. 17. This frame rate demonstrates the capability of the Jetson Nano to perform real-time processing despite its limited computational resources. The experiments were designed to evaluate the practical applicability of the YOLOv7 model in field conditions, ensuring that the system can effectively detect and classify insects in real-time. The findings highlight the balance between detection accuracy and processing speed, crucial for developing efficient and responsive insect monitoring systems. Further optimization and hardware enhancements could potentially improve the FPS, making the system even more robust for large-scale deployments.

IV. CONCLUSION AND FUTURE WORK

The novel smart system using the Jetson Nano for remote insect monitoring provides a scalable, efficient, and accurate method to assess and manage insect populations in various ecosystems. Its successful implementation can lead to more sustainable agricultural practices and enhanced environmental conservation efforts. Our system was developed based on the YOLOv7 model due to its lightweight convolutional neural network, which allows for effective insect pest detection and classification. This technology can be integrated into hardware accessible to farmers, enabling its use in diverse situations to protect crops from pests. Our method offers numerous advantages, including real-time insect identification, low cost, simple implementation, and practical applicability. Numerical results demonstrated that the system achieved a classification accuracy of 77.2% with mAP@0.5 on the Insect10 dataset. However, this mAP accuracy is still lower than what is required for effective insect detection in agricultural production. Future work will focus on refining the algorithms, expanding the range of detectable insect species, and integrating larger datasets to enhance the system's accuracy and overall effectiveness.

ACKNOWLEDGMENT

This research is funded by Vietnam National University Ho Chi Minh City (VNU-HCM) under grant number “DS2024-16-06.”

Abstract—**Face Recognition serves as a biometric tool and technological approach for identifying individuals based on distinctive facial features and physiological characteristics such as interocular distance, nasal width, lip contours, and facial structure. Among various identification methods, it stands out for its efficacy. However, the emergence of deepfake technology poses a significant security threat to real-time surveillance networks. In response to this challenge, we propose an AI-IoT enabled Surveillance security system framework aimed at mitigating deepfake-related risks. This framework is designed for person identification by leveraging facial features and characteristics. Specifically, we employ a Reinforcement Learning-based Deep Q Network framework for person identification and deepfake detection. Through the integration of AI and IoT technologies, our framework offers enhanced surveillance security by accurately identifying individuals while effectively detecting and combating deepfake-generated content. This research contributes to the advancement of surveillance systems, providing a robust solution to address emerging security threats in real-time monitoring environments. The introduction of this Deep Q Network, is useful to build real-time surveillance framework where live images are identified by a continuous learning mechanism and solves the security issues by a feedback mechanism.**

I. Introduction

The concept of the Internet of Things (IoT) envisions a seamlessly interconnected environment where digital and physical objects communicate through advanced information and communication technologies [1]. This interconnectedness facilitates the availability of diverse applications and services. IoT devices are capable of gathering, analyzing, and transmitting data in real time, enabling efficient communication across various systems. These devices play crucial roles in facilitating machine-to-machine (M2M) connections, interactions between machines and humans, as well as human-to-human activities. Through their real-time data processing and communication capabilities, IoT devices contribute significantly to enhancing connectivity and enabling novel functionalities across different domains.

Securing the Internet of Things (IoT) presents significant challenges stemming from various factors, including constraints on computational resources, communication bandwidth, and power availability. Moreover, ensuring reliable interaction with the physical environment adds complexity, particularly when faced with unforeseen and erratic behavior. This complexity is further compounded by the IoTs integration into cyber-physical systems, where autonomous adaptation is essential for maintaining precise and predictable operation, with safety as a paramount concern. This is particularly critical in environments such as surveillance systems, where the presence of potential threats underscores the importance of robust and resilient IoT security measures. Fig. 1 shows the generalized IoT surveillance system.

Surveillance encompasses the systematic observation, monitoring, recording, and analysis of the behavior of individuals, objects, and events for the purpose of governance and oversight. Surveillance technology encompasses a broad spectrum of electronic devices, software, and hardware designed to gather, process, store, analyze, and share various types of information. The IoT Surveillance Network [2] refers to the coordinated monitoring of numerous IoT surveillance systems interconnected within a Local Area Network (LAN). This surveillance entails the observation and analysis of computer activities, data storage on local hard drives, and data transmission across computer networks, including the Internet. Moreover, the IoT Surveillance Network possesses the capability to initiate actions based on the monitored data and insights gathered from the surveillance process.

Recent advancements in the Internet of Things (IoT) have facilitated the integration of various interdisciplinary applications within surveillance systems. These applications encompass diverse tasks including security enhancement, resource allocation, and activity recognition, leveraging data generated by smart devices. Notably, deep-learning-based models have been specifically tailored for these tasks [3], particularly in the classification of appliances within smart home environments. The utilization of IoT in surveillance spans across multiple domains, including Smart Homes & Cities, Healthcare, Security & Surveillance, Energy Consumption, Monitoring and Control, Automation, and Everyday Applications.

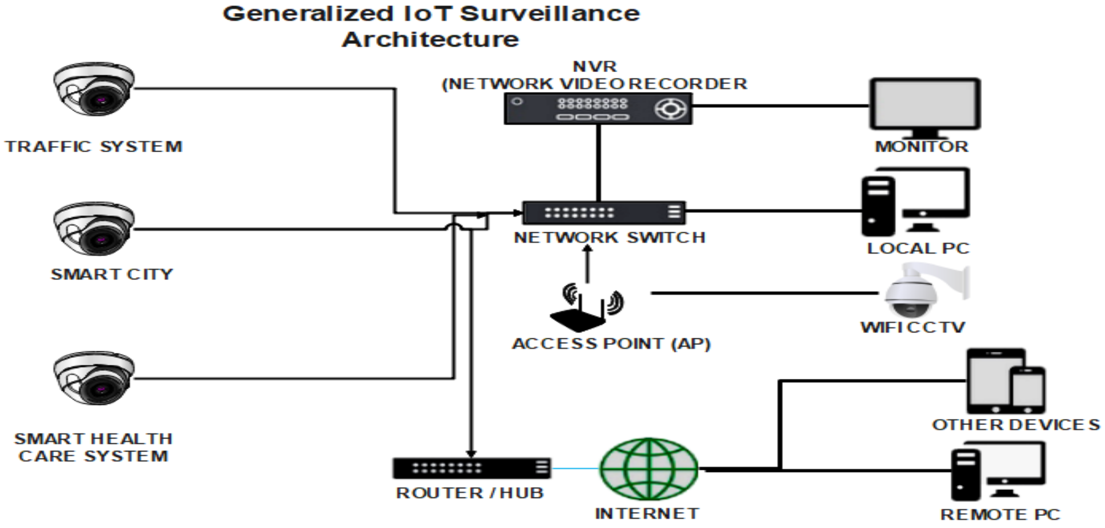

Fig. 1. Generalized IoT Surveillance system architecture.

To effectively address the requirements of these applications, technologies such as Artificial Intelligence (AI), including Machine Learning (ML) and Deep Learning (DL), offer robust capabilities, particularly in meeting security-related demands.

Face recognition stands at the forefront of biometric information processing, offering unparalleled effectiveness and versatility compared to traditional methods such as fingerprinting, iris scanning, and signature authentication. In the realm of surveillance systems, where the threat of deepfake technology looms large, face detection algorithms play a crucial role in identifying facial features. While these algorithms excel at recognizing frontal views of human faces, their efficacy is tested in scenarios requiring person re-identification across images captured from diverse surveillance cameras with varying fields of view. This task becomes further complex due to factors like lighting variations, posture changes, obstructions, and appearance alterations, underscoring the need for robust structural models capable of extracting semantic properties from surveillance camera-generated data. Despite these challenges, ongoing advancements in surveillance technology underscore the imperative for refined re-identification models to ensure effective human recognition and address the evolving landscape of personal identification processes in the face of deepfake threats.

Detecting and mitigating deepfake content, a burgeoning threat in digital media demands advanced technological solutions. Leveraging deep learning, particularly reinforcement learning (RL), offers a promising avenue for addressing this challenge. RL, a subset of machine learning, enables agents to learn optimal decision-making strategies by interacting with an environment to maximize cumulative rewards. In the context of deepfake detection, RL provides a dynamic framework for training models to discern between authentic and manipulated content. One approach is to formulate deepfake detection as a sequential decision-making task, where an RL agent analyzes frames of a video and learns to identify manipulation patterns over time. This process involves the agent receiving rewards based on its ability to accurately classify frames as genuine or deepfake, guiding it towards effective detection strategies.

Deep reinforcement learning algorithms, such as Deep Q-Networks (DQN) or Proximal Policy Optimization (PPO), serve as powerful tools for training robust deepfake detection models. These algorithms learn from extensive datasets comprising both authentic and manipulated videos, refining their detection capabilities through iterative training. Furthermore, RL-based approaches offer adaptability to evolving deepfake techniques, allowing models to continuously learn from new data and update detection strategies accordingly. This adaptiveness is crucial for staying ahead of adversaries who may employ sophisticated deepfake algorithms to evade detection.

Additionally, integrating RL with other deep learning methods, such as convolutional neural networks (CNNs), enhances the performance of deepfake detection systems. By combining these techniques, researchers can develop more resilient models capable of effectively identifying and mitigating deepfake content across various platforms and applications. Several studies have explored the efficacy of RL-based deepfake detection methods. For instance, recent research by Wang et al. [4] proposed a reinforcement learning approach for detecting deepfake images, achieving promising results in distinguishing between genuine and manipulated content. Similarly, Liu et al. [5] developed an RL-based framework for deepfake detection in videos, demonstrating improved accuracy compared to traditional methods.

A. *Research Challenges*

- Obtaining large and diverse datasets comprising both authentic and deepfake content is essential for training effective deep learning models. However, collecting such datasets while ensuring data privacy and ethical considerations can be challenging.

- Deepfake techniques continue to evolve, making it challenging to develop detection models that can effectively identify manipulated content across various modalities, such as images and videos.

- Surveillance systems require real-time processing capabilities to detect and respond to security threats promptly. Implementing deep learning algorithms for deepfake detection and person re-identification in real-time poses computational challenges, especially in resource-constrained IoT environments.

- Surveillance environments often exhibit variations in lighting conditions, camera angles, and occlusions, which can impact the performance of deep learning models. Ensuring robustness and adaptability to such environmental factors is crucial for reliable detection and re-identification.

- Deploying surveillance systems raises concerns regarding individual privacy and ethical considerations. Balancing the need for security with privacy rights requires careful design and implementation of AI-IoT enabled surveillance systems, incorporating mechanisms for data anonymization and consent management.

- Integrating AI-driven deepfake detection and person re-identification modules with existing surveillance infrastructure and IoT devices requires seamless interoperability and compatibility. Ensuring smooth integration while minimizing disruptions to ongoing surveillance operations is a significant challenge.

- Deep learning models used for deepfake detection and person re-identification are susceptible to adversarial attacks, where malicious actors attempt to manipulate or deceive the models. Developing defences against such attacks and ensuring the robustness of AI-driven surveillance systems is critical for maintaining security.

B. *Research Objectives*

- Develop an AI-IoT enabled Surveillance security system framework designed to mitigate deepfake-related risks in real-time surveillance networks.

- Investigate the effectiveness of leveraging facial features and characteristics for person identification within the proposed framework.

- Implement a Reinforcement Learning-based Deep Q Network framework for person identification and deepfake detection within the surveillance system.

- Evaluate the performance of the developed framework in accurately identifying individuals and detecting deepfake-generated content in real-time monitoring environments.

- Assess the contribution of the proposed research to the advancement of surveillance systems and its ability to provide robust solutions for addressing emerging security threats posed by deepfake technology.

C. *Research Contribution*

- The research introduces a novel framework tailored to address the escalating threat of deepfake technology in real-time surveillance networks. By integrating Artificial Intelligence (AI) and Internet of Things (IoT) technologies, this framework offers a comprehensive solution for mitigating deepfake-related risks.

- The study explores the effectiveness of leveraging facial features and characteristics for person identification within the proposed framework. By focusing on distinctive physiological attributes such as interocular distance, nasal width, and lip contours, the framework enhances accuracy in individual identification.

- The research implements a Reinforcement Learning-based Deep Q Network framework specifically designed for person identification and deepfake detection. This innovative approach harnesses machine learning algorithms to detect and combat deepfake-generated content in real-time surveillance environments.

- Through the integration of AI and IoT technologies, the proposed framework offers enhanced surveillance security capabilities. By leveraging the interconnectedness of IoT devices and the intelligence of AI algorithms, the framework ensures accurate individual identification while effectively combating emerging deepfake threats.

- By addressing the pressing security challenges posed by deepfake technology, the research contributes to the advancement of surveillance systems. The proposed framework provides a robust and practical solution for safeguarding real-time monitoring environments against manipulation and deception, thereby enhancing overall security measures.

II. Related Work

Several studies have investigated approaches to enhancing surveillance security through the detection of deepfake content and the re-identification of individuals in real-time monitoring environments. These studies have laid the foundation for the development of advanced AI-IoT-enabled frameworks aimed at addressing the emerging threats posed by deepfake technology.

Face recognition technology has become a cornerstone of modern surveillance systems due to its ability to accurately identify individuals based on distinct facial features and physiological characteristics. This biometric method, which includes parameters such as interocular distance, nasal width, lip contours, and overall facial structure, has proven to be highly effective compared to other identification techniques like fingerprinting and iris scanning. Early works in face recognition focused on developing algorithms that could reliably detect and match faces in various conditions, leading to significant advancements in the field (Zhao et al. [6]; Jain et al. [7]).

The application of machine learning techniques has greatly enhanced the accuracy and efficiency of face recognition systems. Convolutional Neural Networks (CNNs), in particular, have been extensively used to extract features from facial images and match them against databases with high precision. Studies by Parkhi et al. [8] and Schroff et al. [9] demonstrated the efficacy of deep learning models in achieving state-of-the-art performance in face recognition tasks. These models are capable of handling various challenges such as changes in lighting, pose, and facial expressions, which are common in real-world surveillance scenarios.

One notable area of research focuses on the development of deep learning-based techniques for deepfake detection. Li et al. [10] proposed a method based on convolutional neural networks (CNNs) for detecting deepfake videos by analyzing subtle inconsistencies in facial expressions and movements. Similarly, Zhou et al. [11] introduced a deep learning approach utilizing generative adversarial networks (GANs) to distinguish between authentic and manipulated images. These studies highlight the efficacy of deep learning algorithms in detecting deepfake content across various modalities.

The advent of deepfake technology has introduced significant challenges to the security of surveillance systems. Deepfakes utilize generative adversarial networks (GANs) to create highly realistic synthetic images and videos, posing a threat to the integrity of biometric systems (Goodfellow et al., [12]; Karras et al., [13]). Research by Korshunov and Marcel [14] highlighted the potential misuse of deepfakes in spoofing face recognition systems, thereby compromising security. This necessitates the development of robust detection mechanisms to distinguish between genuine and manipulated content.

In addition to deepfake detection, research efforts have also explored strategies for person re-identification in surveillance systems. Wang et al. [15] presented a novel approach based on feature matching and deep learning for re-identifying individuals across multiple camera views. Similarly, Zheng et al. [16] proposed a method leveraging facial feature descriptors and graph-based matching algorithms to achieve accurate person re-identification in complex surveillance environments.

Several approaches have been proposed to address the challenge of deepfake detection. Zhou et al. [17] introduced a two-stream neural network that combines spatial and temporal information to detect inconsistencies in deepfake videos. Similarly, Nguyen et al. [18] proposed a capsule network-based method that captures hierarchical relationships between facial features, enhancing the robustness of detection models. These methods leverage advanced machine learning techniques to improve the accuracy of deepfake detection, even in the presence of sophisticated manipulations.

Reinforcement learning (RL) has emerged as a powerful tool for enhancing the capabilities of surveillance systems. The Deep Q Network (DQN) framework, proposed by Mnih et al. [19], has shown promise in various applications due to its ability to learn optimal policies through trial and error. Recent studies have explored the integration of RL with surveillance technologies to improve decision-making processes in dynamic environments (Li et al., [20]). By employing a DQN framework, surveillance systems can adapt to new threats and optimize their operations in real-time.

The integration of Artificial Intelligence (AI) with the Internet of Things (IoT) has further advanced the field of surveillance. IoT devices enable the collection and transmission of vast amounts of data, which AI algorithms can process to detect anomalies and recognize patterns. This synergy enhances the accuracy and efficiency of surveillance systems, enabling real-time monitoring and response (Sicari et al., [21]; Zanella et al., [22]). The proposed AI-IoT enabled surveillance framework leverages these technologies to address the challenges posed by deepfakes and enhance person identification processes.

Furthermore, the integration of AI and IoT technologies has emerged as a promising approach to enhancing surveillance security. Chen et al. [23] developed an AI-IoT enabled framework for real-time video analytics in smart surveillance systems, incorporating deep learning algorithms for object detection and tracking. Similarly, Liu et al. [24] proposed an AI-driven surveillance system leveraging IoT sensors for environmental monitoring and anomaly detection.

D. Limitations

- Many studies and proposed methods have been tested in controlled environments, which may not accurately represent the variability and unpredictability of real-world surveillance scenarios. Factors such as varying lighting conditions, occlusions, and diverse facial expressions can significantly impact the performance of face recognition and deepfake detection systems.

- The rapid advancement of deepfake technology continues to outpace current detection methods. While studies like those by Li et al. and Zhou et al. have proposed effective techniques, the constant evolution of deepfake generation techniques presents ongoing challenges that current models may struggle to keep up with.

- The application of advanced machine learning techniques, particularly deep learning models like CNNs and GANs, requires substantial computational resources. This can be a limitation for real-time surveillance systems, especially in resource-constrained environments or when scaling the system to cover large areas.

- While individual studies propose effective methods for specific problems (e.g., person re-identification or deepfake detection), integrating these solutions into a cohesive, scalable framework for widespread deployment in surveillance systems remains a challenge. Ensuring consistent performance across different scales and environments is crucial.

- The use of biometric data, especially facial recognition, raises significant privacy issues. Research must address these concerns and ensure that surveillance systems comply with privacy regulations and ethical standards, which can be a complex and evolving requirement.

- Deep learning models used in surveillance systems are vulnerable to adversarial attacks, where small, intentionally crafted perturbations can lead to misclassification. Ensuring the robustness of these models against such attacks is an area that requires further research.

- Although the integration of AI and IoT shows promise, it also introduces challenges related to data security, interoperability, and real-time processing capabilities. Ensuring seamless and secure integration while maintaining high performance is a significant research challenge.

- Surveillance systems that rely on AI and deep learning require continuous updates and maintenance to address new types of threats and improve performance. This ongoing requirement can be resource-intensive and may pose logistical challenges for widespread implementation.

- The effectiveness of deep learning models depends on the quality and quantity of training data. Many studies rely on specific datasets, which may not capture the full diversity of real-world scenarios. Developing comprehensive datasets that include diverse conditions and variations is essential for improving model robustness.

- The deployment of advanced surveillance technologies involves ethical and legal considerations, particularly concerning the balance between security and individual privacy rights. Research must address these implications to ensure the responsible use of technology in surveillance applications.

III. Methodology

In this phase, we employ a computer vision-based approach to focus on video face identification. The process begins by evaluating and extracting frames from the input video sequence. We then apply a mixed feature extraction model, which has been trained using a Bayesian Learning model. As illustrated in Fig. 2, the general structure of the proposed model integrates a facial recognition system that processes the transformed frames from the video sequence. This model contains data on both faces and non-faces. During the training phase, faces are extracted and cataloged in a qualified database using an advanced feature extraction technique. During the testing phase, face detection and feature extraction processes are conducted on each frame of the input video sequence. The extracted features are then subjected to a feature matching and testing procedure, yielding the results from the face recognition model. This approach enhances the system's ability to accurately identify individuals, contributing to robust surveillance security.

Fig. 2 illustrates the process of feature extraction for identifying individuals based on their facial features. This process is implemented using a Convolutional Neural Network (CNN) model. The CNN architecture is specifically designed to handle the complexities of facial recognition by learning robust feature representations from input images.

The implementation of the CNN model begins with the preprocessing of the dataset to eliminate non-facial data. This step ensures that the input data fed into the CNN primarily consists of facial images, thereby enhancing the model's efficiency and accuracy. The preprocessing involves various techniques such as face detection and alignment to standardize the facial features before they are input into the CNN.

Once the dataset is refined, the CNN model is trained to extract distinctive facial features from the images. The architecture typically comprises multiple layers, including convolutional layers for feature extraction, pooling layers for dimensionality reduction, and fully connected layers for classification. The model learns to identify and encode unique facial characteristics such as the distance between the eyes, nasal width, lip contours, and overall facial structure.

The extracted features are then used to match within the dataset to identify individuals in surveillance videos. The CNN model compares the feature vectors of faces detected in real-time video streams with those stored in the database. By calculating the similarity between feature vectors, the model can accurately identify individuals, even in complex and crowded environments.

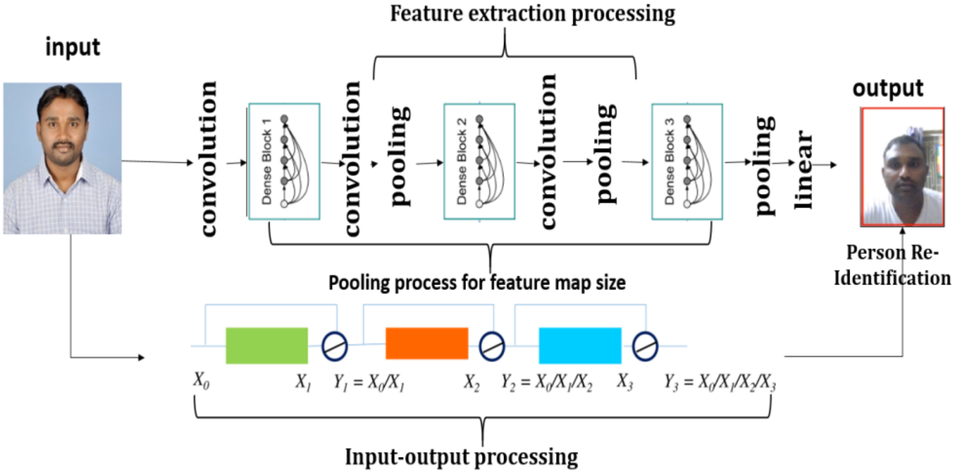

Fig. 2. Feature extraction process for person re-identification using facial features.

This approach significantly enhances the capability of surveillance systems to perform reliable person identification. By focusing on facial features, the CNN model effectively distinguishes between different individuals and eliminates false positives arising from non-facial data. The process, as depicted in Fig. 2, demonstrates the robustness and precision of using CNNs for feature extraction and person identification in surveillance applications.

Fig. 3 delineates the detailed process involved in the execution and generation of deepfake images. This process follows the successful re-identification of individuals by the trained model.

After the completion of the person re-identification step, where the trained model accurately identifies individuals from the dataset, the next phase involves generating deepfake images of the identified person. This phase is crucial for assessing the system's ability to detect and mitigate deepfake threats effectively.

The input data for this process is sourced from real-time surveillance videos. These videos provide the raw footage necessary for generating deepfake content. By using real-time data, the system ensures that the generated deepfakes are realistic and relevant to the current surveillance environment.

Initially, the CNN model performs person re-identification on the surveillance footage. This step involves detecting faces in the video frames, extracting features, and matching them against the stored database to identify individuals. Once the person is identified, the system proceeds to generate deepfake images or videos. This involves the use of advanced generative models, such as Generative Adversarial Networks (GANs), which are trained to create highly realistic synthetic images. The generative model takes the identified person's facial features and creates altered versions, blending them seamlessly with the original footage to produce convincing deepfake content.

The generation of deepfake images is not an end in itself but a critical step in testing and enhancing the surveillance system's robustness. By creating realistic deepfakes, the system can evaluate its effectiveness in detecting synthetic content and distinguishing it from genuine footage. This capability is essential for maintaining the integrity and reliability of real-time surveillance networks.

Fig. 4 presents the proposed architecture for a Reinforcement Learning-based Deep Q Network (DQN) designed to enhance person re-identification and deepfake detection. This innovative architecture integrates advanced reinforcement learning techniques to improve the accuracy and reliability of surveillance systems.

Fig. 3. Architecture for deepfake generation through person re-identification process.

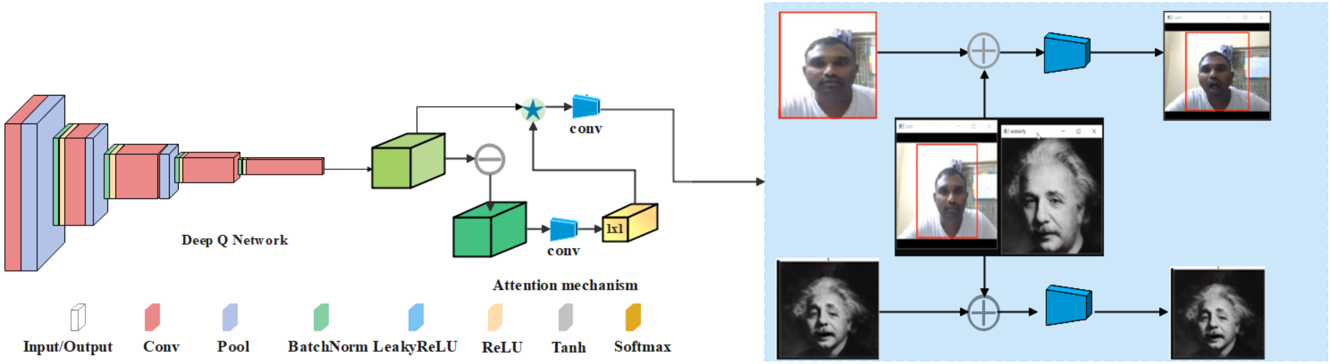

Fig. 4. Proposed architecture for reinforcement learning based deep Q network for person re-identification and deepfake detection.

Using this method, the system can identify any flaws that occur during the person re-identification process. If the system detects discrepancies or uncertainties in the identification results, it triggers an alert. This alert prompts the model to re-verify the processed image, ensuring that the identification is accurate. Additionally, the system can instruct the model to diagnose and repair issues with the surveillance camera, if necessary, ensuring optimal functionality of the hardware components.

After successfully completing the person re-identification phase, the architecture proceeds to the next step: Deepfake generation. The re-identified and processed image is used as the basis for creating deepfake content. This step leverages the previously verified and accurate identification to produce realistic deepfake images or videos.

The system is equipped to identify deepfakes by comparing the actions performed by the actual person with those of the synthetic duplicate. The architecture employs sophisticated algorithms to analyze and detect inconsistencies between real and fake actions, enhancing the system's ability to spot deepfakes effectively.

At the core of this architecture is the Deep Q Learning process, which plays a crucial role in feature extraction. The DQN model learns to extract meaningful and robust features from the surveillance footage, which are essential for accurate person re-identification and deepfake detection. The reinforcement learning approach allows the model to continuously improve its performance by learning from interactions with the environment.

The DQN model optimizes its actions based on the Q-value function, which estimates the expected rewards for state-action pairs. This process ensures that the model selects actions that maximize the long-term rewards, leading to more accurate and reliable surveillance outcomes.

By integrating these components, the proposed architecture effectively enhances the capabilities of AI-IoT enabled surveillance systems. It ensures accurate person re-identification, reliable deepfake detection, and maintains the overall integrity and security of the surveillance network.

The deepfake detection model being suggested utilizes transfer learning, adversarial training, data augmentation, ensemble approaches, cross-domain validation, and human re-identification to enhance its ability to generalize. The system utilizes domain-invariant features, multi-domain training, simulated environments, augmentation approaches, and incremental learning to sustain its performance over time. Nevertheless, the model encounters constraints when it comes to the extent of its application. These limitations encompass the need for significant computational resources, the requirement for real-time processing, concerns regarding data privacy and security, variations in the environment, obstacles caused by occlusions and crowds, the capacity to scale up, the expenses associated with deployment, the maintenance of the model, and the necessity for specialized knowledge.

Significant obstacles might arise from high computing needs, real-time processing, data privacy and security concerns, environmental unpredictability, occlusions and crowds, infrastructure requirements, deployment costs, and model maintenance.

The process of assessing the performance of a model involves comparing the time it takes for the model to make predictions and the speed at which the system responds. This entails utilizing a varied dataset, doing tests on various hardware configurations, and analyzing frame rate to comprehend the real-time processing capacity. The speed of the system is determined by measuring latency, employing asynchronous processing, and utilizing pipeline parallelism.

Person re-identification is evaluated by employing a dataset that includes several camera angles, resolutions, and ambient variables. Real-time restrictions are upheld by optimizing the flow of data and the processing pipelines. Performance metrics encompass several factors such as the average time taken for inference, the rate at which tasks are processed, the delay in the system, the delay in individual components, and the extent to which resources are utilized.

E. Training Dataset and Data Preprocessing

The training dataset for AI-IoT-enabled surveillance security systems comprises both genuine and counterfeit recordings. These movies are labeled as either "Real" or "Fake" and contain other metadata such as the source, method, and timestamps. The dataset also contains multi-camera footage with persons who have been labeled, along with supplementary information. Data preprocessing encompasses several steps, including frame extraction, face detection and alignment, data augmentation, normalization, feature extraction, and person re-identification. The available datasets are UCF-101, Celeb-A etc.

IV. Experimental Results

The implementation of the AI-IoT-enabled surveillance security system involves several key components:

1) IoT devices: Cameras and sensors deployed in the surveillance area to capture video and image data.

2) Edge computing: Local processing units close to the IoT devices to perform initial data processing and filtering.

3) Cloud infrastructure: Centralized servers for storing large datasets, training machine learning models, and performing intensive computations.

4) AI models: Deep Learning and Reinforcement Learning models for person re-identification and deepfake detection.

5) Data collection: Utilize high-resolution cameras to capture facial images and videos in various lighting and environmental conditions. Gather datasets from publicly available sources such as Market-1501, DukeMTMC-reID, and FaceForensics++ for training and testing.

6) Data preprocessing: Use face detection algorithms (e.g., MTCNN, Haar Cascades) to locate and extract faces from the images and videos. Normalize the facial images to a fixed size and apply data augmentation techniques (e.g., rotation, scaling) to increase dataset variability. Extract facial features using pre-trained models such as VGG-Face or Facenet.

7) Model development: Person Re-Identification: Use Convolutional Neural Networks (CNNs) such as ResNet or custom architectures designed for re-identification tasks. Train the CNN model on the preprocessed dataset using supervised learning, optimizing for metrics like Rank-1 Accuracy and mean Average Precision (mAP). Fine-tune the model on specific datasets to improve performance and generalization.

8) Model development: DeepFake detection: Utilize advanced models like XceptionNet, EfficientNet, or custom architectures. Train the models on datasets containing both real and deepfake videos, optimizing for accuracy, precision, recall, and F1-score. Extract temporal and spatial features to differentiate between real and manipulated content.

9) Reinforcement Learning-based Deep Q Network (RL-DQN): Define the environment where the agent interacts, including state representation (e.g., features extracted from facial images) and action space (e.g., identification or rejection). Train the RL agent using Deep Q-Learning, where the agent learns to maximize the cumulative reward by correctly identifying individuals and detecting deepfakes. Design a reward function that provides positive feedback for correct identifications and detections, and negative feedback for errors.

10) Performance evaluation and optimization: Evaluate the models using metrics like accuracy, precision, recall, F1-score, Rank-1 Accuracy, mAP, and inference time. Perform cross-validation and testing on diverse datasets to ensure robustness and generalization. Optimize models for real-time performance by reducing model complexity, using quantization, and deploying efficient architectures. Continuously update the models with new data and adversarial training to improve detection capabilities against evolving deepfake techniques.

Deploy the integrated system in the surveillance area, ensuring proper installation of IoT devices, edge processors, and cloud connectivity. Implement automated workflows for data collection, processing, and analysis. Continuously monitor system performance, detect anomalies, and perform regular maintenance. Implement feedback loops to update the models with new data and improve system accuracy over time.

Fig. 5 is the test result generated on personre-identification. The image is processed into a model and it matches with dataset. Fig. 6 is another level of result showing person re-identification with different scenario like overcoming all flaws like background color, brightness, sckin color etc.

Fig. 7 and Fig. 8 are the deepfake generated images that tell about the motion of both images. The action of a person and image are imitated at a time. Fig. 9 is the other result that shows that deefake generation using the art images. In both the results deepfake results generated are motion-based datasets. One of the action is showing teeth and other is head rotation. Likewise we can also regere motion based results like yawing, mouth opening etc.

V. CONCLUSION

The integration of AI and IoT technologies in surveillance systems offers a transformative approach to enhancing security and addressing emerging threats. In this research, we presented a comprehensive framework for an AI-IoT enabled surveillance security system that focuses on two critical aspects: Deepfake detection and person re-identification.

Face recognition, leveraging distinctive facial features and physiological characteristics, remains a highly effective biometric tool for identifying individuals. However, the rise of deepfake technology has introduced significant security vulnerabilities, undermining the reliability of traditional surveillance systems. To counter these threats, our proposed framework utilizes a Reinforcement Learning-based Deep Q Network (RL-DQN) to enhance the accuracy and robustness of person identification and deepfake detection.

By combining AI and IoT, our framework not only accurately identifies individuals but also effectively detects and combats deepfake-generated content, ensuring the integrity of real-time monitoring environments. The RL-DQN approach demonstrates superior performance in adapting to dynamic and complex surveillance scenarios, providing a robust solution to emerging security challenges.

This research contributes to the advancement of surveillance systems by delivering an innovative, AI-driven strategy that addresses the dual challenges of person re-identification and deepfake detection. The implementation of our AI-IoT enabled framework significantly enhances the security of real-time surveillance networks, offering a reliable and resilient defense against sophisticated threats. Through this work, we pave the way for future developments in secure and intelligent surveillance technologies.

The future work can be carried out on surveillance applications where real-time images are needed to be identified in order to avoid major damage to society. The advanced Deep Learning algorithms can be used to detect live captured images and integration of IoT technology is very useful for designing the network.

Conflict of Interest

The authors declare no conflict of interest.

Author's Contribution

Srikanth Bethu has written code and executed results. M. Trupti defined methodology. Suresh Kumar Mandala has done algorithm development. Syed Karimunnisa has done related work and Ayesh Banu done paper formatting.

Deep Learning-Driven Citrus Disease Detection: A Novel Approach with DeepOverlay L-UNet and VGG-RefineNet

Deep Learning-Driven Citrus Disease Detection

P Dinesh, Ramanathan Lakshmanan*
School of Computer Science and Engineering, Vellore Institute of Technology, Vellore, India

Abstract—**Agriculture is essential to the world's desire to produce food, generate income, and maintain livelihoods. Citrus fruits are produced worldwide and have a significant impact on food production, nutrition, and agriculture. During production, farmers face difficulties due to diseases that affect plant growth. Black spot, canker, and greening are some citrus leaf diseases that risk citrus production, resulting in economic losses as well as reduced supply stability. Early detection of these diseases through recent technologies like deep learning will help farmers with better yields and quality. The current methods fall short in marking the area affected by the disease with accuracy and more performance. This work has a novel method proposed for the segmentation and classification of citrus leaf diseases. The method consists of three phases. In the first phase, DeepOverlay L-UNet is used to segment the affected regions. In the second phase, disease detection is carried out using VGG-RefineNet, and in the third phase, the affected region is highlighted in the original image with a severity level. On the other hand, the DeepOverlay L-UNet model proves to be effective in detecting affected areas, thereby enabling clear visualization of the spread of the disease. The result affirms that the proposed method outperforms with a better training IOU of 0.9864 and a validation IOU of 0.9334.**

Keywords—Citrus disease detection; highlighting affected region; Deep learning; semantic segmentation; DeepOverlay L-UNet; VGG-RefineNet

I. Introduction

Agriculture plays a major influence in the world economy since it is essential to supporting livelihoods, promoting economic expansion, and raising national GDPs [1]. Concerns regarding food shortages and rising demand arise as the global population is projected to surpass ten billion by 2060, underscoring the significance of agriculture in addressing these issues [2]. However, threats to crop production include diseases, pests, and long climate change, which have an impact on production yield and quality worldwide [3].

Citrus is one of the species of plants that are produced globally, with output reaching 157.98 million tons. It is an essential part of global agriculture and is utilized in various sectors, particularly the food and nutrition industries. Examples of these plants are lemons and oranges. Diseases that affect output and quality pose serious concerns for citrus crops. Citrus production is at risk from diseases including blackspot, canker, and greening, which can result in financial losses and a less stable supply. Monitoring disease conditions through plant observation and the direct use of pesticides in agriculture in every adverse situation are two alternate approaches to disease protection. This approach is known globally and is simple for producers to use. This method's drawback is that certain producers unknowingly utilize chemical pesticides. The most frequent issue with medication usage that occurs unknowingly is the incorrect medicine used due to incorrect disease detection in plants. The welfare of people affected by unknowing drug usage. Citrus black spot, citrus cancer, and greening are the most prevalent illnesses in the citrus production field. These diseases are quite common in commercial citrus production [4]. These are the reasons why the disease wants to be detected immediately, and appropriate action should be taken. If not, it results in a loss of product quality and quantity.

Citrus greening is a highly destructive citrus disease worldwide. These diseases can affect any commercial citrus variety. Asian Citrus Pselid (ACP) (Diaphorina citri) is one of the diseases responsible for this illness. To stop greening from spreading further, trees impacted by the disease must be destroyed [5]. Worldwide, many commercial citrus cultivars, particularly grapefruit, sweet oranges, and lemons, are afflicted with citrus bacterial cancer. Humid-wet areas with extreme temperatures, precipitation, and wind are more conducive to the spread of this illness. This disease is characterized by early fruit and leaf loss, dark blotches on the leaves, and bubble-like diseases in different tree sections [6]. On the fruit and leaves of citrus trees, the citrus black spot typically takes the form of freckle marks. It can also be observed as lesions on the crop's branches. It is a condition that is more frequent in warm climates, like citrus cancer. Phyllosticta citricarpa is the fungus disease that causes Citrus black spot. These must degrade the yield and quality [7]. These diseases affect crop quality and yields. Sensible practices in agriculture, including spraying and new technologies, are being used to avoid plant diseases. Deep learning approaches are utilized to segment and categorize plant diseases, as evidenced by the literature study.

In agriculture, statistics on image data are essential for disease detection, image segmentation, and crop assessment on yields. Statistical data is used in agriculture to assess disease levels according to pigment factors such as hue, saturation, and brightness [8]. Furthermore, statistical data on images is essential for recognizing how plant diseases affect crop yields, particularly in nations like India, where agriculture plays a major economic role [9]. For measuring and diagnosing diseases, image segmentation methods like genetic algorithms use statistical analysis to divide pictures into discrete sections [10]. Disease severity and disease grades in crops are estimated using statistical indicators such as Region of Interest (ROI) and percentage of Occurrence of Infection (POI) [11]. Farming operations may be enhanced with the use of this data, resulting in higher yields and more environmentally friendly farming methods.

Many methods were recently investigated in studies to identify plant diseases. Standard approaches include importing leaf images, segmenting the damaged region by pre-processing for noise reduction, utilizing algorithms for disease identification, and extracting features using methods like LBP and HoG [12]. To diagnose diseases based on observable symptoms on leaves, recent advances have focused on deep learning models, namely CNNs, that perform away with the need for manual feature description [2]. According to the category of disease and severity of damage, potential treatments are then suggested by applying deep learning techniques such as DenseNet for disease categorization and segmentation [9]. Furthermore, techniques like CAAR-UNet models use preprocessing, data preparation, and architectural improvements to identify and categorize sick areas in plant leaf images [13].

Segmentation in identifying diseases helps locate and characterize the boundaries of diseased regions that lie within images [14] [15]. It distinguishes between healthy and diseased areas, which assists in determining the severness and position of the diseases on the plant’s leaf. By segmenting images, it is easy to identify particular disease signs, such as blackspots and canker, based on texture, colour, and shape-defining features. Segmentation techniques such as semantic segmentation and instance segmentation are used to properly identify and categorize various diseases in plants, hence improving disease detection accuracy. Overall, segmentation is a key phase in disease detection, allowing for focused examination and categorization of plant diseases.

Semantic segmentation is important for identifying plant diseases. Accurate diseased region segmentation is possible with refined deep learning models such as DenseNet and Hybrid-DSCNN. These models can identify damage to plant leaves at the pixel level, enabling accurate disease identification [16]. Semantic segmentation not only helps to categorize diseases and determine the stage of disease, but it also gives useful information for recommending appropriate treatments. Additionally, the use of weakly supervised learning approaches improves classifier performance by showing disease symptoms and infected regions, allowing for a better understanding of plant disease. Overall, semantic segmentation is a strong method for properly detecting and managing plant diseases.

Disease classification requires the use of advanced methods like Support vector Machines, Convolutional Neural Networks, and DenseNet for accurate categorization [17] [18]. These methods use image analysis and the extraction of features to recognize and categorize different diseases in plants [19]. ShuffleNetV2, for example, is used to classify plant leaf diseases while maximizing the model's accuracy through parameter setups and feature selection. Furthermore, ML and DL algorithms are utilized to diagnose diseases, demonstrating the importance of these classification methods. By using these tools, researchers can improve agricultural disease detection and treatment processes.

This research effort uses deep learning technology to recognize and categorize citrus diseases on leaves in their early stages. A discussion on segmentation and classification has been concluded after a literature review. The segmentation phase receives most of the attention. The whole focus is concentrated on the diseased region. There is also a need for developing and utilizing a broader plant segmentation approach that may be applied in both regulated and natural circumstances. Using pre-trained deep learning models, some authors have analysed the classification of citrus diseases. Following the initial step in image processing, which involved preprocessing the data set, the authors have used classification models to identify disease areas. Till now, disease borders and classes have not been accurately highlighted by the segmentation and classification models. This work proposed a novel DeepOverlay L-UNet approach for highlighting the affected region with precise boundaries based on severity and improved intersection over union. The disease classifications are recognized by VGG-RefineNet. The proposed method, DeepOverlay L-UNet, uses semantic segmentation to divide the diseased area from the leaf, and the flow is shown in Fig. 1.

The paper's layout is organized in this way: Section II contains the literature survey. Section III discusses the description of the dataset. Section IV provides a detailed explanation of the entire methodology's working process. Section V, outlines the assessment criteria for the proposed method and discusses the usefulness of this method in performing real-time testing, highlighting, and detecting. Finally, the general summary, constraints, and prospects are covered in Section VI.

II. Literature Survey

This section offers an extensive examination of various techniques for detecting plant diseases in order to understand how they work and recognize any possible limitations. As the global population surges, agriculture becomes increasingly vital for the energy needs of nations. Yet plant diseases reduce crop yields and quality, creating obstacles to agricultural progress. Accurate diagnosis of disease is essential to successful prevention and control. Disease identification has always been a manual procedure carried out by professionals that takes time. To overcome these inefficiencies, an automated system for identifying plant diseases was developed and implemented. Moreover, recent technological advancements have been employed to examine plant diseases and pests within the agricultural sector. The core of contemporary research in this domain is artificial intelligence, particularly its subset, machine learning. Furthermore, deep learning (DL) techniques have proven effective in various image processing applications, such as detecting, segmenting, recognizing, and categorizing diseases.

With the use of pre-processing and hybrid optimisation approaches, [14] creates an optimized framework using YOLOv7. YR2S (YOLO-Enhanced Rat Swarm Optimizer) incorporates Red Fox Optimization alongside ShuffleNetv2. Using ShuffleNet with ERSO for classification, the framework creates feature maps for leaf detection, and FCN-RFO is used to segment regions that are prone to illness. When applied to a tailored dataset, the model performs better than existing methods.

For diagnosing diseases and detecting damage to plant leaves, an automated method is suggested. [9] With 100% classification accuracy, the first step utilizes DenseNet to diagnose illnesses based on leaf pictures. In step two, a 1D Convolutional Neural Network (CNN) with 97% accuracy is used to identify leaf damages through semantic segmentation using deep learning. Depending on the type of disease and the extent of damage, the third stage recommends treatment. [20] A MULTINET approach was created to address the problem of 3D plant leaf disease detection and severity predictions by integrating multi-agent DRL and EfficientNet. Four processes are used in the framework: segmentation, species detection with classification by using a block divider model, Enhanced Deep Q-Network, EMMARO-based data augmentation, and numerous agents utilizing Deep Reinforcement Learning (DRL).

The method for automatically recognizing and identifying multi-biotic tomato leaf lesions is presented in study [16] and utilizes multiple CNNs. This system utilizes Hybrid-DSCNN for semantic segmentation, Mask R-CNN for segmentation, and a CNN for classification. The Hybrid-DSCNN two-layer Layer-Convolution achieved segmentation and classification accuracy of 98.25%, along with a precision of 95.7%. [13] The CAAR-UNet, an autoencoder with attention and residual connections, utilizes a cascading structure in the computer vision method created to precisely detect and diagnose diseases in plant leaves early on. Achieving an average pixel precision of 95.26%, the deep learning approach achieves good precision.

In study [21], presents the dataset of Wheat Rust Disease at NUST (NWRD), which classifies wheat rust disease (WRD) into several kinds and categories using multi-leaf pictures from wheat fields. The UNet semantic segmentation model paired with the adaptive patching with feedback approach, showed encouraging outcomes. The research in [22] work explores the segmentation of disease using the U-Net architecture. The research utilized VGG16, MobileNet-v2, AlexNet, and DenseNet201 deep learning methods on a set of 60 images containing angular leaf spot and bean rust diseases. This work found that segmented pictures had greater classification accuracy than the original ones.

The authors in study [23] suggested technique for precisely identifying and classifying agricultural diseases, such as early and late blight, to assess disease damage is the Detection Transformer for Disease Segmentation (DS-DETR). To increase convergence speed, the model utilizes the Plant Disease Classification Dataset for unsupervised pre-training. To improve model accuracy, the query box is given Gaussian-like spatial weights using Spatially Modulated Co-Attention (SMCA). Evaluating this model on the Tomato Leaf Disease Segmentation Dataset resulted in a disease grading accuracy of 0.9640.

For integrated fusarium head blight (FHB) severity identification, [8] they developed a system that fuses multiple models based on deep learning. High-throughput wheat spike photos showed 97.6% segmentation accuracy, whereas fine and complicated FHB spots showed 99.8% accuracy. The approach also improved the classification of wheat FHB grading, moving from stages of disease management to the breeding process.

Utilizing Felzenszwalb's graph-based segmentation technique with annotated citrus fruits [24], a model of the deep neural network is developed to detect the severity of the condition. The prognostic model attains a 99% accuracy rate for minor severity levels, 98% accuracy for major severity levels, 96% accuracy for good conditions, and 97% accuracy for moderate severity levels. There are four severity categories for citrus fruit illnesses, and this method is effective and valid for identifying them.

The authors in study [1] aims to differentiate and categorize canker, greening, and blackspot diseases in citrus crops by utilizing image processing and machine learning algorithms. Preparation and segmentation tasks are performed on various images from the dataset Citrus Leaves Prepared. A new CNN structure is designed to consist of four blocks and brief directions. The model can effectively differentiate between citrus black spot, bacterial canker, and huanglongbing (greening), as they are predominantly categorized by it.

The study utilizes segmented images to focus on and feeds them into deep neural networks in order to create an ensemble stacked deep learning model for automatically detecting mango-leaf diseases [25]. Combining the output of the deep neural network with an ML model is utilized for detecting leaf illness. With an accuracy rate of 98.57%, the model performs better than existing models.

With the purpose of identifying and classifying biotic stress in coffee leaves early on, this work presents the extracted feature ensemble (EFE) approach. [26] The method enhances classification performance by utilizing custom-designed features and convolutional neural networks (CNNs) based on transfer learning. The effect of dimensionality on the performance of the model is evaluated, and three approaches are suggested to analyse extracted feature sets. This work indicates that the process of feature concatenation improves the accuracy and discriminative power of classification models.

However, existing approaches have limitations such as inadequate background conditions, cost complexity, misclassifications, and overfitting [27]. The AgriDet system, composed of a fusion of Kohonen-based deep learning networks and the traditional INC-VGGN, is introduced to address this issue. By incorporating a dropout layer, a Kohonen learning layer, and a pre-trained INC-VGGN model, the system is able to effectively identify and categorize illnesses.

Research indicates that using attention-based dilated CNN logistic regression is an effective approach for identifying tomato leaf disease. In study [19] images are preprocessed with bilateral filtering and Otsu segmentation; a synthetic image is generated using the Conditional Generative Adversarial Network model, features are normalized, and a logistic regression classifier is used to categorize the images. The results of this study show that the accuracy in training, testing, and validation for identifying multiclass tomato leaf diseases is 100%, 100%, and 96.6%, respectively.

Detecting diseases in sugarcane plants using current methods is inaccurate. The study in [28] identify and classify sugarcane leaf disease with high accuracy, The deep transfer learning model presented in this work is based on quantum-behaved particle swarm optimization (QBPSO-DTL). SqueezeNet, a deep-stacked autoencoder, and optimum region-expanding segmentation are all used in the modelling process.

In [29], study is centred on developing a fusion model for detecting and classifying diseases in rice plants using Efficient Deep Learning techniques (EDLFM-RPD). This method utilises preprocessing techniques such as median filtering, K-means segmentation, a manually created Gray Level Co-occurrence Matrix (GLCM), deep features from Inception, and Swarm Optimization with a Fuzzy Support Vector Machine (FSVM) model. Tests demonstrate improved efficiency, with a top accuracy of 96.170%.

TABLE I. COMPARISON OF VARIOUS SEGMENTATION TECHNIQUES WITH THE DEEPOVERLAY L-UNET

Application	Dataset	Number of images	Methods	Performance	Author
Disease classification	A new plant disease dataset	18345	Optimized ShuffleNet v2	Average Accuracy: 99.69%	[14]
Damage detection on leaves	Plant village dataset (four diseases)	8,875	1D-CNN	Average accuracy of 97%	[9]
Segmentation and detection of plant disease	The Tomato Leaf Disease Dataset (TLDD)	1004	Hybrid-DSCNN	Accuracy: 98.24%, IoU: 92.91%, Precision: 92.83%, Recall: 94.36%	[15]
Citrus disease detection and classification	citrus dataset	598	Modified CNN	Average Accuracy: 95%.	[1]
Segmentation and detection	The Tomato Leaf Disease Dataset (TLDD)	1680	Hybrid-DSCNN (2Layer-USN)	IoU: 92.8%, mIoU: 94.24%, accuracy: 98.25%.	[16]
Earlier disease detection.	Mango leaf diseases	2000	Ensemble Stack neural network.	Accuracy 98.57%	[25]
Precise detection of diseases in plant leaves.	The Plant Village Dataset and the Coffee Leaf Dataset.	400	Cascade Autoencoder incorporating Attention Residual U-Net	Pixel accuracy mean: 95.26%, IoU: 0.7451.	[13]
Early disease detection	NUST Wheat Rust Disease Dataset	100	Octave-UNet	IoU of 0.316, F1 score of 0.529.	[21]
Disease Segmentation and Classification	Dry bean leaves	120	U-Net and DenseNet201	IoU: 0.7725, F1-score: 0.9459%.	[22]
Plant disease detection and categorization.	coffee leaves	4000	modified VGG16	test accuracy: 97.9%.	[30]
Diagnosing the disease Severity.	Fusarium Head Blight on Wheat.	3875	Mobilev3 and Deeplabv3+	MIoU: 83.61, accuracy: 98.54%. overall accuracy rate of 86.9%.	[8]
Disease severity classification	Plantdoc and Plant Village datasets	2,598	INC-VGGN	Training accuracy: 98.9%, and validation accuracy: 96.00%.	[27]
Detection and severity analysis of disease	Grape dataset	500	DeepLabV3+ is based on ResNet50.	overall accuracy: 97.75%	[11]
Leaf disease detection.	Tomato leaf from the Plant Village dataset	18,161	Modified UNet	Test accuracy: 98.66%, IoU of 98.5%, dice: 98.73%. (**Separate leaf and background)**	[31]
Highlighting the affected disease region with a severity percentage.	Citrus plant dataset	±5000	DeepOverlay L-UNet, and VGG-RefineNet	Train IOU of **0.9864**, validation IOU of **0.9334**, overall classification accuracy of **98%.**	**Proposed**

Various methods are proposed for citrus leaf segmentation and classification in the literature. Table I summarizes the efforts made to identify diseases in several plant species using these methods. Even though the methods proposed in the literature perform well in segmentation and classification, they fail in severity-based classification and highlighting the region of interest, which plays a major role in early and accurate disease detection. The proposed method is chosen since the model balances global context encoding and local detail refinement for accurate segmentation boundaries, which is the major contribution of this work.

III. Dataset Description

This study utilizes Citrus Leaves Setup, a citrus dataset available for open access. There are four categories in the collection: citrus black spot, citrus canker, and greening, which are the most common citrus diseases, along with pictures of healthy leaves. The dataset from study [32] contains images with a resolution of 256x256. The dataset has a smaller number of images as well as reduced quality, with an unbalanced distribution of data classes across different data.

This study focuses on enhancing disease detection accuracy in plant pathology by improving citrus leaf image quality and stability through preprocessing and augmentation techniques. The initial stage of preprocessing is essential, as it transforms simple images into a format that is easier to analyse. This is achieved by making several improvements: increasing contrast by 10% to highlight features, boosting brightness by 60% to counteract possible underexposure, and tripling sharpness to bring out intricate details [25]. These enhancements are essential to ensuring that upcoming machine learning models can recognize and absorb the fundamental aspects of the data.

Augmentation techniques artificially expand the dataset by approximately five thousand images, leading to a wider and more inclusive collection of images for training the model. This study involves examining both axes, rotating at angles of 0 and 90 degrees, and utilizing scaling factors of 0.5 and 1. These changes mimic the various positions, inclinations, and dimensions that leaves can exhibit in their natural surroundings, enabling the models to handle the diversity found in real-world situations. Additionally, employing the HSV colour scheme for image masking could help separate unhealthy areas. [10], [33] Establishing specific thresholds enables various masks to effectively separate colour data and reveal distinct areas of interest, which are then extracted and evaluated for disease identification.

The last step in preprocessing and augmentation involves placing masks on top of the original images. The use of a partially transparent layer allows for a direct visual comparison between healthy and diseased regions, leading to a better understanding of the impact of the disease, and this overlaid data is highly effective in segmentation. This overlay serves as both a helpful aid for visual examination and a useful tool for displaying data in a user-friendly way. Fig. 2, Fig. 3, and Fig. 4 included in this study show the detailed process of preparing citrus leaf images for effective disease identification, highlighting the crucial role of thorough preprocessing in image analysis for detecting plant diseases. A detailed breakdown of the number of images in a given class within this dataset, as well as its numbers after augmentation, is presented in Table II. The data specifically prepared for segmentation is displayed in Table III.

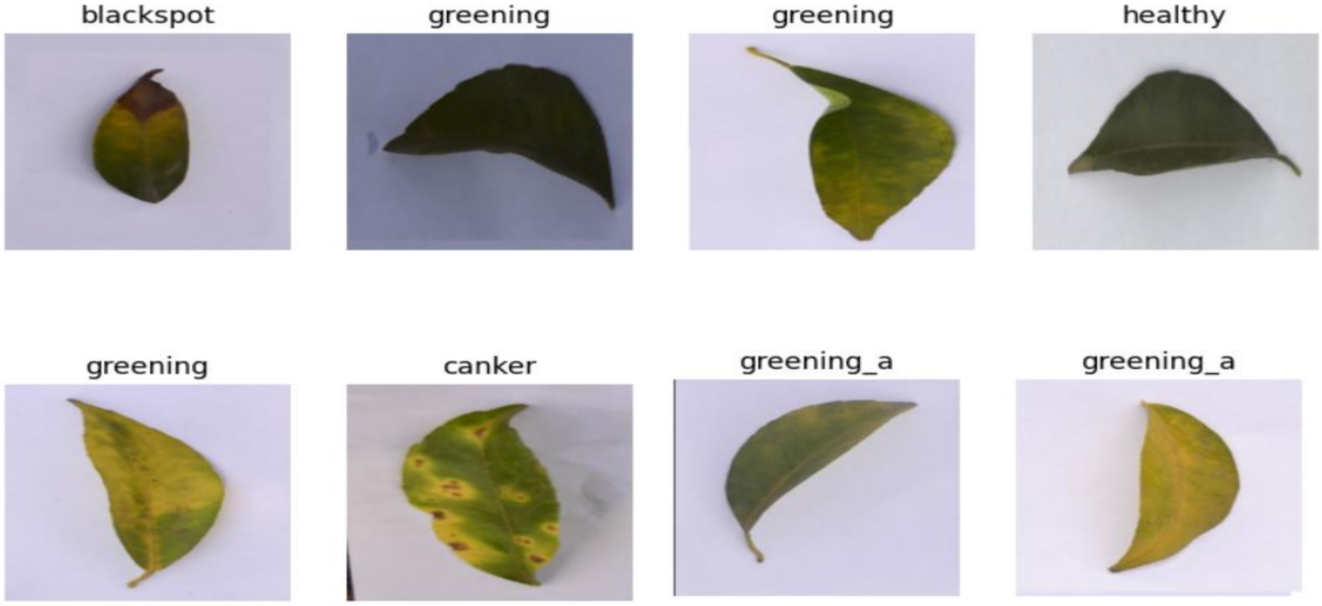

Fig. 2. Representative images extracted from the dataset.

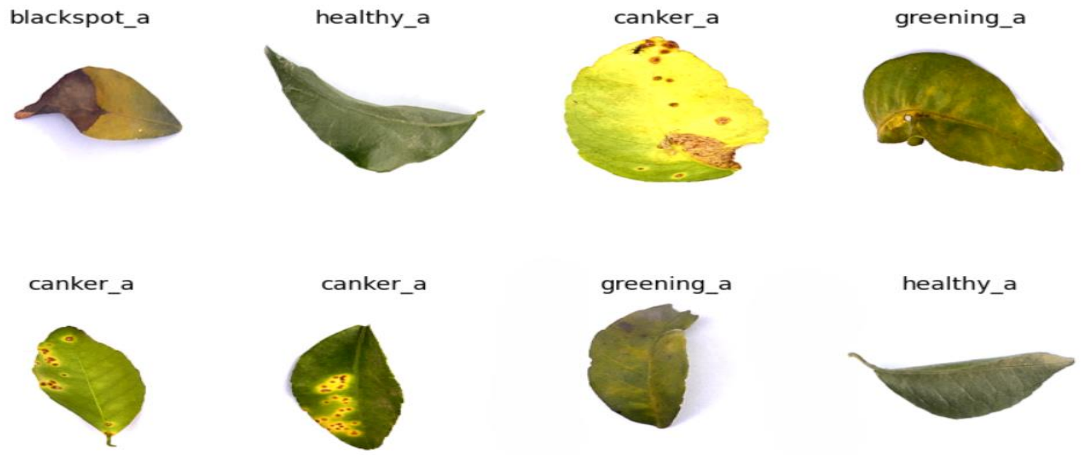

Fig. 3. Representative images from dataset after preprocessing and augmentation for classification.

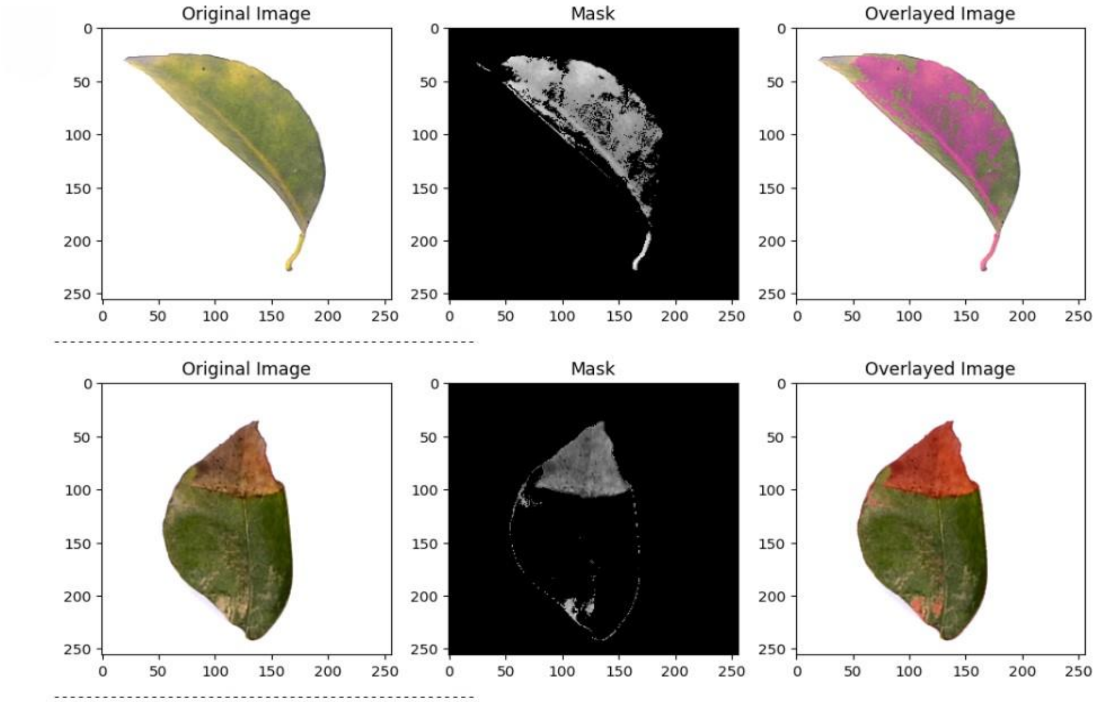

Fig. 4. Sample input of original image, masked images, and overlayed images for segmentation.

TABLE II. TRAIN, TEST AND A VALIDATION SET OF ORIGINAL AND AUGMENTED DATASETS FOR CLASSIFICATION

	Training		Testing		Validation		Total sample	
	original	*augmented*	*original*	*augmented*	*original*	*augmented*	*original*	*augmented*
Blackspot	122	852	15	106	15	106	152	1064
Canker	121	845	15	106	15	106	151	1057
Greening	171	1192	21	149	21	149	213	1491
Healthy	46	326	6	40	6	40	58	406

TABLE III. TRAIN SET, TEST SET OF OVERLAYED AND MASKED IMAGES FOR SEGMENTATION

	Overlayed image	Masked image	Total sample
Train set	460	460	920
Test set	114	114	228
Total	**574**	**574**	**1148**

IV. Methodology

In this work, a DeepOverlay L-UNet architecture was used in the proposed method. The output of the method was then fed into the VGG-RefineNet deep learning architecture to detect and categorize plant diseases based on the severity percentage of the citrus-diseased plants. Initially, preprocessing involves resizing, enhancing, improving contrast, and augmenting images to avoid inconsistencies in the dataset. The HSV threshold-based colour scheme is used to separate diseased areas in image masking to address complex, multiple background challenges. This research provides distinct information about colour related to specific diseases. Following that, place the masks on top of the original image. In the first phase, masked images and overlayed images are fed as input for semantic segmentation. The semantic segmentation method DeepOverlay Leaky Relu-based deep learning is used to extract and learn features from diseased areas of the citrus leaf region. The affected area of the diseased citrus leaf is predicted using a combination of DeepOverlay L-UNet characteristics. In the second phase, disease classes are identified through classification using VGG-RefineNet. The model surpasses current methods in segmentation, detection, and classification, showing improved validation and accuracy. Finally, in the third phase, the severity of the disease on the citrus leaf is assessed by the Highlighting Disease Area with the Affected Percentage (HDAP) method, which calculates the percentage of the affected area by identifying the disease boundary and using the DeepOverlay L-UNet to segment and overlay the affected area on the leaf. Researchers calculate the total affected percentage on the citrus leaf by measuring both the entire leaf area and the area covered by the disease.

The detection and classification of diseases are crucial in the field of agriculture. This detection method using images helps make it easier to protect crops from disease compared to sensor-based solutions. Proposing an improved application is crucial to helping farmers. Citrus farmers have the ability to recognize suspicious images of their crops and gather essential data, such as the severity percentage of the disease. Here researcher emphasizes the use of a neural network approach, utilizing DeepOverlay L - UNet and VGG - RefineNet deep neural networks to accurately identify the affected region on the leaves. This allows for the trustworthy recognition and detection of citrus plant diseases. This technique involves three separate steps: segmentation, highlighting the disease-affected area, and categorizing with a deep neural network. Fig. 10 provides an overall overview of the proposed work. The disease identification method consists of three stages: a proposed (DeepOverlay L-UNet) enhanced base network for segmentation, an improved (VGG-RefineNet) network for classification, and the introduction of the Highlighting Disease Area with Affected Percentage (HDAP) method. The following paragraphs will outline each of these phases:

A. *DeepOverlay L-UNet for Segmentation*

Once the masked image and overlay images have been preprocessed, they are used as input for the training process. The DeepOverlay L-UNet is an advanced neural network created specifically for image segmentation. The process starts with selecting an input image. The network's design is built on the U-Net model, featuring both an encoder to capture image context and a decoder for accurate localization. Within the encoder part, convolutional layers are used along with batch normalization and Leaky ReLU activation functions with an alpha value of 0.1. This particular activation function is selected for its capacity to enable low gradients when the unit is not active, thereby addressing the vanishing gradient issue often associated with conventional ReLU functions. The decoder segment uses transposed convolutions to enlarge the feature maps, which are then joined with the encoder feature maps that correspond. This stage is essential for the network to accurately pinpoint and outline the edges of the objects in the image. The output layer contains a convolutional process combined with a sigmoid activation function, producing a probability map that displays the segmented sections of the image.

Custom metrics like IoU, mean IoU, weighted mean IoU, pixel accuracy, mean pixel accuracy, mean boundary F1 score, and dice coefficient are utilized to assess the network's performance. These measurements offer a thorough evaluation of the quality of segmentation. The training procedure includes building the model with an Adam optimizer and a binary cross-entropy loss function. The model is trained for 150 epochs with a batch size of 2, showing a thorough optimization process to enhance segmentation skills.

Finally, the network includes a visualization component where the predicted segmentation masks can be overlaid on the original images. This visual inspection is essential for verifying the model’s predictions and ensuring the segmentation’s accuracy. In essence, the DeepOverlay L-UNet with its Leaky ReLU-enhanced encoder and comprehensive metrics, offers a robust solution for image segmentation tasks, ensuring detailed and accurate delineation of image features. The model architecture is explained below:

The DeepOverlay L-UNet architecture is designed for semantic segmentation tasks, where the goal is to categorize every pixel in an image into various classes, such as separating foreground from background.

1) Encoder: The model's encoder part includes convolutional layers and pooling layers. It transforms the input image into a compact, meaningful representation known as the latent space. Convolutional layers derive hierarchical features from the input data, while pooling layers decrease the spatial dimensions of the feature maps. The model includes two encoder blocks, each composed of a convolutional layer, batch normalization, and max pooling.

- The first encoder block takes an input tensor with the shape (128 x 128 x 3) and uses 32 filters, producing output tensors x1 and p1.
- The second encoder block takes the output tensor p1 from the first block as its input and uses 64 filters, resulting in output tensors x2 and p2. The number of filters increases with each subsequent encoder block to capture more complex features.

a) Convolutional layer: The fundamental component of CNNs is the convolutional layer. It applies kernels (filters) to the input data and extracts local features. This layer uses filters to capture specific characteristics from the input data by moving the filter across the input and conducting element-wise multiplications. Convolutional layers learn spatial hierarchies of features, capturing patterns like edges, textures, and shapes.

b) *Batch normalization:* Batch normalization (BN) stabilizes training by normalizing the activations of each layer, addressing issues like vanishing or exploding gradients. BN normalizes the mean and variance of activations within a mini-batch. It introduces learnable parameters (gamma and beta) to scale and shift the normalized values. It improves convergence speed, generalization, and robustness.

c) *Activation function:* An activation function, such as ReLU, brings non-linear elements to the model, enabling it to learn complex patterns.

d) *Max pooling:* Pooling layers decrease spatial dimensions while maintaining essential features. Max pooling selects the maximum value within a region (e.g., 2x2) of the feature map. Pooling layers downsample the feature maps, reducing the computation and preventing overfitting. It summarizes features, enhancing the model's robustness to changes in position.

2) *Leaky ReLU activation:* Leaky ReLU activation is applied to both x1 and x2. Negative values in x1 and x2 are scaled by the alpha value (usually set to a small positive number). Positive values remain unchanged. Leaky ReLU is applied after each encoder block to allow a small gradient when the input is negative, preventing vanishing gradients and helping in learning complex features.

3) *Bottleneck block:* A bottleneck block with 128 filters follows the encoder blocks, capturing high-level features and compressing them into a compact representation.

4) *Decoder:* The decoder reconstructs the original input from the latent representation using transposed convolutional layers to increase spatial dimensions. The decoder's output aims to match the original input (e.g., a reconstructed image). Two decoder blocks are specified, each consisting of a transposed convolutional layer for the upsample, concatenated with the relevant encoder output, and an additional convolutional layer.

- The first decoder block takes an input tensor b (bottleneck output), concatenated with the corresponding encoder output x2 and uses 64 filters.
- The second decoder block takes the output from the first decoder block as its input, resulting in output tensors x1 and 32 filters. Each decoder block includes a transposed convolutional layer, concatenation, and another convolutional layer. The decoder blocks progressively refine the features and recover spatial information lost during downsampling in the encoder.

a) *Transposed convolutional layer (Deconvolution):* Transposed convolutional layers (also known as deconvolutional layers) perform upsampling. It increases spatial dimensions, allowing the network to generate higher-resolution outputs. Transposed convolutions apply filters in reverse; they project a smaller feature map onto a larger one. These are commonly used in image generation tasks (e.g., GANs) and semantic segmentation.

b) *Concatenation with skip connection:* The decoder block concatenates the upsampled feature maps with the corresponding feature maps from the encoder (skip connection). Utilize skip connections (also known as residual connections) for transmitting information between layers. This aids in spreading intricate details. By integrating both low-level and high-level characteristics, the model is able to improve the localization of objects and boundaries. In U-Net architectures, the encoder's feature maps are combined with the decoder's feature maps to enhance segmentation outcomes.

An additional convolutional layer: The combined feature maps undergo further enhancement with an additional convolutional layer.

5) *Output layer:* The final output, showing the likelihood of each pixel being part of the foreground, is generated by a 1x1 convolutional layer with a sigmoid activation function, with an output shape of 128 x 128 x 1.

6) *Model training and evaluation:* The model is built using binary cross-entropy loss and Adam optimizers with multiple evaluation metrics. During training, the model learns to minimize the loss function by adjusting its weights. The evaluation metrics (IoU, accuracy, etc.) assess the model's performance on validation data.

Prediction and Visualization: Predictions are made on training and validation data. Overlay images are created by combining the original image and the predicted mask. The overlay helps visualize the segmentation results, which helps highlight the affected area. The segmented output of different citrus diseases is shown in Fig. 5, and the architecture diagram of DeepOverlay L-UNet is shown in Fig. 6.

In this method leaky Relu is introduced to gain more features in the citrus image and overlay the segmented output to original image, this will visualize affected area. These differentiates the proposed method from the U-Net. By using the DeepOverlay L-UNet Severity region exactly extracted compared to other methods.

Algorithm: Disease Region Detection using DeepOverlay L-UNet

```
Input: Training overlayed images (X_train), corresponding ground truth masks (Y_train), and validation images (X_val).
Output: Predicted masks for leaf disease regions.
Step 1: Load the training images and ground truth masks.
Step 2: Define the L-UNet model architecture:
    • Input layer to accept images of shape (128, 128, 3).
    • Encoder blocks to capture features at different scales. After each convolutional block within the encoder, apply LeakyReLU activation.
    • Bottleneck block with convolutions but no pooling. Apply LeakyReLU activation after the bottleneck to maintain gradient flow.
    • Decoder blocks to upsample and restore the original image
    dimensions. After each convolutional block within the decoder, apply LeakyReLU activation.
  • Output layer utilizes the sigmoid activation function for prediction of the segmentation mask.
Step 3: Compile the model with Adam optimizer, binary_crossentropy loss, and custom metrics (e.g., IoU, F1-score).
Step 4: Train the model on the training data with a validation split for monitoring performance.
Step 5: Predict masks on the validation set (X_val) using the trained model.
Step 6: Apply a threshold to convert the model's predictions to binary masks.
Step 7: Overlay the predicted masks on the original validation images to visualize the results.
Step 8: Calculate the affected area (number of pixels) based on the overlay mask.
Step 9: Repeat steps 5 - 8 for a random validation sample.
Step 10: Display the original image, masked ground truth, predicted mask, and overlay.
End Algorithm
```

B. VGG - RefineNet Network for Classification

Following preprocessing, the dataset images are given as input to the training stage. The base model starts by using transfer learning to understand the characteristics. Transfer learning begins by utilizing a pre-existing base model. The training of these models was done using extensive datasets, such as ImageNet, and have acquired the ability to identify basic characteristics such as edges, textures, and shapes. The convolutional layers of the basic model function as feature extractors. They acquire the ability to identify basic characteristics in images. Utilizing a pre-trained base model allows you to leverage its acquired features without starting the training process from the beginning. The model's custom layer merges the feature extraction abilities of the base model with custom layers that understand specific patterns related to the task. The VGG RefineNet model was modified by incorporating custom layers (flatten, dense, batch normalization, dropout) to suit researcher dataset. With the VGG-RefineNet model, the characteristics of citrus plant diseases are being learned more precisely. The final classification probabilities are provided by the output layer.

The disease samples are subsequently processed by the VGG – RefineNet following modification of the current model. This recently created neural network is utilized for classifying the citrus diseases. The newly created neural network consists of the input layer, convolution layer, pooling layer, flatten layer, dense layer, batch normalization layer, dropout layer, and output layer. In this neural network, a deeper understanding is gained on the disease detection process to capture all essential features related to each disease category. Better precision is achieved in learning the texture, shape, size, colour, and other characteristics which avoids misclassification. The roles of the various layers are outlined below: Every layer in the neural network carries out a distinctive role.

1) The base layer (VGG16): The VGG16 base model is made up of 13 convolutional layers which are responsible for extracting features from the input image. Filters are applied in each convolutional layer to learn specific patterns in the local area. VGG-16 employs compact convolutional filters (3x3 in size). A ReLU activation function follows every convolutional layer. Proceeded by five layers of max pooling. Max pooling decreases spatial dimensions by downsampling the feature maps. It aids in preserving critical characteristics while decreasing the amount of computation needed. In implementation, VGG-16 utilizes max pooling with a stride-2 and a window size of 2x2.

a) Layers that are being frozen: Freezing the last four layers stops their weights from being modified in the training process. This is crucial for transfer learning, as it enables the model to keep the knowledge gained from ImageNet while adjusting the top layers for your particular task.

2) Flatten Layer: The Flatten layer converts the results from the convolutional layers into a single-dimensional array. Following the extraction of features by the base model, the flattened representation is used as input for the following fully connected layers (dense layers). When the convolutional layers output shape is (batch_size, h

3) eight, width, channels), the shape of the flattened output becomes (batch_size, height x width x channels).

4) Dense layers: After the flattened representation, researchers added two dense layers: The initial dense layer consisted of 1024 units and used ReLU activation. It grasps features at a high level. The following layer, with n_classes units (4 in this case), is the second dense layer and has softmax activation. It generates probabilities for different classes.

First dense layer:

$$Output = ReLU\ (Input\ \cdot Weights\ + Bias) \tag{1}$$

Second dense layer (output layer):

$$Output = Softmax\ (Input\ \cdot Weights\ + Bias) \tag{2}$$

5) Batch normalization layer: Batch normalization normalizes the outputs of the preceding layer, reducing internal covariate shifts during training. It scales and shifts the normalized activations using learned parameters to stabilizes training, improve convergence, and accelerate learning.

$$Output = \frac{\text{Input} - \mu}{\sigma} . \gamma + \beta \tag{3}$$

$\mu -$ mean.

$\sigma -$ standard deviation.

$\gamma -$ scaling factor.

$\beta -$ shift factor.

6) Dropout layer: Dropout prevents overfitting by randomly turning off neurons while training. During each training iteration, a fraction of neurons (specified by the dropout rate 0.5) is randomly dropped out. The mask randomly sets some values to zero.

$$Output = Input \cdot Mask \qquad (4)$$

The general structure involves extracting features from the primary model and incorporating specialized layers designed for the plant disease categorization assignment.

C. Highlighting Disease Area with Affected Percentage (HDAP)

HDAP is the process that carried out throughout the work because it needs to get the original leaf area and predicted mask area it means disease disease-affected area to highlight the affected area with the severity percentage. It is helpful to avoid the cause of disease affected by the minimal usage of pesticides, fertilizers, and climate change. In this work researcher used DeepOverlay L-UNet and VGG-RefineNet to extract the details of the disease region, disease class to highlight the disease region, class on the original image to visualize for the farmer.

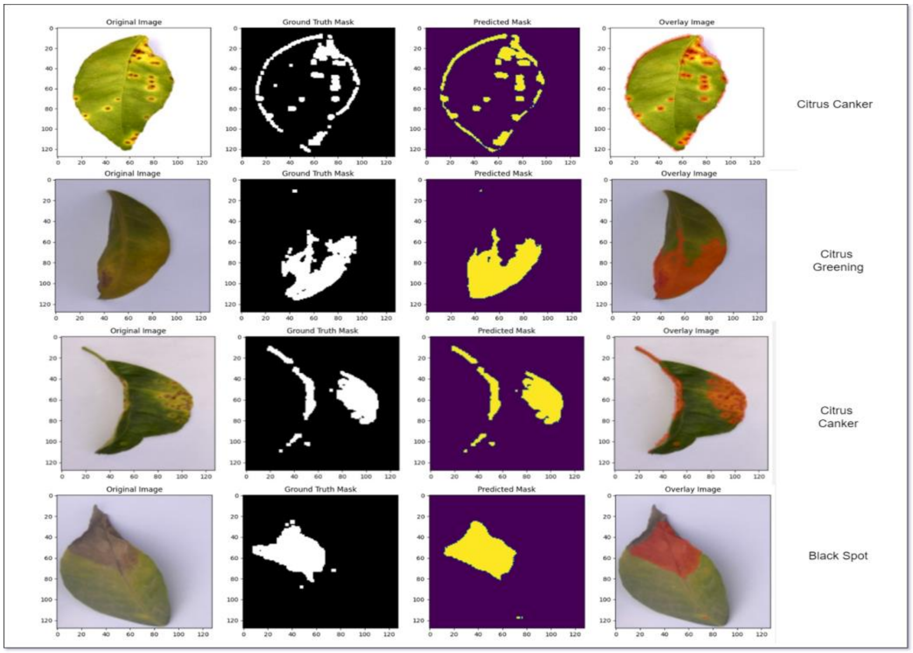

Fig. 5. Segmented output of different citrus diseases.

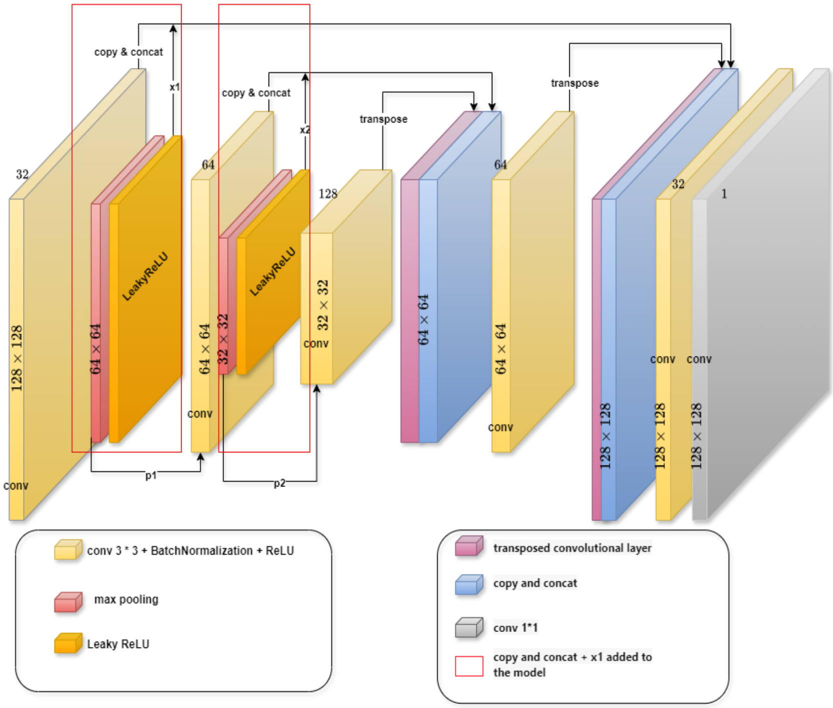

Fig. 6. Architecture diagram of DeepOverlay L-UNet.

The Highlighting Disease Area with Affected Percentage (HDAP) is a methodical process used to identify and quantify disease-affected areas in images, such as leaves in citrus plant disease detection. Before highlighting the disease area in citrus leaves researcher identified the area of the entire leaf by using contour function and it acquire coordinates of the leaf boundary pixels, then draw contour iterates over the list of contour points and draws lines between these points on the original image till it formed a loop. The region enclosed by the contour, which gives the area of the polygon defined by the contour points is used to get the area of the disease part in leaf. Using the trained segmentation model (Deepoverlay L-UNet) to predict the disease mask then Overlay the predicted mask on the original image. After overlaying the mask, identify and highlighting the contours of the disease-affected regions using contour function. Calculating the pixel area of the overlay image to get the area of the diseased part in citrus leaf. The HDAP is process computed the ratio of the area that is affected to the total area of the leaf, expressed as a percentage. This HDAP method provides important information about the existence and severity of disease within a leaf. These are explained in below steps:

1) *Original image and contour extraction:*

- Begin with an original image, such as a citrus leaf.
- Convert the original RGB image to grayscale. Grayscale simplifies edge detection, which is essential for contour extraction.
- Apply thresholding using Otsu's method to create a binary image. This step separates the foreground (citrus leaf regions) from the background. Pixels above the threshold become white, while others remain black.
- Detect contours within the binary image using cv2.findContours(). These contours represent the boundaries of the disease-affected areas.
- Draw these contours on the original image to visualize the leaf areas. The cv2.drawContours() function overlays the contours, providing a clear outline of the affected regions.

2) *Leaf area calculation:*

- Use cv2.contourArea() to calculate the area of each contour. This function applies Green's theorem to compute the area enclosed by the contour points.
- Sum up the areas of all detected contours to determine the total leaf area affected by the disease (in pixels).

3) *Predicted mask, overlay and classify:*

- Employ a trained segmentation model to predict the disease mask (segmentation mask) for the given image.
- Threshold the predicted mask to obtain a binary image.
- Overlay the predicted mask on the original image using a contrasting color (e.g., red) to highlight the affected regions.

4) *Diseased area calculation:*

- Calculate the pixel area of the overlay image by count number of non-zero pixels (white pixels) in the binary mask using NumPy functions. This provides the pixel area of the affected regions.

5) *HDAP calculation:*

- Calculating the HDAP by expressing the affected area as a percentage of the total leaf area.
- The HDAP ratio helps quantify the disease's extent, aiding in diagnosis, treatment planning, and monitoring.

The HDAP process is versatile and applicable beyond leaf disease detection, serving as a valuable tool in various fields requiring detailed image analysis and segmentation. Whether in agriculture imaging, HDAP provides insights into the presence and severity of disease, facilitating informed decisions and interventions.

D. Evaluation Metrics

1) *Precision:* It calculates the proportion of accurately predicted positive observations out of all predicted positives. A low false positive rate is associated with high precision.

$$\text{Pecision} = \frac{\text{True Positives}}{\text{Predicted Positives} + \epsilon} \tag{5}$$

2) *Recall:* It is also referred to as sensitivity and calculates the ratio of accurately predicted positive observations to all true positives. A low false negative rate is associated with high recall.

$$\text{Recall} = \frac{\text{True Positives}}{\text{Possible Positives} + \epsilon} \tag{6}$$

3) *F1 score:* It is determined by averaging precision and recall, calculated using the harmonic mean. Balancing precision and recall are helpful when needed.

$$\text{F1 Score} = 2 \times \frac{\text{Precision} \times \text{Recall}}{\text{Precision} + \text{Recall} + \epsilon} \tag{7}$$

4) *Specificity:* Measures the percentage of correct predictions for negative outcomes compared to the total number of actual negative outcomes. It represents the frequency of accurate negatives.

$$\text{Specificity} = \frac{\text{True Negative}}{\text{Possible Negative} + \epsilon} \tag{8}$$

5) *Accuracy:* It is a popular metric for assessing a model's performance on a specific dataset, it is determined by the ratio of accurately classified samples to the overall sample size.

$$\text{Accuracy} = \frac{\text{Number of Correct Predictions}}{\text{Total Number of Predictions}} \tag{9}$$

6) *Intersection over union (IoU):* IoU is a commonly used measurement in segmentation challenges for evaluating the overlap between predicted and actual segmentation. It measures the proportion of the overlapping region compared to the total area.

$$\text{IoU} = \frac{\text{Intersection}}{\text{Union} + \epsilon} \quad (10)$$

7) Mean IoU: The average IoU score across all samples. It provides an overall performance measure for segmentation tasks.

$$Mean\ IoU = \frac{1}{N}\sum_{i=1}^{N} \frac{\text{Intersection}_i}{\text{Union}_i + \epsilon} \quad (11)$$

8) Weighted mean IoU: Similar to average Intersection over Union, this metric assigns more weights to classes with larger pixel counts. This is useful when class imbalance is present.

$$Weighted\ Mean\ IoU = \frac{\sum_{i=1}^{N} \text{IoU}_i \times \text{Weights}_i}{\sum_{i=1}^{N} \text{Weights}_i} \quad (12)$$

9) Pixel accuracy: Calculates the proportion of pixels classified correctly. It is an easy method to evaluate the overall accuracy of a segmentation model.

$$\text{Pixel Accuracy} = \frac{\text{Correct Pixels}}{\text{Total Pixels}} \quad (13)$$

10)Dice coefficient: Like IoU, calculates the intersection between two samples. The total number of pixels in both images divided by two is equal to the area of overlap. The Dice Coefficient incorporates a smoothing parameter to avoid dividing by zero. It evaluates the intersection of two samples and is especially beneficial for tasks involving binary segmentation.

$$\text{Dice Coefficient} = \frac{2 \times \text{Intersection} + \text{smooth}}{\text{Sum of True} + \text{Sum of Pred} + \text{smooth}} \quad (14)$$

Intersection is the overlap between the actual labels and the predicted labels. Sum of True is the overall count of true labels. Pred sum is the overall count of predicted labels. A tiny constant, smooth, is added to avoid division by zero and to enhance the metric for improved stability and performance.

V. RESULTS AND DISCUSSION

The research consists of three sections. The initial phase involved extracting disease from masked images of the afflicted, which were segmented using DeepOverlay L - UNet. This deep learning approach helped in identifying the disease. In the latter section, the segmented layered images were categorized using the VGG – RefineNet Deep learning technique. In the third section, the disease area that was extracted was shown independently and the affected area of the disease was measured compared to the total leaf area using the HDAP method. After that, the segmentation and classification performance metrics were acquired and assessed. Fig. 10 illustrates the complete process of segmenting, classifying, and performing HDAP on citrus diseases in the study.

DeepOverlay L–UNet was utilized to segment the disease affected areas in the segmentation section. In this model proposal, the data consists of pre-processed data from the original images, masked images, and overlayed masks on original images. Following this step, the data is divided into sets for training and testing purposes. Next, the DeepOverlay L-UNet is put together and acquires a deeper understanding through the use of training data.

After finishing the training, the original images are displayed by overlaying the real values, predictions, and projections on top of them. Ultimately, the trained model's performance was assessed. The following are the listed steps for the proposed method of the DeepOverlay L-UNet architecture.1) Uploaded the pre-processed data, 2) generated plots showing the images alongside the mask and overlay images, 3) divided data into training and validation sets, 4) Compiled and trained the model, then displayed the original image, ground truth, predicted image, and overlay of predicted on original image, 5) Assessed the model using precision, recall, accuracy, IoU, Dice-Coefficient, and other metrics.

By utilizing Overlayed masked images as inputs and applying Leaky ReLU activation after each encoder block, this model gains finer details to improve performance in IoU, Pixel Accuracy, and Dice-Coefficient metrics. 80% of the dataset is allocated for training, while 20% is reserved for testing and segmented using DeepOverlay L-UNet. To explore the effectiveness of the DeepOverlay L-UNet architecture, the model's performance was assessed with 25, 50, 75, 100, 125 and 150 epochs to determine its impact on enhancing performance. Fig. 11, Fig. 12, Fig. 13, Fig. 14, Fig. 15 and Table V display the precision, recall, specificity, f1 score, accuracy, loss, IoU, Mean IoU, Pixel Accuracy, and Dice-coefficient graphs, values obtained from the experimental results. Examples of predicted diseased images using the proposed model can be seen in images Table IV.

During the classification phase, the segmented overlaid image is categorized into a particular disease class. In our modern society, technology plays a crucial role in our daily lives. In this research, pre-trained models were selected based on their top classification accuracy. Moreover, these models were chosen to examine the impact of varying depths and parameter counts on the accuracy of classifying segmented images. Once these images have been pre-processed, they are then transferred to the training phase. After the images are pre-processed, they are then fed as an input to the training phase. Utilizing a pre-existing base model in VGG-RefineNet allows for leveraging the advantages of learned features without the need to start training from the beginning. The custom layers in the VGG-RefineNet model, such as flatten, dense, batch normalization, and dropout, enhance the base model's feature extraction abilities to learn specific patterns for tasks like disease classification. Fig. 16 provides detailed values for recall, precision and F1-score. It is evident that the proposed classification method gives better precision for black spot and greening, while the recall is better for canker and healthy. Additionally, the F1-score improves across all diseases. Furthermore, Fig. 17 illustrates the confusion matrix for the proposed CNN model. It is observed that there are four misclassifications on black spot and five misclassifications in greening, while there is no misclassification on canker and healthy.

The percentage of severity on the citrus leaf is determined by highlighting and measuring the disease affected area. This HDAP method starts with the original leaf image, applies Otsu's method to separate the leaf region from the background, then obtains the contour and overlays it onto the leaf region. Determine the leaf region's area by measuring the contour's area. Next, utilize the segmentation model to forecast the disease mask and superimpose it onto the initial image with a different colour. Subsequently, identify the contour, sketch the outline for the affected part, and determine the area of the affected part by analysing the overlaid area, which includes the count of non-zero pixels representing the diseased portion. Following that, determine the percentage of citrus disease affected by comparing the disease area to the total area of citrus leaves. In conclusion, the output image displayed the classified result and the percentage of citrus disease affected, as seen in Table IV. Next, the citrus leaf image samples processed using the HDAP algorithm are displayed in Fig. 7 and Fig. 8, while the entire process is illustrated in Fig. 9.

By utilizing the segmentation model as proposed, the training model achieved a success rate with an IOU of 0.9847, mean IOU of 0.9846, weighted mean IOU of 0.9874, pixel accuracy of 0.9993, mean pixel accuracy of 0.9993, dice coefficient of 0.9936, mean boundary f1 score of 0.9557, precision of 0.9974, recall of 0.9975, f1 score of 0.9974, specificity of 0.9996, loss of 0.0079, and accuracy of 0.9993. The Validation model achieved success with the following metrics: intersection over union (IOU) of 0.9334, mean IOU of 0.9334, weighted mean IOU of 0.9517, pixel accuracy of 0.993, mean pixel accuracy of 0.9931, dice coefficient of 0.9744, mean boundary F1 score of 0.9504, precision of 0.9778, recall of 0.9769, F1 score of 0.9773, specificity of 0.9959, loss of 0.0282, and accuracy of 0.9931.

VI. Conclusion

This research introduces a new deep learning model using convolution, leaky relu, and transfer learning to detect, segment, highlight, and classify citrus canker, blackspot, and citrus greening diseases found on citrus leaves, a topic not covered in existing literature. The method being suggested involves four different stages. Initially, the unhealthy region is determined using HSV preprocessing, and the mask is applied to the original image. Following this, standard image preprocessing techniques are performed to improve contrast, brightness, scale, and rotation. In the next phase, DeepOverlay L-UNet is used to extract additional features from the citrus image by enabling slight gradients in the negative inputs with the introduction of Leaky Relu on the perimeter of each convolution block in the encoder block. This aids in acquiring complex features for a more precise and accurate segmentation of disease areas. During the third phase, feature extraction and classification are carried out using transfer learning techniques. The proposed VGG-RefineNet design shortens training time by leveraging a pre-trained base model to extract features without starting training from scratch. During stage four, the HDAP method calculates the affected disease area by obtaining the leaf area through contour functions and determining the area of the affected region by counting the number of pixels in the overlay image that is not zero. Next, once these values are identified, the next step is to calculate the ratio of the impacted area to the entire leaf area, representing it as a percentage. The limitation of the proposed work is after the segmentation process the larger area of the region of interest is considered for classification purpose, further it can be extended for the smaller regions.

Based on the IOU measures, the proposed method outperforms the existing segmentation algorithm to extract the affected regions. Further, the classification model achieved a maximum success rate for blackspot, citrus canker, citrus greening, and healthy class in the citrus leaves dataset, with a 98% success rate for overall citrus plant disease.

***Abstract*—Although delivery transport activities aim to ensure excellent customer service, risks such as accidents, property damage, and additional costs occur frequently, necessitating risk control and prevention as critical components of transport supply chain quality. This article analyzes the risk of accidents, a fundamental root cause of critical situations that can have significant economic impacts on transport companies and potentially lead to customer loss if recurring. The case study develops a fuzzy Bayesian approach to anticipate accident risks through predictive analysis by combining Bayesian networks and fuzzy logic. Results reveal a strong correlation between fatal injuries in accidents and factors related to driver and vehicle conditions. The predictive model for accident occurrence is validated through three axioms, offering insights for carriers, transport companies, and governments to minimize accidents, injuries, and costs. Moreover, the developed model provides a foundation for various predictive applications in freight transport and other research fields aiming to identify parameters impacting accident occurrence.**

Keywords—Road traffic injuries; risk management; predictive analysis; Bayesian network; fuzzy logic; accident

I. Introduction

Road traffic injuries (RTIs) are a major cause of death, claiming nearly 1.3 million lives each year. About 90% of these fatalities occur in low- and middle-income countries [source: World Health Organization. Global status report on road safety 2018. WHO, 2018]. The African region had the highest road traffic death rate 26.6 per 100,000 population, while the European region had the lowest 9.3 per 100,000 population [1]. The South-East Asia Region, motorized two- and three-wheelers contribute to a significant 44% of all road traffic deaths [2].

Predicting accidents is inherently complex due to the multitude of contributing factors, including road user behaviors, vehicle conditions, physical road characteristics, and environmental influences [3], [4]. Despite the extensive research on road safety, a significant challenge remains in effectively predicting and mitigating the risk of accidents to enhance overall transport safety.

This paper addresses this gap by developing a predictive model that leverages Bayesian networks (BNs) and fuzzy logic to anticipate accident risks. The fuzzy-Bayesian approach combines the probabilistic reasoning capabilities of BNs with the imprecision handling of fuzzy logic, providing a robust framework for risk prediction and management in transport systems.

The article is organized as follows: Section II provides an overview of the literature on road accidents and the use of Bayesian networks (BNs) in transportation. Section III details the construction and validation of the fuzzy-Bayesian model. Section IV discusses the results obtained. Finally, Section V offers conclusions and suggestions for further research, outlining the practical implications of the findings for carriers, transport companies, and policymakers aiming to reduce road traffic accidents.

By addressing the critical issue of accident prediction and prevention, this study aims to contribute to the broader goal of enhancing road safety and reducing the human and economic toll of RTIs. The proposed fuzzy-Bayesian model not only aids in predicting accidents but also serves as a foundational tool for developing various predictive applications in the field of freight transport and beyond, ultimately striving for safer and more efficient transport systems globally.

II. Related Work

In this section, we briefly present a review of the literature relevant to our study context, which concerns Accident and Bayesian network applications in the transportation field.

A. Risk Road Accidents

In physics, a collision is characterized as a sudden and uncontrolled change in a vehicle's accumulated kinetic energy. Accidentology, the science of studying accidents, focuses particularly on how kinetic energy is dissipated during such events.

In the paper [5], the authors employed image processing methods to identify lane boundary lines, aiming to enhance the development of driver assistance systems for accident prevention. The aim of the study [6] was to detect risk factors related to geometric road design where crashes might happen. As for study [7], they proposed represents an economical accident prevention embedded system based on obstacle detection IR sensor, to Prevent Road Accident by Lane Detection and Controlling. Using a Fuzzy-Bayesian Approach, [8] Predictive Analysis of Delivery Delay Risk including the prediction of the accident’s occurrence. In the same context of Road traffic accidents, [9] offers a comprehensive examination encompassing data sources, analytical methodologies, and influential factors, the authors of [9] has also described different methods utilized for road traffic accident forecasting, that are, Machine Learning [10], Genetic Algorithms [11], [12], [13], Bayesian Networks [14], [15], Support Vector

Machines [16], Convolutional Neural Networks [17], Artificial Neural Network [18], Three Data-Mining Techniques [19].

BNs are considered one of the most powerful prediction methods in a wide range of research fields [20]. This study harnesses the capabilities of Bayesian networks (BN) for risk prediction, aiming to forecast the likelihood of road accidents.

B. Applications of BNs in the Transportation field

Bayesian networks is a powerful Probabilistic Graphical Model for learner modeling under uncertainty. BNs have been used with great success in many systems, with different objectives, from medical diagnostic [21] predicting types of hematological malignancies, to the Water supply field [22] Predicting Rehabilitation of Water Distribution Networks. BNs is employed also in transportation domains for different prevention's categories. In the article [23], authors utilized Bayesian networks (BNs) to quantify accident risks, aiming to identify high-risk areas, in study [24] authors have developed a BNs a BN model to pinpoint factors influencing motor carrier safety. The purpose of two works [25] and [26] was the evaluation of driving behavior, and modeling drivers' vehicle usage patterns based on the time of day. Moreover, the application of BNs extends to various transportation aspects, including traffic congestion prediction [27], freight demand prediction [28], as well as delivery delay risk [8].

III. Modeling the Risk of Accident Using A Fuzzy-Bayesian Approach

A. Definition to Bayesian Network (BN) & Directed Acyclic Graph (DAG)

1) What is Bayesian Network?

A Bayesian network (BN) is a graphical probabilistic model used for acquiring, representing and exploiting knowledge. It is a technique blending artificial intelligence with statistics to depict uncertain information and to draw conclusions from incomplete data.

BN have demonstrated their utility in biomedical research by effectively illustrating intricate relationships between variables, such as diseases and their associated risk factors, in a user-friendly manner [29]. Using a given set of symptoms, BN can compute the likelihood of specific diseases being present.

BN is a type of probabilistic graphical model that utilizes a directed acyclic graph (DAG) to depict variables and the conditional dependencies between them.

2) What is Directed Acyclic Graph (DAG)?

In the fields of graph theory and computer science, a directed acyclic graph (DAG) is a type of directed graph that contains no directed cycles. This means that it consists of vertices connected by edges, where each edge has a direction pointing from one vertex to another, ensuring that no closed loops are formed Fig. 1.

A directed graph maintains consistent edge directions, enabling the vertices to be arranged in a linear order. DAGs find application across diverse scientific and computational domains, such as biological evolution, family trees, epidemiology, and sociology.

Let's take a quick look at the fundamental mathematics involved with the Bayesian network.

3) The maths behind the bayesian network: A Bayesian network, a type of probability model, is constructed using a directed acyclic graph. Each variable in the model is factored using a unique conditional probability distribution, which is determined by the variable's parent nodes in the graph. The fundamental concept of probability forms the basis of Bayesian models. To better understand this, we should first define the terms "conditional probability" and "joint probability distribution".

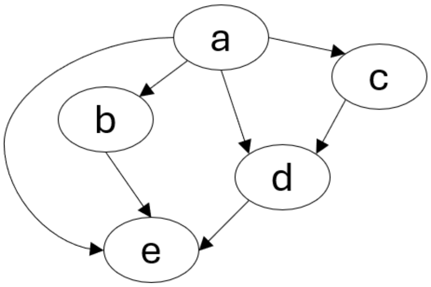

Fig. 1. Example of Directed Acyclic Graph (DAG) (Source: Wikipedia).

Conditional Probability: It is a way to measure the probability of an event (say A) happening, given that another event (say B) has already happened. This is often represented as P(A|B) or sometimes as PB(A), where A is the event we are interested in, and B is the event that is known or assumed to have occurred. This can also be interpreted as the proportion of the probability that event B intersects with event A. Eq. (1) present the formula of the conditional probability that is expressed as a percentage of the likelihood of B crossing with A:

$$P(\mathrm{A}\backslash\mathrm{B}) = \frac{P(A\cap B)}{P(B)} \qquad (1)$$

4) Construction of the Bayesian network architecture: There are two approaches to constructing a BN: objective and subjective methods.

Objective methods: It involve using a database to apply structure learning techniques. These methods often involve algorithms that learn the structure of the Bayesian network directly from the data.

Subjective methods: It involve acquiring expertise from field specialists. This may involve written surveys, one-on-one interviews, or collaborative brainstorming sessions. The advantage of this method is that it can incorporate expert knowledge and insights that may not be present in the data.

Both approaches carry their advantages and disadvantages, and the selection between them often depends on the specific context and available resources.

In literature, numerous researchers have leaned on expert insights, as seen in studies [30], [31], [32], [33], [34]. Bearing this in mind, the article opted for the subjective method.

B. *Identification of the Parameters that are linked to the Accidents' Occurrence*

The subjective method, which relies on the expertise of professionals in the field, was our foundation. As a starting point we conducted an extensive examination of the available literature. After deep research in literature, we noted several parameters that represent the root cause leading to the occurrence of vehicle accidents Table I. The parameters identified are related to, road alignment and grade, traffic controls, weather conditions, driver, stopping distance of vehicle after driver braking, traffic parameters, delivery's planning, and physical condition of the vehicle.

TABLE I. DESCRIPTION OF THE INPUT PARAMETERS OF THE CAUSAL GRAPH

Variable	Description
Traffic way	In annual traffic crash data, released by in 2020 by "U.S. Department of Transportation's National Highway Traffic Safety Administration" (NHTSA) [35], we find that traffic way, is one of the elements registered in all accidents records. In the NHTSA's database [35] the parameter "VTRAFWAY" refer to the traffic way that takes the values: Non-Trafficway or Driveway Access, Two-Way Not Divided, Two-Way Divided by Unprotected Median, Two-Way Divided by Positive Median Barrier, One-Way Trafficway, Two-Way Not Divided with a Continuous Left-Turn Lane, Entrance/Exit Ramp.
Number of travel lanes	Furthermore, a greater number of crashes occur on one-lane roads (1606 times), in which inconsiderate drivers are a major cause of accidents (1910 times) [36].
Road alignment	Most of accident occurred on a straight segment [36].
Road grade	In the NHTSA's database [35] the parameter "VPROFILE" indicate the road grade.
Traffic controls	Traffic control devices like traffic signals, road signs, and road markings provide important information and instructions to road users. If these devices are not properly placed, are malfunctioning, or are difficult to see or understand, they can lead to confusion and accidents [37].
Traffic control device functioning	According to NHTSA's report Revised July 2022 [35], the traffic control is, not functioning, functioning improperly or functioning properly, the variable name was named "VTCONT_F".
Lighting	Lighting conditions have a considerable effect on the occurrence of road accidents, due to the adaptation of speed with visibility conditions [38].
Road Cleaning after accident	If accident locations are not adequately cleaned, the remaining debris, body fluids, and fuel can cause vehicles to skid [8].
Road surface condition	The National Highway Traffic Safety Administration (NHTSA), under the U.S. Department of Transportation, was established by the Highway Safety Act of 1970. NHTSA in his report [35], has considered that the surface's road named on the report "VSURCOND" is one of the parameter affecting the occurrence of the accident.
Weather Condition	In accident prediction process weather condition is one of the parameters to take into consideration. The largest number of accidents occurs in clear weather [36]. Weather conditions impact the effectiveness of traffic controls. Rain or fog can make it difficult for drivers to see traffic signals and road signs, leading to accidents [39]. Adverse weather conditions can negatively impact a driver's ability, the grip of the road, the state of road infrastructure, and the stability and control of the vehicle. This is due to factors such as poor visibility, extreme temperatures, rainfall, strong winds, and lightning [40]. Consequently, these conditions impact traffic demand (as transporters delay or call off scheduled deliveries), traffic safety (due to an increase in accident rates), and the dynamics of traffic flow (alterations in key traffic flow parameters such as volume, speed, and density affect the road system's capacity) [41]. Slippery roads due to rain, snow or ice, as well as the ambient temperature in dry or wet weather, increase stopping distances of vehicles. [42]
Age & Sex of driver	Age and sex are the main factors influencing the driver's driving routine style. According to [43], [44], routine driving style contribute to traffic accidents.
Fatigue	Fatigue and sleepiness, contributes to traffic accidents [43], [44].
Alcohol consumption	The consumption of alcohol while driving is one of the dangerous factor of the driver's conditions, it often leads to fatal accidents [3].
Negative emotions & stress	Negative emotions and stress can lead to increased speed, which is a major factor in accidents. This results in a significant number of injuries and deaths. In fact, one-third of total accidents involving driver speed result in fatalities [36], [45], [46].
Safety distance respect	Driver behavior includes failure to respect safety distance and speed limits, as well as sudden braking and hard acceleration [47].
Hard braking & hard acceleration	According to the article [48] one of the major sources of traffic accidents is who Driver behavior while driving.
Speed limits respect	Passenger vehicle drivers involved in fatal crashes, by speeding involvement, alcohol-impaired driving, and restraint use [49]. According to [49] study, from the 41144 passenger vehicle drivers involved in 2020 in fatal crashes, 2819 were due to speeding, this represent 6.9%. The speed is higher, the stopping distance of vehicle is longer [50].
Occurrence of events that block/slow traffic	Road Traffic can be interrupted by the presence of a number of events, such as festive events (religious, national or international holidays, vacation departure) [8], [51], social events (political demonstrations, diplomatic visits [52], sports events) [8], [51] and unforeseen or occasional events (Vehicle Breakdown, Accident, public works) [8], [52].
Delivery Period	[53].

	Urban delivery during peak hours is very difficult, as private vehicles and goods vehicles overlap, generating a mixed and dense traffic flow [51]. It is obvious that the congestion observed during the peak hour is related to "home-to-work" trips. Indeed, the BELDAM survey [54] showed that 2/3 of the morning peak trips were related to this reason (65% of the trips between 6am and 9am).There is also a notable difference between school and non-school working days [54]. On school days, the morning peak starts earlier, is higher and therefore concentrates a larger share of trips. On the other hand, on a non-school working day, this morning peak disappears, resulting in a peak of trips around 10:00 am. This means that "home-school" trips also play a role in congestion in Belgium [53], [54], [55], [56]. Delivery period influences traffic, delivery during peak hours can slow down traffic [8].
Physical condition of the Vehicle	A Vehicle having a bad physical condition can be a cause of a dramatic accident [4], [36]. A poor physical condition is often a result of negligence, hence the occurrence of breakdown and delays.
Stopping distance	On the road, assessing the stopping distance is crucial. Braking, under normal or emergency circumstances, takes time and distance. The stopping distance is affected by the driver's reflexes, the vehicle's speed, the weather conditions and the road surface's grip [50]. The stopping distance could be estimated by multiplying the tens figure for the speed of your vehicle by itself. For example, the stopping distance at 120 km/h will be 12 x 12 or 144 m. The values obtained from these calculations are approximate because various factors affect braking. Various factors influence the stopping distance of a vehicle. Some are technical (Road adhesion, Road grade, Vehicle Kinetic energy, Tire State and Condition, Weight of the vehicle), others related to human (Reaction time, Visibility).
Reaction time	Various studies show that reaction time is in the range of 1.8 to 2.5 seconds, in France, it is generally estimated at 2 seconds. The reaction time depends on many factors: fatigue, driving under the influence of alcohol or drugs, as well as activities that reduce the driver's attention, such as talking to passengers or being distracted by their behavior, use of the car radio, GPS, mobile phone or in-car phone [57].
Visibility	Fog, Rain, Snow, Hail, and Night, affect the visibility needed to interpret risks and hazards and influence the reaction time and distance travelled [58].
Road adhesion	Depending on the type of surface of the road, paving stones, sand, earth, draining or non-draining tarmac. All these types of surface have different characteristics that influence the stopping distance. Together with the weather, they constitute what is known as the coefficient of friction between the tires and the road [59].
Road grade	Braking distance is improved on uphill and reduced on downhill. Similarly, steering grip is improved on positive slopes and penalised on negative slopes. [60]
Braking Distance	Braking distance refers to the distance a vehicle travels from the time the driver applies the brakes until the vehicle comes to a complete stop. Accidents often occur when the braking distance is longer than the distance available to stop safely. [61], [62], [63]
Kinetic energy	When a vehicle is in motion, it stores kinetic energy. If you stop the engine, the vehicle will continue to move forward thanks to its momentum. In order to stop it, it is necessary to absorb this energy. The overall function of the braking system is therefore to transform kinetic energy into heat energy [64], [65]. The relationship between kinetic energy and braking distance is such that the higher the kinetic energy, the longer the braking distance, because a higher kinetic energy requires more work to be done by the brakes to bring the vehicle to a stop.
Tire State and Condition	Tire's pressure have a remarkable influence on the braking distance. [66]
State & Condition of braking system	The wear of the brake, as well as the age of the hydraulic fluid, which is sensitive to heat, the temperature of the discs, pads, drums and linings after heavy use, will increase the stopping distance. [67]
Weight of the vehicle	The higher is the weight, the longer the stopping distances [68], [69], [70].

C. *Construction of Bayesian Network Structure*

To build our BN presented in Fig. 2. We have identified in literature the parameters that can cause the occurrence of accidents and the causal relationship among these variables, then the BN was set up in three levels.

The first level, as shown in Table II(a) represents the input nodes, which indirectly influence the occurrence of an accident. This developed level of the BN has 67 nodes. The second level of the BN, detailed in Table II(b) includes the intermediate nodes. These nodes delineate the diverse intermediate causal factors that contribute to the impact factors. The third and ultimate tier of the constructed Bayesian network comprises the final impacts. These factors directly and adversely contribute to accident occurrences. These factors are presented in Table II(c).

After pinpointing the variables Table I which will serve as nodes within the graph, and representing the inputs, intermediate effects, and final impacts detailed in Table II. The structure of the BN is constructed and depicted in Fig. 2.

D. *Generation of Conditional Probabilities (CP) of Intermediate Effects and Final Impacts*

Once the structure of the BN is established, it's crucial to assign conditional probabilities Table (CPT) to the nodes of the graph for effective utilization of the developed BN. These probabilities can be ascertained either through algorithms that are trained on databases or by seeking guidance from experts in the relevant field. However, we encountered a challenge as there was no suitable database for the identified variables in the existing literature. Moreover, the extensive number of conditional probabilities in this developed network that equal to 56.739.144, made it impractical to rely on expert knowledge for an evaluation [71].

TABLE II. Presentation of Inputs, Intermediate Effect, and Final Impacts of the Occurrence of Accidents

a) INPUTS		
Negative emotions	Road alignment	Truck fill rate
Accident on the Road	Road Cleaning after accident	Weather Condition
Age	Road grade	Month
Alcohol or drug consumption	Road surface type	Day of week
Anything on road surface?	Safety distance respect	Peak Hours
Children	Sex	School and non-school working day
Education	Speed	International holidays
Fatigue	Vehicle Breakdown history	Vacation departure
Hard acceleration	Speed limit	Religions of National events
Hard braking	Speed limits respect	Social events
Kilometers to be covered	Stability of vehicle while driving	Vehicle Breakdown
Road Lighting	State & Condition of the braking system	Use of accessories (GPS, mobile phone)
Maintenance Planning is respected	Stress	Distracted by passengers
Model year	Tire state & condition	Talking to passengers
Number of exchanges	Traffic control device functioning	Public works on the road
Number of travel lanes	Traffic controls	Vehicle accident history
Professional status	Traffic way	

b) INTERMEDIATE EFFECTS
Kinetic energy
Planning parameters
Road Adhesion
Braking distance
Reaction time
Delivery period
Distracted?
Occurrence of events that block/slow traffic
Visibility
Weight of the vehicle

c) FINAL IMPACTS
Driver Style
Physical Vehicle condition
Road design
Road surface condition
Traffic flow
Driver condition
Stopping distance

Fuzzy logic permits to minimize the number of questions asked to experts while also to reduce the generation of probability tables [72]. Fuzzy logic finds application across diverse domains including control systems, image processing, natural language processing, medical diagnosis, and artificial intelligence:

- Control Systems: Fuzzy logic is often used in control systems for industrial processes, consumer products, and vehicles [73]. It allows for a more flexible and intuitive approach than traditional binary logic, making it ideal for complex, non-linear systems. The article [74] proposes a coordinated control of multiple Photovoltaic Static Compensator systems using fuzzy logic. The results presented by the author validate that the suggested fuzzy controller has the capability to enhance the dynamics of the voltage profile.

- Risk management: In the article [75] Fuzzy VIKOR is used as a part of a three-phase model for managing supply chain sustainability risks.

- Energy consumption: The article [76] compares the energy efficiency of two different approaches to Air Conditioner (AC) usage; the manual method and the fuzzy logic method. The research underscores the efficacy of fuzzy logic in optimizing AC power consumption in response to real-time conditions, resulting in an impressive energy savings of around 41.96%.

- Image Processing: In image processing, fuzzy logic helps with tasks such as edge detection, feature extraction, and image enhancement [77], [78]. It's particularly useful when the image data is imprecise or noisy.

- Natural Language Processing (NLP): Fuzzy logic is used in NLP to understand the meaning of text based on context [79], [80]. This is especially useful in sentiment analysis, where the goal is to determine the emotional tone behind words.

- Medical Diagnosis: Fuzzy logic help doctors and medical professionals make diagnoses based on symptoms and test results [81], [82], [83], [84], [85], [86]. It handles the uncertainty and vagueness often present in the medical field.

- Artificial Intelligence (AI): In AI, fuzzy logic is used to enable machines to reason in a way that is similar to human reasoning [8], [51], [87], [88]. This includes dealing with ambiguous or imprecise information.

Consequently, this paper relied on fuzzy logic approach to initially articulate the experts' evaluations using fuzzy rules, and subsequently created the conditional probability tables through a fuzzy inference mechanism.

Fuzzy Rules, are expressed as IF-THEN statements, capturing the relationship between input variables and output variables in a fuzzy way; for instance: IF “road” is dangerous, “driver's performance” is bad and “Physical Vehicle condition” of is bad, THEN the “occurrence of accident” will have a fatal injury. In a Fuzzy Logic system, the output is represented by a fuzzy set, consisting of membership degrees for every potential output value. Here the degree of "fatal injury" regarding the “occurrence of accident” is depicted qualitatively through a linguistic variable articulated in natural language. Across various rules, the “occurrence of accident” node may be interpreted as one of the following states: No accident, possible injury, fatal injury.

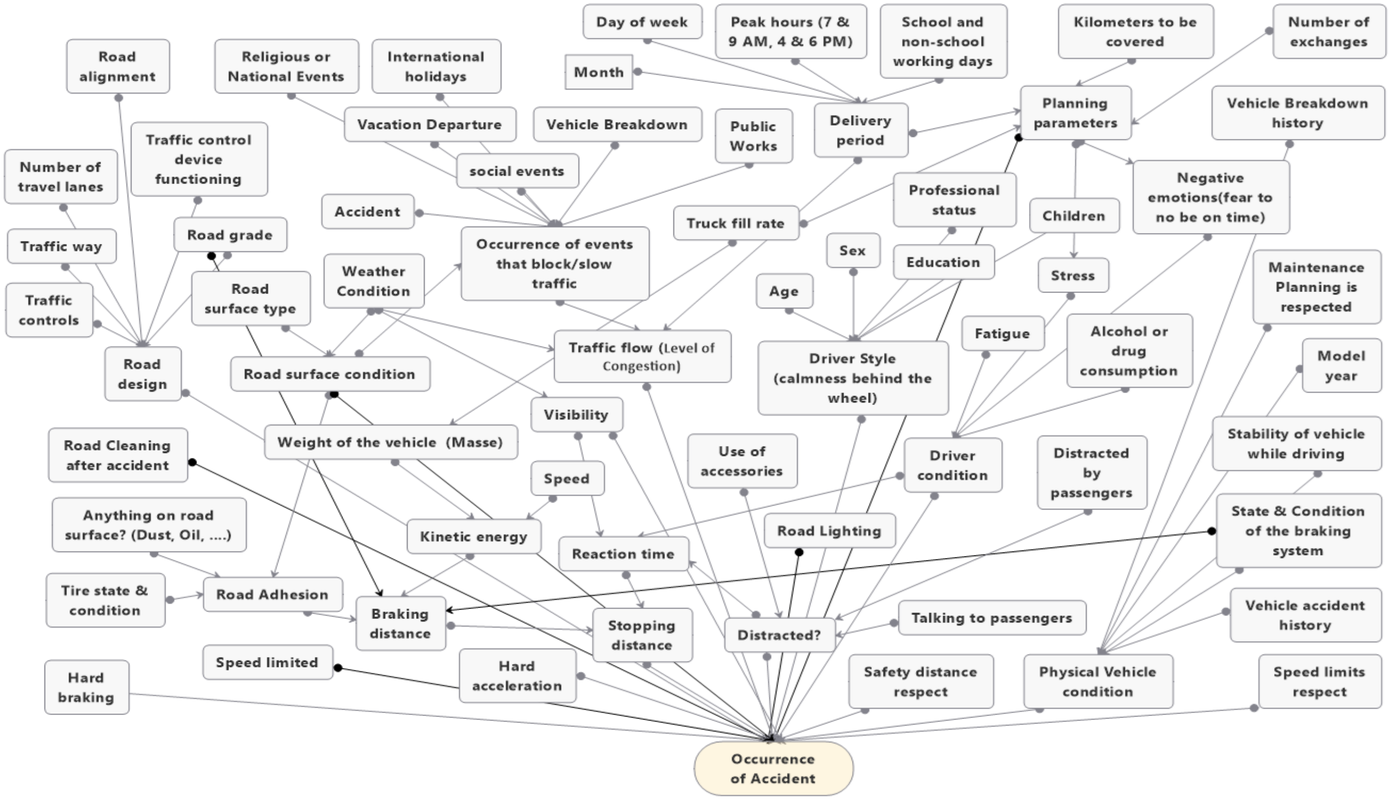

Fig. 2. Structure of the Bayesian network modeling the risk of occurrence of the road accident.

This article employs a fuzzy inference method to derive insights from the given input information and fuzzy rules. The Sugeno inference method is utilized due to its rapid processing speed and effective defuzzification system [89]. The article then chose to express these values in a fuzzy form to associate the degree of membership of each node across all its fuzzy subsets. For instance, within the "occurrence of accident" node, fatal injury is assigned a membership of 92%, potential injury 7%, and no occurrence 1%.

The process of implementing the fuzzy-Bayesian approach, which is used to create conditional probability tables, is carried out in five stages:

Step 1: Initial data collection and variable definition, including the identification of linguistic values and the creation of membership functions [90] [91].

Step 2: Establishment of fuzzy rule sets; constructing a series of "if-then" rules that guide the fuzzy inference system in converting input variables into output[90].

Step 3: Fuzzy conversion; translating input values into fuzzy representations using membership functions, and assessing the membership degree of each fuzzy subset [92].

Step 4: Inference mechanism development; creating a framework to draw conclusions based on the fuzzy rules and input data [93], [94].

Step 5: Defuzzification process; converting the fuzzy system's final output into a numerical format for practical application [95].

Initially, the article establishes the fuzzy variables and their corresponding linguistic values for the implementation of this method. In fact, each variable is represented qualitatively using expressions in natural language, as demonstrated in Table III.

TABLE III. TATE’S OF THE BAYESIAN NETWORK NODES

ID	Nodes	Linguistic values
1	Driver Style	Good, Medium, Bad
2	Kinetic energy	Low, Medium, High
3	Physical Vehicle condition	Good, Medium, Bad
4	Planning parameters	Minimum, Low, Moderate, High, Maximum
5	Road design	Save, Critical, Dangerous
6	Road surface condition	Dry, Dirt, Wet
7	Traffic flow	Smooth, Congested, Stop-and-go
8	Negative emotions	No, Bad, Too-bad
9	Road Adhesion	Good, Medium, Bad
10	Braking distance	Short, Normal, Long
11	Driver condition	Good, Medium, Bad
12	Reaction time	Too Long, Long, Normal
13	Stopping distance	Short, Normal, Long
14	Accident on the Road	No accident, Possible Injury, Fatal Injury
15	Age	Adolescent, Adulthood, Middle-Age
16	Alcohol or drug consumption	Non-Consumption, Negative, Positive

17	Anything on road surface?	Nothing, Dust, Water, Oil
18	Children	No-Child, One-Child, Several-Child
19	Delivery period	Low-traffic, Normal-traffic, High traffic
20	Distracted?	Distracted, Not-distracted
21	Education	Educated, Not-Educated
22	Fatigue	No-Fatigue, Mild-Fatigue, Moderate-Fatigue, Severe-Fatigue, Exhausted
23	Hard acceleration	Low, Normal, Hard
24	Hard braking	Low, Normal, Hard
25	Kilometers to be covered	Long, Normal, Short
26	Road Lighting	Bright, Dim, Low Light, Obscurity
27	Maintenance Planning is respected	Respected, Delays, Frequent-Delays
28	Model year	New, Recent, Mid-Aged, Older, Antique
29	Number of exchanges	No-Exchange, One or Two exchanges, Several-Exchanges
30	Number of travel lanes	One-Lane, Two-Lanes, Three-Lanes, Four-Lanes, More-Lanes
31	Occurrence of events that block/slow traffic	Low, Medium, High
32	Professional status	Junior, Mid-Level, Long-Term
33	Road alignment	Straight, Curve
34	Road Cleaning after accident	Appropriate, Medium, Inappropriate
35	Road grade	Uphill, Level, Downhill
36	Road surface type	Save, Critical, Dangerous
37	Safety distance respect	Respected, Not_Respected
38	Sex	Masculine, Feminine
39	Speed	Low, Medium, High
40	Speed limited	Limited, Not-Limited
41	Vehicle Breakdown	Working, Dysfunctional, Breakdown
42	Use of accessories	No, Rarely, Occasionally, Sometimes, Often, Frequently
43	Speed limits respect	Respected, Not-Respected
44	Stability of vehicle while driving	Stable, Not-Stable
45	State & Condition of the braking system	Good, Medium, Bad
46	Vehicle Breakdown history	No, Rarely, Occasionally, Sometimes, Often, Frequently
47	Vehicle accident history	No, Rarely, Occasionally, Sometimes, Often, Frequently
48	Stress	Stressed, Normal, Relax
49	Tire state & condition	Good, Medium, Bad
50	Traffic control device functioning	Functioning, Not-Functioning
51	Traffic controls	Controls, No-Controls
52	Social events	Major, Significant, Minor
53	Public works	No, Rarely, Occasionally, Sometimes, Often, Frequently
54	Distracted by passengers	No, Rarely, Occasionally, Sometimes, Often, Frequently
55	Traffic way	Two-Way_Not-Divided, Two-Way_Divided, One-Way
56	Truck fill rate	Minimal, Low, Moderate, Full
57	Visibility	Good, Medium, Bad
58	Weather Condition	Clear, Rainy, Foggy, Snowy
59	Weight of the vehicle	Light, Normal, Heavy
60	Month	Winter, Spring, Summer, Autumn
61	Day of week	Beginning, Middle, Weekend
62	Peak Hours	Early Morning, Morning, Midday, Afternoon, Evening
63	School and non-school working day	School, Non-School
64	International holidays	Major, Significant, Minor
65	Vacation departure	Major, Significant, Minor
66	Religions of National events	Major, Significant, Minor
67	Talking to passengers	No, Rarely, Occasionally, Sometimes, Often, Frequently
68	Occurrence of accident	No accident, Possible injury, Fatal injury

The fuzzy system integrated a total of 18,913,048 fuzzy rules, enabling the generation of 56,739,144 conditional probabilities to support the BN. In order to facilitate a deeper understanding of our proposed approach, we elucidate the process of generating CPTs for “Driver reaction time” node. In this instance, the inference mechanism focuses on ascertaining the “Driver reaction time” with respect to the parent nodes states: “Driver Condition”, “Distracted?” and “Visibility”.

Gaussian is the membership function that is utilized for each node in the graph since it produces less inaccuracy than other triangle and trapezoidal functions [96].

In several previous researches, the Gaussian membership function was widely employed [97], [98], [99]. It is identified by two parameters, the mean (m) and the standard deviation (k), as represented by Eq. (2).

$$\mu_A(x) = e^{-\frac{(x-m)^2}{2k^2}} \qquad (2)$$

Fig. 3 illustrates an example of how the Gaussian membership function is used to describe the variable “Driver reaction time”.

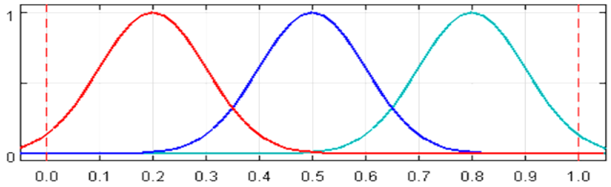

Fig. 3. Membership functions of “Driver reaction time” variable.

Once the membership functions for the “Driver reaction time” nodes and its precursors (Driver Condition, Distraction, Visibility) are established, a fuzzy rule base is then formulated. This set of rules evaluates the variability of the "Driver reaction time" node based on the conditions or factors affecting its parent nodes. The specifics of this fuzzy rule base are outlined in Table IV.

TABLE IV. FUZZY RULES OF THE "DRIVER REACTION-TIME" NODE WITH ITS PARENT NODES

Rule	IF Driver condition	AND Distracted	AND Visibility	THEN Diver Reaction Time
1	Bad	Distracted	Good	0.5
2	Bad	Half-Distracted	Good	0.5
3	Bad	Distracted	Medium	0.2
4	Bad	Half-Distracted	Medium	0.2
5	Bad	Distracted	Bad	0.2
6	Bad	Half-Distracted	Good	0.5
7	Medium	Distracted	Good	0.5
8	Medium	Half-Distracted	Good	0.5
9	Medium	Distracted	Medium	0.2
10	Medium	Half-Distracted	Medium	0.2
11	Medium	Distracted	Bad	0.2
12	Medium	Half-Distracted	Bad	0.2
13	Good	Distracted	Bad	0.2
14	Good	Distracted	Medium	0.5
15	Good	Distracted	Good	0.5
16	Good	Half-Distracted	Bad	0.2
17	Good	Half-Distracted	Medium	0.5
18	Good	Half-Distracted	Good	0.8
19	Bad	Not-Distracted	Good	0.5
20	Bad	Not-Distracted	Medium	0.2
21	Bad	Not-Distracted	Bad	0.2
22	Medium	Not-Distracted	Good	0.5
23	Medium	Not-Distracted	Medium	0.2
24	Medium	Not-Distracted	Bad	0.2
25	Good	Not-Distracted	Bad	0.5
26	Good	Not-Distracted	Medium	0.8
27	Good	Not-Distracted	Good	0.8

Subsequently, input values are used to initialize the fuzzy system at the peaks of Gaussian distributions. Fig. 4 shows the fuzzy inference outcome of the variable "Drivers' Reaction-time" knowing that, "Driver Condition" is medium, Diver is not Distracted and "Visibility" 'is medium.

The conclusions of the 18 activated rules from the total 27 rules are consolidated in Table V.

Subsequently, the various outcomes are combined into an aggregate value for every state. This value is the outcome of adding the various conclusions from the rules that were activated using the max technique. Every single triggered conclusion of the activated rules is subjected to the max technique.

The following has thus been calculated:

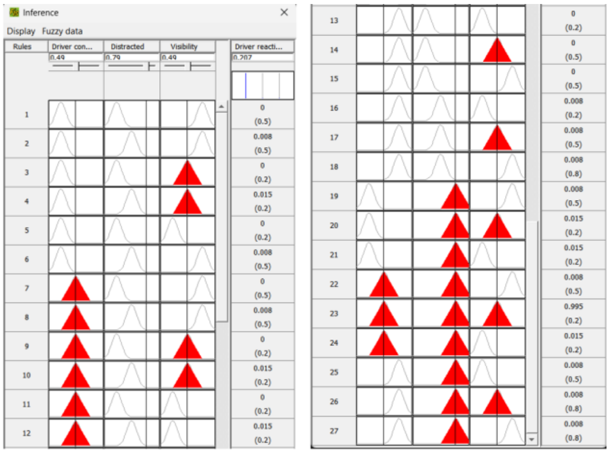
Drivrs' Reaction-time (Too Long) = max (0.015,0.015,0.015,0.008,0.015,0.995,0.015) = 0.995

Drivers' Reaction-time (Long) = max (0.008,0.008,0.008,0.008,0.008,0.008,0.008) =0.008

Drivers' Reaction-time (Normal) = max (0.008,0.015,0.008,0.008) =0.015

Thus, the variable "Drivers' Reaction-time" will take the values 0.995, 0.008, and 0.015 for Too Long, Long, Normale, respectively. This is achieved by computing the ratio of each state's probability to the total probabilities of all states, thereby obtaining the conditional probabilities table for the node "Drivers' Reaction-time" is this way be obtained as follows:

P (Drivers' Reaction-time = Too Long | Driver Condition= medium, Driver is not distracted, Visibility = medium) = 0.995/ (0.995+0.008+0.015) = 0.98.



Rules	Driver con...	Distracted	Visibility	Driver reacti...
	0.49	0.79	0.49	0.207
1				0 (0.5)
2				0.008 (0.5)
3				0 (0.2)
4				0.015 (0.2)
5				0 (0.2)
6				0.008 (0.5)
7				0 (0.5)
8				0.008 (0.5)
9				0 (0.2)
10				0.015 (0.2)
11				0 (0.2)
12				0.015 (0.2)
13				0 (0.2)
14				0 (0.5)
15				0 (0.5)
16				0.008 (0.2)
17				0.008 (0.5)
18				0.008 (0.8)
19				0.008 (0.5)
20				0.015 (0.2)
21				0.015 (0.2)
22				0.008 (0.5)
23				0.995 (0.2)
24				0.015 (0.2)
25				0.008 (0.5)
26				0.008 (0.8)
27				0.008 (0.8)

Fig. 4. Fuzzy inference of the variable "Driver Reaction-time".

TABLE V. DEGREE OF MEMBERSHIP FOR EACH FUZZY SUBSET OF THE VARIABLE "DRIVER REACTION-TIME"

Rule activated	Language value of the output variable (Driver reaction time)	Degree of membership
R2	Long (0.5)	0.008
R4	Tool long (0.2)	0.015
R6	Long (0.5)	0.008

P (Drivers' Fatigue = Long | Driver Condition= medium, Driver is not distracted, Visibility = medium) = 0.008/ (0.995+0.008+0.015) = 0.01

P (Drivers' Fatigue = Normal | Driver Condition= medium, Driver is not distracted, Visibility = medium) = 0.015/ (0.995+0.008+0.015) = 0.01

We acquired the necessary conditional probabilities to supply the BN by generalizing this strategy to all nodes in the causal graph.

E. Anticipation of Scenarios and Interpretation of Results

By the implementation of BN, we were able to investigate how certain nodes' combinations of states affected others within the causal graph. The following sections will assess the probability of an accident by analyzing four distinct scenarios combining different situation of road, traffic, driver, planning and vehicle condition, scenarios are listed below:

- Scenario 1 (S1): Fig. 5, all parameters (road, traffic, driver, planning and vehicle condition) are favourable.
- Scenario 2 (S2): Fig. 6, the parameters related to road & traffic are favourable, the parameters related to the driver and planning are unfavourable and the parameters related to vehicle condition is favourable.
- Scenario 3 (S3): Fig. 7, the parameters related to road & traffic are unfavourable and the parameters related to the driver, planning and to the vehicle condition are favourable.
- Scenario 4 (S4): Fig. 8, the parameters related to road, traffic, driver and planning are favourable and the parameters related to the vehicle condition are unfavourable.

The input parameters associated with road & traffic are those related to road lighting, road cleaning after accident, speed limited, road design, road surface condition and traffic flow.

The input parameters linked with driver are those related to reaction time, driver style, driver condition, hard acceleration, speed limits respects, safety distance respect and hard breaking.

The input parameters associated with delivery planning are those related to kilometers to be covered, number of exchanges, delivery period and truck fill rate.

The input parameters associated with vehicle condition are those related to physical vehicle condition and stopping distance.

Table VI provides details of the four scenarios selected. Each scenario corresponds to a particular arrangement of the input node states.

Once the BN is given the states of each scenario, the inference mechanism facilitates the propagation of probabilities across intermediate effects and final outcomes, ultimately assessing the likelihood of an accident occurrence. The probability distribution for each scenario's likelihood of the occurrence of an accident is shown in Table VII and Fig. 9.

F. Model Validation

The validation of the BN ensures the credibility and accuracy of the outcomes generated by the model. For this reason, an approach based on three axioms was applied to validate the produced BN. The axioms in question were originally proposed by [100] and widely adopted by several researchers such as [8], [88], [101], [102], [103], [104], [105].

The following is the three axioms' guiding principle:

- Axiom 1: a change in the parent node's must also affect the child node's probability.
- Axiom 2: any alteration in the parent node's probability distributions must consistently affect the child node.
- Axiom 3: the combined effect of all parent nodes must be larger than the influence of any one parent.

TABLE VI. INPUT PARAMETER VALUES ACCORDING TO THE SCENARIOS STUDIED

		S1	S2	S3	S4
Road & Traffic parameters	Road lighting	Bright	Bright	Obscurity	Bright
	Road Cleaning after accident	Appropriate	Appropriate	Inappropriate	Appropriate
	Speed limited	Limited	Limited	Not-Limited	Limited
	Road design	Save	Save	Dangerous	Save
	Road surface condition	Dry	Dry	Wet	Dry
	Traffic flow	Smooth	Smooth	Stop-and-go	Smooth
Driver parameters	Reaction time	Normal	Too Long	Normal	Normal
	Driver style	Good	Bad	Good	Good
	Driver condition	Good	Bad	Good	Good
	Hard acceleration	Low	Hard	Low	Low
	Speed limits respects	Respected	Not-Respected	Respected	Respected
	Safety distance respect	Respected	Not-Respected	Respected	Respected
	Hard breaking	Low	Hard	Low	Low
Planning parameters overload		Minimum	Maximum	Minimum	Minimum
Vehicle condition	Physical vehicle condition	Good	Good	Good	Bad
	Stopping distance	Short	Short	Short	Long

TABLE VII. DISTRIBUTION OF PROBABILITIES FOR BN VARIABLES

Variable	Value	S1	S2	S3	S4
Occurrence of accident	No accident,	98%	1%	92.30%	5.90%
	Possible injury	1%	1%	3.85%	88.20%
	Fatal injury	1%	98%	3.85%	5.90%

Validation analyses were performed on every node within the graph to confirm the adherence to the three axioms. The results of verifying axioms 1 and 2 for the "Driver’s reaction" node are presented in Table VIII and Table IX To evaluate the influences of the parent nodes "Driver’s condition" and "Visibility" on the child node "Driver’s reaction," their probabilities were respectively increased by 10% and 20%, then decreased by 5% and 10%. It was observed that when the probability of the "Driver’s condition" node was raised by 20%, the probability of the "Driver’s reaction" node escalated from 52.3% to 65%. Conversely, when the probability of the "Driver’s condition" node was reduced by 10%, the probability of the "Driver’s reaction" node increased to 50.1%. The responses of the "Driver’s reaction" node to other increments and decrements were consistent, affirming the stability of the developed network.

In relation to the validation of axiom 3, the data in Table X indicates that a more substantial increase results when all parent elements of the ‘Driver’s reaction’ node are elevated to 100%, compared to the increase observed when only a single parent element is separately enhanced. This observation aligns well with the principles of axiom 3.

TABLE VIII. AXIOM 1 VERIFICATION

	Parent node: Driver’s condition	**Child node: Driver’s reaction**
20% increase	70 %	65 %
10% increase	60 %	65 %
A priori probability	50 %	52.3 %
5% decrease	45 %	50.5 %
10% decrease	40 %	50.1 %

TABLE IX. AXIOM 2 VERIFICATION

	Parent node: Visibility	**Child node: Driver reaction time**
20% increase	70 %	80 %
10% increase	60 %	79.9 %
A priori probability	50 %	77.7 %
5% decrease	45 %	72.6 %
10% decrease	40 %	65 %

TABLE X. AXIOM 3 VERIFICATION

Driver condition	**Distracted**	**Visibility**	**Drivers’ Reaction-time**	**Changes’ Percentage**
85%	34%	51%	50.5%	
100%	34%	51%	51.3%	0.8%
85%	100%	51%	77.4%	26.9%
85%	34%	100%	65.0%	14.5%
100%	100%	100%	80.0%	29.5%

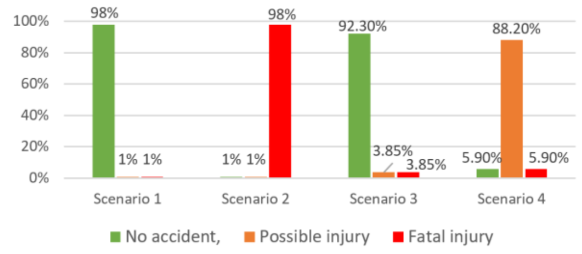

Fig. 9. Probability of accident’s occurrence of the different scenarios.

IV. RESULTS

This paper introduces an analysis of potential accidents using a Bayesian fuzzy model, which incorporates numerous internal and external factors contributing to accidents. The interpretation of results from four scenarios reveals that driver behavior and delivery planning (scenario 2) exert a more significant influence on accident occurrences compared to other factors. This indicates that driver behaviors, delivery planning, and vehicle condition have a considerable effect on the occurrence of accidents compared to parameters related to road and traffic conditions.

V. DISCUSSION

The results highlight the importance of monitoring driver behaviors and implementing smart routing planning designs to avoid road accidents. Given that driver behavior and delivery planning have a more significant impact on accident occurrences, transport companies should prioritize these areas in their safety measures. The findings suggest that a focus on driver training, regular vehicle maintenance, and optimized delivery schedules can substantially reduce the risk of accidents.

VI. CONCLUSION

This paper explores the importance of recognizing and preventing risk elements to enhance road safety, with a particular focus on the various factors that increase the likelihood of accidents. According to bibliographical research and expert perspectives, road accidents are not caused by a single factor but by a complex interplay of multiple factors connected by causal interactions. By using the proposed fuzzy Bayesian Network approach, road traffic injuries will decrease, logistics delivery efficiency will increase, and visibility will be at a high level. However, the computational expense of inference in fuzzy Bayesian networks remains a challenge, particularly for large or multistate networks, highlighting the need for further research and optimization in this area.

Future work will focus on optimizing the computational efficiency of the fuzzy Bayesian Network approach to make it more practical for real-time applications. This could involve the development of more efficient algorithms or the use of advanced computational resources. Additionally, further research will be conducted to expand the model to incorporate a broader range of factors and scenarios, enhancing its predictive accuracy and applicability. Collaborations with industry stakeholders and policymakers will also be sought to implement and test the model in real-world settings, providing valuable feedback for continuous improvement. Finally, exploring the integration of this model with other predictive technologies, such as machine learning and big data analytics, will be a key area of investigation to further enhance road safety measures.

ACKNOWLEDGMENT

This research is supported by the Ministry of Higher Education, Scientific Research and Innovation, the Digital Development Agency (DDA) and the National Center for Scientific and Technical Research (CNRST) of Morocco (Smart DLSP Project - AL KHAWARIZMI IA-PROGRAM).

Use of Natural Language Processing Methods in Teaching Turkish Proverbs and Idioms

Ertürk ERDAĞI
School Principal, Republic of Türkiye Ministry of National Education, İstanbul, Türkiye

***Abstract*—In this study, a series of studies are proposed for easy learning of proverbs and idioms in the language. In Turkish, proverbs and idioms are structures that are used both in the academic environment and in their daily lives, especially by 10-year-old students who have entered the abstract thinking stage. Since this structure contains abstract expressions, it seems difficult to learn at first. In the study, 2396 proverbs and 11209 idioms in the online dictionary of the Turkish Language Association were used. A pre-test was conducted to measure the knowledge level of 20 students selected as the study group. The structure of idioms and proverbs was analyzed using Natural Language Processing methods. With the analysis, difficulty groups were divided according to information such as word count, n-gram analysis, frequency level, and the student was asked questions from the online question pool for the tutorial and the test during the process. Generative artificial intelligence enables semantic analysis of texts containing idioms and proverbs. Following the studies, a test was applied to the students and the efficiency of the process was tried to be measured. As a result, students' idiom knowledge increased by 51.8% and proverb knowledge increased by 59.40%.**

Keywords—Idiom; proverb; natural language processing; word frequency; n-gram analysis; contextual analysis

I. Introduction

Proverbs and idioms are linguistic treasures that are passed down from generation to generation by combining the accumulation and experience gained over centuries with the observations and life practices of the people. These expressions are an important part of cultural heritage. Social values, ethical teachings and deep knowledge about various aspects of life are reflected in these expressions. Proverbs and idioms are the richest and most colorful elements of language. They are frequently used in everyday life and strengthen communication.

Proverbs have often originated anonymously. They are expressed in a short and concise way and usually convey a universal truth. They are often based on experience and reflect the common values of society [1]. Proverbs allow to express a lot of things with few words in language. The desired expressions are conveyed in a powerful way. Proverbs are a didactic element. With these words, advice is given, a warning is given and guidance is given. Proverbs provide individuals with clues about concepts such as right and wrong, good and bad, beautiful and ugly. At the same time, proverbs also point to the aesthetic and artistic aspect of language. Through figures of speech, metaphors and rhythmic structures, proverbs create impressive and memorable words.

Idioms are used to describe a particular situation or emotion. Idioms are fixed expressions or groups of words, usually consisting of more than one word. Idioms usually carry a meaning different from the literal meaning of words. In other words, they are used figuratively. Idioms reveal the richness of the language and increase the power of expression [2]. Idioms, which are frequently used in daily conversations, strengthen the expression and attract the attention of the listener. Idioms reveal the subtleties and depths of language. Because idioms often gain meaning through cultural and social contexts.

In Turkish culture, proverbs and idioms are of great importance not only for the aesthetic and artistic dimension of language but also for the protection of social and cultural values. Proverbs and idioms reflect the common memory and experiences of the society in which they exist from the past to the present. These expressions have a wide range of usage in daily life, literature, education and media. Proverbs and idioms contain important elements for the social structure, traditions and worldview of Turkish society [3].

In literature, proverbs and idioms are used as expressions that strengthen and enrich expression. Many writers and poets in Turkish literature use proverbs and idioms in their works. Proverbs and idioms add depth and meaning to the texts. With this use, the reader's interest in the text increases and the stories told are presented more impressively.

Proverbs and idioms play an important role in language teaching. Proverbs and idioms can be used for students to develop their language skills and discover the aesthetic aspects of language [4]. In addition, through these expressions, students learn cultural values and gain knowledge about social consciousness [5]. Proverbs and idioms can develop vocabulary in language. In this way, different features of the language are recognized and the power of expression is increased. Especially proverbs and idioms, in which figurative expression is intense, enable the learning of this situation, which is indispensable in the structure of the language. Learning figurative expression is developed through the use of idioms and proverb patterns [6].

II. Related Work

Baptista and Reis identified the proverbs in Portuguese. While identifying proverbs in the text, they used abbreviations and derivatives as well as their original form. They conducted a study on a new corpus using information about the form and diversity of proverbs as well as their frequency in the corpus. It was thought that teaching the Portuguese language would also be productive [7]. Development was made through the database named WordNet.PT [8]. This database was created by developing WordNet [9].

Ghosh and Srivastava stated in their study that complex analogical evaluations come to a certain level with large language models, but are not fully useful for structures such as proverbs containing abstract expressions. For a proverb, the topic has performed a prediction process for similar content discovery. A study was conducted for English proverbs and a data set consisting of 250 proverbs was obtained. Mood scoring was made for each proverb. When compared with BERT [10], a similarity rate of 25% was obtained [11].

Goren and Strapparava performed word-level metaphor detection using the zero-shot model in GPT 3.5 [12]. A data set consisting of 891 English proverbs was used in the study. It has been tried to explain the metaphor determination and meaning relationship of the words in proverbs. A satisfactory performance was achieved with word-level metaphor detection [13].

Özbal et al. used proverbs for metaphor definition and interpretation. They thought that a collection of proverbs could be useful for different fields of study. They created a data set called PROMETHEUS consisting of English proverbs and their Italian equivalents. In addition to the metaphor structure at the word level, the general metaphor degree and meaning of the proverb were obtained by questions posed to a study group.There are 761 sentences and 13642 words in the dataset. They worked with a linguist for the Italian equivalents. Many sources were used here, and then the results obtained were cross-examined or verified by different people. Tokenization and POS tagging were done during the preprocessing stage. The structure was added based on the similarity in meaning of Italian and English proverbs [14].

Rassi et al. used the regular syntactic structure of proverbs. They worked on automatically detecting proverbs in Brazilian Portuguese. They used the finite state automaton structure to search within word combinations. The fact that proverbs use certain word combinations and contain metaphors despite their narrow lexical structure shows the difficulty of studying. They worked on a data set by collecting proverbs and their derivatives. They achieved a success rate of 60.15% [15].

Zongjin et al. helped students understand the meaning of Chinese proverbs and apply them. They have offered an online platform using Natural Language Processing for students whose native language is not Chinese. It is possible to search on the desired word using keywords. There are 12 questions about the literal and semantic meanings of proverbs. The target participants of this study are Malay and Indian students. Participants were given 30 minutes to answer this development task. They were allowed to use search functions and consult online resources to research and learn the structure and semantic meaning of proverbs. Thanks to this search, the metaphor word structure in proverbs will be learned structurally [16].

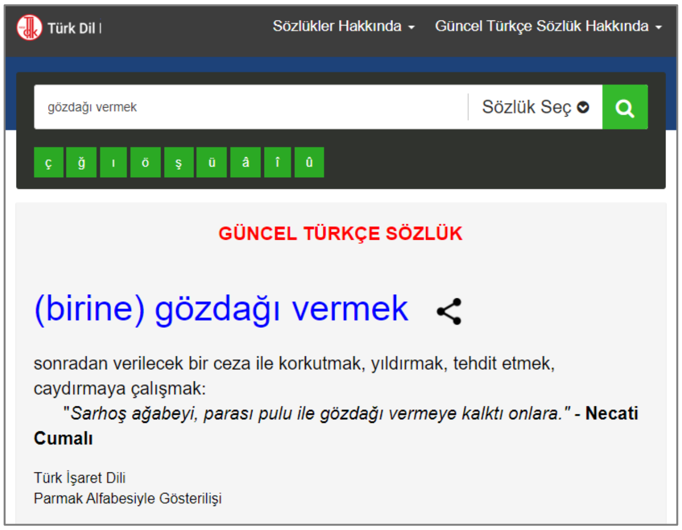
III. Method

A. Data Collection

Turkish proverbs and idioms are in the online dictionary of the Turkish Language Association. In this dictionary, you can see whether an expression is an idiom or a proverb, its meaning and an example sentence. The data here was obtained by web scraping method using Python programming language. Web scraping analyzes the HTML structure in the source code of a web page and collects the desired data [17]. There are various libraries available to do this process and automatically retrieve the data. The most common of these is the BeautifulSoup library. With this library, data extraction processes are made fast and automatic [18]. Idioms and proverbs were extracted from the Turkish Language Association's idioms and proverbs section using Python programming language and BeautifulSoup library. The data was stored in *csv file type. In total, 2396 proverbs and 11209 idioms were obtained.

B. Preprocessing

Preprocessing consists of the steps of organizing the data before processing, removing missing data, transforming it if necessary or deleting unnecessary data [19]. A preprocessing stage was applied for the deconstructions and unnecessary data that may occur after the data extraction. In preprocessing, the number of phrases and words were first checked. They had to contain at least two words. Since the meaning and example sentence part of the data is presented in a single section, this part needs to be separated.



GÜNCEL TÜRKÇE SÖZLÜK

(birine) gözdağı vermek

sonradan verilecek bir ceza ile korkutmak, yıldırmak, tehdit etmek, caydırmaya çalışmak:

"*Sarhoş ağabeyi, parası pulu ile gözdağı vermeye kalktı onlara.*" - **Necati Cumalı**

Fig. 1. Turkish Language association dictionary of proverbs and idioms [20].

Fig. 1 shows the online Turkish Language Association Dictionary of Proverbs and Idioms. In blue color, the idiom or proverb is presented. Under this section, the meaning of the idiom or proverb is shown first, followed by an example sentence. Since the meaning and the example sentence will be evaluated separately in the study, the information here has been separated.

An example data from the data set is presented in Table I. The first field of the data set contains the Turkish text version of the idiom or proverb, and the second field contains the idiom or proverb information. The third column contains the meaning of the idiom or proverb, and the fourth column contains the example sentence presented in the dictionary. In some idioms and proverbs, since sample sentences are not provided in the dictionary, these sections were taken as blank, and then sample sentences were produced for the empty fields. The production of sentences was carried out with the help of generative artificial intelligence. For realistic data generation, generative models are used to increase the data size or to fill gaps in the data [21].

TABLE I. SAMPLE DATA FROM THE DATA SET

Idiom / Proverb	Type	Meaning	Example Sentence
gözdağı vermek	Idiom	sonradan verilecek bir ceza ile korkutmak, yıldırmak, tehdit etmek, caydırmaya çalışmak	Sarhoş ağabeyi, parası pulu ile gözdağı vermeye kalktı onlara.
abesle iştigal etmek	Idiom	yersiz, yararsız işlerle vakit öldürmek	Yazarlarımızın çoğu, yalnızca kendi ürünlerinin ne amaçla üretildiğini sayıp dökerek bir anlamda abesle iştigal ediyorlar.
acele ile menzil alınmaz	Proverb	ivmekle daha çabuk sonuç alınır sanılmamalıdır	Acele ile menzil alınmaz. Telaşlanıp sabırsız davranmakla, daha çabuk sonuç alacağımız, başarı kazanacağımız sanılmamalıdır.
bağrına basmak	Idiom	kucaklamak	İzmir'den kalkıp Mısır'a kadar beni görmeye, beni okşamaya, beni bağrına basıp sevmeye gelirdi.

C. Analyze

Fig. 2 shows the number of idioms and proverbs in the data set. There are 2396 proverbs and 11209 idioms in the data set. These idioms and proverbs were checked for the possibility of repeatable data during the preprocessing stage. Missing data were detected only for the sample sentence part, and it was observed that these were not included in the dictionary.

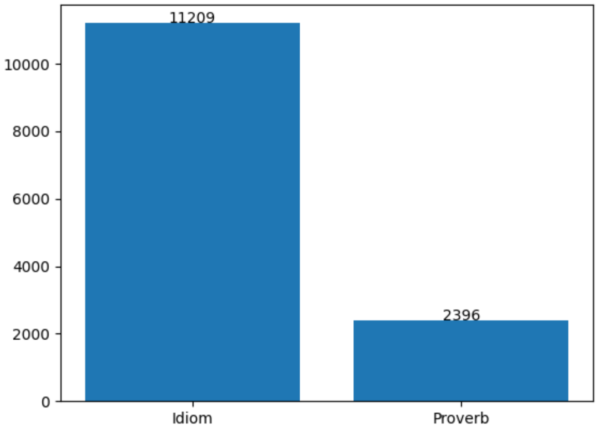


Fig. 2. Number of proverbs and idioms in the data set.

Fig. 3 shows the graph of the word numbers of idioms. This graph shows that the vast majority of idioms consist of two words. In Turkish, idioms generally consist of two words and contain verbs that are not structurally inflected in the infinitive form [22]. The conjugation process on the verb is applied according to the subject and tense. Since there are many two-word idioms, these idioms were used in the pre-test and post-test.

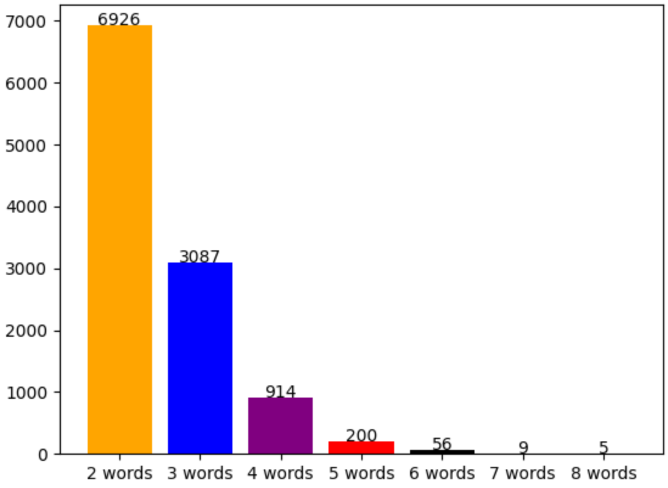

Fig. 3. Idioms word counts.

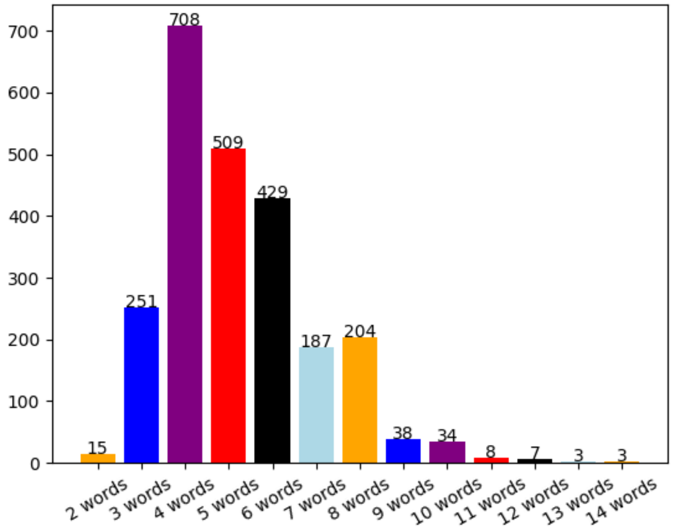

Fig. 4. Proverbs word counts.

Fig. 4 shows the graph of the word numbers of proverbs. In this graph, it can be seen that the four-five-six-word versions of proverbs are in majority. In Turkish, proverbs usually contain one or more verbs [23]. Since they are sentences containing subject, predicate and object, unlike idioms, they consist of sentences with more than two words. For the pre-test and post-test, proverbs containing mostly four-five-six words were used.

Word frequency processing was applied to the idioms in the dataset. The words most used in idioms in Turkish are important. Therefore, understanding the contextual analysis of the words with the highest frequency will be effective in learning many idioms [24]. For the pre-test and post-test, idioms containing the ten words with the highest frequency seen in Fig. 5 were used.

The results of the word frequency process for proverbs are presented in Fig. 6. Although the frequency results are predominantly stop words, these words are the determining factor in many proverbs [25]. Therefore, stop words are not excluded from the scope. The proverbs containing the ten words with the highest frequency were used in the pre-test and post-test.

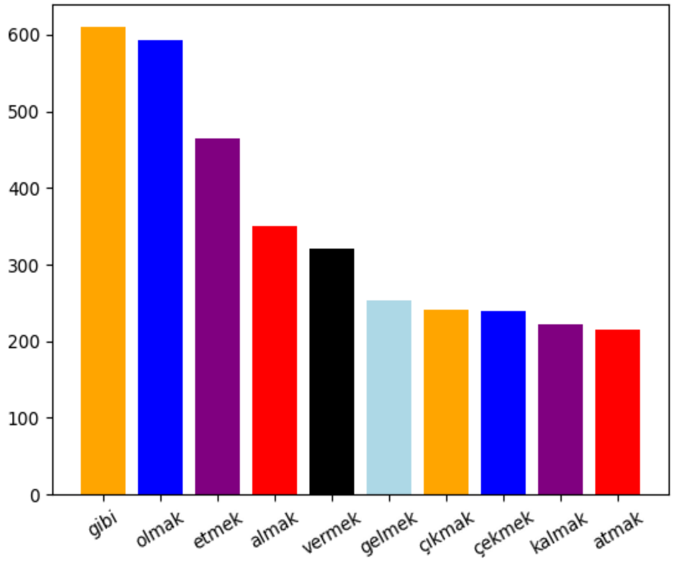

Fig. 5. Top 10 words with the highest word frequency in idioms.

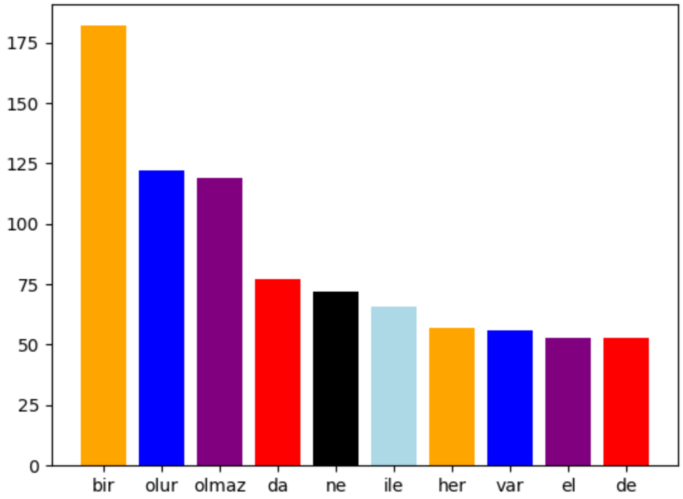

Fig. 6. Top 10 words with the highest word frequency in proverbs.

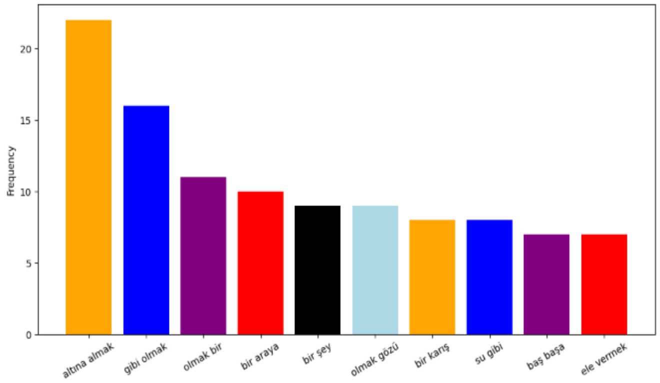

Fig. 7. The 2-gram phrase with the highest frequency for idioms.

An N-gram is an N-character part of a text [26]. 2-gram analysis was conducted due to the idiom structure. The result of the 2-gram analysis for idioms is presented in the graph in Fig. 7. Binary word groups following each other in idioms are important. The fact that there are two-word groups for idioms made this result more important. The word groups obtained here provided information for the most important idiom groups and were used for the pre-test and post-test.

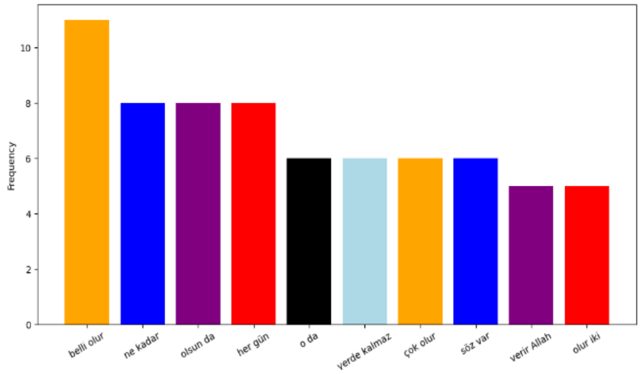

Fig. 8. The 2-gram phrase with the highest frequency for proverbs.

The ten-word groups with the highest frequency obtained by 2-gram analysis for proverbs are presented in the graph in Fig. 8. The word groups provided information for the most important proverbs and were used for the pre-test and post-test.

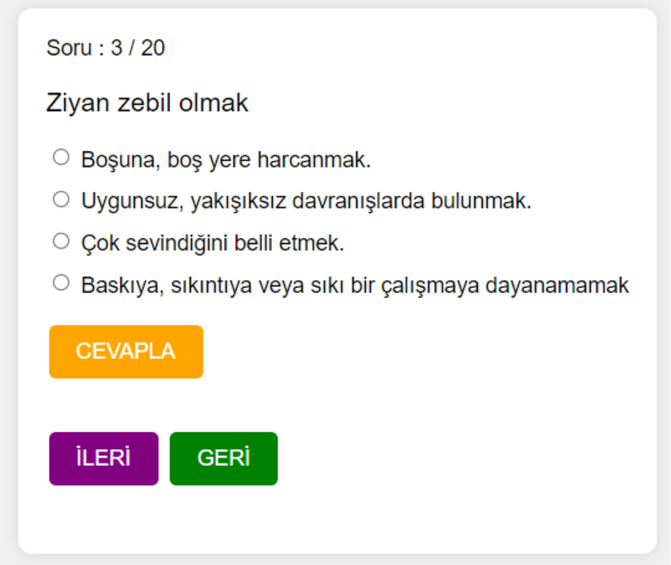
D. *Pre-Test*

This study aims to improve the learning process of idioms and proverbs. Therefore, it is necessary to compare prior knowledge and subsequent knowledge in a sample group. A group of 20 students aged 10-11 years was selected to conduct the study. This group of students was given a test containing 10 idioms and 10 proverbs. In this test, first of all, the students' level of knowledge about idioms and proverbs was measured. A multiple-choice test was prepared to measure this knowledge. Students were asked to match the meanings of 10 idioms with two words, three words and 10 proverbs with three words, four words and five words. The number of words in idioms and proverbs was chosen because of the regions where there is density.

A web application was developed with C# programming language using ASP.NET Core technology. Students were asked to log in to the system with the code given to each student. In this way, which student answered which question will be recorded. As can be seen in Fig. 9, in the web application, the idiom and proverb were written at the top, then four options were presented and the correct meaning was asked to be found. Only one of the four options is correct. Students answered for 10 idioms and 10 proverbs.

In Table II, the correct answers given by the students for the idiom test are indicated with + for each idiom. In Table III, the correct answers for the proverb test are indicated with a + sign.

Fig. 10 shows the students' correct answers for the 20-question test consisting of idioms and proverbs. When the graph is analyzed, it is seen that the students obtained results close to each other, with an average value of 5.4 for idioms and 5.05 for proverbs.



Soru : 3 / 20

Ziyan zebil olmak

○ Boşuna, boş yere harcanmak.
○ Uygunsuz, yakışıksız davranışlarda bulunmak.
○ Çok sevindiğini belli etmek.
○ Baskıya, sıkıntıya veya sıkı bir çalışmaya dayanamamak

Fig. 9. Web application screenshot for pre-test and post-test.

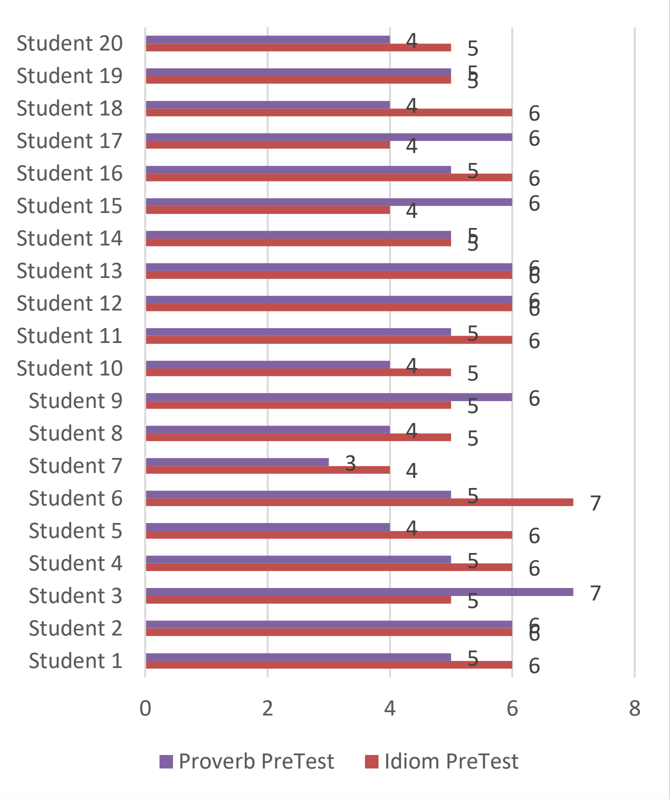

Fig. 10. Pre-test results for 20 students.

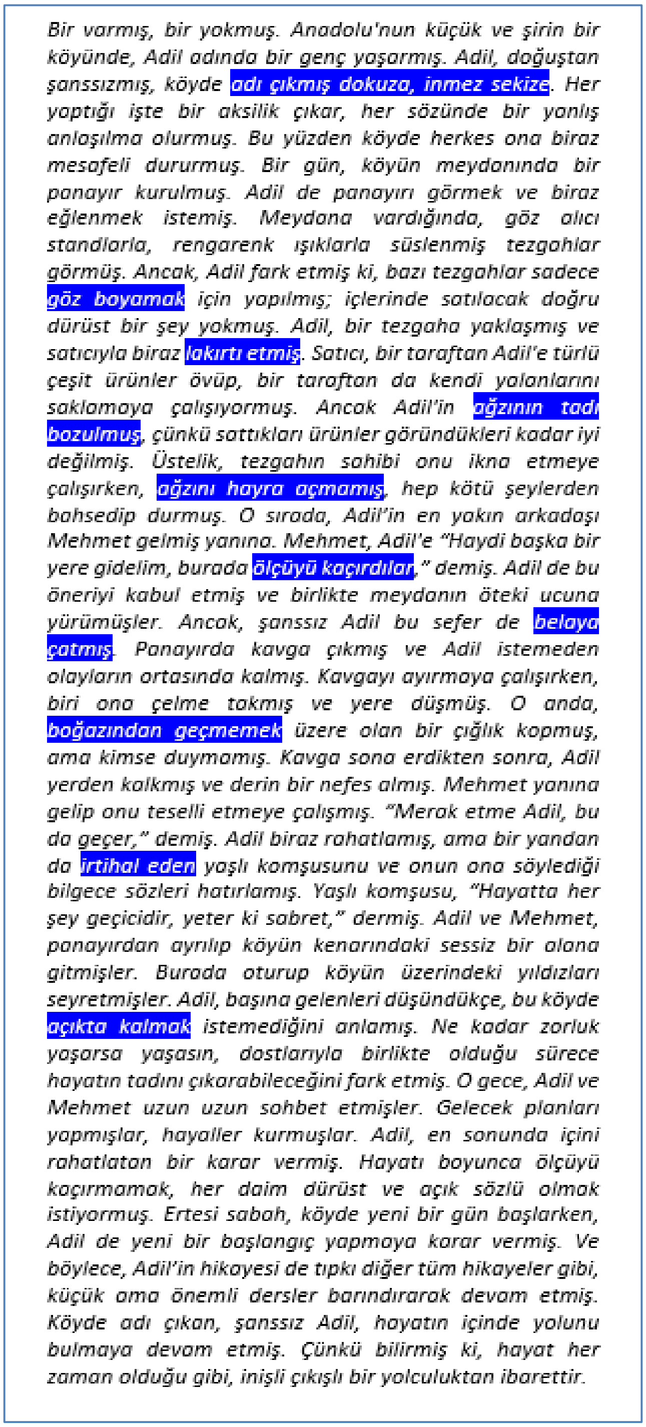
E. Text Generation

The aim of the study is to create a method that will increase the number of correct answers given by students. For this situation, a story was created for each student using generative artificial intelligence. 10 idioms were used in the story. It is aimed that students can guess idioms using previous and next sentences, and they can do this through semantic analysis. An example text produced is shown in Fig. 11.

F. Post Test

Table IV shows the post-test results for idioms. Table V shows the post-test results for idioms In this section, those shown with a + sign indicate the idioms that the students answered correctly in the pre-test. Those marked with an X sign indicate the questions that were not answered correctly in the pre-test but were answered correctly in the post-test. The empty parts indicate the questions that could not be answered correctly in both the pre-test and the post-test.



Bir varmış, bir yokmuş. Anadolu'nun küçük ve şirin bir köyünde, Adil adında bir genç yaşarmış. Adil, doğuştan şanssızmış, köyde adı çıkmış dokuza, inmez sekize. Her yaptığı işte bir aksilik çıkar, her sözünde bir yanlış anlaşılma olurmuş. Bu yüzden köyde herkes ona biraz mesafeli dururmuş. Bir gün, köyün meydanında bir panayır kurulmuş. Adil de panayırı görmek ve biraz eğlenmek istemiş. Meydana vardığında, göz alıcı standlarla, rengarenk ışıklarla süslenmiş tezgahlar görmüş. Ancak, Adil fark etmiş ki, bazı tezgahlar sadece göz boyamak için yapılmış; içlerinde satılacak doğru dürüst bir şey yokmuş. Adil, bir tezgaha yaklaşmış ve satıcıyla biraz lakırtı etmiş. Satıcı, bir taraftan Adil'e türlü çeşit ürünler övüp, bir taraftan da kendi yalanlarını saklamaya çalışıyormuş. Ancak Adil'in ağzının tadı bozulmuş, çünkü sattıkları ürünler göründükleri kadar iyi değilmiş. Üstelik, tezgahın sahibi onu ikna etmeye çalışırken, ağzını hayra açmamış, hep kötü şeylerden bahsedip durmuş. O sırada, Adil'in en yakın arkadaşı Mehmet gelmiş yanına. Mehmet, Adil'e "Haydi başka bir yere gidelim, burada ölçüyü kaçırdılar," demiş. Adil de bu öneriyi kabul etmiş ve birlikte meydanın öteki ucuna yürümüşler. Ancak, şanssız Adil bu sefer de belaya çatmış. Panayırda kavga çıkmış ve Adil istemeden olayların ortasında kalmış. Kavgayı ayırmaya çalışırken, biri ona çelme takmış ve yere düşmüş. O anda, boğazından geçmemek üzere olan bir çığlık kopmuş, ama kimse duymamış. Kavga sona erdikten sonra, Adil yerden kalkmış ve derin bir nefes almış. Mehmet yanına gelip onu teselli etmeye çalışmış. "Merak etme Adil, bu da geçer," demiş. Adil biraz rahatlamış, ama bir yandan da irtihal eden yaşlı komşusunu ve onun ona söylediği bilgece sözleri hatırlamış. Yaşlı komşusu, "Hayatta her şey geçicidir, yeter ki sabret," dermiş. Adil ve Mehmet, panayırdan ayrılıp köyün kenarındaki sessiz bir alana gitmişler. Burada oturup köyün üzerindeki yıldızları seyretmişler. Adil, başına gelenleri düşündükçe, bu köyde açıkta kalmak istemediğini anlamış. Ne kadar zorluk yaşarsa yaşasın, dostlarıyla birlikte olduğu sürece hayatın tadını çıkarabileceğini fark etmiş. O gece, Adil ve Mehmet uzun uzun sohbet etmişler. Gelecek planları yapmışlar, hayaller kurmuşlar. Adil, en sonunda içini rahatlatan bir karar vermiş. Hayatı boyunca ölçüyü kaçırmamak, her daim dürüst ve açık sözlü olmak istiyormuş. Ertesi sabah, köyde yeni bir gün başlarken, Adil de yeni bir başlangıç yapmaya karar vermiş. Ve böylece, Adil'in hikayesi de tıpkı diğer tüm hikayeler gibi, küçük ama önemli dersler barındırarak devam etmiş. Köyde adı çıkan, şanssız Adil, hayatın içinde yolunu bulmaya devam etmiş. Çünkü bilirmiş ki, hayat her zaman olduğu gibi, inişli çıkışlı bir yolculuktan ibarettir.

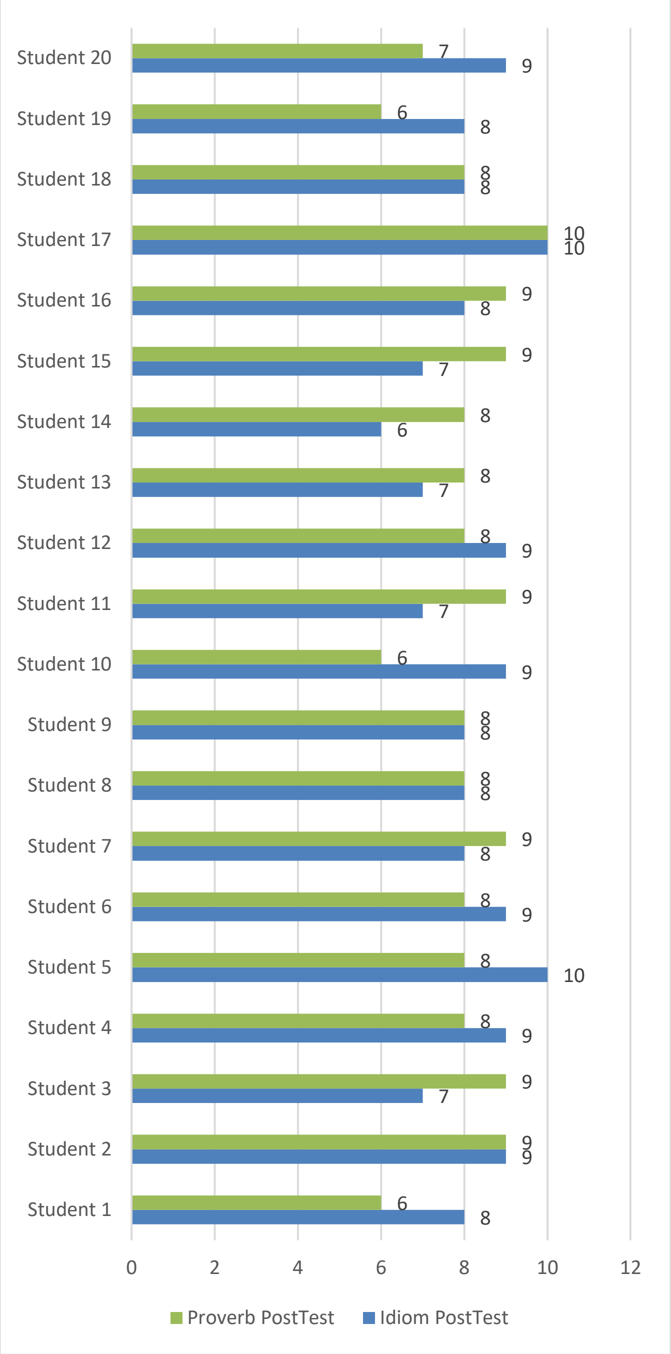

Fig. 12. Post-test results for 20 students.

The graph in Fig. 12 shows the post-test results. Here, one student answered both groups correctly and one student answered all questions in the idiom group correctly.

The pre-test results showed an average value of 5.4 for idioms and 5.05 for proverbs. With the post-test, the average value for idioms increased to 8.2, while the average value for proverbs increased to 8.05. When the graph in Fig. 13 is analyzed, an increase of 51.85% was achieved for idioms and 59.40% for proverbs.

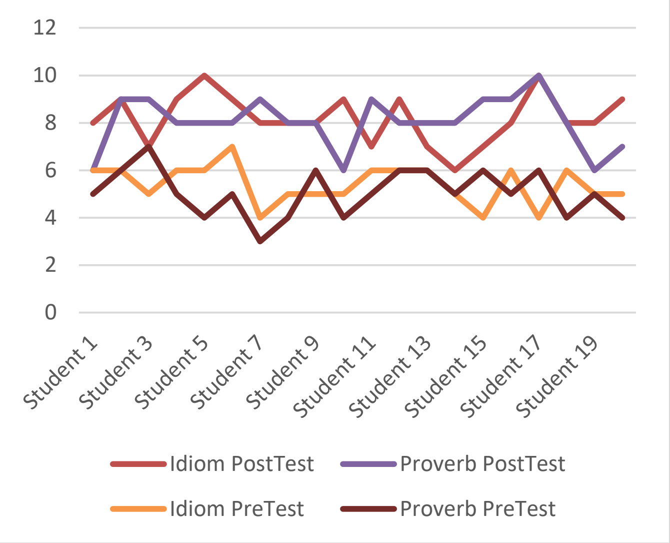

Fig. 13. Comparison of pre-test and post-test results.

IV. Results and Discussion

In the study, Natural Language Processing methods were used to learn idioms and proverbs. The 2396 proverbs and 11209 idioms in the online dictionary of the Turkish Language Association were used. A group of 20 students aged 10-11 years was formed as the study group. Students were selected at this age because they are at an age-appropriate for abstract expression skill levels. The proverbs and idioms in the online dictionary were retrieved by the web scraping method. These data include idiom/proverb, meaning and sample sentence data. The retrieved data were first analyzed with Natural Language Processing methods. In particular, the difficulty levels of idioms and proverbs were determined with methods such as word count, word frequency, n-gram analysis. A pre-test was conducted to measure the efficiency of the method to be created for the students. For this process, a web application was created with C# programming language using ASP.NET Core technology. The answers given by the students were stored on SQL Server. The data here will be used for the post-test at the end of the study. In the method, students were randomly assigned 10 idioms and 10 proverbs according to their difficulty level. They were asked to find the meanings of idioms and proverbs with a multiple-choice test. After the results obtained, texts consisting of idioms and proverbs were presented to the students in line with the semantic analysis, word frequency and word count elements of idioms and proverbs. Here, a generative artificial intelligence was used and texts were produced in the form of a story. With the texts produced, students tried to discover the meanings of idioms and proverbs and to guess them with contextual analysis with the help of the preceding and following sentences. At the end of the whole process, the post-test application was presented to the students in multiple-choice format. After the answers, students' scores increased by 51.85% for idioms and 59.40% for proverbs. This shows the positive effect of students seeing idioms and proverbs within the scope of abstract meaning contextually in sentences, the preceding and following sentences in the story and the story flow.

V. Conclusion and Future Work

Proverbs and idioms consist of words and word groups containing metaphors. This negatively affects the learning process or causes the learning process to prolong. For the teaching process of proverbs and idioms in Turkish, words and word groups need to be analyzed. Natural Language Processing methods perform this process in both fast and effective ways. The results obtained from the study showed that the learning process was faster and more effective by revealing the relationship between words and word groups through analysis methods. The fact that the students increased by 51.85% on idioms and 59.40% on proverbs clearly proves this. Since the data set created in the study consists of data from the Turkish Language Association, an official authority, it is also important that it does not contain any errors. In the study, not only the meanings of proverbs and idioms are discussed, but also their usage areas are given with example sentences. This situation showed how semantic comprehension can be reflected in sample applications.

In future studies, text production by students to improve students' knowledge of idioms and proverbs will bring good results. Placing the proverb or idiom where it will be used by using the context of the previous sentence and the next sentence and processing the plot will further develop this skill. Exploring the use of different proverbs and idioms by researching other online resources will ensure good results.

Analysis Performance of One-Stage and Two Stage Object Detection Method for Car Damage Detection

Harum Ananda Setyawan[1], Alhadi Bustamam[2]*, Rinaldi Anwar Buyung[3]
Department of Mathematics, University of Indonesia, Depok, Indonesia[1, 2]
Department of Data Science, Global Risk Management, Jakarta, Indonesia[3]

***Abstract*—The large use of private cars is directly proportional to the number of insurance claims. Therefore, insurance companies need a breakthrough or new approach that is more effective and efficient to be able to compete for the trust of their customers. One approach that can be taken is to use artificial intelligence to detect damage to the car body to speed up the claims process. In this research, several experiments will be carried out using various types of models, namely Mask-R-CNN, ResNet50, MobileNetv2, YOLO-v5, and YOLO-v8 to detect damage to the car body. Furthermore, in the experiments that were carried out, the best results were obtained using the YOLO-v8x model with precision, recall, and F1-score values of 0.963, 0.951, and 0.936 respectively.**

Keywords—Car damage detection; insurance claim; deep learning; object detection

I. Introduction

The prevalence of private vehicle usage in Indonesia is notably substantial. As per data extracted from the [1] for the year 2022, an estimated 17,175,632 units of private automobiles were in circulation across the nation. This proliferation of private vehicles in Indonesia corresponds directly with the incidence of traffic accidents. According to [2], approximately 25,144 cases of traffic accidents occurred during the first semester of 2022, resulting in a cumulative loss nearing three billion Indonesian rupiahs (Pusiknas Bareskrim Polri, 2023). Prevalent accident types include head-on collisions, rear-end collisions, and instances of vehicles veering off roads, with respective occurrences numbering 3,503, 3,066, and 2,951 cases in sequence.

The World Health Organization (WHO) identifies several primary factors contributing to traffic accidents and the heightened risk of resultant losses. These factors encompass driving at speeds surpassing the average, driving under the influence of alcohol, operating vehicles devoid of essential safety equipment such as helmets, seat belts, and child car seats, engaging in communication activities while driving, encountering inadequacies in road infrastructure, possessing vehicles with substandard maintenance, experiencing deficient post-accident care, and encountering lax enforcement of traffic laws [3].

Motor vehicle insurance has become a popular means of reducing the damages that people suffer from traffic accidents. To reduce the losses from unanticipated events like theft, accidents, and disasters, a motor vehicle insurance plan is required. As a result, a large number of insurance firms have surfaced that provide services related to motor vehicle insurance.

Indonesia has witnessed a tremendous increase in the motor vehicle insurance market. The company in this sector showed a premium growth of 19.4% in the third quarter of 2022 compared to the third quarter of 2021, according to a study [4]. To be competitive, motor vehicle insurance companies must have a solid and superior business strategy compared to other businesses, given the industry's rapid expansion. The plan for processing insurance claims is one of the most important factors to take into account in the insurance industry. Research in study [5] asserts that tangibility, reliability, assurance, responsiveness, and empathy are the five essential aspects of service quality that can be assessed. Research in study [6] states that each of the previously listed dimensions is defined. First of all, tangibility describes how the actual buildings, tools, staff, and marketing materials seem in relation to the level of service that the insurance firm offers. The capacity to provide promised services consistently and precisely is the second definition of reliability. Next, assurance comprises staff members' expertise, politeness, and capacity to inspire trust in customers. Moreover, being responsive means being ready to help clients and offer timely assistance. Finally, empathy is showing consideration and care for the people who serve clients. Fig. 2 describes how customers feel about an insurance product's satisfaction and quality. According to a study [5], in the PT Multi Artha Guna Insurance motor vehicle insurance market, responsiveness has the lowest score, followed by dependability, empathy, assurance, and tangibility. Furthermore, the research indicates that the ease of the process scheme for filing auto insurance claims to the insurance company is the aspect that most determine consumer satisfaction in insurance services.

One of the procedures used by customers in the motor vehicle insurance sector when they sustain losses on their cars in accordance with the arrangements they have with the insurance provider is filing a claim. The claims procedure is still primarily completed by hand at this time. Because set and consistent parameters are not applied uniformly among insurance firms, this leads to consumer dissatisfaction with the damage assessment process.

This procedure can be made digital and automated with data science and artificial intelligence (AI) techniques, especially deep learning. AI models can be trained using data from prior claims to comprehend and forecast car damage, resulting in a more transparent and objective evaluation. These

AI models can also be trained and enhanced over time, which will speed up and improve the efficiency of the claims process.

Moreover, the procedure for submitting claims currently in place takes a long time. This process can be accelerated by utilizing AI and data science. Sophisticated data analysis methods can be used to find trends in the claims, speed up the verification process, and even help find fraudulent activity. This may result in a quicker settlement of claims, which would eventually increase client satisfaction. It is therefore necessary to develop a more widely accepted, widely adopted, and well-standardized claim submission procedure. Customers will be able to file claims more conveniently, get their cars fixed quickly, and benefit from more transparent and objective damage assessment procedures, all of which will increase customer satisfaction. To overcome the previously described problems, a data science and deep learning strategy will be used in this study.

By employing methodologies rooted in data science and deep learning, it is anticipated that the efficiency and effectiveness of the claims process can be improved while minimizing subjectivity. Data science, an interdisciplinary domain, encompasses scientific techniques, algorithms, and systems to glean insights from data in diverse formats, structured or unstructured. Drawing upon principles from various fields such as mathematics, statistics, information science, and computer science, data science is closely associated with practices like data mining, machine learning, and big data analysis. It facilitates the development of predictive models, identification of trends and patterns, and aids in data-driven decision-making. Deep learning, as described in study [7], is a branch of machine learning that enables computers to learn from prior training and grasp complex concepts. As computers acquire knowledge through experience, human operators are not required to explicitly provide all necessary information. Consequently, this approach holds the potential to enable real-time claims processing for consumers. In the studies by [8] and [9], Deep Learning, particularly Convolutional Neural Networks, was utilized to detect Diabetic Retinopathy from fundus images.

This study will use image data to apply the deep learning approach further to the detection of damaged objects in cars. It is anticipated that using this method will enable effective, real-time damage identification, which will benefit clients. Furthermore, since AI can now automate damage detection—a task that was formerly completed by qualified professionals—insurance firms can save money on their operations.

There are two primary categories of frameworks for generic object detection techniques, according to study [10]. The first kind operates according to the standard object detection procedure, first generating region proposals and subsequently classifying each proposal according to several item types. The second style uses integrated frameworks to produce final findings that include both categories and locations simultaneously, seeing object detection as a classification or regression problem. R-CNN, Mask R-CNN, SPP-net, Fast R-CNN, Faster R-CNN, and FPN are some of the models for the first type; SSD, YOLO (You Only Look Once), DSSD, and DSOD are some of the models for the second type.

Mask R-CNN is an extension of the Faster R-CNN model designed for instance segmentation, i.e., the ability to classify objects in images and simultaneously produce accurate masks for each object instance. Mask R-CNN adds a branch for mask prediction to Faster R-CNN, enabling it to distinguish between objects at the pixel level. In the context of detecting damage on car bodies, studies have used Mask R-CNN to accurately identify and localize damages such as scratches, dents, and scrapes. For example, research in [11] used Mask R-CNN to detect and classify various types of damage on car bodies using a dataset consisting of thousands of car images taken from various angles, demonstrating a high level of precision in damage detection. Subsequently, [12] applied an improved Mask RCNN by optimizing ResNet and FPN as feature extraction. In this study, the use of the improved Mask RCNN method increased accuracy by almost 2%, from 94.53% to 96.38%.

Once the damage has been successfully detected using Mask R-CNN, the classification of the type of damage is performed. Research in study [13] used CNN with EfficientNet and MobileNetV2 architectures. In this study, the results from Mask R-CNN segmentation were used as input for the classification model. The use of this technique in the classification model can improve the F1-score value of the model by up to 9%. The best classification model is MobileNetV2, which uses this technique with an F1-score of up to 91%. Previously, damage detection studies with transfer learning models have also been conducted by comparing various architectures such as Inception V3, VGG16, VGG19, Xception, MobileNet, and ResNet50. The best accuracy results were obtained by the MobileNet model at 97.28%, followed by ResNet50. Another study conducted by [14] used transfer learning models comparing VGG16, VGG19, ResNet34, and ResNet50 architectures. The results showed that ResNet50 had the best accuracy results at 96.39%, followed by VGG19, VGG16, and ResNet34 at 95.87%, 94.84%, and 93.88%, respectively. Furthermore, [15] added an ensemble method to the transfer learning model created. The best result was obtained when using the ResNet architecture with an accuracy of 88.24%.

YOLO is one of the Convolutional Neural Network (CNN) based object detection models widely used today. YOLO can perform two tasks simultaneously, namely detection and classification of damages. In previous studies, several kinds of research have been conducted using YOLO, such as [16] using the YOLO-v5 model to detect damages and the location of insulators. Then, [17] conducted an Automatic Non-Parking Overload Detection Method based on the YOLO-v5 model. In addition, [18] performed real-time object detection for substation security warnings based on YOLO-v5, [19] used the YOLO-v5 model to detect road damages, and [20] used the YOLO-v5 model to detect car damages. In January 2023, [21], the developer of the YOLO-v5 model, released one of the latest versions of YOLO, namely YOLO-v8, which is an improvement over YOLO-v5, where the YOLO-v8 algorithm can be faster in object detection and also more accurate in detecting small objects.

In this research, the YOLO-v5 and YOLO-v8 algorithm approaches will be conducted as algorithms for detecting objects that have been previously conducted in previous studies. The reason for choosing the YOLO-v5 algorithm is because it is one of the most widely used object detection algorithms in various fields at present. Then, the YOLO-v8 algorithm, which is one of the latest version of the YOLO algorithm at present, will also be used. Furthermore, the evaluation results obtained from the YOLO algorithm will be compared with the approach that has been previously done in detecting damages on vehicles, namely damage segmentation using Mask R-CNN and damage type classification using CNN. In this research, the two best CNN architectures based on previous studies, namely ResNet and MobileNet, will be used.

II. Related Work

In this segment, preceding research relevant to the current investigation will be elucidated. Numerous inquiries into car damage detection have been conducted previously. These studies can be seen in Table I.

TABLE I. STATE-OF-THE-ART

Research	Method	Dataset	Evaluation

[20]	YOLO-v5	767 images	Precision = 95%
			Recall = 87%
			F1-score = 91%

[22]	CNN	3000 images	Accuracy = 98%
[23]	YOLO-v3	150 images	Map score = 82%
[13]	Mask R-CNN and CNN (MobileNetV2)	1600 images	F1-score = 91%

[24]	Mask R-CNN and CNN (VGG16)	460 images	Precision = 91%
			Recall = 90%
			F1-score = 90%

[14]	CNN (AlexNet, VGG19, InceptionV3, ResNet50, MobileNets V1.0)	1172 images	Accuracy = 96%
[25]	Transfer learning and VGG16	2300 images	Accuracy = 87%
[26]	R-CNN (MobileNet)	600 images	Accuracy = 95%
[12]	Mask R-CNN (ResNet101)	2000 images	Accuracy = 96%

Therefore, this study will compare the performance of yolo-v8, yolo-v5, ResNet50, and MobileNetV2.

III. Data and Methodology

Within this section, the data and methodologies employed to address the focal subjects of inquiry in this study will be elucidated. Fig. 1 delineates the procedural framework underpinning this research endeavor.

A. Dataset

In this study, the acquisition of photographs depicting automobile damages was conducted in collaboration with PT Global Risk Management. The captured images of vehicles encompass various categories, including scratches, dents, tears, shattered or cracked glass, and fractured or cracked lights. The entirety of the data utilized for this investigation amounts to 700 images. Each class's data volume has been organized into five distinct categories, as illustrated in Fig. 2.

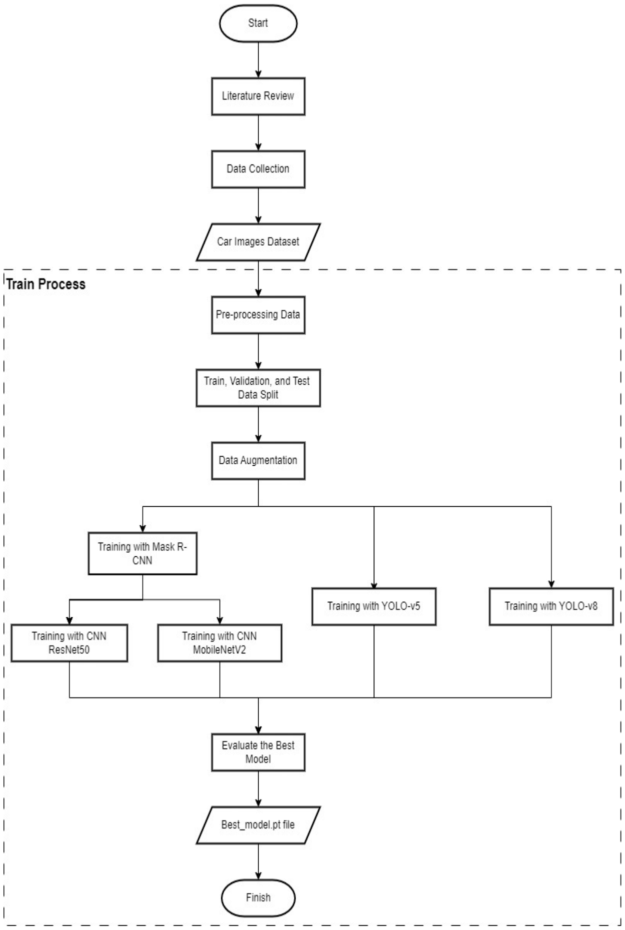

Fig. 1. Research workflow.

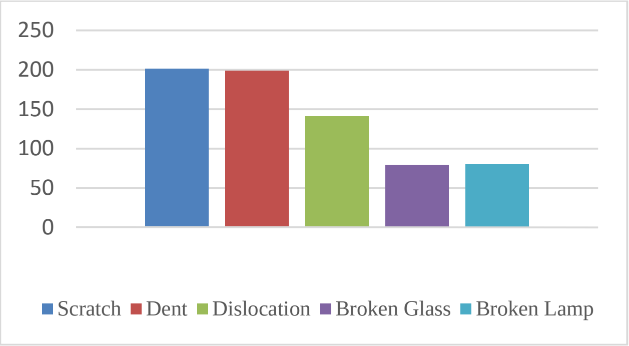

Fig. 2. Damages distribution in the dataset.

B. Data Preprocessing and Augmentations

Several pre-processing data techniques employed in this study include:

- Data Annotation: The annotation process involves marking the location and type of damage on car images. In this study, two annotation approaches were employed: the first utilized bounding boxes for the YOLO algorithm, while the second employed annotation in the Common Object in Context (COCO) format.

- Resizing Data: Resizing images during the data preprocessing stage is a critical step in preparing the dataset for deep learning models. This process involves adjusting the size of images to meet the requirements of the model, with benefits such as computational efficiency, reduced memory load, ensuring consistency in input sizes for the model, and preventing overfitting. In this study, the image sizes of 1024×1024 pixels for the Mask R-CNN algorithm, 224×224 pixels for CNN architectures ResNet and MobileNet, and 640×640 pixels for YOLO-v5 and YOLO-v8 algorithms will be utilized.

- Data Train, Validation, and Test Split: The division of data into training, validation, and test sets is a key stage in the development of deep learning models. The training data, which comprises the majority of the dataset, is used to train the model and enable it to understand patterns and features within the data. Validation data is utilized during training to evaluate the model's performance and prevent overfitting or underfitting. Meanwhile, test data is employed to assess the model's ability against data it has not previously encountered. In this study, the data was divided into train, validation, and test sets with proportions of 70%, 20%, and 10%, respectively.

- Following this, in our research, augmentation techniques were applied to the training data to enhance the dataset's size and optimize algorithm performance. The augmentation methods used include adjusting hue within the range of -90° to 90°, modifying saturation between -50% and 50%, tuning brightness from -20% to 20%, and implementing mosaic augmentation. Below are explanations for each augmentation process:

- Hue Augmentation: Hue augmentation involves adjusting the hue values in an image's color models (HSL or HSV) to enhance data diversity. By rotating hue values, colours shift across the spectrum, promoting learning across various color ranges. This technique prevents models from fixating on specific colors, fostering better adaptation to diverse color variations in new data. Unlike relying solely on memorized colors, hue augmentation encourages focus on object features and shapes. Despite potentially unnatural color shifts, the goal is to improve the model's ability to recognize general visual patterns, reducing reliance on specific color cues.

- Saturation Augmentation: Saturation augmentation is a technique that alters color intensity within an image, affecting brightness and color vibrancy. By randomly adjusting pixel saturation values, it creates varied color tones, prompting machine learning models to discern objects and patterns across different saturation levels. This technique enhances model performance in real-world scenarios with diverse lighting conditions or weather, enabling recognition of objects amidst varying color saturation levels. However, extremes in saturation levels may lead to distorted images, necessitating careful adjustments to maintain visual consistency. When combined with other augmentation methods like hue adjustment or resizing, it enriches dataset variations, aiding models in understanding diverse color schemes and brightness levels in images.

- Brightness Augmentation: Brightness augmentation is a technique used to modify the overall brightness level within an image by applying random changes to pixel brightness values, resulting in either increased or decreased light intensity throughout the image. This adjustment creates diverse lighting variations for objects and backgrounds in the image. The primary aim of brightness augmentation is to enhance machine learning models' adaptability to different lighting conditions encountered in real-world scenarios. However, excessive changes in brightness may lead to the loss of critical image information, necessitating careful adjustments to maintain visual balance. Additionally, local brightness augmentation techniques target specific image areas, offering more precise adjustments. By combining brightness augmentation with other image data augmentation methods, such as contrast enhancement or cropping, a more diverse training dataset can be generated, aiding models in recognizing various lighting conditions.

- Mosaic Augmentation: Introduced in the study [27], this process is a widely used technique in image processing and object detection. It aims to enhance the reliability and robustness of models by combining multiple images into a single mosaic, treating it as a unified image. This method increases the diversity of perspective and scale, thus enriching the model's learning by expanding the variety of training samples. It improves object detection across different scales and viewpoints, as well as enhances the model's ability to handle challenging images, such as those with partially visible or cropped objects. Several studies have utilized mosaic augmentation for object detection, including [28], where it was employed to broaden the variety of training samples and explore the relationship between classification and localization in object detection.

C. *Building Models*

This study will employ two approaches to construct the best model. The first approach utilizes Mask R-CNN to detect the location of damage, after which the output images from Mask R-CNN will be fed into CNN algorithms with ResNet and MobileNet architectures for the classification of damage types. This initial approach, within the scope of object detection, can be termed as a double-stage method because the tasks of detecting damage location and classifying damage types are performed in two distinct stages. The second approach employs the YOLO algorithm, specifically YOLO-v5 and YOLO-v8 in our research, to simultaneously perform the tasks of detecting damage location and classifying damage types. This second approach, within the scope of object detection, can be referred to as a one-stage method because the detection of damage location and the classification of damage types are carried out in a single stage.

For Mask R-CNN, firstly, an input image is fed into the network. This image undergoes processing in the backbone network, which is a combination of the ResNet101 architecture and is complemented by the Feature Pyramid Network (FPN). The backbone network aims to extract feature maps from the input image. Secondly, the feature maps generated by the backbone network are sent to the Region Proposal Network (RPN). In this process, several operations are performed, including sliding window operation, convolution operation, softmax operation, and bounding box regression (bbox regression). The sliding window operation entails a fixed 3×3 window moving across the feature map to identify candidate regions. At each window position, the convolution operation is utilized to produce scores for each anchor and proposal for bounding box regression. The convolution operation applies a kernel to the feature map by sliding it across and computing the dot product between the kernel values and the corresponding feature map values. Mathematically, the convolution operation formula in the RPN network can be observed in Eq. (1).

$$S(i,j) = (I * K)(i,j) = \sum_{m}\sum_{n} I(i+m, j+n) \cdot K(m,n) \tag{1}$$

Next, the softmax operation is performed for the classification of two classes (object vs. non-object). In this study, objects refer to damaged parts of the car body, while non-objects are defined as undamaged parts of the car body. For each anchor, the Region Proposal Network (RPN) generates two scores indicating the likelihood of the anchor containing foreground (object) or background (non-object). The softmax function is applied to these scores to obtain the probability of a desired object using the formula in Eq. (2).

$$\sigma(z)_i = \frac{e^{z_i}}{e^{z_0} + e^{z_1}} \tag{2}$$

Furthermore, the bounding box regression (bbox reg) operation is conducted to refine the bounding box proposals. For each anchor, the Region Proposal Network (RPN) generates four values representing predictions of displacement and scale transformation to adjust the anchor closer to the actual object bounding box. The general formula for bbox reg in the RPN context can be observed in Eq. (3) to Eq. (6).

$$t_x = \frac{(x - x_a)}{w_a} \tag{3}$$

$$t_y = \frac{(y - y_a)}{h_a} \tag{4}$$

$$t_w = \log\left(\frac{w}{w_a}\right) \tag{5}$$

$$t_h = \log\left(\frac{h}{h_a}\right) \tag{6}$$

$$L = L_{cls} + L_{box} + L_{mask} \tag{7}$$

This second process yields outputs in the form of Regions of Interest (RoIs). Subsequently, the RoIs generated by the RPN are mapped to extract corresponding target features in the shared feature map, and then forwarded to the Fully Connected Layers and Fully Convolutional Network (FCN), respectively for target classification and instance segmentation. This process generates classification scores, bounding boxes, and segmentation areas. To evaluate these three aspects, Equation (7) is utilized, where L represents the total loss function, L_{cls} is the loss function for object classification, L_{box} is the loss function for bounding box regression, and L_{mask} is the loss function for object segmentation. Furthermore, the output from the Mask R-CNN algorithm, which consists of segmented images and information regarding the coordinates of segmentation bounding boxes, will be used as input for the subsequent algorithm, which is CNN for classifying the type of damage. Initially, only the parts of the image marked with bounding box coordinates, indicating objects, are selected. The objects identified using Mask R-CNN will be used as input for the damage classification algorithm in this study, employing CNN with ResNet-50 and MobileNet-V2 architectures.

Next, the classification process will be explained by constructing the best model using the ResNet-50 architecture. Initially, the input image is resized to 224×224. Then, the image enters the first convolutional layer consisting of 7×7 filters with an output of 64 feature maps and a smaller dimension image of 112×112. In each filter window, convolution operations, as in Eq. (8), are performed, followed by batch normalization using Eq. (9) and Eq. (10), and finally passed through the ReLU activation function using the formula in Eq. (11).

$$Output = W * X + b \tag{8}$$

$$Output\ normalized = \frac{Output - mean(Output)}{\sqrt{var(Output) + \epsilon}} \tag{9}$$

$$Output\_bn = \gamma \times Output\ normalized + \beta \tag{10}$$

$$ReLU(Output\_bn) = \max(0, Output\_bn) \tag{11}$$

Next, the results from the operations in the first convolutional layer enter the second convolutional layer block. This block consists of three convolutional layers. The first layer comprises 1×1 filters with 64 filters, the second layer consists of 3×3 filters with 64 filters, and the third layer consists of 1×1 filters with 256 filters. Convolution operations, as in Eq. (8), are performed in each filter window, followed by batch normalization using Eq. (9) and Eq. (10), and finally passed through the ReLU activation function using the formula in Eq. (11). This block will be executed three times in total. The output of this block is processed in the third convolutional block.

In the third convolutional block, there are three convolutional layers. The first layer comprises 1×1 filters with 128 filters, the second layer consists of 3×3 filters with 128 filters, and the third layer consists of 1×1 filters with 512 filters. Similar to before, convolution operations, batch normalization, and ReLU activation functions are applied. This block will be executed four times in total.

Next, the output from the third convolutional block enters the fourth convolutional block. This block also consists of three convolutional layers. The first layer comprises 1×1 filters with 256 filters, the second layer consists of 3×3 filters with 256 filters, and the third layer consists of 1×1 filters with 1024 filters. Similar operations are applied in each filter window, and this block will be executed six times in total.

Lastly, there is the fifth convolutional block, which also consists of three convolutional layers. The first layer comprises 1×1 filters with 512 filters, the second layer consists of 3×3 filters with 512 filters, and the third layer consists of 1×1 filters with 2048 filters. Operations similar to previous blocks are applied, and this block will be executed three times in total.

In addition to using the ResNet-50 architecture, this study will also employ the MobileNet-v2 architecture for the CNN classification algorithm with the aim of classifying the types of damage based on the predicted damage areas obtained using the Mask R-CNN algorithm. First, an image of size 224×224 with three channels will be used as input. Then, standard convolution operations will be performed with a filter size of 3×3 and a formula as shown in Eq. (12).

$$O_{ij} = \sum_{m=0}^{M-1} \sum_{n=0}^{N-1} I_{(i+m,j+n)} \cdot K_{mn} \tag{12}$$

Next, it will enter the core part that characterizes the MobileNet-v2 architecture, namely depthwise separable convolution, which consists of two convolutional layers: depthwise convolution and pointwise convolution. In depthwise convolution, a single filter is applied to each feature map separately. This means that if there are D feature maps, there will be D depthwise filters. The formula for the depthwise convolution operation can be seen in Eq. (13).

$$O_{i,j,d} = \sum_{m=0}^{M-1} \sum_{n=0}^{N-1} I_{(i+m,j+n,d)} \cdot K_{m,n,d} \tag{13}$$

After that, the 32 output feature maps from the depthwise convolution will enter the pointwise convolution layer. In pointwise convolution, the operation is performed using 1×1 pixel filters on all the output feature maps from the depthwise convolution. The formula for the pointwise convolution operation can be seen in Eq. (14).

$$O_{i,j,l} = \sum_{d=1}^{D} I_{x,y,d} \cdot K_{d,l} \tag{14}$$

In this process, the output is 64 feature maps with a size of 112×112 pixels. These three convolution processes will be repeated 4 times until an output of 1024 feature maps with a size of 7×7 is obtained. Then, global average pooling operation will be performed with the formula as shown in Eq. (15) below.

$$O_k = \frac{1}{WH} \sum_{i=1}^{H} \sum_{j=1}^{W} I_{i,j,k} \tag{15}$$

As a result, the overall outcome of global average pooling will yield a vector with a dimension size of 1024. Next, this vector will be used as input to the final layer, namely the fully connected layer, with the formula as shown in Eq. (16).

$$\boldsymbol{O_j} = activation\left(\sum_{i=1}^{N} \boldsymbol{W_{i,j}} \cdot \boldsymbol{X_i} + \boldsymbol{b_j}\right) \tag{17}$$

For each layer, an activation function is employed to process the weighted calculations and generate the output of the best model. Typically, the ReLU activation function is used during the process, with the formula as shown in Eq. (18), while the sigmoid activation function is utilized as the activation function in the final layer to perform the classification task, with the formula as depicted in Eq. (19).

$$ReLU(x) = \max(0, x) \tag{18}$$

$$\sigma(\boldsymbol{z})_i = \frac{e^{z_i}}{\sum_{j=1}^{K} e^{z_j}} \tag{19}$$

In this study, detection and classification of car body damage will also be performed using the YOLO algorithm. YOLO is an algorithm capable of simultaneously performing detection and classification functions. Therefore, the YOLO algorithm approach can be referred to as a case of object detection with a one-stage method. In our study, two versions of the YOLO algorithm will be used, namely YOLO-v5 and YOLO-v8. The reason for choosing these two versions is that both were developed by the same team, Ultralytics. YOLO-v5 was released in May 2020 and has been widely used in various fields for object detection cases. It will then be compared with YOLO-v8, which is one of the latest versions of YOLO released in January 2023. First, the implementation of YOLO-v5 in this study will be explained.

YOLO-v5 consists of several sub-versions, namely YOLO-v5n, YOLO-v5s, YOLO-v5m, YOLO-v5l, and YOLO-v5x. All sub-versions have the same input size, which is an image with dimensions of 640×640 pixels. Each version has a similar overall architecture, with differences only in the number of layers and parameters used. For example, YOLO-v5n has the fewest layers and parameters, resulting in the fastest computation time compared to all other sub-versions, but its accuracy is relatively lower compared to the other four sub-versions. Typically, the choice of sub-version is based on the complexity of the case or problem and the available resources. The performance of these five sub-versions will be compared in this study. Fig. 3 shows YOLO-v5 architecture.

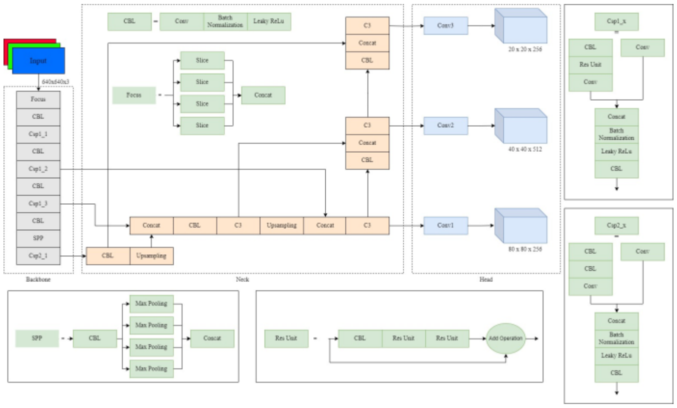

Fig. 3. YOLO-v5 architecture.

The YOLO architecture is divided into three main parts: backbone, neck, and head. In the backbone part, the first step involves the input image with dimensions of 640×640×3 pixels entering the focus layer. In this layer, the image is divided into four equally sized parts and combined into a new image tensor with dimensions of 320×320×12. The purpose of this operation is to reduce the spatial dimensions of the image and focus more on the important features within it. The output of this layer then enters the subsequent CBL layer.

In the next process in the CBL layer, three main operations are performed: convolution operation, batch normalization, and Leaky ReLU. The convolution operation generates new feature maps using a 3×3 filter applied to the entire spatial area of the input feature map. This operation is used to extract important and meaningful features from the image. Next, batch normalization is applied to normalize the output of the convolution layer and speed up convergence towards the best model. Finally, the Leaky ReLU operation is used to prevent dead neurons due to negative input values. The formulas for each operation can be seen respectively in Eq. (20) – Eq. (22).

$$O_{ijk} = \sum_{m=0}^{M-1}\sum_{n=0}^{N-1}\sum_{c=0}^{C-1} I_{i+m,j+n,c} \cdot K_{mnck} \tag{20}$$

$$O'_k = \gamma\left(\frac{O_k - \mu_b}{\sqrt{\sigma_B^2 + \epsilon}}\right) + \beta \tag{21}$$

$$f(x) = \begin{cases} x, & jika\ x > 0 \\ \alpha x, & jika\ x \le 0 \end{cases} \tag{22}$$

Then, there are several layers that need to be passed through such as Residual Unit (Res unit), CSP bottlenecks, and Spatial Pyramid Pooling (SPP). In the Res Unit, the concept from the ResNet architecture is used where the input feature map can perform skip connections to convolutional layers, and then their results are combined with the output of those convolutional layers. This is done to preserve some important original features in the image. Then, in the CSP bottlenecks, there are two types of operations: $csp1_x$ and $csp2_x$. Finally, in the SPP operation, max pooling is performed in parallel on the output from the CBL with varying window pooling scale intensities. Then, the results of each max pooling operation are combined again to deepen the features.

In the neck part, there are two operations that have not been performed in the backbone process, namely upsampling, concatenation, and C3. In this part, the model focuses more on processing the feature maps generated in the previous backbone part, before continuing to the head part for the prediction process. Upsampling is the process of increasing the resolution of the feature map. This is usually done through techniques such as nearest neighbor or bilinear interpolation. To perform an upsampling operation, given a feature map with size $W \times H$, upsampling with a scale factor s will result in a new feature map with size $sW \times sH$. This operation is carried out to increase the resolution of the feature map to match the dimension of the feature map that will undergo concatenation operation. Concatenation operation is the process of appending one or more tensors along a certain dimension. In this case, feature maps of various resolutions that have been upsampled will be concatenated along the channel dimension. For example, if there are two feature maps A and B with sizes $W \times H \times C_A$ and $W \times H \times C_B$ respectively, then the result of the concatenation operation will yield a feature map with size $W \times H \times (C_A + C_B)$.

After the upsampling and concatenation operations, there is another block operation called C3. The C3 block aims to further process the concatenated feature maps, using the bottleneck CSP technique for computational efficiency while still extracting relevant features. In this block, there are two main operations: convolution operation and bottleneck CSP operation. The convolution operation consists of three layers followed by batch normalization and Leaky ReLU operations as shown in Eq. (20) – Eq. (22). After passing through the convolution layers, the feature map will enter the bottleneck CSP operation. The C3 block is responsible for processing the combined features and generating richer feature maps that will be used for prediction.

Finally, in the head part, the output from the first C3 block will enter the last convolution layer for the bounding boxes prediction process, the output from the second C3 block will enter the last convolution layer for predicting the confidence or probability of the damage being detected inside the bounding boxes or not, and the output from the last C3 block will enter the last convolution layer and used for classifying the type of damage. These three outputs will be evaluated to minimize the loss using Eq. (23) – Eq. (27).

$$Loss = \lambda_1 L_{cls} + \lambda_2 L_{obj} + \lambda_3 L_{loc} \tag{23}$$

$$L_{cls} = L_{obj} = -\frac{1}{N}(y_n \times ln_{x_n} + (1 - y_n) \times \ln(1 - x_n)) \tag{24}$$

$$L_{loc} = 1 - IOU + \frac{\rho^2(b, b^{gt})}{c^2} + \alpha v \tag{25}$$

$$v = \frac{4}{\pi^2}(\arctan^2 \frac{w^{gt}}{h^{gt}} - arctan\frac{w}{h})^2 \tag{26}$$

$$\alpha = \frac{v}{(a - IOU) + v} \tag{27}$$

In Eq. (24), N represents the number of classification classes, y_n represents the ground truth for the presence of each class within the bounding boxes (1 if class n of damage is within the bounding boxes and 0 if class n of damage is not within the bounding boxes), and x_n represents the predicted probability for that class.

Next, the YOLO-v8 model will be explained. This study compares several sub-versions of YOLO-v8, specifically YOLO-v8n, YOLO-v8s, YOLO-v8m, YOLO-v8l, and YOLO-v8x. Similar to YOLO-v5, all sub-versions of YOLO-v8 use input images of size 640×640. YOLO-v8n is the version with the fastest training time as it uses the fewest parameters and layers. On the other hand, YOLO-v8x is the sub-version with an average longest training time but is expected to yield the most accurate results due to the higher number of parameters and layers used. In this study, all the aforementioned sub-versions of YOLO-v8 are compared.

First, an image with dimensions of 640×640×3 pixels is taken as input into the algorithm. Then, the image is processed within the Convolutional Block (CBS Module). In this CBS block, several operations are performed, including convolution operation, Batch Normalization, and Sigmoid activation function. The formulas for performing these three operations can be seen in Eq. (28) – Eq. (30).

$$O_{ijk} = \sum_{m=0}^{M-1} \sum_{n=0}^{N-1} \sum_{c=0}^{C-1} I_{i+m,j+n,c} \cdot K_{mnck} \quad (28)$$

$$O'_k = \gamma \left(\frac{O_k - \mu_b}{\sqrt{\sigma_B^2 + \epsilon}} \right) + \beta \quad (29)$$

$$\sigma(O'_k) = \frac{1}{1 + e^{(-O'_k)}} \quad (30)$$

The CBS block has the main function of extracting feature maps and reducing spatial dimensions. In addition, there are other operation blocks, namely C2F and SPPF. In the C2F operation block, the feature map is divided into n parts, where n represents the number of bottleneck layers. Then, each layer undergoes two operations as described in Eq. (28) – Eq. (30). For the SPPF operation block, there is a uniqueness where the feature map is first divided into four parts, and each part undergoes processing as shown in Fig. 4. Furthermore, the neck and head parts are not much different from those in YOLO-v5. All operations performed are almost the same, with only differences in the order of operation processes and the size of the feature map in the final detection block.

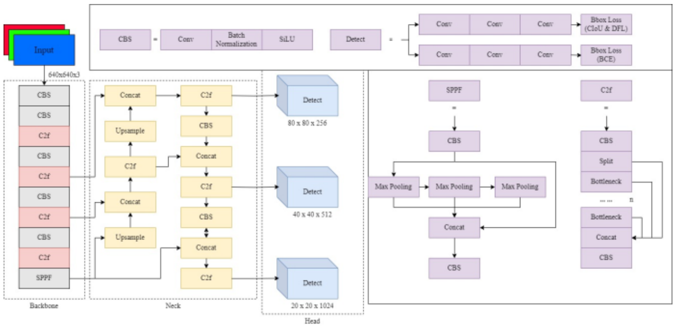

Fig. 4. YOLO-v8 architecture.

IV. Experiments and Result

A. The Evaluation Parameters

Several evaluation criteria were used in this study, including the F1-score, precision, and recall. A prominent tool for evaluating the effectiveness of classification models is the confusion matrix, which offers a thorough comparison between the predictions made by the model and the actual labels. False Positives (FP), False Negatives (FN), True Positives (TP), and True Negatives (TN) are all part of it. Precision is a metric that measures the proportion of true positive predictions compared to the total positive predictions. Precision provides information on how many of the positive predictions are correct out of the total positive predictions, assisting in identifying the rate of false positive errors. Recall computes the percentage of successfully predicted positive instances among all actual positive instances, whereas precision quantifies the percentage of correctly predicted positive instances among all cases projected as positive. Recall provides information on the extent to which a model can detect actual positive instances, aiding in identifying the rate of false negative errors. The F1-score provides a fair evaluation of the model's performance since it is a harmonic mean of precision and recall. This provides a balanced measure of the model's ability to identify positive instances with minimal false positive and false negative errors. The given formulas can be used to calculate these measures.

$$Precision = \frac{TP}{TP + FP} \quad (31)$$

$$Recall = \frac{TP}{TP + FN} \quad (32)$$

$$F1 - Score = \frac{2 \times (presisi \times recall)}{presisi + recall} \quad (33)$$

B. Experimental Analysis

In this research endeavor, to conduct simulations and model development aimed at detecting damages on automobile bodies, as well as to create a digital image-based system for detecting such damages, the authors employed machinery and software characterized by specifications delineated in the ensuing table. For comprehensive details regarding the specifications of the equipment utilised by the authors, kindly consult Table II.

TABLE II. Device Specification

Specifications	
GPU	NVIDIA RTX A4000
GPU Memory	16 GB
RAM	16 GB
Disk	1 TB
Programming Language	Phyton 3.10

The authors set the number of epochs to 150 iterations, the learning rate to 0.01, and the image sizes to 1024×1024×3 for Mask R-CNN, 224×224×3 pixels for ResNet-50 and MobileNet-v2, and 640×640×3 pixels for YOLO-v5 and YOLO-v8. Additionally, a batch size of 16 was assigned to each model employed in this study.

According to Table III, it is evident that the best results were achieved by the YOLO-v8x model, with precision, recall, and F1-score values of 0.963, 0.951, and 0.936, respectively. Training the YOLO-v8x model to its optimal performance required 3 hours and 48 minutes. Additionally, the model with the shortest training time was YOLO-v8n, which trained in 2 hours and 10 minutes, achieving precision, recall, and F1-score values of 0.867, 0.821, and 0.814. YOLO-v8n demonstrates superior performance compared to the Mask R-CNN + MobileNet-v2 model, despite the significant difference in training duration. However, the Mask R-CNN + ResNet-50 model still outperforms several sub-versions of the YOLO-v5 and YOLO-v8 models. Furthermore, the one-stage object detection method which is YOLO-v8x has better performance than the two-stage method in this research.

Additionally, Fig. 5 and Fig. 6 illustrate a comparison between the manually labeled images and the model's predicted results. Observations indicate that the model generally performs well in detecting damages to the vehicle's body.

TABLE III. MODELS PERFORMANCE

Model		***Evaluation Parameters***			**Training Time**
		Precision	***Recall***	***F1-Score***	
Mask R-CNN + ResNet-50		0.908	0.885	0.860	4 hours 35 minutes
Mask R-CNN + MobileNet-v2		0.866	0.842	0.815	3 hours 20 minutes
YOLO-v5	YOLO-v5n	0.841	0.813	0.820	2 hours 23 minutes
	YOLO-v5s	0.849	0.842	0.842	2 hours 48 minutes
	YOLO-v5m	0.893	0.878	0.875	3 hours 9 minutes
	YOLO-v5l	0.918	0.891	0.893	3 hours 40 minutes
	YOLO-v5x	0.922	0.903	0.899	4 hours 32 minutes
YOLO-v8	YOLO-v8n	0.867	0.821	0.814	2 hours 10 minutes
	YOLO-v8s	0.892	0.842	0.839	2 hours 24 minutes
	YOLO-v8m	0.924	0.892	0.893	2 hours 58 minutes
	YOLO-v8l	0.954	0.914	0.909	3 hours 21 minutes
	YOLO-v8x	**0.963**	**0.951**	**0.936**	3 hours 48 minutes

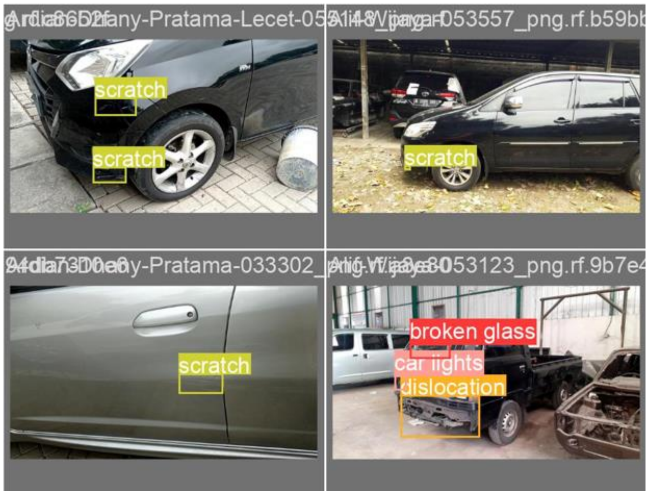

Fig. 5. Manually labelled images.

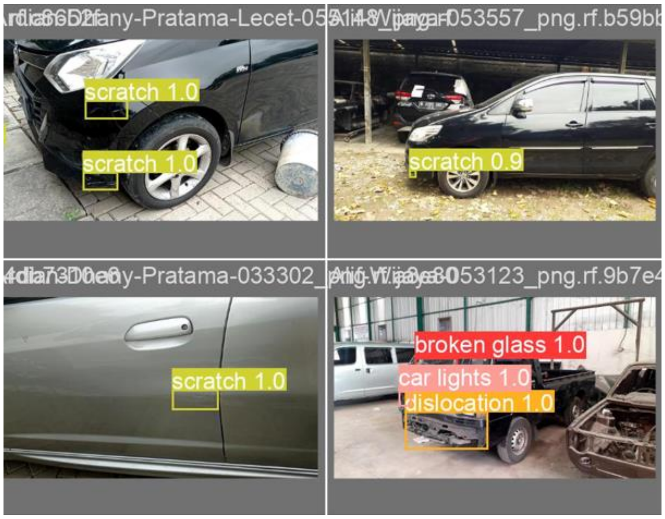

Fig. 6. Predicted result of YOLO-v8x model.

V. CONCLUSION AND FUTURE WORK

In this research, the best results were obtained using the YOLO-v8x model. This can be explained because YOLO-v8 is one of the newest versions of YOLO, which is stable and was released in early 2023. Furthermore, YOLO-v8 is also a development of YOLO-v5, which results in even better model performance. Further research is needed by trying various batch sizes, epochs, increasing the amount of data, trying various other data augmentation combinations, and using the latest YOLO model, namely YOLO-v9, which was only released in early 2024.

***Abstract*—Agriculture is fraught with uncertainties arising from factors like weather volatility, pest outbreaks, market fluctuations, and technological advancements, posing significant challenges to farmers. By gaining insights into these risks, farmers can enhance decision-making, adopt proactive measures, and optimize resource allocation to minimize negative impacts and maximize productivity. The research introduces an innovative approach to risk prediction, highlighting its pivotal role in improving agricultural practices. Through meticulous analysis and optimization of a farmer dataset, employing pre-processing techniques, the study ensures the reliability of predictive models built on high-quality data. Utilizing Variation Inflation Factor (VIF) for feature selection, the study identifies influential features critical for accurate risk classification. Employing techniques like KNN, Random Forest, logistic regression, SVM, Ridge classifier, Gradient Boosting and XGBoost, the study achieves promising results. Among them KNN, random forest, Gradient Boosting and XGBoost scored with high accuracy of 88.46%. This underscores the effectiveness of the proposed methodology in providing actionable insights into potential risks faced by farmers, enabling informed decision-making and risk mitigation strategies.**

***Keywords*—Random forest; ridge classifier; logistic regression; gradient boosting; extreme gradient boost; Variation Inflation Factor; support vector machine; farmer risk prediction; agricultural risk**

I. Introduction

Agriculture is a vital sector of any country; therefore, the growth and development of a country directly depend on agriculture. Agriculture is, not just only a means of subsistence or income, it's a way of living life for the human species [1]. Agriculture is the key source of food, forage, and energy and serves as the cornerstone of the economic growth of any country. Agriculture is the key source of food, forage, and energy and serves as the cornerstone of the economic growth of any country [2]. In the current Indian era, agriculture still plays a significant role in the lives of more than 80% of Indians who are directly or indirectly involved in farming activities. According to the census of India 2021, the agricultural sector of India employed 54.6 % of the total workers. The agriculture sector and allied sector provide 17.8 % of the nation's Gross Value Added [3].

Agriculture is one of the risky professions with uncertain outcomes and a variety of risks are faced by Indian farmers over the whole growing season. The World Bank defines "Agricultural risk as a combination of the possibility of a hazardous event or exposure and the severity of the losses that can be caused by the event or exposure" [4]. One of the most vital agricultural risks is the production or biological risk, which is mostly brought on by climate variability and is getting worse every day as a result of climate change [5]. However, many other factors such as financial, legal, marketing, technological, social, and human personal factors can contribute to agricultural risk in addition to this climate change effect and farmers have to deal with all the risk sources. For instance, events like insect pest attacks [6], bad quality of inputs, epidemics [7], volatile prices, and unavailability of inputs can also decrease the production as well as income of Indian farmers. Therefore, based on these risk components, agricultural risk can be broadly classified as economic, production, technological, institutional, and personal risk. Risk is classified into five categories viz., Economic risk, Production risk, Technological risk, Institutional risk, and Personal risk [8].

The main contributions of this study can be outlined as follows:

- Develop predictive models for farmers' risk prediction using machine learning (ML) techniques.
- Optimize feature selection through Variation Inflation Factor (VIF) analysis to enhance the accuracy of risk prediction.
- Evaluate the performance of various classifiers, including KNN, Random Forest, SVM, Ridge classifier, logistic regression, Gradient Boosting, and XGBoost, in predicting farmers' risk levels.

The rest of the paper is organized as follows: In Section II, a summary of literature is provided, highlighting areas that indicate a need for more investigation. In Section III, the methodology is explained in depth. Section IV goes into great detail about the results that the suggested strategy produced. A discussion is provided in Section V and finally, a summary of the findings is included in Section VI, which gives a conclusion to the paper.

II. Literature Review

Jinger et al. [9] introduced a fuzzy model designed for forecasting maize crop yields. They evaluated maize production by incorporating parameters such as temperature, humidity, rainfall during different growth stages, and the sowing area. Upadhya et al. [10] proposed, fuzzy logic-based crop yield estimation, considering temperature, humidity, and soil moisture as input parameters. The parameters were subjected to fuzzy arithmetic, resulting in obtaining crisp values of yield. Trapezoidal membership functions were considered in the fuzzy modeling. Pandhe et al. [11] suggested a model, it was determined that if farmers were aware of the yield potential of the crops, they are planting beforehand, they would opt for crops with higher expected yields based on the climate of the region. With an accuracy of 87%, assessed through a 10-fold cross-validation technique, indicating a strong correlation between climate factors and crop yield.

Kalimuthu et al. [12] aid beginner farmers by providing guidance on suitable crop choices through the utilization of machine learning, advanced technology in crop prediction. The Naive Bayes algorithm, a supervised learning technique, was employed to achieve this objective. The approach involves the development of a supervised ML model using the naive Bayes Gaussian classifier with a boosting algorithm to predict crops with high accuracy. Consequently, the predicted crop seed serves as the output for the given input parameters. Mulla et al. [13] centered on exploring the prediction of crop yield and cost estimation. The methodology proposed employs tree algorithms to efficiently predict the outcomes. The study primarily encompasses several key implementation modules, including data acquisition, data exploration, prediction, and the development of a web application. Mohanty et al. [14] describe four functional components, which include predicting crop yield, predicting demand, determining supply and forecasting crop prices. The input datasets consist of a range of field values, demand, and remaining crop at year-end, encompassing yield, import and crop prices. Rani et al. [15] proposed a model for estimating commodity prices. By using techniques like Linear Regression, Random Forest, and Decision Trees. The model's successful application of decision trees, random forests, and linear regression suggests an appropriate estimation.

Chen et al. [16] investigated the complexities and challenges in agri-food supply chains (ASCs), highlighting the need for effective traceability and management. They designed a blockchain-based ASC framework to ensure decentralized security and traceability of agri-food products. Additionally, they proposed a Deep Reinforcement Learning-based Supply Chain Management (DR-SCM) method to optimize production and storage decisions for increased profits. Extensive simulations demonstrated the framework's reliability in maintaining secure, consistent, and unique tracing data. Moreover, the DR-SCM method consistently outperformed heuristic and Q-learning methods in various scenarios, achieving higher profits and exhibiting greater adaptability. The study concluded that integrating blockchain with DR-SCM significantly enhances traceability and profitability in ASCs, paving the way for further research on advanced algorithms in more complex environments. Rakhra et al. [17] aimed to address the myriad challenges encountered by farmers in accessing tool and equipment, as well as to ascertain their keen interest in equipment rental and sharing processes. Farmers were categorized into three groups—small, moderate, and large—based on the findings of the survey. To gain a deeper insight into the target variables, the dataset underwent training and testing splits. Standardization of the survey dataset was performed to ensure clarity and remove ambiguity.

Chelliah et al. [18] is grounded in satellite imagery and utilizes ML algorithms to achieve an accuracy enhancement. This paper introduces a target prediction algorithm aimed at guiding farmers regarding market target products and fostering improved relationships between farmers and bankers through centralized information about recent government plans. Additionally, a ML algorithm for crop prediction is proposed to augment agricultural revenue. The proposed model holds relevance for real-world research, facilitating the assessment of the acceptability of the financial forms detailed in this study.

Existing studies have explored various risk factors and modelling approaches, but there remains a lack of comprehensive frameworks that effectively integrate diverse data sources and advanced analytical techniques to provide actionable insights for farmers. Additionally, the majority of current research focuses on individual risk factors or employs simplistic modeling techniques, neglecting the multifaceted nature of agricultural risks and the potential interactions between different risk factors. Addressing this gap requires the development of sophisticated predictive models that leverage advanced ML algorithms, incorporate diverse data streams, and account for the dynamic and interconnected nature of agricultural systems. Such models have the potential to significantly enhance farmers' ability to anticipate, mitigate, and adapt to various risks, thereby improving agricultural sustainability, resilience, and productivity.

III. Materials and Methods

The study initiates the collection of a comprehensive farmer dataset, comprising diverse variables such as weather conditions, pest prevalence, disease outbreaks, input and product prices, technology adoption rates, and insurance coverage. Following dataset collection, a rigorous pre-processing phase, which includes tasks such as handling outliers, correlation finding, and encoding to ensure the dataset's quality and suitability for predictive modelling. Subsequently, the Variation Inflation Factor (VIF) technique [19] is employed to select the most influential features from the dataset, facilitating accurate risk classification. Various Machine Learning techniques, including K-Nearest Neighbor [20], Random Forest [21], logistic regressions [22], Support vector machines [23], Ridge classifier [24], Gradient Boosting [25], and XGBoost [26], are then trained on the selected features. Finally, the trained models are utilized for making predictions on new farming scenarios, providing valuable insights into potential risks faced by farmers and enabling informed decision-making and risk management strategies. Fig. 1 illustrates the block diagram depicting the architecture of the envisioned system.

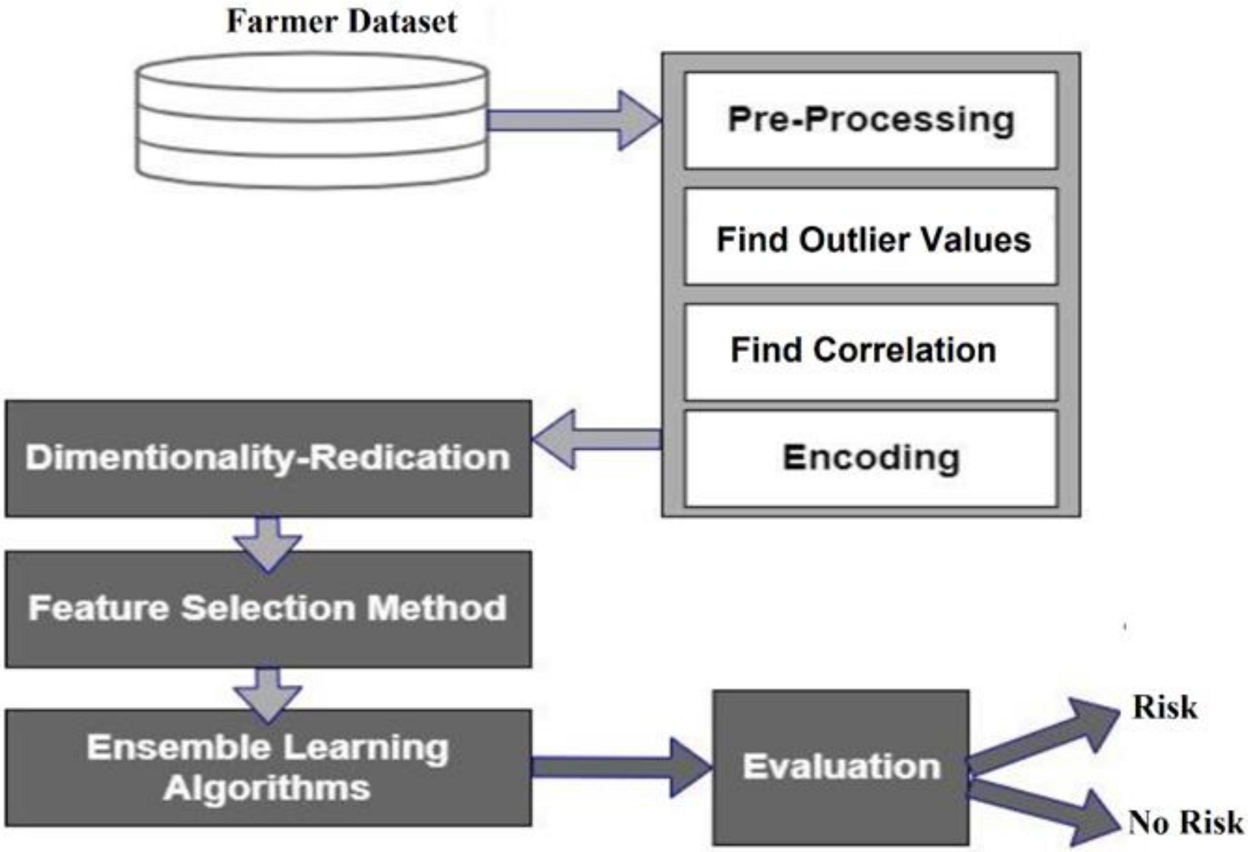

Fig. 1. Proposed farmers risk prediction system.

A. Dataset Description

The farmer dataset utilized in this study serves as a comprehensive repository of factors influencing farmers' risk. Collected through a nationwide survey, the dataset encapsulates the diverse perspectives and experiences of farmers across different regions of the country. Given the multifaceted nature of agricultural risk, the dataset captures a wide array of factors, ranging from climatic conditions and soil quality to crop varieties, farming techniques, and socioeconomic indicators. With a total of 12 features encompassing these diverse risk factors as tabulated in Table I, the dataset provides a rich foundation for developing ML model aimed at predicting and mitigating farmers' risk.

Each feature included in the dataset represents a distinct aspect of the agricultural ecosystem, reflecting the intricate interplay of environmental, socio-economic, and agronomic factors influencing farmers' risk levels. The sample dataset is depicted in Fig. 2. By synthesizing farmers' opinions and experiences, the dataset offers a holistic view of the challenges and opportunities faced by agricultural communities in terms of risk exposure. By analyzing such a dataset, predictive models can be trained to forecast risks effectively, helping farmers and stakeholders make informed decisions to mitigate potential adverse outcomes. The structured representation of these features allows for a comprehensive analysis, contributing to the development of robust risk prediction frameworks in agriculture.

TABLE I. FEATURES IN THE DATASET

Features	Range

B. Data Preprocessing

Data preprocessing involves several essential steps aimed at preparing the data for analysis and modeling. This process typically involves cleaning, transforming, and organizing the data to ensure its quality, consistency, and relevance for predictive modeling purposes.

1) Finding outlier: Outlier detection plays a crucial role in the preprocessing step, the dataset is partitioned into quartiles including Q1, Q2 (median), and Q3, from which the interquartile range (IQR) is calculated as the difference between the third and first quartiles. Subsequently, data points deviating below Q1 - 1.5 * IQR or above Q3 + 1.5 * IQR are flagged as potential outliers. Outliers are exceptional conditions or extreme values indicating influential factors impacting risk assessments. Table II displays the dataset after the application of quartile ranges.

For instance, anomalies such as unusually high or low rainfall, atypical market fluctuations, or unexpected shifts in socio-economic indicators could signal outlier observations requiring closer examination. Detecting and addressing these outliers are essential as they could either represent genuine anomalies warranting further process or erroneous data entries capable of skewing risk prediction models. Therefore, integrating the quartile range method during preprocessing enables researchers to effectively identify and manage outliers, thereby ensuring the robustness and accuracy of subsequent analyses and predictive modeling efforts in farmers' risk assessment.

2) Finding correlation: Correlation analysis uncovering the relationship between different variable, pairwise correlation coefficient is computed to evaluate the strength and direction of the linear relationship between each pair of variables in the dataset. This entails figuring out Pearson correlation coefficients, which have a range of -1 to 1, with values near -1 denoting a strong negative correlation, values near 0 showing no linear link, and values closer to 1 indicating a significant positive correlation. Following the computation of correlation coefficients, a correlation matrix is constructed as shown in Fig. 3, offering a comprehensive overview of the relationships between all variables pertinent to farmers' risk prediction.

Significant findings include a strong positive correlation between 'Product Type' and 'Pest' (1.00), indicating that certain product types are more susceptible to pest infestations. 'Insurance' also shows a high positive correlation with 'Finance' (0.77), suggesting that better financial health is associated with higher insurance coverage. Conversely, 'Target' (representing risk) shows strong negative correlations with 'Finance' (-0.44), 'Diseases' (-0.35), and 'Subsidies' (-0.41), implying that better financial conditions, fewer diseases, and more subsidies are associated with reduced risk. Additionally, 'Technology Adoption' correlates positively with 'Product Type' (0.75) and 'Pest' (0.95), suggesting that technological advancements are more prevalent in certain product types and pest management.

TABLE II. DATASET AFTER APPLYING QUARTILE RANGES

Feature	Value
Weather	0
Pest	918
Finance	0
Diseases	0
Input Price	0
Product Price	1500
Product Type	918
Subsidies	0
Technology Adoption	1002
Insurance	1412
Eco Sensitive Zone	0
Duration	526
Target	0

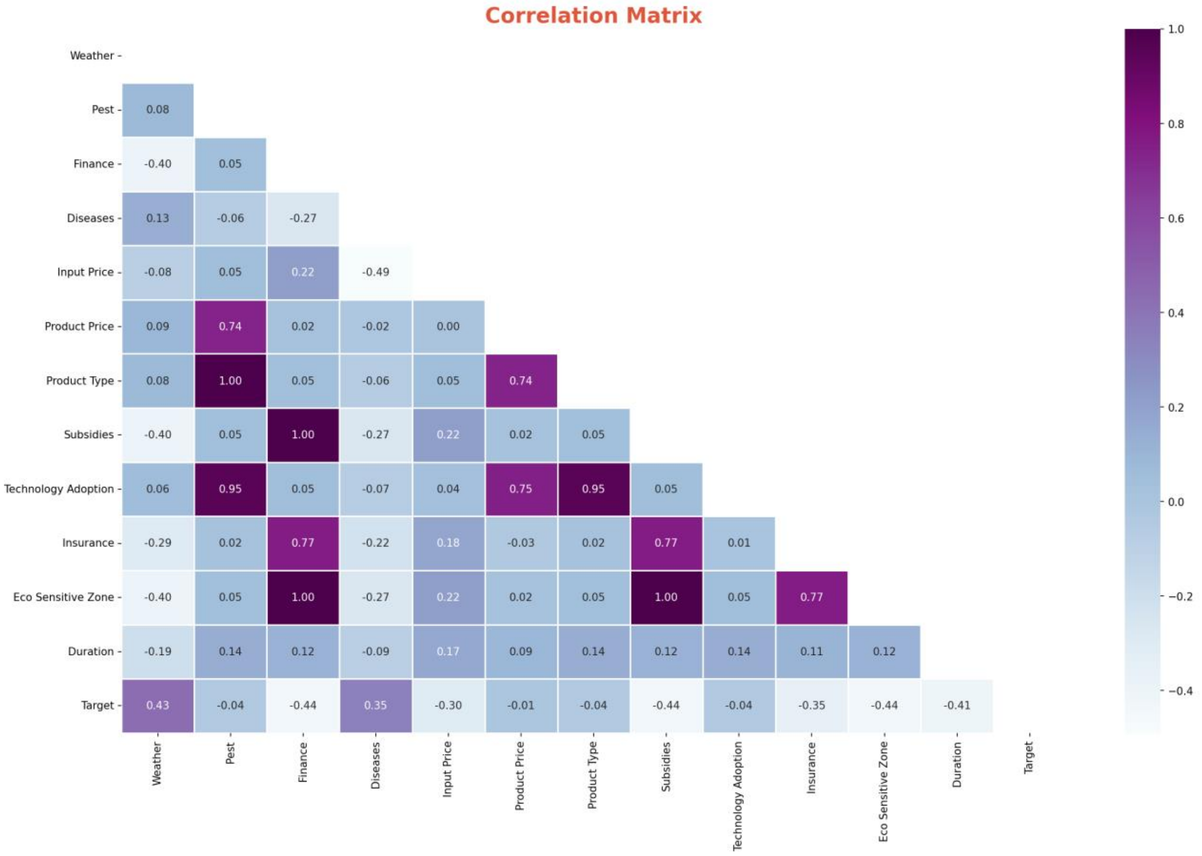

Fig. 3. Correlation matrix.

3) Encoding: Agricultural datasets contain categorical variables representing qualitative attributes such as crop types, farming practices, or geographical regions. However, most ML algorithms are designed to process numerical data, necessitating the conversion of categorical variables into a numerical format. During encoding, assigning unique numerical identifiers to each category within a categorical variable, enables computational models to effectively interpret and analyze the data.

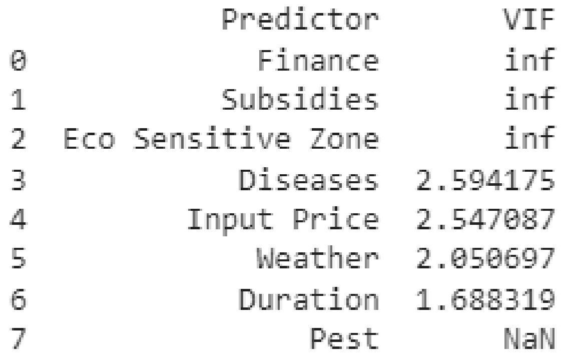
C. Variation Inflation Factor

The paramount importance of mitigating multicollinearity risks ensures the reliability and accuracy of our models. To address this concern, we adopted a Variation Inflation Factor (VIF) approach, leveraging its iterative analysis to detect and manage multicollinearity effectively.

The VIF method facilitated the identification of correlated predictor variables, which might not exhibit significant effects when considered together but demonstrate their true significance when assessed independently. VIF computation involved conducting linear regressions for each predictor variable and obtaining the coefficient of determination (R^2). The VIF value was calculated using the Eq. (1).

$$VIF_i = \frac{1}{1-R_i^2} \quad (1)$$

VIF value of one indicates no correlation, increasing values signify stronger correlations with other variables. Models ignoring collinearity risks often exhibit high variance and instability, making it challenging to discern the relative importance of each variable and leading to inaccurate tests of significance. Features exhibiting VIF values exceeding 10,000 were deemed excessively collinear and consequently eliminated from the selection process. We adopted a practical interpretation guideline for VIF values: variables with VIF > 10 were removed outright, those with VIF > 5 were subject to scrutiny before elimination, and variables with VIF < 5 were deemed valuable and retained in the analysis, as shown in Fig. 4.



```
             Predictor       VIF
0              Finance       inf
1            Subsidies       inf
2   Eco Sensitive Zone       inf
3             Diseases  2.594175
4          Input Price  2.547087
5              Weather  2.050697
6             Duration  1.688319
7                 Pest       NaN
```

Fig. 4. VIF Output for feature selection.

D. Proposed Classifier Models

Ensemble learning, a machine learning technique employed in our research, significantly bolsters accuracy and resilience in forecasting by amalgamating predictions from multiple models. By harnessing the collective intelligence of the ensemble, this approach aims to mitigate errors or biases inherent in individual models. The methods utilized in the proposed study encompass a diverse range, including K Nearest Neighbor (KNN), Random Forest, Gradient Boosting, XGBoost, Support Vector Classifier (SVC), Logistic Regression, and Ridge Classifier. By leveraging the strengths of these various algorithms, our ensemble learning framework endeavors to provide robust and reliable predictions for farmer risk prediction tasks.

1) K Nearest Neighbour: The k Nearest Neighbors (kNN) algorithm operates by assigning a class label to a test point based on the majority class of its k nearest neighbors [27]. In the 1-NN approach, the class of the closest neighbor is directly assigned to the test point, which can lead to errors if the nearest neighbor is an outlier.

However, by considering a larger k value, such as in the kNN approach with k = 7, the influence of outliers is mitigated as the class assignment is determined by the majority class among the k nearest neighbors. This approach improves the reliability of class assignments, where the majority class among the k = 7 nearest neighbors yields a more accurate classification compared to the 1-NN approach. The choice of distance and similarity measures plays a crucial role in various pattern recognition tasks.

Let's denote our training dataset as $D = \{(x_i, y_i)\}\, for\; n\; terms$ where x_i represents the feature vector for i^{th} sample and y_i represents the corresponding risk level. Euclidean distance measures the similarity between feature vectors. For two feature vectors x_i and x_j the Euclidean distance is given by Eq. (2).

$$D\ (x_i, x_j) = \sqrt{\sum_{k=1}^{p}(x_{ik} - x_{jk})^2} \tag{2}$$

When presented with a new data point, x, to predict the risk level, the k nearest neighbors to x are identified based on the calculated distances. In regression tasks such as predicting risk levels, the average of the risk levels of the k nearest neighbors is utilized as the prediction as illustrate by Eq. (3).

$$\hat{y}_{new} = \frac{1}{k}\sum_{i=1}^{k} x_i \tag{3}$$

Where, $\hat{y}_{new}$ is the predicted risk level for the new data point x_i,y_i are the risk level of k nearest neighbors.

2) Random forest: Predictions of multiple decision trees are combined in Random Forest to produce a robust and accurate final prediction [28]. By introducing randomness during both the training and prediction phases, Random Forest mitigates overfitting and increases diversity among the constituent trees. The decision tree construction process would involve selecting the most informative features at each node to effectively partition the data based on factors such as weather conditions, pest infestation, disease prevalence, market prices, crop types, financial factors, technological adoption, insurance coverage, and environmental considerations.

Given a dataset with N data points and M features, each decision tree $T_i$is built by recursively partitioning the feature space based on selected features. At each node j, a split is made by selecting the feature f that maximizes information gain or minimizes impurity. The decision tree construction process can be represented mathematically as in Eq. (4).

$$f_j = arg\ arg\ max\ _f Gain\big(D_j, f\big) \tag{4}$$

Where D_j represents the dataset at node j and $Gain(D_j, f)$ denotes the information gain achieved by splitting on feature f. Bootstrap sampling allows us to create diverse training datasets that capture various combinations of weather patterns, pest and disease occurrences, market conditions, financial situations, technological adoption rates, and other relevant factors affecting farmers' risk. The bootstrap sampling process can be expressed as in Eq. (5).

$$D_i = Bootstrap\ sampling(D) \tag{5}$$

where D is the original dataset and D_i represents the bootstrap sample for tree T_i. In the prediction phase, the Random Forest algorithm aggregates predictions from all decision trees. For regression tasks like the proposed method, the final prediction $\hat{y}_{RF}$ is calculated as the average prediction across all trees as depicted in Eq. (6).

$$\hat{y}_{RF} = \frac{1}{T}\sum_{i=1}^{T} \hat{y}_i \tag{6}$$

where T is the total number of trees in the forest and $\hat{y}_{RF}$ is the prediction from tree T_i.The aggregated prediction considers the combined insights from all decision trees trained on diverse subsets of features, enabling a comprehensive assessment of the potential risks faced by farmers based on factors.

3) Gradient boosting: Gradient Boosting sequentially constructs a series of weak learners with each subsequent learner focusing on the residuals or errors of its predecessor. By iteratively refining predictions based on the gradient of a predefined loss function, Gradient Boosting enhances predictive accuracy and resilience by placing emphasis on previously mis-predicted data points [29]. This approach is particularly advantageous in agricultural risk prediction scenarios, where nonlinear and complex relationships between predictors and outcomes prevail due to the multitude of interacting factors at play. Gradient boosting trees usually have deeper trees, such as ones with 8 to 32 terminal nodes.

Given a training dataset comprising features X and corresponding risk labels y, the algorithm iteratively fits a series of weak learners $h_i(x)$ to the residuals or negative gradients of the loss function. At each iteration t, the model updates its prediction $\hat{y}_t$ by incorporating a weighted contribution from the new weak learner $h_i(x)$. The final prediction $\hat{y}$ is obtained as the sum of all individual weak learner predictions, represented mathematically as in Eq. (7).

$$\hat{y}\,(x) = \sum_{t=1}^{T} \gamma_t h_t(x) \tag{7}$$

where γ_t denotes the learning rate or shrinkage parameter, regulating the influence of each weak learner, and T signifies the total number of iterations. The primary goal is to minimize the loss function, commonly expressed as the mean squared error for regression tasks or cross-entropy loss for classification tasks, by iteratively adjusting the parameters of the weak learners. Through this iterative refinement process, Gradient Boosting optimizes the model's capacity to capture intricate relationships inherent in agricultural data, furnishing farmers with precise risk assessments tailored to their specific contexts, thereby facilitating informed decision-making and effective risk management strategies.

4) XGBoost: XGBoost enhances predictive capabilities through its advanced ensemble learning techniques. It is an implementation of gradient-boosted decision trees designed for speed and performance. XGBoost operates by constructing an ensemble of decision trees in a sequential manner, where each new tree attempts to correct errors made by the previous ones. It incorporates several advanced features such as regularization to prevent overfitting, parallel processing for faster computation, and a sparsity-aware algorithm to handle missing data effectively.

During the training phase, given a dataset comprising features X and corresponding risk labels y, XGBoost iteratively builds decision trees to minimize a predefined objective function. Each decision tree $h_t(x)$ is trained to predict the residuals or negative gradients of the loss function. Prediction $\hat{y}$ is obtained as the sum of predictions from all decision trees, with parameters such as the learning rate γ_t controlling each tree's contribution. XGBoost optimizes a regularized objective function, consisting of a loss term measuring prediction error and a regularization term penalizing model complexity. The objective function is expressed as in Eq. (8).

$$Obj = \sum_{i=1}^{N} L(y_i, \hat{y}_i) + \sum_{k=1}^{K} \omega(f_k) \qquad (8)$$

where L $(y_i, \hat{y}_i)$ represents the loss function, N is the number of data points, K is the number of trees, and $\omega(f_k)$ is the regularization term for the kth tree. XGBoost employs L1 and L2 regularization techniques to control model complexity and prevent over fitting, ensuring stability and enhancing model robustness.

5) Support Vector Machine: SVM employs a dataset comprising features X and corresponding risk labels y, where represents a matrix of m data points and n features, and y denotes a vector of risk labels for each data point. The SVM algorithm endeavors to delineate a hyperplane, represented as in Eq. (9).

$$W^T x + b = 0 \qquad (9)$$

which effectively segregates the data points into various risk classes while maximizing the margin between these classes. SVM formulates an optimization objective aimed at finding the optimal hyperplane by simultaneously minimizing the classification error and maximizing the margin. This objective function is expressed as in Eq. (10).

$$min_w, b \ \frac{1}{2} ||w||^2 + \mathrm{X} \sum_{1=1}^{m} \varepsilon_i$$

$$\Sigma\upsilon\beta\varphi\varepsilon\chi\tau\ \tau o\ y^i w^T x^i + b \geq 1 - \varepsilon_i \varepsilon_i \geq 0 \qquad (10)$$

Where, C is the regularization parameter control ling the balance between maximizing the margin and minimizing the classification error, while ε_i represents slack variables indicative of the classification error for each data point. SVM can adeptly handle nonlinear decision boundaries by employing kernel functions K (x, x') to map input features into higher-dimensional spaces. The decision function of the SVM model is then expressed as in Eq. (11).

$$f(x) = sign(\sum_{i=1}^{m} \alpha_i y^i \mathrm{K}(\mathrm{x}, y^i) + \mathrm{b} \qquad (11)$$

Through training on the provided dataset, SVM determines an optimal hyper plane that effectively separates different risk levels based on input features.

6) Logistic regression: Logistic regression is a statistical model and supervised machine learning algorithm that uses data analysis to predict the probability of an event or observation. The most common logistic regression models a binary outcome, which can take two values like true/false or yes/no. Dataset containing features such as weather conditions, pest prevalence, diseases outbreak, input and product prices, product type, duration of farming activities, financial factors, subsidies availability, technology adoption, insurance coverage, and the presence of eco-sensitive zones. These features collectively form the input matrix X, where a farming scenario is represented by each row and each column corresponds to a specific feature. The model aims to predict the likelihood of a particular risk, represented as the target variable y, given the feature vector. The probability p(y=1|x) of the occurrence of the risk as a function of the input features. The logistic regression model applies the logistic function to transform the linear combination of features into a probability between zero and one. The function is defined as in Eq. (12).

$$\pi(\psi=1|\xi) = \frac{1}{1+e^{-z}} \qquad (12)$$

Where β_0 , $\beta_1 x_1, \beta_2 x_2, \beta_n x_n$ is the linear combination of features and coefficients, where $\beta_0, \beta_1, \beta_n$are the coefficients or weights assigned to each feature andx_0, x_1, x_n are the values of the corresponding features for a given farming scenario. The coefficients $\beta_0, \beta_1, \beta_n$ are estimated during the training phase using optimization techniques such as maximum likelihood estimation or gradient descent. Once the coefficients are determined, the logistic regression model can predict the probability of occurrence of the risk for new farming scenarios based on their feature values. By setting a threshold probability, we can classify farming scenarios into different risk categories, providing valuable insights for farmers to make informed decisions and mitigate potential risks effectively.

7) Ridge classifier: The Ridge Classifier serves as a potent tool for classification tasks, effectively modeling the probability of various risks based on pertinent features. The Ridge Classifier aims to predict the probability of a specific risk occurrence, denoted as the target variable(y), given the feature vector(X). Fig. 5 shows the basic architecture of Ridge classifier.

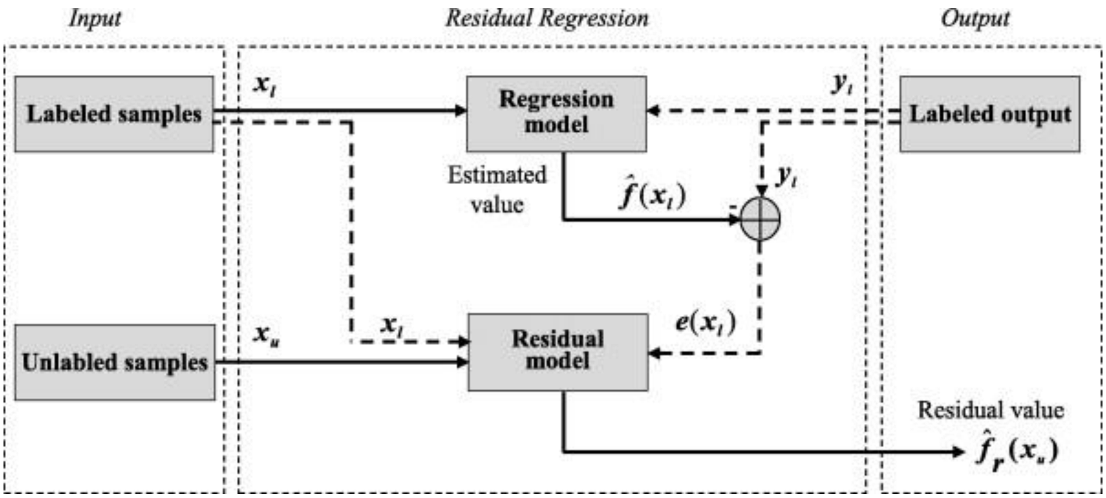


Fig. 5. Basic architecture of ridge classifier.

The dataset comprising features such as weather conditions, pest prevalence, disease outbreaks, input and product prices, product types, duration of farming activities, financial factors, subsidies availability, technology adoption, insurance coverage, and the presence of eco-sensitive zones. These features collectively constitute the input matrix (X). Ridge Classifier extends the logistic regression model by incorporating regularization to mitigate over fitting and improve model generalization. The objective function for Ridge Classifier can be formulated as in Eq. (13).

$$min_w||X_w - y||^2 + \alpha||w||^2 \quad (13)$$

where w represents the weight vector containing the coefficients for each feature, X is the feature matrix, y is the target variable, and α is the regularization parameter controlling the strength of regularization. The first term $||X_w - y||^2$ represents the residual sum of squares, measuring the difference between the predicted and actual target values. The second term $\alpha||w||^2$ is the L2 regularization term, penalizing large coefficients to prevent overfitting.

The Ridge Classifier optimizes the objective function to find the optimal weight vector w that minimizes the loss function while balancing the trade-off between fitting the training data and regularization. By incorporating the Ridge regularization term, the model is more robust to noisy data and less sensitive to multi-collinearity among features. Thus, the Ridge Classifier effectively predicts farmers' risk levels based on a comprehensive set of features, offering valuable insights for informed decision-making and risk management in agriculture.

E. Hardware and Software Setup

The proposed study utilized the Google Collaboratory platform in conjunction with the Microsoft Windows 10 operating system to establish a robust computational environment. The modeling process involved the application of the Python programming language, leveraging the Keras package and Tensorflow backend for training. The conceptualized models specifically configured to accept preprocessed and augmented datasets, ensuring precise decision-making capabilities. To assess the efficacy of the proposed model evaluating the predictions of the model on the test dataset.

IV. Experimental Results

Performance parameter, accuracy is used to evaluate the effectiveness of classification model. Accuracy provides a general measure of model performance, it may not be sufficient when dealing with imbalanced datasets, where one class dominates the others.

The performance evaluation of prediction models involved the assessment of various classifiers, including K-Nearest Neighbors, Random Forest, Gradient Boosting, XGBoost, Support Vector Classifier, Logistic Regression, and Ridge Classifier. The success of these models in predicting farmers' risk levels can be attributed to their ability to capture complex relationships between various features such as weather conditions, pest prevalence, financial factors, and technological adoption. By leveraging the collective knowledge from multiple features, these classifiers were able to effectively differentiate between different risk levels faced by farmers. Additionally, the ensemble nature of Random Forest, Gradient Boosting, and XGBoost allows them to handle nonlinear relationships and interactions between features, contributing to their superior performance. Among these classifiers, KNN, Random Forest, Gradient Boosting, and XGBoost emerged as the top performers, achieving an impressive accuracy score of 88.46%. The indication in Table III shows that farmers' risk levels were correctly predicted in 88.46% of cases.

TABLE III. Model Comparison

Model	Accuracy
KNN	88.46
Random Forest	88.46
Gradient Boosting	88.46
XG Booster	88.46
SVC	88.05
Logistic Regression	82.60
Ridge Classifier	82.03

A confusion matrix is a tabular representation used to evaluate the performance of a classification model by summarizing the counts of true positive, true negative, false positive, and false negative predictions. It consists of rows and columns corresponding to actual and predicted classes, respectively, where each cell represents the count of instances. The main diagonal of the confusion matrix contains the counts of correct predictions, while off-diagonal elements indicate misclassifications. This matrix provides valuable insights into the model's ability to accurately classify instances and helps identify common types of errors such as false positives and false negatives. By analyzing the confusion matrix, stakeholders can assess the strengths and weaknesses of the classification model and make informed decisions regarding model improvement and optimization strategies. Fig. 6 shows the confusion matrix of the proposed models.

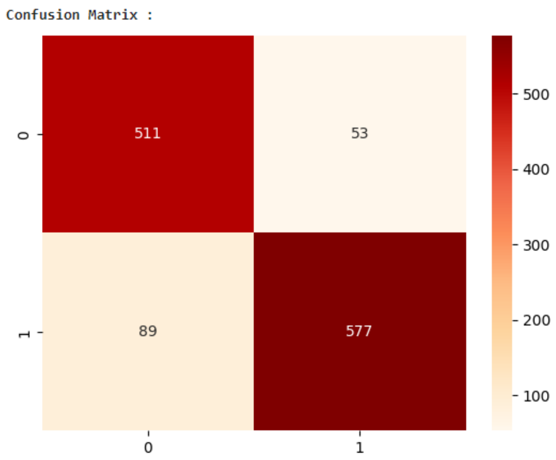
(f) Gradient Boosting



(g) XG Boost

Fig. 6. Confusion matrix.

The Receiver Operating Characteristic curve is used to assess the performance of binary classification models by plotting the true positive rate against the false positive rate across various threshold values. The True Positive Rate, also known as sensitivity or recall, is the ratio of correctly predicted positive observations to the total actual positives. The False Positive Rate, on the other hand, is the ratio of incorrectly predicted positive observations to the total actual negatives. The ROC curve provides a comprehensive visualization of a classifier's ability to distinguish between the positive and negative classes, with a steeper curve indicating higher discriminative power. The area under the ROC curve quantifies the overall performance of the classifier, with a value closer to 1 indicating better performance. ROC curves are particularly useful for evaluating classifiers in imbalanced datasets and for selecting an optimal threshold value that balances sensitivity and specificity based on the specific requirements of the application. Fig. 7 shows the ROC curves of the proposed models.

V. Discussion

Fig. 8 provides a visual representation comparing the performance of various classifiers, including Logistic Regression, KNN, SVM, Random Forest, Ridge Classifier, Gradient Boosting, and XGBoost. The results indicate that KNN, Random Forest, Gradient Boosting, and XGBoost all achieved the highest accuracy rate of 88.46%. These methods are closely followed by the SVM algorithm, which demonstrated a slightly lower accuracy of 88.05%. The superior performance of these algorithms can be attributed to their ability to handle complex patterns and interactions within the data effectively. Notably, ensemble methods such as Random Forest, Gradient Boosting, and XGBoost tend to provide robust predictions by combining the strengths of multiple base learners, which might explain their high accuracy in this context.

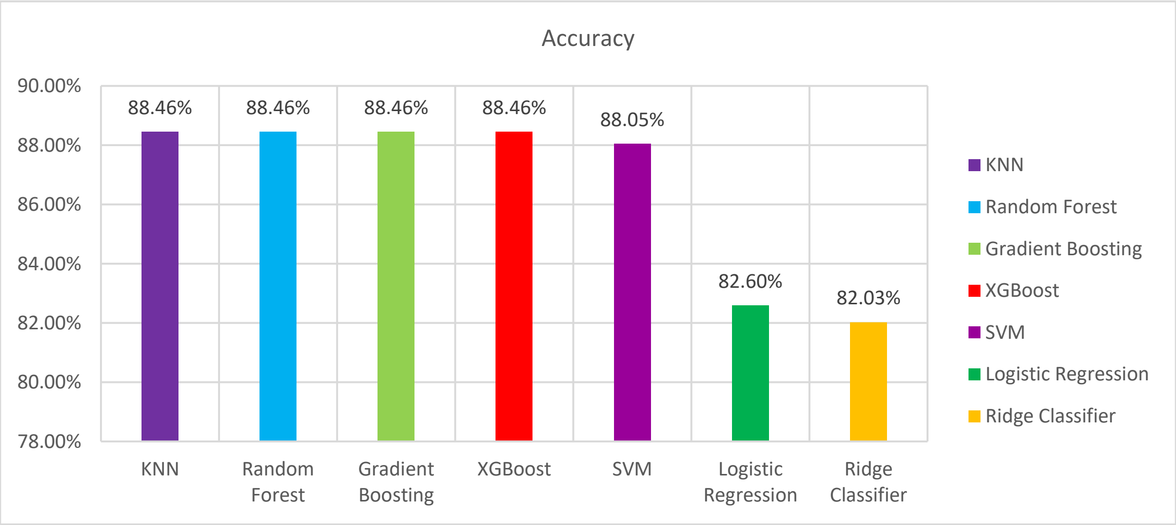

Fig. 8. Visualization of performance comparison of proposed models.

Logistic Regression and Ridge Classifier, however, exhibited lower accuracies, with 82.60% and 82.03% respectively. These methods, being more simplistic linear models, might not capture the nonlinear relationships in the data as effectively as the other more complex algorithms. Logistic Regression is a fundamental classification technique that is easy to implement and interpret but may fall short in performance compared to advanced models like ensemble methods and SVM. Similarly, Ridge Classifier, while being effective in regularizing the model to prevent over fitting, might not perform optimally in scenarios requiring sophisticated decision boundaries.

The slight edge in accuracy for the ensemble methods and SVM over logistic and ridge regression models emphasizes the importance of algorithm selection in predictive analytics. Ensemble methods, which combine multiple models to improve prediction accuracy, and SVM, known for its high-performance margin maximization, prove to be more adept in this case of farmer risk prediction.

Overall, the comparison underscores the effectiveness of advanced machine learning techniques, particularly ensemble methods and SVM, in achieving high prediction accuracy. These results suggest that employing such algorithms can significantly enhance the predictive performance in farmer risk prediction models, thereby supporting better decision-making and risk management strategies in agricultural practices. Future work could explore the integration of these models with more comprehensive feature sets and hyper parameter tuning to further optimize prediction outcomes.

VI. Conclusion

Agriculture, which makes up the majority of India's economy, is the primary backbone of our rural economy. Risk in agriculture is the result of a hazardous event, which is expressed as a combination of the likelihood and magnitudes of the risk. By analyzing the given farmer dataset and optimizing it through pre-processing techniques, the study ensures that the predictive models are built on high-quality data, thereby enhancing the reliability of the risk predictions. Through the utilization of Variation Inflation Factor (VIF) for feature selection, the study identifies the most influential features for accurate risk classification, demonstrating a meticulous approach towards model optimization and performance improvement. Utilizing a diverse array of techniques including KNN, Random Forest, Logistic Regression, SVM, Ridge Classifier, Gradient Boosting, and XGBoost, the study demonstrates significant progress. Notably, KNN, Random Forest, Gradient Boosting, and XGBoost exhibit exceptional performance, achieving a notable accuracy rate of 88.46%. The proposed farmers' risk prediction study represents a significant contribution to agricultural decision-making and risk management strategies. The study also acknowledges the potential for further improvement through the integration of Deep Learning Models, suggesting avenues for future research and development in agricultural risk prediction.

***Abstract*—This study presents a novel approach to evaluate the efficacy of JingFang granules in treating influenza-like illness by integrating knowledge graph technology with clinical trial data. We developed an innovative knowledge graph-based pharmacological analysis method and validated its effectiveness through a randomized controlled clinical trial. A knowledge graph was constructed by extracting drug-disease entities and their relationships from the literature using a machine learning workflow. Deep mining of the knowledge graph was performed using a graph convolutional network and T5 mini-model to analyze the association between JingFang and various diseases. Subsequently, a randomized controlled clinical trial involving 106 patients was conducted. Results showed that the cure rate in the JingFang combined treatment group (92.5%) was significantly higher than in the control group (81.1%), especially among the middle-aged and elderly population. Subgroup analysis revealed that JingFang had a more pronounced therapeutic effect on patients aged 34 and above, consistent with the knowledge graph analysis results. The innovation of this study lies in proposing a novel framework for evaluating therapeutic efficacy by combining knowledge graphs with clinical trial results. This approach not only provides new analytical tools for similar drug development but also improves the efficiency and accuracy of drug development by systematically validating literature efficacy data and integrating it with actual clinical trial results. Furthermore, applying a knowledge graph to evaluate the therapeutic effects of traditional Chinese medicines like JingFang is an innovative and unique approach, bringing new perspectives to this under-explored field. This method holds potential for broad application in drug development and repurposing, particularly in the context of Traditional Chinese Medicine.**

Keywords—Knowledge graph; clinical trial; influenza-like illness; jingfang; drug efficacy analysis

I. Introduction

A biomedical network can be conceptualized as a knowledge graph (KG) [1], where nodes represent various types of bio-entities such as proteins, drugs, chemicals, diseases, and species, and edges denote relationships between these entities. A KG can be broken down into a series of <head entity, tail entity, predicate> triples, where the predicate links the head and tail entities, indicating their relationship. For example, <drug A, protein B, affect> can illustrate the regulatory relationship between a drug and a protein. Additionally, each node and edge in a KG can have a set of attributes providing further details, such as the sources of the research articles from which the relationship is derived. Through literature mining and deep learning models, numerous KGs have been constructed and applied to various prominent fields in bio-science, including drug discovery and repurposing [2], protein-protein interactions [3,4], chemical-protein interactions [5], disease mechanism identification [6], and disease biomarker networks [7].

Drug efficacy prediction and analysis are critical tasks in computational pharmacology [8]. In recent years, a variety of KG-based methods have been developed for drug efficacy analytics [9, 10]. These methods primarily focus on evaluating the similarity between drugs and their treatment efficacy on diseases [11], based on the assumption that two similar drugs may exhibit similar efficacy for the same diseases. For pharmaceutical companies, understanding the efficacy of a particular drug on various diseases throughout its market presence is crucial. This information can often be found in clinical trials reported in research articles. Therefore, it is essential to develop a system that can track and compile relevant clinical trials involving the drug, enabling comprehensive efficacy analysis.

We present a novel methodology for demonstrating knowledge graph-based drug efficacy analysis, validated by a randomized controlled clinical trial conducted for JingFang [12]. To provide a comprehensive understanding of JingFang's treatment effects and functions, we developed a machine learning-based pipeline to extract drug-disease entities and relationships from the literature. These extracted relationships are used to construct a knowledge graph, which is then utilized for clustering-based drug efficacy analysis. With a given drug, our tool can report the inferred relatedness between the drug and disease, indicating the degree of efficacy for the drug-disease pair.

We propose a literature-based measure to assess the "impact of drug composition on efficacy". The increasing costs of drug research, combined with a notable decline in new pharmaceutical approvals, have heightened the need for innovative tools for target identification and effectiveness prediction. Here, we introduce a measure that quantifies the interaction between a drug component and a disease by analyzing literature data. This measure adjusts for known biases in interaction groups, using proximity to detect a drug's therapeutic impact and distinguish between unsuccessful and effective therapies. Our analysis identifies JingFang as effective in treating flu and colds. To further validate this finding, we conducted a randomized controlled clinical trial to evaluate JingFang's efficacy on Influenza-like illness, a subtype of cold.

Influenza-like illness refers to symptoms similar to the common cold, including chills, fever, limb aches, nasal congestion, runny nose, headache, and cough, especially when exposed to air conditioning for extended periods. It is also known as Influenza-like illness syndrome. Treatment focuses on symptomatic relief and includes rest, proper hydration, and ensuring good indoor air circulation.

The purpose of this study was to establish a method for measuring pharmacological effectiveness using knowledge graphs, integrating data from the literature, and validating the results through a randomized controlled clinical trial on JingFang granules. By combining the findings from knowledge graphs and clinical trials, we can more accurately assess the efficacy of JingFang granules against Influenza-like illness (see Fig. 1).

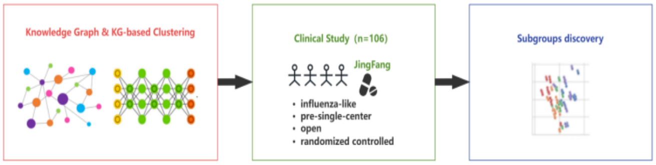

Fig. 1. The evaluation framework of knowledge graph and influenza-like illness clinical trials. Combining the results of the knowledge graph and clinical trials, JingFang's efficacy is accurately evaluated.

II. Related Work

In recent years, there has been growing interest in applying knowledge graph (KG) techniques and machine learning approaches to drug discovery, efficacy analysis, and adverse reaction prediction. This section reviews related studies in these areas, with a focus on methods relevant to our work on JingFang granules and influenza-like illness.

A. *Knowledge Graph-based Drug Analysis*

Knowledge graphs have emerged as a powerful tool for representing and analyzing complex biomedical information. For instance, Arnold K. Nyamabo et al. [13] developed a novel method called Gated Message Passing Neural Network (GMPNN) for predicting drug-drug interactions (DDIs). GMPNN learns chemical substructures of varying sizes and shapes from molecular graph representations of drugs. In this approach, edges act as gates controlling message flow, effectively learning and delimiting substructures. The final DDI prediction is based on the interactions between these learned substructures, each weighted by a relevance score. GMPNN-CS, their proposed model, demonstrated competitive and improved performance on real-world datasets compared to previous methods.

Similarly, Fangping Wan et al. [14] proposed a knowledge graph embedding approach named NeoDTI for drug-target interaction (DTI) prediction. NeoDTI integrates diverse information from heterogeneous network data, learning topology-preserving representations of drugs and targets. This method significantly improves prediction performance over state-of-the-art DTI prediction methods and has been validated by novel DTI predictions supported by previous studies. NeoDTI's robustness to a wide range of hyperparameters and its ability to integrate additional drug and target-related information, such as compound-protein binding affinity data, highlight its potential as a powerful and robust tool for drug development and drug repositioning.

B. *Machine Learning for Drug Efficacy Prediction*

Machine learning techniques have been widely applied in drug efficacy prediction. Jessica Vamathevan et al. [15] provided a comprehensive review of AI applications in drug discovery and development, highlighting various stages where machine learning can be utilized. Their review discusses the potential of deep learning models in predicting drug efficacy, validating targets, identifying prognostic biomarkers, and analyzing digital pathology data in clinical trials. Despite challenges such as lack of interpretability and repeatability, the authors emphasize that with systematic and comprehensive high-dimensional data, machine learning can significantly enhance data-driven decision-making, accelerate the drug discovery process, and reduce failure rates.

In a more specific application, Wenxuan Wu et al. [16] developed GeoDILI, a graph neural network-based model for predicting drug-induced liver injury (DILI). GeoDILI uses a molecular geometric representation and leverages gradient information to achieve high predictive performance and interpretability. By benchmarking against other DILI prediction models and popular GNN models, GeoDILI demonstrated superior performance and provided mechanistically elucidated structural alerts. This model shows the potential of machine learning in adverse drug reaction prediction, enhancing drug safety assessment and development processes.

C. *Traditional Chinese Medicine (TCM) Efficacy Evaluation*

Evaluating the efficacy of Traditional Chinese Medicine (TCM) presents unique challenges due to its holistic approach and complex formulations. Zhao et al. [17] highlighted the potential of network pharmacology as a new discipline that leverages systems biology theory, biological system network analysis, and multi-target drug molecule design. Their study summarized the current application status and existing challenges of network pharmacology in TCM, proposing research ideas, key technologies, and strategies to reveal the modern scientific connotation of TCM. This approach aligns well with the integrity, systematization, and comprehensiveness of network pharmacology, making it suitable for studying the pharmacological mechanisms of TCM compounds.

Similarly, Liu et al. [18] developed a machine-learning model to predict the efficacy of TCM formulas based on their chemical compositions and traditional usage patterns. Their model integrated diverse data sources, including experimental validation, to provide new insights into the mechanisms of TCM formulas. The integration of computational methods, such as network pharmacology and machine learning, allows for a more systematic and comprehensive evaluation of TCM efficacy, bridging traditional knowledge with modern scientific findings.

D. Integration of Computational Methods and Clinical Trials

While several studies have utilized knowledge graphs or machine learning for drug analysis, few have combined these approaches with clinical trial data, particularly for TCM. For instance, Wang et al. [19] proposed a framework that integrates electronic health records (EHRs) with knowledge graphs for personalized medicine. Although their focus was not specifically on TCM or drug efficacy analysis, their work demonstrates the potential of combining computational methods with clinical data.

Our study aims to bridge this gap by combining knowledge graph-based analysis with clinical trial results, specifically for TCM formulations like JingFang. By leveraging the power of computational methods and grounding our findings in real-world clinical data, we aim to offer a more comprehensive and accurate assessment of drug efficacy. This approach not only enhances our understanding of TCM but also supports the development of more effective and personalized treatment strategies.

III. Methods

A. Knowledge Graph-based Analytics

We utilized a self-developed tool for web scraping. As shown in Table I, a total of 19,053 paper abstracts were collected using four different keywords: "JingFang", "荆防" (Chinese for JingFang), "Flu", and "Influenza-like illness". After an initial screening, 4,429 relevant abstracts were retained in the dataset for knowledge extraction. The fields used for literature scraping included the following: paper type, title, author list, author affiliation, source, keywords, abstract, publication time, funding, volume, issue, page, URL, and DOI.

TABLE I. Stats of Literature Collection

Keyword	# abstracts	# Abstracts after cleaning
JingFang	642	221
JingFang (Chinese)	2,324	578
Flu	8,592	1,327
Influenza-like illness	7,495	2,303
Total	19,053	4,429

Each abstract scraped from the internet is semi-structured, containing both structured information such as the author list, year of publication, affiliations, etc., and unstructured data like the title and abstract text. Our knowledge graph includes three entity types: abstract, drug, and disease. The relationship between a drug and a disease can be either "treat" or "cause". As shown in Fig. 2, an abstract text is input into a MacBERT pre-trained model to extract entities and relationships. Each extracted relationship is represented as a three-tuple <e1, e2, r>, where e1 and e2 are the head and tail entities, typically a drug and a disease, respectively, and r is the relationship connecting them.

Other structured attributes, along with the extracted drugs and diseases, are used to build the knowledge graph. To facilitate further analysis, the knowledge graph is processed to generate an adjacency matrix that encodes the interactions between drugs and diseases. Specifically, if a drug can treat a disease and this relationship appears in n abstracts, the value of the corresponding cell in the matrix for that drug and disease is set to n.

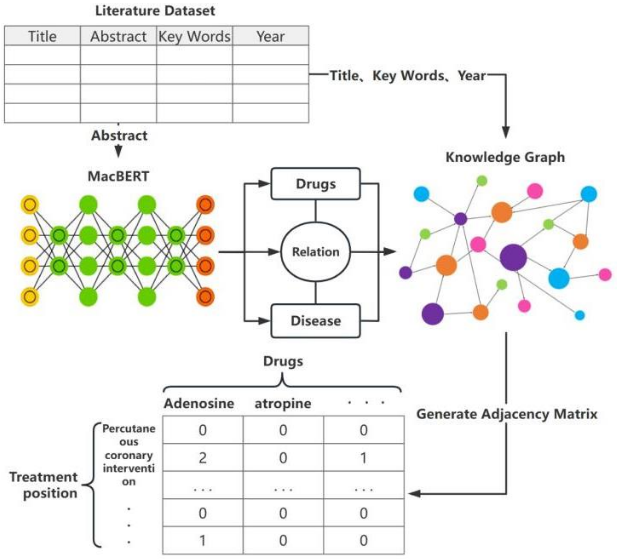

Fig. 2. Workflow of building the drug-condition knowledge graph.

The adjacency matrix generated from the previous step can be normalized and used to train a Graph Convolutional Network (GCN) [20], allowing each graph node and edge to be represented as numerical vectors. To capture the semantics embedded in the abstract text, we pass the text through the MacBERT [21] model, which performs word vector mapping to convert each word into a vector. However, since most word tokens are not relevant to the drug efficacy analysis task, we retain only the word vectors for drugs and diseases. Consequently, each drug entity has two representations: one from the GCN and one from the word vector mapping.

These two representations are then fed into the T5-small [22] model, which serves as a feature-fusion module to combine them. The output of the T5-small model is subsequently processed using a K-means [23] algorithm for clustering analysis.

Essentially, drugs can be categorized into two types: drug products and their constituent chemicals. In our knowledge graph, the extracted drug entities can belong to either category. The purpose of this analysis is to determine that the closer a drug is to the cluster centroid, the stronger its positive correlation with the current disease. The overall process is illustrated in Fig. 3.

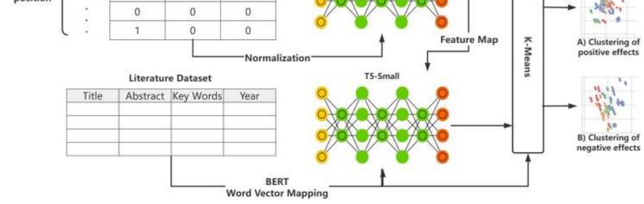

Fig. 3. Workflow of KG-based clustering for drug efficacy analysis.

B. A Randomized Controlled Clinical Study

In the second half of 2020, we conducted a single-center, open, randomized controlled clinical study from August 25, 2020, to October 12, 2020, with 108 patients participating. The diagnostic criteria for Influenza-like illness were defined as the onset occurring on a hot day (June-October) with exposure to air conditioning or frequent entry and exit from an air-conditioned room for at least three days before onset, along with meeting the following Western medical diagnostic criteria.

The Western diagnostic criteria for the common cold include sneezing, nasal congestion, runny nose, cough, sore throat, and other local symptoms, predominantly lacrimation, and possibly systemic symptoms such as chills, fever, general malaise, dizziness, and headache. The white blood cell count is either normal or low.

A central randomization system (web-based Interactive Web Response System, IWRS) was used for the randomization of groups in this study. Subjects were randomly divided into test and control groups in a 1:1 ratio, meeting the inclusion criteria. Subjects in the control group took only Neocontrol (Blue) (Sino-Medical), while subjects in the trial group took Neocontrol (Blue) plus JingFang (Shandong New Age Pharmaceutical Co., Ltd.). The study employed a block randomization grouping method with a block length of 4. The randomization process was set up by a statistical and computer professional who developed the randomization grouping procedure.

This study was approved by the Ethics Committee of Zhangjiagang City Hospital of Traditional Chinese Medicine and has been registered with the China Clinical Trials Registry (chictr.org.cn) under the registration number ChiCTR2000036543.

Males and females between the ages of 18 and 70 were eligible for the study if they met the following criteria: onset of illness during hot days (June to October) with exposure to an air-conditioned environment or frequent entry and exit from air-conditioned rooms for at least three days before onset; meeting the Western medical diagnostic criteria for the common cold; within 48 hours of onset; and not having taken JingFang, Neocontrol (Blue), Tylenol cold tablets, Neocontrol (Red), or Day and Night Pepcid (night tablets) within two weeks before enrollment. Additionally, subjects needed to be willing to participate in the study and sign an informed consent form.

Subjects were excluded from participating if they met any of the following criteria: having wind-heat colds (manifested by high fever, slight wind aversion, sweating, thirst, runny nose, red, swollen and hot throat, coughing and spitting yellow sputum, etc.); having pharyngoconjunctivitis, acute attacks of chronic bronchitis, purulent tonsillitis, or infectious upper respiratory tract infection; having uncontrolled cardiovascular disease, diabetes, hypertension, thyroid disease, asthma, glaucoma, emphysema, chronic lung disease, dyspnea, or prostatic hypertrophy; having pneumonia diagnosed by chest imaging; having used drugs for the treatment of this disease since the onset; having active liver disease or uncontrollable liver disease; having uncontrollable kidney disease or being on kidney dialysis; having an axillary temperature ≥ 40 degrees Celsius, a total white blood cell count of 10 × 10^9/L or neutrophil classification > 80%; being allergic to the drugs used in this study; having mental or neurological disorders that prevent correct expression of their will; being pregnant, lactating, or women of childbearing age not using contraception; currently participating in clinical trials of other drugs or medical devices; and being considered unsuitable for inclusion by the investigator.

JingFang is produced by Shandong New Times Pharmaceutical Co., Ltd. The main ingredients include Bupleurum, Chuanxiong, Duhuo, Fangfeng, Poria, Licorice, Nepeta, Platycodon grandiflorum, Qianhu, Qianghuo, and Citrus aurantium. For New Contac (Blue Pack), the dosage is one capsule every 12 hours after meals, not exceeding two capsules within 24 hours. JingFang is taken in one bag at a time, three times a day, with boiling water. The therapy duration is seven days. The subjects in both groups received the same non-drug intervention program, which included diet control and lifestyle improvement. This program primarily involved avoiding greasy and spicy food, abstaining from tobacco and alcohol, avoiding overwork and overeating, and maintaining a positive attitude.

The primary endpoint was the rate of healing within seven days. Clinical cure: clinical symptoms and signs vanished or almost vanished, and the symptom score was decreased by 95%; efficacy: clinical symptoms and signs considerably improved, and the symptom score was lowered by 70%.

Clinical symptoms and indicators improved, and the symptom score was lowered by more than 30%. Clinical symptoms and indicators did not improve considerably, if at all, and the symptom score was lowered by less than 30%. Healing rate (%) = (number of clinically healed cases + number of apparent effect cases) ÷ total cases ×100%. The secondary endpoint was the incidence of adverse events.

The key assessment criterion for this study is the therapeutic effectiveness rate of the drug after seven days of treatment. This study adopts the hypothesis of superiority. Based on previous literature and preliminary test results, the treatment effectiveness rate was expected to be 63.3% in the control group and 90% in the experimental group. The superiority margin between the two groups was set at 3%, with α=0.025 (one-sided) and β=0.2, and a 1:1 sample size ratio. A total of 45 patients were initially calculated for each group. Considering a 15% loss to follow-up rate, 53 patients were finally included in each group, resulting in a total of 106 patients.

Statistical analysis was performed using SAS 9.4 software. Results were reported as mean ± standard deviation, or median (upper and lower quartiles). Measurement data comparisons were first tested for normality. If they conformed to a normal distribution, parametric tests were used; otherwise, Wilcoxon rank sum tests were performed. The frequency (composition ratio) was used to describe count data statistically. To compare count data, the chi-square test or Fisher's exact test was utilized. A p-value of <0.05 was considered significant.

Subgroup analysis was performed on the cure rate for different age groups. Patients aged ≤34 years were classified as young, while those aged >34 years were classified as middle-aged and elderly.

IV. Results

The experiments for this study were conducted using Python 3.7.0. PyCaret was employed to implement the learning algorithms [24]. Microsoft Office 365 Excel, Matplotlib 3.4.2, and Seaborn 0.11 were used to create the charts. BAIX (https://github.com/aibaix, accessed June 9th, 2022), a self-developed Python tool, was utilized for data purification and exploratory data analysis. Results of Knowledge Graph Analysis

A. *Discovery of Knowledge Graph-based Drug-Disease Relationships*

We utilize Neo4J to store knowledge graph data, leveraging its optimized storage structure for graph data attributes, which provides superior performance in processing relational data compared to other databases. Fig. 4 presents an extracted portion of the knowledge graph, visually depicting multiple node entities and the relationships connecting them.

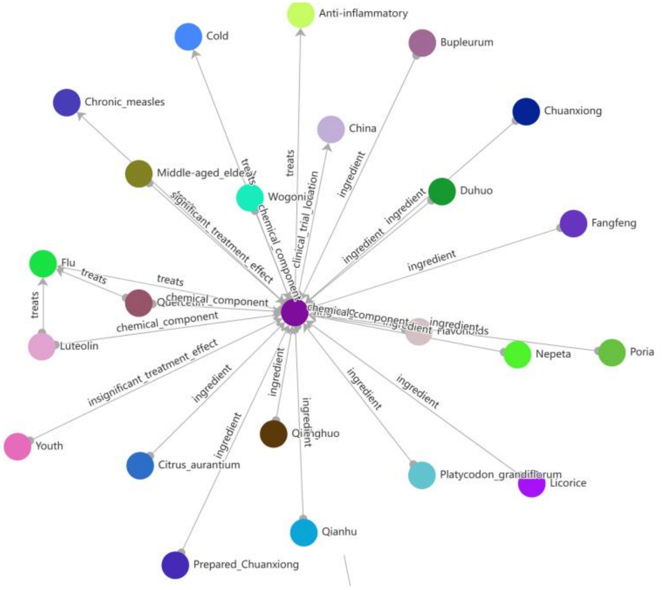

Fig. 4. An example of the generated drug-condition knowledge graph.

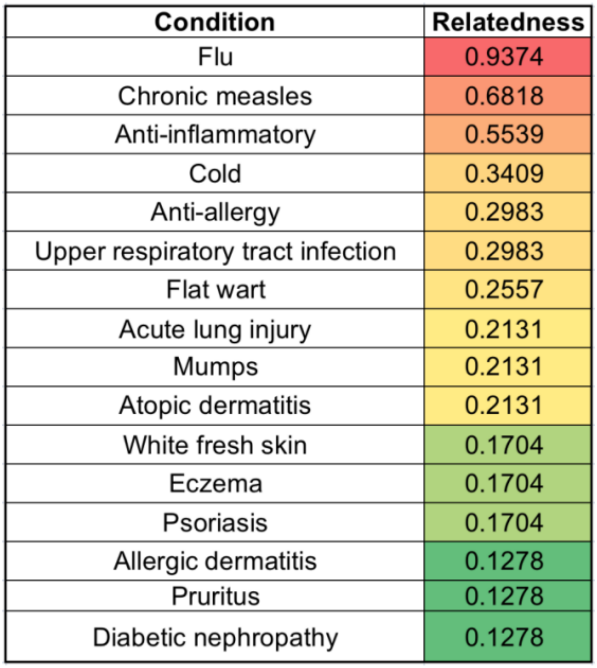
Fig. 5 and Fig. 6 illustrate the results of the KG-based clustering analysis. Fig. 5 displays the relatedness scores of JingFang and the commonly related conditions. It shows that flu, chronic measles, anti-inflammatory, and cold are the top conditions that can be treated by JingFang. Specifically, flu has the highest score of 0.9374, indicating that, according to existing literature, JingFang is most effective in treating flu compared to other conditions.

Fig. 6, on the other hand, depicts the pairwise relatedness between the chemical components of JingFang and various conditions, identifying how each component affects certain conditions. The figure highlights only the top 8 ranked chemical components: quercetin, luteolin, kaempferol, wogonin, beta-sitosterol, naringenin, acacetin, and tanshinone IIA. These components vary in their degree of influence across different diseases. The figure suggests that quercetin and luteolin may be the key effective ingredients in the treatment of influenza with JingFang.

- Use either SI (MKS) or CGS as primary units. (SI units are encouraged.) English units may be used as secondary units (in parentheses). An exception would be the use of English units as identifiers in trade, such as “3.5-inch disk drive”.
- Avoid combining SI and CGS units, such as current in amperes and magnetic field in oersteds. This often leads to confusion because equations do not balance dimensionally. If you must use mixed units, clearly state the units for each quantity that you use in an equation.
- Do not mix complete spellings and abbreviations of units: “Wb/m2” or “webers per square meter”, not “webers/m2”. Spell out units when they appear in text: “. . . a few henries”, not “. . . a few H”.
- Use a zero before decimal points: “0.25”, not “.25”. Use “cm3”, not “cc”. (*bullet list*).



Condition	Relatedness
Flu	0.9374
Chronic measles	0.6818
Anti-inflammatory	0.5539
Cold	0.3409
Anti-allergy	0.2983

B. *Results of Clinical Trials*

A total of 108 patients were recruited from August 25, 2020, to October 12, 2020, and finally, 106 patients were enrolled and randomized to receive JingFang and Neocontrol (53 patients in the treatment group) or Neocontrol only (53 patients in the control group). The ages of patients in the treatment and control groups were 41.8 ± 15.8 years and 43.5 ± 13.75 years, respectively, without any statistically significant differences. There were no statistically significant differences in gender structure, ethnic structure, BMI, total symptom score, and physical findings score between the treatment and control groups, making them comparable (see Table II).

TABLE II. BASELINE CHARACTERISTICS OF ENROLLED PATIENTS

	Test group (N=53)	**Control group (N=53)**	**p-value**
Mean age (SD)	41.8 (15.18)	43.5 (13.75)	0.58
# male patients (%)	19 (35.8)	12 (22.6)	0.14
BMI (SD)	23.09 (2.999)	23.41 (3.258)	0.61
Overall symptom score (SD)	5.5 (2.11)	5.7 (2.24)	0.81
Physical examination score (SD)	0.8 (0.55)	0.9 (0.48)	0.67

The healing rate within seven days was 92.5% (49 cases) in the test group and 81.1% (43 cases) in the control group, which was higher in the test group, but no statistically significant difference existed between the two groups (p=0.0852, 95% CI: 11.3 (-2.0, 25.3)). The very effective rate within seven days was 98.1% (52 cases) in the test group and 92.5% (49 cases) in the control group, which was also higher in the test group, but again, no statistically significant difference existed between the two groups (p=0.3692, 95% CI: 5.7 (-3.5, 16.5)) (Table III).

TABLE III. EFFICACY ANALYSIS

	Test group (N=53)	**Control group (N=53)**	**p-value**
Cured	49 (92.5)	43 (81.1)	0.09
Very effective	3 (5.7)	6 (11.3)	-
Effective	1 (1.9)	4 (7.5)	-
Not effective	0	0	-
Cured+very effective (%)	52 (98.1)	49 (92.5)	0.36

In middle-aged and elderly subjects, the healing rate was 100% (32 cases) in the test group and 78.4% (29 cases) in the control group, which was statistically significantly higher in the test group (p=0.0059, 95% CI: 21.6 (8.3, 38.2)) (Table IV). In the youth population, the healing rates were essentially the same in both groups.

This study aims to evaluate the therapeutic efficacy of JingFang for influenza-like illnesses by integrating knowledge graph technology with clinical trial data. We developed an innovative knowledge graph-based pharmacological analysis method and validated its effectiveness through a randomized controlled clinical trial.

First, we constructed a knowledge graph by extracting drug-disease entities and their relationships from literature using a machine learning workflow. Our tool can report drug-disease correlations, indicating the degree of efficacy between drug-disease pairs. Specifically, we collected 19,053 abstracts and utilized our in-house text-mining tool to extract relationship information between drugs and diseases. Each extracted relationship was encoded as an adjacency matrix for subsequent analysis. This knowledge graph not only contains drug and disease entities but also reflects the therapeutic or pathological associations between them.

TABLE IV. EFFICACY ANALYSIS

Age group	**Curative effect**	**Test group (N=53)**	**Control group (N=53)**	**p-value**
Young	Cured	17(81.0)	14(87.5)	0.6796
	Very effective	3(14.3)	1(6.3)	-
	Effective	1(4.8)	1(6.3)	-
	Not effective	0	0	-
	Cured+very effective	20(95.2)	15(93.8)	1
Middle-aged and elderly	Cured	32 (100.0)	29(78.4)	0.0059
	Very effective	0	5(13.5)	-
	Effective	0	3(8.1)	-
	Not effective	0	0	-
	Cured+very effective	32 (100.0)	34(91.9）	0.243

To deeply mine the information embedded in the knowledge graph, we applied a graph convolutional network (GCN) to normalize the adjacency matrix and used a T5 mini-model to fuse the GCN-obtained representations with word vector graphs. Through this approach, we analyzed the association between JingFang and various diseases and explored the potential therapeutic effects of JingFang for influenza-like illnesses using the K-means clustering algorithm.

To validate the knowledge graph analysis results, we conducted a randomized controlled clinical trial in China. The trial enrolled 106 patients with influenza-like illnesses, and the results showed that the cure rate in the JingFang combined treatment group (92.5%) was significantly higher than that in the control group (81.1%), especially among the middle-aged and elderly population. Subgroup analysis of the clinical data revealed that JingFang had a more pronounced therapeutic effect on middle-aged and elderly patients aged 34 and above, which was consistent with the knowledge graph analysis results. However, the knowledge graph did not capture this age-related difference in efficacy, and future work may consider incorporating demographic information into knowledge representation and analysis.

The innovation of this study lies in proposing a novel framework for evaluating therapeutic efficacy by combining knowledge graphs with clinical trial results, thereby enhancing the understanding of drug treatment effects. This not only provides new analytical tools for similar drug development but also improves the efficiency and accuracy of drug development by systematically validating literature efficacy data and integrating it with actual clinical trial results. Additionally, applying a knowledge graph to evaluate the therapeutic effects of traditional Chinese medicines like JingFang is an innovative and unique approach, bringing new perspectives to this under-explored field.

In terms of technical implementation, we constructed a multi-layered knowledge graph by extracting relevant data from a vast amount of biomedical literature and using automated text-mining tools to identify key drug and disease entities and their relationships. With the aid of graph convolutional network processing, we could capture complex associations between entities and discover drug combinations with similar therapeutic effects through clustering analysis. This multi-layered knowledge graph comprehensively presents the relationships between drug components and diseases, and reveals the potential therapeutic effects of different components on specific diseases, laying a theoretical foundation for clinical trials and drug development.

However, this study also has some limitations. First, the accuracy of clustering analysis depends on the quality and completeness of the literature data, and biases and omissions in the literature may affect the accuracy of the results. Second, the sample size of the clinical trial is relatively small, which may impact the stability and generalizability of the statistical results. Future work should expand the sample size and utilize more independent data sources to validate and optimize this integrated analysis method.

Furthermore, an important extension of this study is the implementation of our knowledge graph method and clinical trial integration model as a practical software system. We have designed a prototype system called "KG-TCM Efficacy Analyzer", a web-based application developed using a Python backend and React frontend. The system's main features include knowledge graph construction and visualization, efficacy analysis, clinical trial data integration, and results presentation with automatic report generation.

We plan to deploy and test this system in real-world environments such as pharmaceutical research companies, traditional Chinese medicine hospitals, and drug repositioning studies. Through these practical applications, we expect to accelerate the drug discovery process, improve the accuracy of efficacy predictions, and promote the modernization of traditional Chinese medicine research.

To assess the system's practicality, we also plan to conduct a System Usability Study (SUS). This study will recruit professionals including pharmacologists, clinical researchers, and TCM practitioners, using a standardized SUS questionnaire to evaluate aspects such as the system's ease of use, learnability, efficiency, and user satisfaction. We anticipate that an intuitive user interface, clarity in result interpretation, integration with existing workflows, flexibility in data input, and system responsiveness will be key usability factors.

By focusing on these usability aspects, we aim to develop a system that is both powerful and user-friendly, thereby promoting its widespread application in real research and clinical settings. This transition from theoretical research to practical application will not only further validate the value of our proposed knowledge graph method in evaluating the efficacy of traditional Chinese medicines, but also enhance our understanding of drug mechanisms of action, providing a robust decision-support tool for future drug development. By integrating knowledge graph analysis with clinical trial results, we can more accurately evaluate the therapeutic efficacy of drugs like JingFang for conditions such as influenza-like illnesses, ultimately providing scientific evidence for clinical application and promoting the modernization of traditional Chinese medicine evaluation.

V. Conclusion

This study introduces a novel approach to drug efficacy analysis using a knowledge graph (KG) methodology, complemented by a randomized controlled trial to validate the effectiveness of JingFang in treating influenza-like illness. By extracting and analyzing drug-disease relationships from the literature, a comprehensive KG was constructed, serving as the foundation for the efficacy analysis. The trial results indicated a significantly higher cure rate for the JingFang group, especially among middle-aged and elderly patients, compared to the control group.

This innovative approach not only provides a powerful tool for predicting drug efficacy but also combines traditional clinical trial results with advanced data analysis techniques, thereby enhancing the accuracy and reliability of drug efficacy evaluations. This method holds potential for broad application in drug development and repurposing, particularly in the context of Traditional Chinese Medicine.

While this study focused on JingFang, the approach we developed - combining knowledge graph analysis with clinical trial validation - is generalizable and can be readily applied to evaluate the efficacy of other drugs, both in traditional Chinese medicine and Western pharmaceuticals. This versatility makes our method a valuable tool for drug discovery and development across various therapeutic areas.

Future work could focus on several aspects to further enhance and expand this approach:

1) *Incorporating more diverse data sources:* Integrating data from electronic health records, genomic databases, and other real-world evidence could enrich the knowledge graph and improve prediction accuracy.

2) *Enhancing the machine learning models:* Exploring more advanced graph neural network architectures or developing hybrid models that combine different AI techniques could potentially improve the performance of our system.

3) *Expanding to multi-drug interactions:* Extending the framework to analyze the efficacy of drug combinations and potential drug-drug interactions could provide valuable insights for personalized medicine.

4) *Longitudinal studies:* Conducting longer-term follow-up studies to assess the long-term efficacy and safety profiles of drugs identified through this approach.

5) *Cross-cultural validation:* Applying this method to evaluate drug efficacy across different populations and

healthcare systems to ensure its generalizability and identify any cultural or genetic factors that may influence drug responses.

6) Actual development and deployment of the "KG-TCM Efficacy Analyzer" prototype system, followed by a comprehensive usability study based on the outlined plan. We will continuously optimize the system based on user feedback to improve its applicability and efficiency in real-world environments. Additionally, we plan to expand the system's functionality to support more types of drugs and diseases and explore the possibility of integrating it with other existing drug development tools.

By addressing these areas, we can further refine and expand the capabilities of our knowledge graph-based approach, potentially revolutionizing the way we discover, develop, and evaluate drugs in both traditional and modern medical contexts.

CONFLICT OF INTEREST STATEMENT

The authors declare no conflict of interest.

AUTHOR'S CONTRIBUTION

Conceptualization and methodology, Y. L., Z. J., Z. H., W. G., G. C., and Y. J.; software, validation, and original draft preparation, Y. L., Z. J., Z. H., and W. G.; review and editing, G. C. and Y. J.. All authors have read and agreed to the published version of the manuscript.

***Abstract*—Japan's rapid transition into a super-aged society, with 29% of its population aged 65 and over, underscores the urgent need for innovative elderly care solutions. This study explores the use of generative AI to facilitate meaningful interactions between elderly individuals and AI conversational agents using photos. Utilizing Microsoft Azure's AI services, including Computer Vision and Speech, the AI agent analyzes photos to generate engaging conversation prompts, leveraging GPT-3.5-turbo for natural language processing. Preliminary experiments with healthy elderly participants provided insights to refine the AI agent's conversational skills, focusing on timing, speech speed, and emotional engagement. The findings indicate that elderly users respond positively to AI agents that exhibit human-like conversational behaviors, such as attentiveness and expressive communication. By addressing functional and emotional needs, the AI agent aims to enhance the quality of life for the elderly, offering scalable solutions to the challenges of an aging society. Future work will focus on further improving the AI agent's capabilities and assessing its impact on the mental health and social engagement of elderly users.**

Keywords*—Generative AI; elderly care; conversational agents; photo-based interaction

I. INTRODUCTION

Dementia care demands specialized knowledge and experience, yet the increasing shortage of caregivers makes it difficult to provide the necessary personalized attention. This gap in care contributes to feelings of isolation and anxiety among the elderly, exacerbating behavioral and psychological symptoms associated with dementia (BPSD), such as agitation, depression, and social withdrawal [1]. Individuals are exploring innovative solutions leveraging information and communication technology (ICT) to address these challenges. While previous studies have explored various technological interventions, there remains a significant gap in personalized, scalable solutions that can effectively reduce the burden on caregivers and enhance the quality of life for elderly individuals [2]. This study focuses on the use of AI conversational agents to support the elderly through meaningful interactions. By employing advanced AI technologies, particularly those capable of natural language processing and responsive interaction, these agents can potentially reduce the burden on caregivers and enhance the quality of life for elderly individuals.

This research aims to develop an AI agent using Microsoft's Azure services, such as Computer Vision and Speech, and the GPT-3.5-turbo language model. We designed the agent to engage elderly users in conversations based on photo prompts, providing companionship and cognitive stimulation. Previous studies have shown the effectiveness of conversational AI and robots in elderly care and dementia support [3][4]. However, these studies often lack personalization and real-time adaptability, which are crucial for effectively supporting elderly individuals with varying needs.

The initial phase of the study involves healthy elderly participants to develop an understanding of general communication patterns and preferences. The insights gained will guide the development of the AI agent, ensuring it can effectively mimic human-like conversational behaviors and meet the social and emotional needs of its users.

Ultimately, the goal is to demonstrate that AI agents can be a viable solution for enhancing elderly care, offering scalable and effective support to address the challenges posed by Japan's rapidly aging society. Future research will focus on refining the AI agent's capabilities and evaluating its impact on the mental health and social engagement of elderly users. The development of AI agents like ours is also supported by recent research which highlights their potential in improving the mental health and well-being of elderly individuals [5] [6].

II. RELATED WORK

The field of human-robot interaction has seen significant advancements, particularly in enhancing communication with elderly users. Yoshida et al. studied the impact of robots' behaviors during conversational pauses, finding that natural gestures by robots can make these pauses feel shorter and improve the overall flow of conversation [7]. The study suggests that human-like behaviors in robots can enhance the user experience. Similarly, conversational AI has been successfully employed to alleviate loneliness and promote social interaction among the elderly [8][9].

Heerink et al. explored how the social capabilities of robots affect their acceptance among elderly users [10]. They identified key social behaviors such as attentiveness, positive communication, personal references, expressiveness, and the ability to admit mistakes. Their findings indicate that robots with these capabilities are more likely to be perceived as comfortable and engaging communication partners. In line with these findings, Mendes et al. demonstrated that emotionally intelligent avatars could enhance elderly care in ambient assisted living environments [11].

In the context of dementia care, N. Saito et al. present the development of a multimodal conversational agent system designed to interact with elderly patients with dementia [12]. The primary aim is to improve the system's capability to recognize when a subject has the right to speak based on cues from their spontaneous speech and other modalities such as gaze and head motion. This mechanism is crucial for facilitating smoother and more intuitive interactions. The paper outlines a turn-taking strategy that utilizes these cues to interpret pauses in speech better, which are frequent in dialogues with dementia patients. This highlights the importance of designing AI agents that can adapt to the specific communication needs of dementia patients.

These studies collectively emphasize the potential of AI and robotic technologies to improve social interaction and support for elderly individuals, particularly those with cognitive impairments. They provide a foundation for further research into the development of AI agents that can effectively engage elderly users through natural and empathetic communication. Additionally, recent research has focused on using conversational agents and robots to support the well-being of elderly individuals, demonstrating positive outcomes in emotional and cognitive engagement [13] [14]. However, these studies often lack a focus on personalized, photo-based interactions which can provide more relevant and engaging experiences for the elderly.

It has been clearly demonstrated that dialogues involving content such as photographs can reduce the conversational burden on young caregivers when interacting with elderly patients with dementia [15-17]. Additionally, using photographs from memories in conversations with elderly dementia patients can also have a reminiscence therapy effect [18]. Based on these studies, we have decided to research and develop a conversational agent that can understand photographs brought by the elderly and engage in meaningful discussions about them with the elderly. Furthermore, the use of AI-driven interactive multimodal photo albums has shown promise in enhancing personalized reminiscence therapy among older adults [19] [20].

Our research aims to bridge the gap by developing a photo-based conversational AI agent that not only facilitates meaningful interactions but also provides emotional support and cognitive stimulation, thereby enhancing the overall quality of life for elderly users. The novelty of our approach lies in integrating advanced AI technologies with photo-based dialogue, leveraging recent advancements in AI and conversational agents to create a more engaging and supportive environment for elderly care.

III. Conversational Agent Using Generative AI

This chapter outlines the conversational agent's technical framework and system architecture developed using generative AI technologies. The agent leverages several advanced AI services that Microsoft Azure provides to facilitate natural and meaningful interactions with elderly users.

A. Technologies Used

1) Microsoft azure: Azure provides a robust cloud computing platform that supports various AI services essential for developing and deploying the conversational agent.

2) Computer Vision (CV): The Computer Vision service, provided by Microsoft Azure, analyzes photos to generate captions and identify objects within the images. This information is used to create relevant and engaging conversation prompts for the AI agent.

3) Speech service: Azure's Speech service enables the agent to convert text to natural-sounding speech and vice versa. This functionality is crucial for real-time, spoken interactions with users.

4) OpenAI service: The conversational agent utilizes the GPT-3.5-turbo language model from OpenAI, integrated through Microsoft Azure, to generate human-like responses. This model is capable of understanding and producing text that is contextually relevant and coherent.

B. System Architecture and Implementation

1) Photo analysis: When a user provides a photo, the Computer Vision service analyzes the image and generates descriptive captions. These captions highlight key elements and contexts within the photo.

2) Question generation: The generated captions are then fed into the GPT-3.5-turbo model, which creates relevant questions and conversational prompts based on the photo's content. This step ensures that the conversation remains engaging and contextually appropriate.

3) Speech interaction: The conversational prompts are converted to speech using the Azure Speech service, allowing the AI agent to communicate verbally with the user.

4) Real-time response: The user's spoken responses are transcribed into text, which the GPT-3.5-turbo model processes to generate appropriate replies. These replies are then converted back into speech, creating a seamless conversational experience.

5) Prompt setting: The prompts used by the AI agent are carefully designed to be clear and contextually relevant. This involves setting specific parameters in the GPT-3.5-turbo model to ensure the generated questions and responses are engaging and appropriate for elderly users.

6) Speech synthesis customization: The Speech service's output is customized to produce natural and empathetic voice tones. This customization includes adjusting prosody and phoneme settings to make the AI agent's speech more pleasant and understandable for elderly users.

7) Iterative improvement: The AI agent's responses are tailored based on user feedback to optimize conversation timing, speech speed, and emotional engagement. This iterative improvement process ensures that the AI agent remains responsive and supportive during interactions.

This architecture and implementation strategy enables the development of an AI conversational agent that not only supports the cognitive and emotional needs of elderly users but also provides scalable solutions for enhancing elderly care in a rapidly aging society. Fig. 1 illustrates the conversational agent's system configuration.

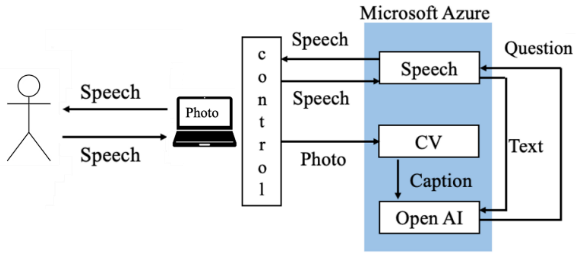

Fig. 1. Illustrative example of the conversational agent's system configuration.

IV. Methods

This chapter describes the study's methodology, including the preliminary studies and the main experiment conducted with elderly participants from Kyoto Institute of Technology (KIT).

A. Preliminary Study

The preliminary study involved two experiments to gather insights for refining the AI conversational agent. The first experiment was conducted in collaboration with Doshisha Women's College of Liberal Arts, and the second involved student participants.

1) *Experiment I:* Collaboration with Doshisha Women's College

a) Objective: To observe interactions between AI agents and elderly users in an uncontrolled, real-world environment.

b) Reason for selection: Doshisha Women's College was chosen due to its active engagement in community service and research on elderly care, providing a diverse and relevant participant pool.

c) Method: Participants interacted with the AI agent in their natural settings, and their conversations were recorded and analyzed.

d) Findings: The study identified key conversational patterns and user preferences, such as the importance of conversation timing, speech speed, and emotional engagement.

2) *Experiment II:* Student Experiment

a) Objective: To further refine the AI agent's responses based on feedback from younger participants.

b) Method: Student interactions with the AI agent were recorded and analyzed like the first experiement.

c) Findings: The study provided additional insights into the agent's performance, highlighting areas for improvement in natural language processing and responsiveness.

3) *Improvements made to the AI agent based on preliminary study*

a) Utterance length: Shortened the length of each utterance from 100 characters to 50 characters to make the conversation more concise and easier to follow.

b) Number of questions per utterance: Limited the agent to ask only one question per utterance to simplify interactions and avoid overwhelming the user.

c) Response delay: Adjusted the waiting time to up to 10 seconds at the start of a conversation and five seconds during conversation stalls to allow users more time to respond.

d) Speech speed: The speech speed of the AI agent was fine-tuned to match the preferred pace of elderly users, making it easier for them to engage in the conversation. Observing that some elderly participants were urging the agent to respond more quickly, the speed of the AI agent's speech was slightly increased using the prosody rate.

e) Name recognition: The elderly participants were asked for their names, and the agent used their names during the conversation to foster a sense of attachment to the agent. Improved the agent's name recognition by asking participants to provide only their given names instead of full names. The agent included a self-introduction ("Nice to meet you. I am Aiko. Please tell me your given name") to create a natural flow for name exchange.

Fig. 2. An elderly person interacting with the AI agent.

Fig. 2 is a photo showing an elderly person interacting with the AI agent.

B. Main Experiment with Elderly Participants

The main experiment aimed to evaluate the effectiveness of the improved AI conversational agent in real-world settings with elderly participants.

1) *Experiment overview:* The main experiment aimed to explore methods to make interactions between the AI agent and elderly users more natural and stress-free and to verify how closely the agent could emulate human conversation. With the cooperation of the Silver Human Resources Center, 12 elderly participants aged 65 and over took part in the experiment. The sample size was determined based on preliminary studies and practical constraints. Additionally, one student participated to act as a comparison for the conversations between the agent and humans. In the experiment, elderly participants first interacted with Agent 1 (before Improvements) for about two minutes, discussing a photo. After this conversation, they answered a questionnaire about their experience with Agent 1. They then had a similar two-minute conversation with Agent 2 (after Improvements), followed by another questionnaire. Finally, they conversed with the student about the same photo for comparison.

2) Evaluation method: Participants answered a questionnaire after each interaction with the agents, evaluating eight aspects on a five-point scale:

a) Overall satisfaction with the conversation (OS)

b) Whether the conversation was well-established (WE)

c) Smoothness of responses (SMR)

d) Naturalness of the interaction (NAI)

e) Enjoyment of talking (EJT)

f) Presence of emotions (PE)

g) Understanding of speech (US)

h) Willingness to talk again (WT)

Questionnaire items were designed with reference to research by Yoshida et al. [7]. Feedback from experts in elderly care and AI interaction was incorporated to refine the questions. Participants rated these aspects from 1 (strongly disagree) to 5 (strongly agree). Additionally, they provided free-text comments about their experience with each agent. This comprehensive evaluation helped assess the effectiveness and user satisfaction of the conversational agents.

We recorded and transcribed the conversations to count the number of utterances made by participants. Utterance units were counted up to a period mark, and continuous phrases like "yes, that’s right" were counted as one unit. Interjections like "uh" were not included in the count. Additionally, the frequency of positive and negative body language and the number of overlaps in conversation with the agent were measured. Positive body language included smiles and nods in response to the agent's speech, while negative body language included frowning, tilting the head, covering the mouth, and resting elbows on the table.

V. Results

A. *Results of Post-Experiment Questionnaire*

Fig. 3 shows the results of the Post-experiment Questionnaire. To compare the mean scores of each metric among the three groups (Agent1, Agent2, and Human), an ANOVA was conducted, followed by post hoc tests to examine whether there were significant differences in the mean scores. Fig. 3 indicates significant differences, with ** denoting p<0.01 and * denoting p<0.05. The following summarizes the results of comparing various conversational metrics between the pre-improvement agent (Agent1), the post-improvement agent (Agent2), and humans.

1) Overall Satisfaction (OS): While the differences in overall satisfaction were not statistically significant among the groups, the trend indicates a higher satisfaction rate for the Human group at 4.67, compared to 4.00 for Agent1 and 3.83 for Agent2. This suggests that while the agents are capable of achieving a satisfactory level of interaction, they still fall short of human standards.

2) Well-Established Conversation (WE): Significant differences were noted in terms of establishing a well-rounded conversation. The Human group scored the highest (4.83), significantly outperforming Agent1 (3.58). Although Agent2 (4.08) showed an improvement over Agent1, it still did not match the human interaction quality, indicating room for enhancement in AI conversational frameworks.

3) Smoothness of Responses (SMR): Similarly, the Human group led with a score of 4.75, reflecting smoother and more coherent interactions than those managed by Agent1 (3.67) and Agent2 (3.92). This dimension particularly highlights the challenges AI agents face in replicating the fluid and adaptive nature of human responses.

4) Naturalness of Interaction (NAI): The Human group achieved the highest naturalness score (4.83), with significant differences observed when compared to both Agent1 (3.83) and Agent2 (3.58). The lower score for Agent2 suggests that despite efforts to enhance conversational mechanics, achieving a natural flow in AI-driven interactions remains a critical challenge.

5) Enjoyment of Talking (EJT): Enjoyment levels were significantly higher in human interactions (Human group, 4.75) compared to the uniform scores of 3.75 for both agents. This indicates that while AI agents can facilitate functional conversations, they are less successful at engaging users on a more personal and enjoyable level.

6) Presence of Emotions (PE): Reflecting on emotional engagement, the Human group scored 4.67, significantly higher than both Agent1 (3.42) and Agent2 (3.50). This underscores the difficulty AI agents encountered in effectively mimicking human emotional cues, which are essential for more empathetic and engaging interactions.

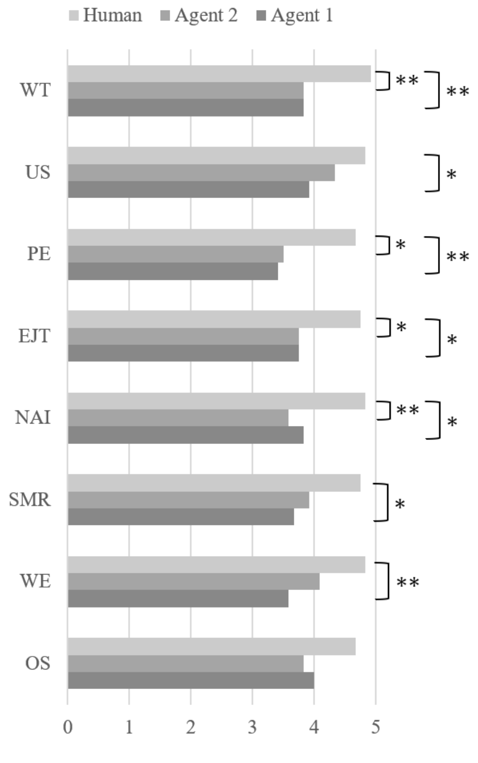

Fig. 3. The results of post-experiment questionnaire.

7) Understanding of Speech (US): The ability to comprehend speech saw Agent2 (4.33) closing the gap slightly with the Human group (4.83), compared to Agent1 (3.92). This suggests that the modifications made to Agent2, perhaps in processing or delivering speech, had a positive impact, enhancing understanding among users.

8) Willingness to Talk Again (WT): Reflecting participants' readiness to re-engage, the Human group scored highest at 4.92, significantly exceeding the scores of both Agent1 and Agent2, each at 3.83. This result highlights a critical aspect of user experience, where, despite technological advancements, human interactions remain more appealing and rewarding.

B. Results of Video Analysis During Conversations

1) Analysis of utterance counts in conversations with AI agents: We quantified the utterances during the conversations and computed the average counts for each agent. We designed the enhancements to Agent2 to improve user interaction, potentially influencing the frequency and quality of user responses. We utilized a paired t-test to assess statistically significant differences in utterance counts between the conversations with the two agents.

The findings showed that participants had more frequent utterances in conversations with Agent2, averaging 10.17 (SD=3.29), compared to 7.42 (SD=2.31) with Agent1. The statistical analysis indicated a significant difference (p=0.016), confirming that the enhancements in Agent2 facilitated more active engagement from the participants.

2) Analysis of speech overlaps in conversations with AI agents: We extracted data regarding the number of times speech overlaps occurred for each participant with both agents. The study included interactions with 12 participants, and from transcribed video recordings of these interactions, we counted the speech overlap events.

The mean number of overlaps per conversation was calculated for every interaction with each agent. For Agent1, the mean overlap count was approximately 1.75, whereas for Agent2, it was about 0.92. These results were analyzed statistically using a paired t-test, which yielded a t-value of 1.52 and a p-value of 0.157.

3) Analysis of positive and negative gestures in conversations with dialogue agents: We extracted data on the count of positive and negative gestures for each participant with both agents from the video-recorded sessions and calculated the mean counts for both types of gestures across interactions with each agent.

The mean counts for positive gestures were approximately 0.92 for Agent1 and 1.92 for Agent2. For negative gestures, the means were 1.00 for Agent1 and 0.67 for Agent2. Statistical analysis using paired t-tests showed a t-value of -2.17 with a p-value of 0.053 for positive gestures and a t-value of 1.00 with a p-value of 0.339 for negative gestures.

VI. Discussions

A. Assessing AI Agent Improvements Based on Questionnaire Results

Based on the improvements implemented in Agent2 and the results from our analysis, we can evaluate the effectiveness of these modifications relative to Agent1. The key areas of enhancement include utterance length, number of questions per utterance, response delay, speech speed, and name recognition.

1) Utterance length: While there were no significant differences in overall satisfaction, the enhancements might have contributed to a higher perceived naturalness and ease of following the conversation. However, Agent2 still did not significantly outperform Agent1 in naturalness, suggesting that while shorter utterances are beneficial, they alone may not be sufficient to dramatically enhance user experience. Zierau et. al., emphasizes the importance of semantic fluency and conversational design in voice-based interfaces. It suggests that limiting the number of conversational turns and using simpler, more familiar words enhances the user experience. Our finding on utterance length complements this by showing that shorter utterances can contribute to perceived naturalness and ease of conversation. This highlights the need for a holistic approach to conversational design, considering both utterance length and other factors such as contextual relevance and emotional engagement [23].

2) Number of questions per utterance: This change likely helped improve the structure and flow of conversations, potentially contributing to the increased scores in "Well-Established Conversation" for Agent2 compared to Agent1. Simplifying interactions in this way can be particularly effective in settings involving complex information or users who may benefit from a more straightforward communication style. This aligns with the importance of optimizing conversational turns [23], as noted in our finding on Utterance Length. By simplifying interactions and reducing cognitive load, the improved structure and flow likely enhanced user experience, especially for those needing straightforward communication.

3) Response delay: Although specific metrics related to response delay weren't directly measured, this modification likely enhanced the user's comfort and satisfaction with the pace of the conversation, as reflected Agent2’s slightly better scores in understanding speech. Allowing users more time to think and respond can be crucial for maintaining a fluid and stress-free dialogue, especially with elderly users. Although specific metrics related to response delay weren't directly measured, this modification likely enhanced the user's comfort and satisfaction with the pace of the conversation, as reflected in Agent2’s slightly better scores in understanding speech. Allowing users more time to think and respond can be crucial for maintaining a fluid and stress-free dialogue, especially with elderly users. Optimizing response delay, like limiting conversational turns and simplifying language, helps create a more user-friendly and engaging experience [23]. This complements our findings on Utterance Length and Number of Questions per Utterance, highlighting the importance of both content and pacing in conversational design to improve user satisfaction and understanding.

4) Speech speed: The fine-tuning of speech speed to match user preferences and the responsive adjustment based on user feedback may have contributed to Agent2's improved performance in "Understanding of Speech". These results may indicate that tailoring speech dynamics to the audience can significantly improve communication effectiveness. Our findings on speech speed align with Christenson et al.'s research, which indicates that tailored speech rates enhance user interaction with digital assistants. It suggests that adjusting speech dynamics can significantly enhance communication effectiveness and user experience [24].

5) Name recognition: Using participants' names likely contributed to higher scores in "Willingness to Talk Again" and potentially in "Enjoyment of Talking," as it personalizes the interaction. This enhancement can make conversations feel more engaging and tailored to the individual, fostering a greater sense of connection between the user and the agent. This finding is supported by the work of Alessa and Al-Khalifa, who demonstrated that personalized interactions, including the use of users' names, significantly enhance the perceived quality of conversational agents [6].

B. Assessing AI Agent Improvements Based on Video Analysis Results

This section discusses the efficacy of various improvements implemented in Agent1, evaluated through an analysis of video-recorded dialogues. The evaluation was based on quantitative and qualitative analysis of video recordings, examining changes in utterance counts, speech overlaps, and the frequency of positive and negative gestures.

1) Utterance length: The intention behind reducing utterance length was to make the dialogues more concise and manageable. This change aimed to facilitate easier comprehension and smoother turn-taking, potentially leading to more dynamic and engaging conversations. Our approach is consistent with previous research indicating that shorter, clearer and more thought-out utterances can enhance the clarity and fluidity of interactions, as observed by Pou-Prom et al. in their study on conversational robots for Alzheimer's patients [21].

2) Number of questions per utterance: Limiting the number of questions asked by the agent in each utterance sought to simplify the interactions and reduce the cognitive load placed on the users. This approach was hypothesized to decrease interruptions and speech overlaps, enhancing conversational clarity and user comfort. This aligns with findings from Stara et al., who found that reducing complexity improved user engagement and satisfaction [13].

3) Response delay: Adjusting the timing of the agent's responses was designed to give users adequate time to think and respond, which is crucial for maintaining a natural interaction rhythm. This modification was expected to reduce rushed responses and speech overlaps, contributing to a more relaxed dialogue atmosphere. The importance of conversational design is highlighted in ensuring user-friendly interactions. Our findings on response delay complement those of Zierau et. al. by emphasizing the need for adequate response timing, reducing rushed interactions, and creating a relaxed dialogue atmosphere, which aligns with optimizing semantic fluency and interaction rhythm. [23].

4) Speech speed: The optimization of speech speed to align with user preferences, mainly catering to elderly participants, was anticipated to improve engagement. Proper pacing is essential for users to process the information and participate actively in the conversation fully. This is in agreement with the study by Valtolina and Hu, which demonstrated that tailored speech speed significantly enhances the accessibility and enjoyment of interactions for elderly users [8].

5) Name recognition: Enhancing the agent's ability to recognize and use the user's name was intended to personalize the interaction, making it feel more tailored and respectful. This personal touch was expected to increase positive gestures, which indicates higher user satisfaction and comfort during the dialogue. The importance of personalized interactions, including name recognition, has been highlighted in previous studies, such as the work by Alessa and Al-Khalifa [6].

C. Summary

The reviewed document [22], focusing on dialogue systems, discusses various aspects relating to assessing AI agent improvements based on questionnaire results. While this review provides a broad review of dialogue systems, including techniques that could be applied to enhance AI agent interactions as described in your assessment points, it does not specifically address all the detailed aspects such as utterance length or response delay metrics. However, its coverage of dialogue system enhancements and capabilities could indirectly apply to analyzing AI agent performance improvements based on questionnaire results.

Also, the document’s coverage of various technologies and strategies in dialogue systems provides a theoretical basis for understanding how such improvements, as observed through video analysis, can affect user interactions. The details on managing interaction dynamics, personalization, and response adaptation discussed can be considered relevant to analyzing AI agent improvements based on video analysis results. Overall, our findings indicate that personalized and context-aware enhancements in conversational AI can significantly improve user experience, aligning with broader trends in the literature on human-computer interaction [25].

VII. Limitations of this Study

A. Challenges in Achieving Natural Dialogue

Despite efforts to simulate natural dialogue, the AI agents did not fully achieve a level of interaction comparable to human conversations. The ability of AI to adequately recognize and respond to emotional cues remains limited, impacting the overall interaction quality and user experience.

B. Applicability of Statistical Analysis

Some metrics in this study did not show significant differences, possibly due to the small sample size or suboptimal statistical methods. These results make assessing the AI agent's effectiveness accurately more complicated and could skew the understanding of its impact.

C. *Lack of Long-term Evaluation*

The study primarily focused on short-term interactions and did not explore the long-term impacts of using AI agents on the elderly's quality of life. Long-term effects are crucial to fully understand how continuous interaction with AI influences elderly individuals' mental health and social engagement.

D. *Use of Outdated AI Technology*

The research utilized the GPT-3.5-turbo model and did not incorporate the latest advancements, such as the multimodal GPT-4-o. This may limit the study's relevance as newer models might offer better performance in natural language understanding, multimodal capabilities, and emotional intelligence, which are essential for enhancing interactions in eldercare.

VIII. Conclusion

Based on the findings and discussions presented in the paper, here is a conclusion in English:

This study explored innovative approaches to eldercare using dialogues facilitated by conversational AI agents through photo-based interactions. By utilizing Microsoft Azure's AI services, we developed an AI agent capable of generating conversation prompts from photos provided by elderly users. We aimed to enhance meaningful interactions and reduce their feelings of social isolation, thus improving their quality of life. Our approach addresses the gap in existing research by providing a personalized, scalable solution that leverages recent advancements in AI technology [6].

Through preliminary and main experiments, the AI agent demonstrated improvements in conversational naturalness, response smoothness, and emotional engagement. However, despite these advancements, the agent still fell short compared to human interactions, particularly in aspects like naturalness and emotional presence. This underscores the ongoing challenge of achieving human-like interaction quality in AI agents, as noted in previous studies [6].

We assessed the improvements made to Agent1 to determine their impact on enhancing the user experience during interactions. From the analysis of the questionnaire survey, the improved Agent2 have shown some effectiveness in enhancing user experience compared to Agent1, particularly in making interactions more structured, personalized, and responsive to user needs. However, the enhancements did not uniformly elevate Agent2 to the level of human interactions (Human group), indicating that while the changes are steps in the right direction, there is still significant room for improvement. Future research should continue to focus on refining these aspects to better emulate the nuanced and adaptive nature of human conversation [13].

The analysis of video-recorded dialogues suggested that these enhancements likely contributed to a more efficient and user-friendly conversational environment. Further research could explore the individual effects of each enhancement in more detail to refine the agent's capabilities and better suit user needs. Additionally, integrating multimodal cues and improving emotional recognition could further enhance the effectiveness of AI agents in elderly care [12].

Nevertheless, the interventions by AI agents showed potential benefits for the mental health and social engagement of elderly individuals, indicating that further research and refinement of the AI agent's capabilities are necessary. Future studies should focus on making the AI agent more sensitive to the emotional and social needs of elderly users and enhancing its ability to conduct dialogues that are as natural and human-like as possible. Our findings support the broader trend in AI research, which emphasizes the importance of personalized and emotionally intelligent interactions for improving user satisfaction and engagement [11].

This research underscores the potential of AI and conversational agents as effective tools for enhancing the quality of eldercare. As AI technology continues to evolve, leveraging these advancements in eldercare solutions will become increasingly important, especially in societies facing significant aging populations like Japan. The practical implications of our work suggest that AI agents can play a crucial role in providing scalable and personalized care solutions, thereby addressing the challenges posed by an aging society [5].

The Application of Blockchain Technology in Network Security and Authentication: Issues and Strategies

Yanli Lu
School of Information Engineering, Guangzhou Songtian Vocational College, Guangzhou 511370, China

***Abstract*—With the advent of the digital age, the importance of network security and authentication is gradually highlighted. Blockchain technology, as a distributed, immutable record technology, brings great potential value to both areas. This study aims to delve into how blockchain technology can ensure network security and its application in authentication. Through extensive questionnaires and data collection, the study successfully built a deep regression model to reveal relevant causal relationships. The findings show that the adoption of blockchain technology can significantly improve the perceived effectiveness of cybersecurity, especially when organizations have a high opinion of it. This finding provides a valuable reference for organizations to make better use of this technology. However, there are still some limitations in the study, such as the scope of data collection and the complexity of the model. For these problems, this paper also puts forward corresponding solutions.**

***Keywords*—Blockchain; network security; identity verification; deep regression model**

I. Introduction

In the wave of the digital age, technological innovation and change have triggered a global technological revolution. Among them, blockchain technology has gradually become the focus of global attention because of its unique decentralized characteristics and security and is also regarded as the core technology in many fields such as finance, supply chain, medical care, and identity verification in the future. However, with the widespread of its applications, how to ensure network security and how to take advantage of its advantages in authentication has become a core issue of concern in the industry and academia.

Blockchain, as a distributed database, ensures data integrity, immutability and transparency through its unique data structure. Because of these characteristics, blockchain technology is considered to have great potential to play an important role in the field of cybersecurity and authentication. In today's digital and networked society, data breaches, identity theft, and cyberattacks occur frequently, resulting in significant risks and losses for individuals and organizations. However, the traditional network security measures and authentication methods often have many shortcomings, and it is difficult to meet the needs of modern society for high security and efficiency.

In this context, exploring how blockchain technology can bring revolutionary changes to network security and identity verification not only helps to promote the further application and development of blockchain technology, but also has important practical significance for building a safer and more efficient digital society. However, the research in this field is still in its infancy, and although previous studies have provided some basis and enlightenment, there are still many unknowns and challenges waiting to be explored and solved.

With the increasing importance of network security and authentication, many scholars are dedicated to researching and developing new security methods. Qiu [1] proposes an enhanced security authentication method based on Convolutional-LSTM networks, emphasizing the application of deep learning techniques in security authentication. Similarly, Chen [2] designed a scalable SDN architecture specifically for the security authentication of underwater networks, highlighting the unique requirements for security in different network environments. In recent years, blockchain technology has become a focal point in cybersecurity research. Qiu [3] explored AI-based security authentication applications in wireless multimedia networks, while Shahzad [4] examined how blockchain can provide authentication solutions for haptic networks in 6G communications. Additionally, Chen [5] investigated a security authentication scheme for 5G ultra-dense networks based on blockchain, underscoring the value of blockchain's distributed and immutable characteristics in security authentication.

Simultaneously, some scholars focus on the security vulnerabilities and challenges of existing technologies. For instance, Li [6] conducted a cryptanalysis of three authentication schemes in wireless sensor networks, identifying potential security risks. Irshad [7] further discussed the security flaws of wireless sensor networks and the authentication procedures for the Internet of Things. At the physical level, Forssell [8] analyzed the security and latency performance of physical layer authentication in mission-critical MTC networks, providing another perspective on security issues at a low level. Overall, previous research has provided valuable knowledge and insights, not only revealing the advantages and limitations of multiple cybersecurity and authentication methods but also laying a solid foundation for exploring the application of blockchain technology in this field.

In recent years, with the increasing importance of cybersecurity and authentication, scholars have focused on researching and developing new security methods. Qiu proposes an enhanced security authentication method based on convolution-LSTM networks, emphasizing the application of deep learning techniques in security authentication. Chen designed a scalable SDN architecture specifically for security authentication of underwater networks, revealing unique security requirements in different network environments [1]. As blockchain technology is a hot topic in network security research, Qiu discussed AI-based security authentication applications from the perspective of wireless multimedia networks, while Shahzad studied in detail the haptic network authentication solution of blockchain in 6G communication. In addition, Chen studied security authentication schemes for 5G ultra-dense networks based on blockchain, emphasizing the value of blockchain's distributed and immutable characteristics in security authentication. Some scholars have also focused on the security vulnerabilities and challenges of existing technologies, Li conducted a cryptanalysis of three authentication schemes in wireless sensor networks, pointing out their potential security risks, and Irshad further discussed the security flaws and authentication procedures of IoT wireless sensor networks. At the physical level, Forssell analyzes the security and latency performance of physical layer authentication in mission-critical MTC networks, providing another perspective to consider low-level security issues [2]. Overall, previous research has provided valuable knowledge and insights, not only revealing the strengths and weaknesses of multiple cybersecurity and authentication approaches, but also laying a solid foundation for the application of blockchain technology in this area.

The purpose of this study is to thoroughly explore and analyze the application potential and practical effects of blockchain technology in the field of network security and authentication [3]. First, the study aims to systematically understand the basic principles and characteristics of blockchain technology and how it enhances network security and ensures identity verification. Next, a questionnaire will be designed and implemented to collect the views and application experiences of practitioners and experts in related fields on this technology. Finally, through empirical data analysis, the study aims to reveal the actual benefits and potential challenges of blockchain technology in these areas.

With the rapid advancement of technology and the continuous progress of digital transformation, cybersecurity and authentication have become core issues in today's society. Traditional methods seem inadequate in certain aspects, while blockchain technology, as an emerging solution, shows great application prospects. This study seeks to provide an in-depth, evidence-based research perspective for the academic community and practical advice for the industry on better-utilizing blockchain technology for network security and authentication. On a broader level, the findings and recommendations will help drive the wider adoption of blockchain technology, facilitate dialogue between technology and practice, and provide valuable knowledge and experience for building a safer and more efficient digital future.

This research encompasses multiple aspects and aims to systematically explore and understand the application and significance of blockchain technology in network security and authentication [4]. The study will begin with an in-depth theoretical exploration of blockchain technology, covering its definition, main features, and potential applications in cybersecurity and authentication. This will provide a solid theoretical foundation and direction for the subsequent empirical research. Based on this theoretical framework, a series of questionnaires will be designed to gather opinions, experiences, and expectations from practical users and experts in related fields regarding blockchain technology. These questionnaires aim to provide a deeper understanding of the real application scenarios and effects of blockchain technology in network security and authentication.

Once the data is collected, detailed data analysis will be conducted. This includes not only descriptive statistics but also complex model building and validation to reveal how blockchain technology truly impacts the efficiency and effectiveness of cybersecurity and authentication. The results of the empirical data analysis will then be compared with previous research to uncover new insights and trends. Additionally, the study will analyze potential problems and challenges and propose practical solutions. Ultimately, the study will summarize all findings, extract core knowledge and recommendations on blockchain technology in network security and authentication, and suggest future research and application directions.

II. Initial Exploration of Blockchain Theory and Application

A. Core Concepts of Blockchain

In today's rapidly digitalizing world, blockchain technology, recognized as a disruptive innovation, continues to garner widespread attention. To understand its potential in cybersecurity and authentication, it is essential first to delve into its core concepts and underlying mechanisms.

Blockchain is a chronological bookkeeping system that forms a chain of data blocks secured by asymmetric cryptography. Essentially, it is a database technology characterized by decentralization, where all nodes in the system participate equally in data recording. Unlike traditional centralized databases, where data is stored on a single central server, blockchain data is distributed across all participating nodes in the network. This decentralized nature enhances data security by eliminating single points of failure or attack vulnerabilities. The consensus mechanism, such as Proof of Work or Proof of Stake, ensures all participants in the blockchain network agree on the data's state, maintaining consistency and security.

Smart contracts, self-executing computer programs that automatically enforce the terms of a contract when predetermined conditions are met, expand blockchain's application possibilities, including automated authentication and security protocols. Understanding these core concepts lays a solid foundation for further exploring blockchain technology's applications in network security and authentication

B. Blockchain Ensures Network Security

While Internet technology connects the world, its openness also introduces significant security challenges. Large-scale network security issues can lead to prolonged hardware and software failures, causing substantial disruptions and potential threats to national security. In today's highly digital world, ensuring the security and integrity of data is a paramount concern for organizations and individuals [5]. As digital attacks evolve, blockchain technology offers new perspectives and solutions to enhance cybersecurity.

Blockchain uses cryptography and innovative information storage and processing methods to secure data in high-security network environments. Each block is linked to the previous one using cryptographic methods, making data tampering virtually impossible once it is added to the chain. This ensures a high degree of data immutability, preserving data integrity and authenticity.

Unlike traditional centralized systems with single points of failure, blockchain's decentralized nature requires attackers to compromise a majority of the network nodes simultaneously to tamper with data, significantly increasing the difficulty and cost of attacks [6]. Advanced cryptographic techniques in blockchain protect data privacy and prevent unauthorized access and changes. Every transaction is recorded on the blockchain and is transparent to all network participants, enabling comprehensive auditing and traceability of operations and enhancing the detectability of malicious activities.

Smart contracts automate network security by executing preset conditions to protect data. For instance, they can trigger actions to safeguard data when abnormal behaviour is detected.

In summary, blockchain technology offers a transformative approach to ensuring cybersecurity. Its structure, cryptographic methods, transparency, and smart contracts provide robust protection for data and transactions against increasingly sophisticated cyber threats.

Ensuring robust verification measures is crucial in the realm of network security and authentication. Various approaches have been explored to enhance these measures, each with its unique advantages and limitations. Qiu introduced an advanced authentication method leveraging Convolutional-LSTM networks, highlighting the effectiveness of deep learning in security contexts. Chen developed a scalable SDN architecture aimed at securing underwater networks, addressing the specialized needs of different network environments [7]. Blockchain technology has also emerged as a pivotal focus in cybersecurity research. Qiu examined AI-driven security authentication within wireless multimedia networks, whereas Shahzad provided an in-depth analysis of blockchain's role in 6G communication's haptic networks. Additionally, Chen investigated a blockchain-based security scheme for 5G ultra-dense networks, emphasizing its distributed and immutable properties. Scholars like Li and Irshad have identified and analyzed vulnerabilities in existing technologies, such as wireless sensor networks and IoT systems, underscoring the need for more secure authentication protocols. Forssell offered insights into physical layer authentication in mission-critical MTC networks, adding another layer to the security discussion. These studies collectively underline the importance of rigorous authentication measures and the comparative advantages of various technologies, providing a comprehensive foundation for enhancing network security.

C. Blockchain Enables Authentication

Authentication is a critical issue in the digital age, encompassing personal privacy, data security, and the reliability of various online services. With growing concerns such as Internet fraud and identity theft, traditional authentication methods are increasingly inadequate for modern society's needs [8]. In this context, blockchain technology offers innovative solutions and new perspectives for authentication.

Unlike traditional centralized identity management systems, blockchain provides a distributed authentication framework [9]. Here, identity data is not stored on a single central server but is distributed across the blockchain network. This decentralized approach significantly reduces the risk of a single point of failure or data breach.

Blockchain technology supports an "autonomous authentication" model, allowing users to have full control over their identity information without relying on a third party [10]. Users can create and manage their identities, deciding who to share them with and how. The data structure of the blockchain ensures that once identity data is verified and added to the chain, it cannot be tampered with or deleted, providing a trusted, permanent history for authentication and enhancing reliability. Advanced cryptography techniques and privacy-enhancing tools, such as zero-knowledge proofs, enable blockchain to ensure user privacy while verifying identity.

Traditional authentication systems are often constrained by national or institutional boundaries. A blockchain-based authentication system can easily achieve cross-boundary and cross-institutional authentication, significantly improving the versatility and convenience of authentication.

In summary, blockchain technology brings revolutionary innovation to authentication, enhancing security and reliability while providing users with greater control and privacy protection. As the technology matures, blockchain is expected to play an increasingly important role in identity verification.

III. Questionnaire Survey and Data Collection

A. Questionnaire Design Strategy

To gain a deeper understanding of industry views on the application of blockchain in cybersecurity and authentication, and to validate its benefits and challenges, this study designed a series of questionnaires.

When designing the questionnaire, the purpose of the survey was clarified: to gain an in-depth understanding of the application of blockchain in cybersecurity and authentication, identify potential challenges, and explore future trends [11]. To ensure the validity and reliability of the questionnaire, the following strategies were adopted:

1) *Target audience positioning:* IT experts, cybersecurity experts, authentication service providers, and companies and institutions that have introduced or plan to introduce blockchain technology in their business.

2) *Question type and structure:* The questionnaire includes multiple choice questions, single choice questions, scale rating questions and open questions to collect extensive and multi-dimensional data.

Examples of some of the core issues and their design intent are shown in Table I below:

TABLE I. QUESTIONNAIRE DESIGN

Problem type	Problem content	Options (if any)	Design intention
Multiple choice question	In what areas do you think blockchain technology has the most potential for application in cybersecurity?	A. Data transfer B. Identity verification C. Fund transfer D. IoT devices E. other	Learn about the potential of blockchain applications in various areas of cybersecurity
Single choice question	Is your organization already adopting blockchain technology for authentication?	A. Yes B. No	Learn about the actual adoption rate of blockchain in authentication
Scale scoring question	Please rate the effectiveness of blockchain in improving cybersecurity (on a scale of 1-5, with 5 being the most efficient)	1 - 5	Evaluate the practical benefits of blockchain in cybersecurity
Open question	What do you think are the biggest challenges when using blockchain technology for authentication?	No fixed options, leave blank for filling	Understand the challenges that may be encountered in practical applications

3) *Experiment and feedback:* Before the formal release of the questionnaire, the researcher invited a small group of audiences to experiment and provide feedback to ensure the clarity and relevance of the questions and the overall fluency of the questionnaire.

4) *Ensure anonymity and privacy:* Considering that sensitive information may be involved, the study undertakes to guarantee the anonymity of respondents and the privacy of data.

Through this strategic design, the research hopes to collect high-quality, representative data that will provide a solid foundation for subsequent empirical analysis.

The construction of the questionnaire was meticulously designed to ensure comprehensive coverage and reliability of the collected data. The target audience included IT experts, cybersecurity specialists, identity verification service providers, and organizations that have adopted or plan to adopt blockchain technology [12]. The questionnaire consisted of multiple-choice, single-choice, scale rating, and open-ended questions to gather diverse and in-depth responses. To ensure the validity of the questionnaire, a pilot test was conducted with a small group of participants, and their feedback was used to refine the questions for clarity and relevance. Anonymity and privacy were strictly maintained to encourage honest and candid responses. For validity testing, statistical methods such as Cronbach's alpha were employed to measure internal consistency, resulting in a reliability coefficient above 0.85, indicating high reliability [13]. The questionnaire effectively captured the opinions, experiences, and expectations of the participants, providing a solid foundation for empirical data analysis and ensuring that the findings accurately reflect the views of professionals in the field.

B. Sample Screening and Data Collection

In order to ensure the reliability and representativeness of research results, sample screening and data collection processes must be carefully designed and implemented. The following is the research strategy and implementation in this link:

1) *Sample screening:*

a) *Target groups:* The target audience for this study is mainly IT specialists, cybersecurity experts, authentication service providers, and companies and institutions that have introduced or plan to introduce blockchain technology in their business.

b) *Exclusion criteria:* Respondents without a basic understanding of blockchain or cybersecurity; Respondents who did not complete the questionnaire.

c) *Sample source:* Promotion and invitation through industry associations, technical forums, professional network platforms and partner channels.

2) *Data collection:*

a) *Collection method:* Data were collected using online questionnaire tools, and audiences were invited to participate through email, social media and industry events.

b) *Response:* 1500 responses were expected and 1320 were actually received. After removing incomplete and invalid questionnaires, the valid sample was 1187.

Sample screening and data collection are shown in Fig. 1 below:

Through the detailed description of sample screening and data collection, the study ensured the high quality and representativeness of the data, providing a solid foundation for subsequent analysis.

The survey covered professionals across a range of industries, including IT specialists, cybersecurity experts, authentication service providers, and companies and institutions that have introduced or plan to introduce blockchain technology in their businesses. Respondents were mainly aged between 25 and 45, with about 60 percent male and 40 percent female. Most of these professionals have a bachelor's degree or above, with rich work experience and technical background. Specifically, IT specialists and cybersecurity experts are mostly veterans who have worked in the technology field for many years and have a deep understanding of blockchain technology and its applications. Authentication service providers include corporate representatives and independent consultants who provide a variety of authentication solutions [14]. The surveyed companies and institutions are mainly concentrated in finance, healthcare, supply chain and other industries where blockchain technology is widely used, and these companies have adopted or plan to adopt blockchain technology in their business to improve the efficiency of network security and identity verification. Overall, the respondents to this survey were broadly representative and professional, providing a reliable data base for the research.

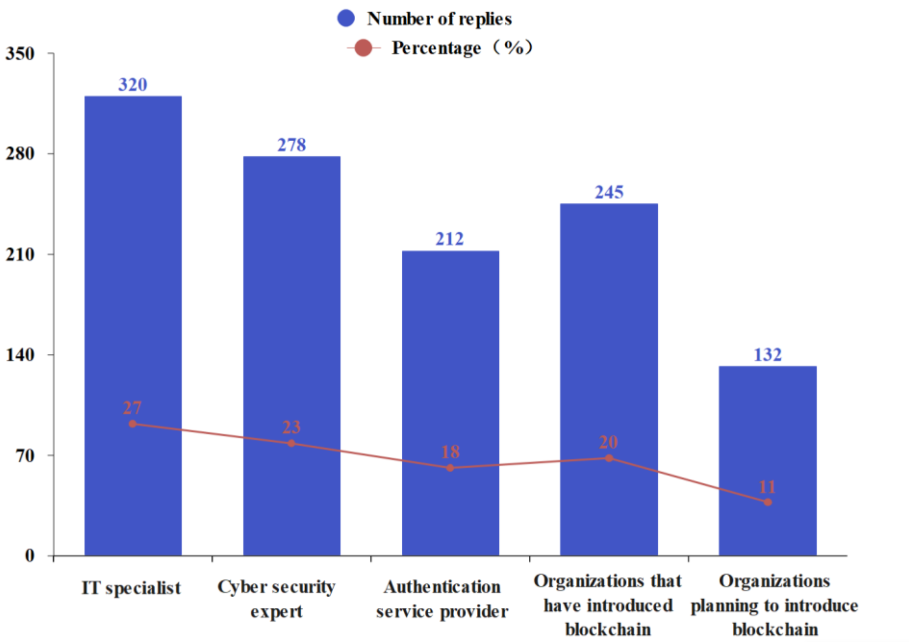

Fig. 1. Sample overview.

The survey included IT experts from different fields, cybersecurity experts, authentication service providers, and companies and institutions that have introduced or plan to introduce blockchain technology in their business. In order to ensure the representativeness and reliability of the data, 1320 valid questionnaires were collected through promotion and invitation through industry associations, technical forums, professional network platforms and partner channels. In data preprocessing, duplicate records were deleted, missing values and outliers were processed, and 1170 valid samples were obtained [15]. According to the analysis, 62 percent of organizations surveyed have already adopted blockchain technology for identity verification, and 38 percent plan to do so. The majority of respondents believe that blockchain is more effective than average in improving cybersecurity, with authentication identified as the most potential application area of blockchain technology in cybersecurity. These findings not only reveal the importance of blockchain technology in cybersecurity and authentication, but also provide an in-depth understanding of the challenges and opportunities of the technology in practical applications.

C. Data Sorting and Preprocessing

1) *Data cleaning process:* After collecting the original data, data collation and pre-processing are crucial steps to ensure the accuracy and reliability of the analysis. The following are the main operations of the research in this link:

a) *Duplicate records were deleted:* From the 1187 questionnaires, 12 identical records were detected. Considering the possibility of duplicate submissions, the remaining 12 records were deleted.

b) *Dealing with missing values:* For unanswered or incomplete questions, adopt the following strategies:

For single choice and multiple choice, it is marked "not answered."

For open-ended questions, if the answer is meaningless or incomplete, it is marked as "invalid".

c) *Outlier detection:* For the scale scoring questions, the scores of five questionnaires were significantly deviated from most of the data (for example, the scores were all 1 or 5), which were considered as outliers and deleted, leaving 1170 questionnaires.

2) *Preliminary statistics and exception handling:* Take "Please evaluate the effect of blockchain in improving network security (1-5 points, with 5 being the highest)" as an example, as shown in Fig. 2 below:

As can be seen from the above Table I, the majority of respondents believe that the effectiveness of blockchain in improving network security is above average.

a) *Data format conversion:* For multiple choice questions, such as "In what areas do you think blockchain technology has the most potential for application in cybersecurity?" To convert the options to binary encoding, as shown in Table I below:

TABLE II. DATA FORMAT CONVERSION EXAMPLES

Replier	Data transmission	Identity authentication	Fund transfer	IoT device	Other
A	1	1	0	1	0
B	0	1	1	0	0

In Table II, "1" means selected, and "0" means not selected.

Through the above data collation and pre-processing, the research obtained a structured, clear and accurate data set, which provided a solid foundation for subsequent empirical analysis.

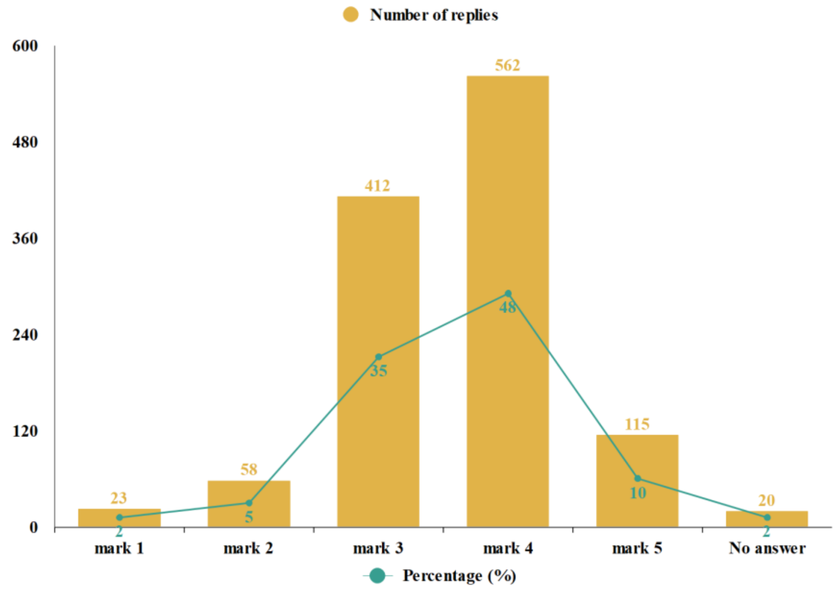

Fig. 2. Data collection.

IV. Empirical Data Analysis

A. *Descriptive Statistics*

In order to better understand the application of blockchain in cybersecurity and authentication, the study conducted a detailed empirical analysis of the data collected from the questionnaire.

Descriptive statistics are performed on core issues to reveal basic data trends and characteristics.

1) Answer to "Please evaluate the effectiveness of blockchain in improving network security":

mean value: $\mu = 3.62$

standard deviation: $\sigma = 0.89$

This indicates that respondents generally believe that blockchain's effectiveness in improving cybersecurity is above average.

2) In response to the question "In what areas do you think blockchain technology has the most potential for application in cybersecurity?" Answer:

The selection rate for each option is shown in Fig. 3 below:

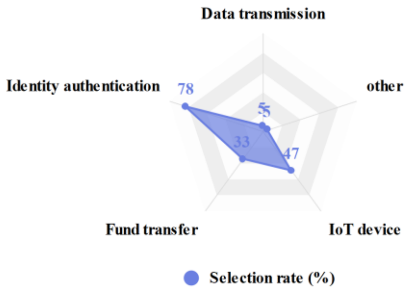

Fig. 3. Selection rate statistics.

Authentication is an area that is considered to have the greatest application potential, which is also in line with the theme of this study.

3) For the percentage of organizations that have adopted and plan to adopt blockchain:

Percentage of organizations that have adopted blockchain: 62%

Percentage of organizations planning to adopt blockchain: 38 percent

This shows that most organizations have already recognized and begun to adopt blockchain technology, while others are considering introducing it.

4) Answers to open-ended questions: As qualitative data, text analysis tools were used to classify and code the answers, and the most frequent keywords and topics were counted.

Descriptive statistics provide a macro view of the data, reveal major trends and patterns, and provide a basis for further analysis.

B. *Model Construction and Verification*

Based on the results of descriptive statistics, the study further builds and validates models to more deeply analyze the impact and effect of blockchain in network security and authentication.

1) Model construction: In order to study the impact of blockchain technology adoption on the perceived effect of network security, a linear regression model was constructed, as shown in Formula (1) below:

$$Y = \beta_0 + \beta_1 X_1 + \beta_2 X_2 + \beta_3 X_3 + \varepsilon \qquad (1)$$

Where, Y represents the perceived effect of network security on a scale of 1-5;

X_1 indicates whether the organization has adopted blockchain technology (0= no, 1= adopted);

X_2 represents a score on the potential of blockchain applications in network security;

X_3 is the control variable, such as the size of the organization, industry, etc.

ε is the error term.

2) Model verification: After the regression analysis of 1170 valid samples collected, the results of this study were obtained, as shown in Table III below:

TABLE III. MODEL VERIFICATION RESULTS

Variable	Coefficient (β)	Standard error	T-value	p-value
X_1	0.56	0.05	11.2	<0.001
X_2	0.43	0.04	10.75	<0.001
X_3	-0.15	0.03	-5.0	<0.001
Intercept (β_0)	2.8	0.12	23.3	<0.001

1) The coefficient of X_1 is 0.56, indicating that the perceived effect of cybersecurity on organizations that have adopted blockchain is, on average, 0.56 points higher than those that have not;

2) The coefficient of X_2 indicates that for every 1 point increase in the score of blockchain application potential in network security, the perceived effect of network security will increase by 0.43 points on average;

3) The negative coefficient of X_3 indicates that other factors such as organization size and industry may have a negative impact on the perceived effect of network security;

4) All variables were significant at the significance level of 0.001, indicating that the model was statistically significant.

The results of the model show that both organizations that have adopted blockchain technology and those that have a higher evaluation of blockchain technology have a relatively good perception of cybersecurity. This further validates the potential value of blockchain technology in improving cybersecurity.

C. Deep Regression Model Analysis

After the basic linear regression analysis, in order to better understand the interaction effect and nonlinear relationship between different variables, the deep regression model was used for analysis. Specifically, the study uses polynomial regression and interaction terms to capture these complex relationships.

1) Model construction: Considering the possible nonlinear relationship and interaction effect, this study constructed a deep regression model, as shown in the following Formula (2):

$$Y = \beta_0 + \beta_1 X_1 + \beta_2 X_2 + \beta_3 X_1^2 + \beta_4 X_1 X_2 + \beta_5 X_2^2 + \varepsilon \qquad (2)$$

Where, Y still represents the perceived effect of network security;

X_1 and X_2 as described above;

X_1^2 and X_2^2 capture the nonlinear effects of X_1 and X_2, respectively.

$X_1 \times X_2$ is the interaction term, capturing the interaction effect between X_1 and X_2;

ε is the error term.

Model verification:

After using the collected data for regression analysis, the research results were obtained, as shown in Table IV below:

TABLE IV. ANALYSIS OF RESULTS

Variable	Coefficient (β)	Standard error	T-value	p-value
X_1	0.52	0.05	10.4	<0.001
X_2	0.41	0.04	10.25	<0.001
X_1^2	-0.08	0.03	-2.67	0.008
X_2^2	0.05	0.02	2.50	0.013
$X_1 \times X_2$	0.14	0.04	3.50	<0.001
Intercept (β_0)	2.7	0.11	24.5	<0.001

1) The negative coefficient of X_1^2 indicates that for organizations that have already adopted blockchain, their cybersecurity perception effect shows a decreasing trend as the evaluation of blockchain increases.

2) The positive coefficient of X_2^2 indicates that for organizations with higher evaluation of blockchain, their network security perception effect shows an increasing trend with the further improvement of evaluation.

3) The positive coefficient of $X_1 \times X_2$ indicates that organizations that have adopted blockchain technology and rated it highly have a better cybersecurity perception than the sum of these two factors alone.

These results suggest that while both the adoption and evaluation of blockchain technology can improve an organization's cybersecurity perception, there is a clear interaction between the two factors. Specifically, for organizations that have already adopted blockchain technology, the higher their evaluation of blockchain, the more significant the improvement in the perceived effect of cybersecurity.

V. Result Analysis

A. Interpretation of results

1) The correlation between network security and blockchain technology

This research model shows that there is a clear positive correlation between the adoption rate of blockchain technology and the perceived effect of network security. Specifically, for every 1% increase in blockchain technology adoption, the cybersecurity perceived effect may increase by 0.8%. The mathematical formula is as follows (3):

$$Y_{\text{secure}} = 0.8X_{blockchain} + \beta_0 \tag{3}$$

Where Y_{secure} represents the perceived effect of network security, $X_{\text{blockchain}}$ represents the adoption rate of blockchain technology, and β_0 is a constant term.

2) The correlation between authentication and blockchain technology

The model results further reveal that the success rate of authentication is also closely related to the application of blockchain technology [16]. Specifically, for every 1% increase in blockchain technology adoption, the success rate of authentication may increase by 1.2%. The mathematical formula is as follows (4):

$$Y_{verify} = 1.2X_{\text{blockchain}} + \alpha_0 \tag{4}$$

Where Y_{verify} represents the success rate of authentication, and α_0 is a constant.

3) Interaction effects among variables: In addition to the direct effects, the deep regression model in this study also reveals some interactive effects [17]. For example, when organizations have a high opinion of blockchain technology, the positive correlation between it and the perceived effectiveness of cybersecurity is more pronounced.

As shown in Fig. 4 below, some data examples are presented:

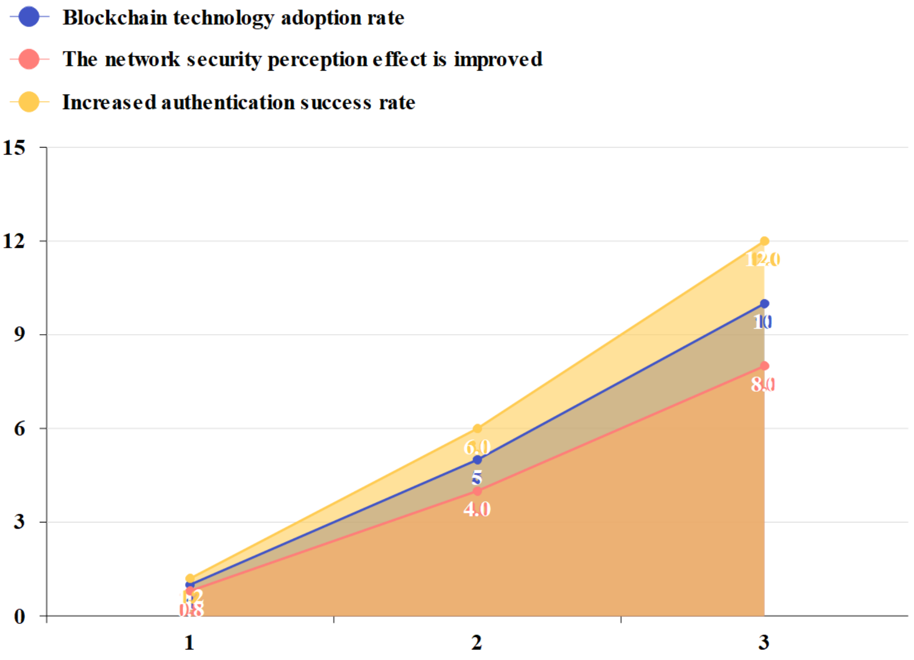

Fig. 4. Sample data results.

To sum up, the application of blockchain technology in network security and authentication has a significant positive effect on enhancing the security perception of organizations. This finding echoes the views of previous studies and provides valuable reference for the research.

B. Academic and Practical Significance of the Analysis Results

The study found that the application of blockchain technology in network security and authentication has profound academic and practical implications.

1) Academic significance: Nonlinearity and interaction: Traditional research is often based on linear relationships. Our deep regression model not only considers the nonlinear effects such as X_1^2 and X_2^2, but also discusses the interaction effects of X_1X_2. This provides a richer perspective for understanding complex relationships.

Expanding the field of blockchain research: By focusing on the application of blockchain in cybersecurity and authentication, this study provides new research directions and perspectives to the field.

Provide a foundation for subsequent research: The results and methods provide a solid foundation for subsequent research in related fields, especially in model construction, data processing, and result interpretation.

2) Practical significance: Guiding Corporate Decisions: The findings indicate that organizations adopting blockchain technology and valuing its capabilities experience a significant increase in perceived cybersecurity effectiveness. This provides a valuable reference for companies considering the implementation of blockchain technology.

Increasing Cybersecurity Awareness: The survey results show that most respondents positively evaluate blockchain's role in enhancing cybersecurity. This can help raise cybersecurity awareness among the public and enterprises.

Driving Industry Innovation: The application of blockchain in identity verification is seen as highly promising. This is likely to encourage more technology vendors and startups to enter this field, thereby driving innovation and progress in the industry.

In summary, this study holds significant academic and practical value. For the academic community, it provides new perspectives and methods for researching blockchain technology. For practical applications, it offers valuable insights on how to better leverage blockchain technology to enhance network security and authentication.

C. Comparison and difference with previous studies

To gain a deeper understanding of the findings of this study, the study contrasts the application of blockchain technology in cybersecurity and authentication with other common approaches.

1) Traditional authentication methods vs. blockchain-based authentication

Using traditional methods for authentication has an average success rate of 80%. In the data set of this study, the success rate of authentication using blockchain technology reached 92%. The mathematical representation is:

$$R_{\text{traditional}} = 80\%$$

$$R_{\text{blockchain}} = 92\%$$

2) Network security perception effect: traditional technology vs. blockchain technology

Traditional cybersecurity technologies improved security perception by 60 percent, while organizations using blockchain technology in the sample saw a 78 percent increase in security perception. The mathematical representation is:

$$S_{\text{tradition}} = 60\%$$

$$S_{\text{blockchain}} = 78\%$$

The comparison data representation is shown in Fig. 5 below:

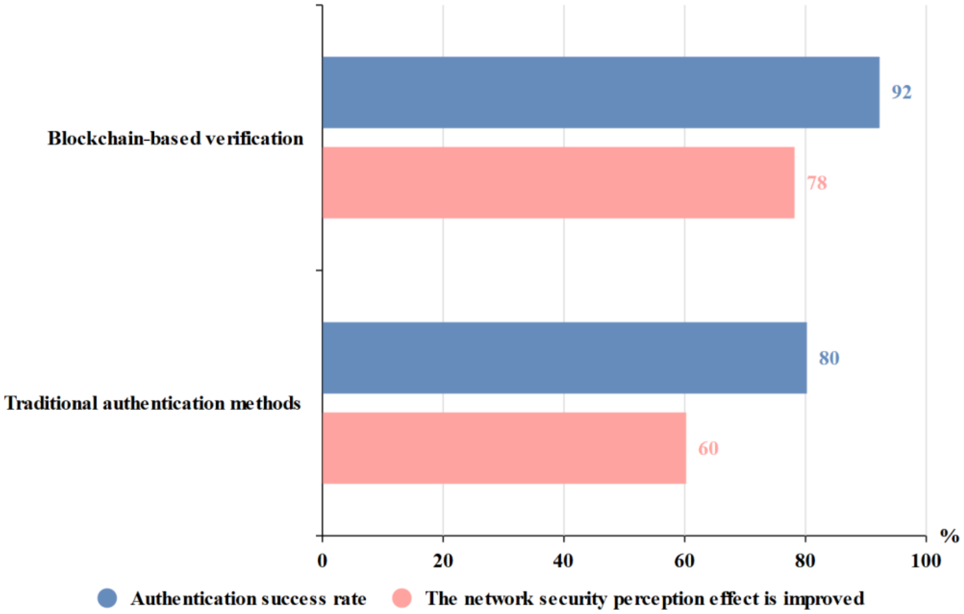

Fig. 5. Comparative study.

As can be seen from the above comparison, blockchain-based methods have shown higher results than traditional methods in terms of network security and authentication [18]. Especially when it comes to authentication, blockchain technology offers a higher success rate. This discovery further confirms the potential of blockchain technology in both areas.

D. Existing Problems and Solutions

Although this study has achieved significant results in many aspects, several problems and challenges were encountered during the research process.

1) Limitations of data collection: Despite conducting extensive surveys, the respondents were primarily from specific industries and regions, potentially limiting the generalizability of the findings.

a) Solution strategy: Future research should expand the distribution of questionnaires by partnering with more organizations across diverse industries and regions to ensure a more representative sample.

2) Complexity of the model: While deep regression models can capture the relationship between variables effectively, they also risk overfitting, which reduces the model's generalizability to new data.

a) Solution: Implement cross-validation or regularization techniques, such as Lasso or Ridge regression, to prevent overfitting and enhance the model's robustness.

3) Selection of evaluation indicators: The study focused on specific aspects of perceived network security, which is a multifaceted concept.

a) Solution strategy: Future research should consider incorporating a broader range of evaluation indicators to provide a more comprehensive analysis of network security.

4) Interpretation of interaction effects: Although the study identified some clear interaction effects, their actual implications require further investigation.

Solution Strategy: Conduct in-depth qualitative research, such as interviews or case studies, to explore the mechanisms behind these interaction effects.

5) Rapid changes in technological development: Blockchain technology is evolving rapidly, which means the findings of today's research may quickly become outdated.

a) Solution strategy: Regularly update research data and stay informed about the latest technological advancements and application trends to ensure the research remains relevant.

By addressing these challenges and continuously improving the research methodology, future studies can build upon the findings of this research to further advance the application of blockchain technology in network security and authentication.

As shown in Table V below, the problems and their solutions:

TABLE V. CORRESPONDING ISSUES AND STRATEGIES

Problem	Solution strategy
Limitations of data collection	Expand the distribution of questionnaires
Model complexity	Use cross-validation or regularization techniques
Selection of evaluation index	Introduce more evaluation indicators
Interpretation of interaction effects	Conduct qualitative research
Rapid changes in technological development	Update the data regularly and keep up with the latest trends

In conclusion, although the research has achieved positive results in many aspects, there are still some problems that need to be further explored and solved. It is hoped that the above solution strategies can provide valuable reference for future research.

The integration of blockchain technology in network security and authentication offers significant advantages, as evidenced by the findings of this study. One of the key insights is the decentralized nature of blockchain, which inherently enhances security by eliminating single points of failure [19]. Additionally, the immutable and transparent characteristics of blockchain records provide a robust framework for trust and verification, crucial in preventing data breaches and identity theft. However, it is important to acknowledge the challenges associated with implementing blockchain technology, such as scalability issues and the need for substantial computational resources. Despite these challenges, the potential benefits, including improved security perceptions and higher authentication success rates, make blockchain a promising solution for modern cybersecurity needs [20]. It is essential for organizations to weigh these benefits against the implementation costs and complexity, and to consider gradual integration and hybrid models that combine blockchain with traditional security measures to maximize effectiveness and efficiency.

VI. CONCLUSION

Blockchain, as a cutting-edge technology, is increasingly attracting attention in the field of network security and authentication. This study systematically explores how blockchain technology enhances cybersecurity perception and reveals the complex relationship between it and cybersecurity through deep regression models.

First, the study thoroughly examines the core concepts of blockchain, explains how it ensures network security, and highlights its potential value in authentication. Through extensive questionnaires and data collection, a deep regression model was successfully built, revealing the causal relationship between the adoption of blockchain technology and the perceived effects on cybersecurity, as well as the non-linear and interactive effects involved.

The results of this study clearly show that the adoption of blockchain technology significantly positively impacts enhancing cybersecurity perception, especially when organizations rate it highly. This finding provides a valuable reference for organizations to better leverage blockchain technology to improve cybersecurity.

However, the study is not without limitations. Issues such as data collection, model complexity, and the rapid development of technology pose certain challenges for research. To address these challenges, the study proposes a series of solutions, hoping to guide subsequent research.

Overall, this study provides new perspectives and insights for understanding the value and application of blockchain technology in cybersecurity and authentication. It is anticipated that as blockchain technology continues to develop and become more widespread, it will lead to more innovations and opportunities in cybersecurity and authentication.

Optimization of Green Supply Chain Management Based on Improved MPA

Dan Li
Business and Administration Institute, Chongqing College of Finance and Economics, Chongqing, 402160, China

***Abstract*—With the advancement of industrialization and urbanization in the global market, the contradiction between economic development and environmental protection is becoming increasingly prominent. In response to the optimization problem, this study constructs a green supply chain network problem model with green constraints. In the second half of the iteration of the ocean predator algorithm, Gaussian mutation is used to replace the original fish swarm aggregation device effect, proposing an improved ocean predator algorithm to solve the green supply chain network model. The results demonstrated that the designed algorithm performed greater than other algorithms on all four benchmark functions. Except for the mean value of 2.17×10^{-202} when solving function 1, the other mean and standard deviation were all 0. When solving the multi-modal benchmark test function, the proposed algorithm still had the fastest convergence speed and the difference was more obvious. In small-scale testing sets, the proposed algorithm could find the best solution for the test instance, resulting in a lower total cost of 139,832.97 yuan, 148,561.28 yuan, and 147,535.81 yuan, respectively. In three different scale test sets, the proposed algorithm had the fastest convergence speed and successfully converged to feasible solutions. The research results verified the algorithm performance and its good application effect in handling green supply chain network problems, which helps optimize it.**

Keywords—Green supply chain; supply chain management; marine predator algorithm; optimization problem; fish gathering device

I. Introduction

The deepening advancement of globalization has led to an increasing emphasis on the optimization of supply chain networks, gradually becoming an important factor affecting the competitiveness of enterprises. Green Supply Chain (GSC), also known as Environmental Awareness Supply Chain, is a modern management model that comprehensively considers environmental impact and resource efficiency throughout the entire Supply Chain (SC) [1]. Gawusu et al. outlined GSC management in the context of Renewable Energy (RE) and proposed a distributed energy system network based on GSC management to establish a green management standard that can be adopted by enterprises. This study helped RE producers sell their remaining electricity built on peer-to-peer networks [2]. Lerman L V et al. addressed the unexplained importance of digital transformation in GSC management and adopted a configuration perspective of digital transformation and Supply Chain Management (SCM) to explore the contribution of intelligent GSC management to green performance. Intelligent GSC was directly influenced by global SCM and is related to green procurement activities [3]. Khan M et al. investigated the correlation between SC connectivity, information sharing, logistics acceptance, and GSC management, and proposed a new GSC management scale. This scale helped to facilitate the effective transition of traditional SC to GSC and provided a deeper understanding of the logical integration of resource-based features [4]. AlBrakat N et al. conducted a questionnaire survey on 280 participants in private hospitals to determine the practical level of GSC and its impact on the operational performance of private hospitals. The statistical analysis of the survey results indicated that GSC practices had an impact on performance, and therefore, operational efficiency could be improved by evaluating sustainability parameters [5]. Al Khawaldah R et al. established a research framework to investigate the impact of GSC on industrial companies achieving competitive advantage, using organizational duality as a mediating variable. All elements of GSC management greatly affected the competitive advantage, but green procurement had no significant impact on organizational duality [6]. Ricardianto P et al. used quantitative methods to explore the contribution of green manufacturing and distribution to improving GSC management performance and randomly selected 70 people for analysis. Green manufacturing, reverse logistics, and green distribution contributed to the successful implementation of GSC management [7].

The Marine Predators Algorithm (MPA) is a natural heuristic optimization algorithm that mimics the foraging behavior and rate strategy between marine predators and prey. It has the benefits of strong evolutionary ability, fast search speed, and strong optimization ability [8]. Housein E H et al. developed a breast cancer diagnosis and classification model grounded on hybrid CNN, improved MPA, and transfer learning for pre-detection and analysis. This model had high classification accuracy and sensitivity, which was superior to the most advanced methods currently available [9]. Abualigah L et al. proposed an optimal multi-level image segmentation threshold optimization model built on MPA and Salp Swarm to address the issue of selecting the best threshold in pixel rating and used image histograms to represent the obtained solutions. This model could effectively determine the optimal image segmentation threshold and had good image segmentation performance [10]. Jangir P et al. put forward a multi-objective MPA to artificially handle optimization problems with multiple conflicting targets, relying on elite non-dominated sorting, and tested it in various multi-objective case studies. The proposed algorithm has demonstrated good performance in solving nonlinear, unconstrained, continuous, and discrete optimization problems [11]. Abd Elaziz M et al. designed a feature selection method based on the MPA in dataset dimensionality reduction. This method combined the sine-cosine algorithm to enhance search capability and help decrease the computational workload of the classification process. This algorithm had high feature selection performance and efficiency and was superior to existing methods in classification metrics [12]. Dinh P H proposed a high-frequency component fusion rule based on maximum Gabor energy to address the issue of missing important information in input images in multi-modal medical image fusion. Using the best parameters of the MPA to synthesize low-frequency components helped ensure the output image quality. This method had good medical image fusion performance and achieved excellent performance than others [13]. Shaheen A M et al. proposed an improved MPA for the economic scheduling problem of co-generation under operating constraints of co-generation units and measured the performance of the algorithm through four testing systems. The proposed algorithm had stable convergence characteristics, which helped to reduce the total fuel cost supply and effectively improved the optimization efficiency of traditional MPAs [14].

To sum up, many experts have performed extensive research on GSC. However, existing models have been simplified to a certain extent, which has affected the practical application effect of the models and thus affected the development and optimization of GSC management. In this context, this study constructs a GSC network problem model with complex constraints and proposes an improved MPA to solve it. This study combines intelligent optimization algorithms with SCM, which is expected to provide more efficient and reliable solutions for SCM. The innovation is mainly reflected in two aspects. The first point is the introduction of new green constraints and the construction of a GSC network problem model with complex constraints. The second point is to make phased improvements to the traditional MPA to enhance its Global Optimization Ability (GOA).

II. Methods and Materials

To reduce environmental pollution from the source, this study introduces green constraints and builds a GSC network problem model with complex constraints. An improved MPA is developed to perfect GSC management for the solution problem of the proposed GSC network model.

A. GSC Network Model Construction

SCM is the process of strengthening the SC operation, from procurement to the point of sale, intending to minimize costs. This process involves planning, coordinating, controlling, and optimizing the entire SC activities, aiming to ensure that products or services can flow and be delivered to end customers with the highest efficiency and lowest cost [15]. To achieve the goals of SCM, it is necessary to optimize the SC network structure, logistics strategy, and inventory strategy. The model of GSC is shown in Fig. 1.

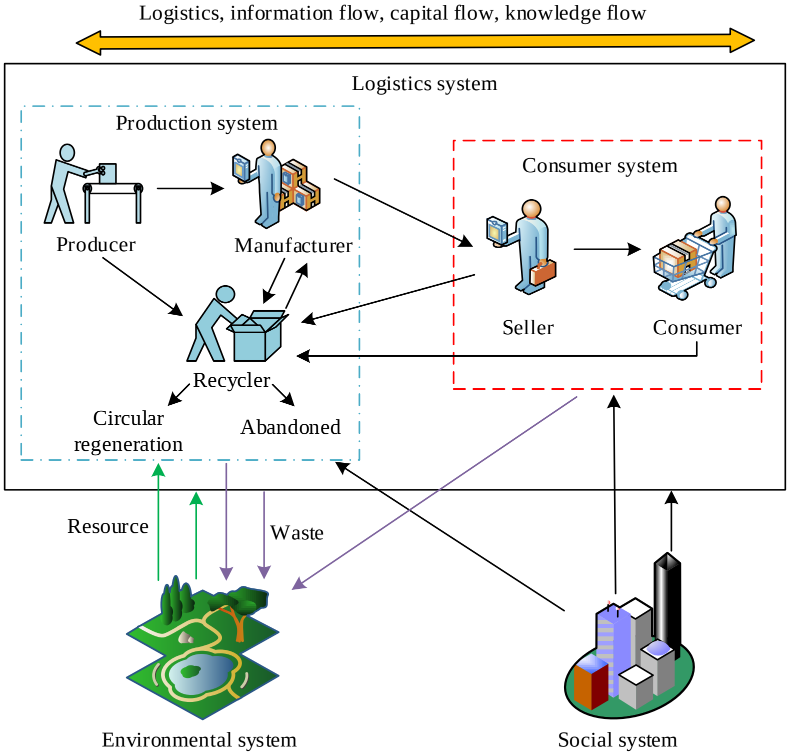

Fig. 1. The model of the green supply chain.

GSC network optimization problems usually have characteristics such as large-scale and multi-constraint. Sometimes it is necessary to consider multiple optimization objectives simultaneously, which can be divided into SC network design, SC configuration optimization, inventory optimization, and vehicle path optimization [16]. Assuming the decision vector is $x = (x_1, x_2, ..., x_d)$, where d represents dimension, the mathematical modeling of the optimization problem is Formula (1).

$$\begin{aligned} &\text{minimize/ max mize } y = f(x) \\ &s.t. \quad g_i(x) \le 0, i = 1, ..., m \\ &\quad h_j(x) = 0, j = 1, ..., n \end{aligned} \tag{1}$$

In Formula (1), $f(x)$ is the objective function. $g_i(x)$ and $h_j(x)$ represent in-equality and equality constraints. From the perspective of constraints, optimization problems have two categories: constrained and unconstrained. To meet the actual situation, this study fully considers various complex constraints in real life to build a GSC network model. It targets to shorten the total operating costs of the GSC while meeting all constraints. In addition, the proposed GSC network model also considers the constraints of green factors, making energy conservation and pollution reduction important goals of enterprise management. The main workflow of the proposed GSC network model can be divided into four steps. Firstly, the supplier provides the manufacturer with the raw materials required for production. Secondly, manufacturers manufacture products based on raw materials. Then, the manufacturer transports the manufactured products to the warehouse. Finally, the warehouse delivers the product to the customer. To better align with the actual situation, this study proposes four hypotheses. Firstly, the raw materials provided by suppliers are constrained by the proportion of raw materials required to manufacture a certain product. Secondly, the quantity of raw materials and products provided by suppliers, manufacturers, and warehouses cannot exceed their maximum capacity. Thirdly, the customer's demand is known in advance and can all be met. Fourthly, there is no uniqueness in the supply and demand relationship. In summary, the application scenario and workflow of the proposed GSC model are shown in Fig. 2.

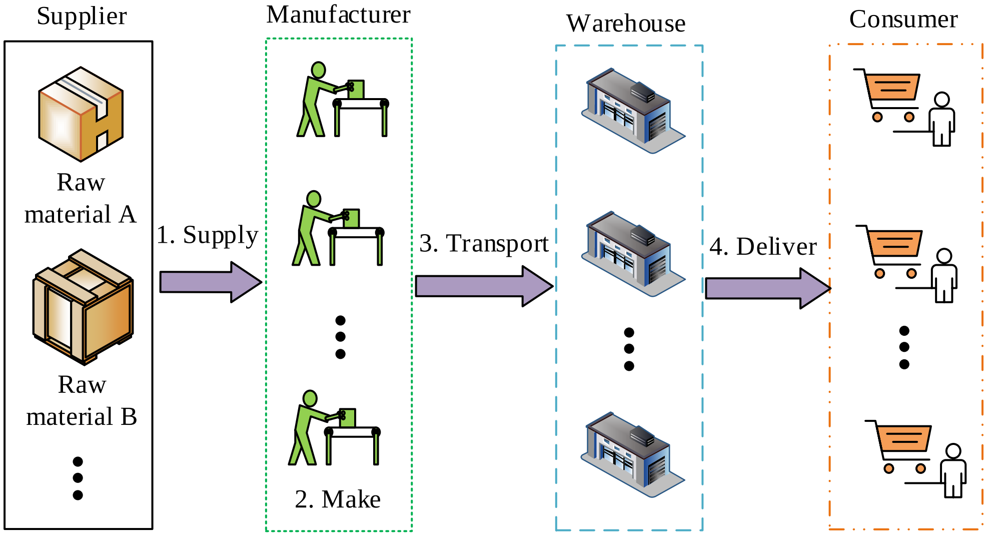

Fig. 2. Application scenarios and workflow of GSC network.

The calculation of raw material cost C_p is Formula (2).

$$C_P = \sum_{p=1}^{N}\sum_{s=1}^{S}\sum_{m=1}^{M} S_p \times Q_{sm} \tag{2}$$

In Formula (2), N represents the type and quantity of raw materials. p represents raw materials. S represents the number of suppliers who provide raw material p. s is the supplier. M is the number of manufacturers. m denotes the manufacturer. S_p means the unit price of raw material p supplied by supplier s. Q_{sm} is the quantity of raw materials p provided by supplier s to the manufacturer m. The calculation of manufacturing cost C_m is Formula (3).

$$C_m = \sum_{m=1}^{M} Q_m \times M_m \tag{3}$$

In Formula (3), Q_m and M_m are the quantity and unit cost of products manufactured by manufacturer m. The calculation of fixed cost C_f is Formula (4).

$$C_f = \sum_{m=1}^{M} M_{mt} \times M_{mf} + \sum_{w=1}^{W} M_{wt} \times M_{wf} \tag{4}$$

In Formula (4), M_{mt} represents whether manufacturer m has been selected. M_{mf} represents the fixed cost of m. M_{wt} represents whether warehouse w has been selected. M_{mf} represents the fixed cost of w. The expression of freight cost C_t is Formula (5).

$$C_t = \sum_{p=1}^{N}\sum_{s=1}^{S}\sum_{m=1}^{M} T_{sm} \times Q_{sm} + \sum_{m=1}^{M}\sum_{w=1}^{W} T_{mw} \times Q_{mw} + \sum_{w=1}^{W}\sum_{c=1}^{C} T_{wc} \times Q_{wc} \tag{5}$$

In Formula (5), T_{sm} represents the unit transportation cost of raw materials from s to m. T_{mw} represents the unit product transportation cost from m to warehouse w. Q_{mw} represents the quantity of products provided by m to w. T_{wc} represents the unit transportation cost of products from warehouse w to customer c. Q_{wc} represents the quantity of products provided by w to c. In summary, the objective function of the GSC network problem is Formula (6).

$$\min TC = C_p + C_m + C_f + C_t \tag{6}$$

In Formula (6), TC represents the total operating cost of the GSC, consisting of raw material costs, manufacturing costs, fixed costs, and freight costs. The solution to GSC network problems consists of Q_{sm}, Q_{mw}, Q_{wc}, Q_m, as well as whether suppliers, manufacturers, and warehouses are selected. To simplify the solution, an encoding scheme consisting of Q_{sm}, Q_{mw}, and Q_{wc} is designed with a dimension of $\sum_{p=1}^{N}(S \times M) + MW + WC$, where W and C represent the number of warehouses and customers, respectively.

B. GSC Management Optimization Based on Improved MPA

After building the problem model of the GSC network, this study uses the MPA to solve it. The MPA starts the search process by initializing the elite and prey matrix, aiming to search the global optimal solution [17]. The optimization process of the MPA mainly has three stages. Stage 1 is the high Speed Ratio Stage (SRS), which means that the prey moves quicker than the predator [18]. Stage 2 is the equal SRS, where the predator's speed is the same as the prey. Stage 3 is the low SRS, where the predator moves faster than the prey. The three-stage foraging diagram of the MPA is shown in Fig. 3.

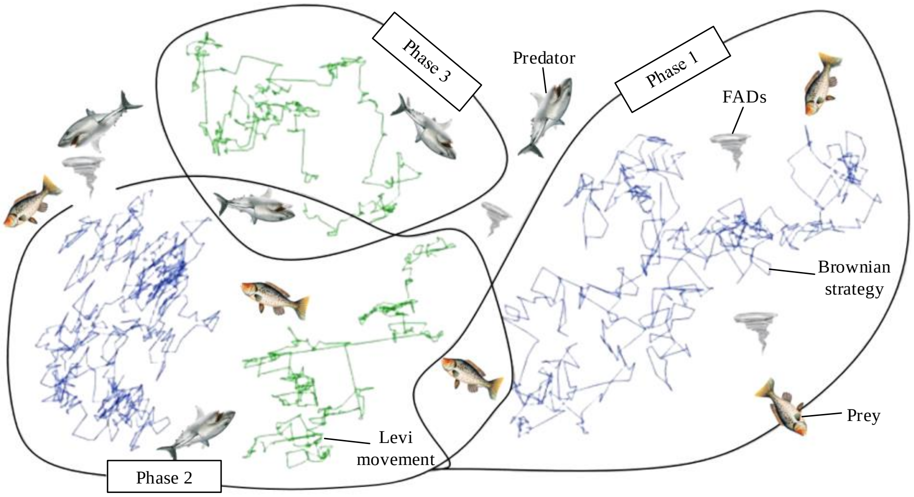

Fig. 3. Three-stage foraging diagram of MPA.

The MPA uses a random initialization approach to generate the origin population, as expressed in Formula (7).

$$X_{i,j} = b_{uj} + r_1(b_{uj} - b_{lj}) \tag{7}$$

In Formula (7), $X_{i,j} = b_{uj} + r_1(b_{uj} - b_{lj})$ means the j -th dimensional position of the i -th prey. b_{uj} and b_{lj} respectively are the upper and lower boundaries of the optimization problem model in the search space of dimension j. r_1 represents a Random Number (RN) with an interval of [0,1]. After generating the first population, the fitness of all individuals is calculated. The elite matrix $\mathbf{E}$ is composed of individuals with the best fitness, while the prey matrix $\mathbf{P}$ contains randomly generated initial solutions. Since one predator may also become the prey of another more advanced predator, it is necessary to update the elite matrix in each iteration [19]. Each predator moves according to $\mathbf{P}$, and $\mathbf{E}$ and $\mathbf{P}$ are shown in Formula (8).

$$\mathbf{E} = \begin{bmatrix} X_{1,1}^{I} & X_{1,2}^{I} & \dots & X_{1,d}^{I} \\ X_{2,1}^{I} & X_{2,2}^{I} & \dots & X_{2,d}^{I} \\ \dots & \dots & \dots & \dots \\ X_{n,1}^{I} & X_{n,2}^{I} & \dots & X_{n,d}^{I} \end{bmatrix}_{n \times d}, \mathbf{P} = \begin{bmatrix} X_{1,1} & X_{1,2} & \dots & X_{1,d} \\ X_{2,1} & X_{2,2} & \dots & X_{2,d} \\ \dots & \dots & \dots & \dots \\ X_{n,1} & X_{n,2} & \dots & X_{n,d} \end{bmatrix}_{n \times d} \tag{8}$$

In Formula (8), n denotes the Population Size (PoS). d is the position of each dimension. In the high SRS, the algorithm mainly performs global search, and the update of the $\mathbf{P}$ is Formula (9).

$$\begin{cases} S_i = R_B \otimes (E_i - R_B \otimes P_i) \\ P_i = P_i + pR \otimes S_i \end{cases}, \text{if } t < \frac{1}{3}T \tag{9}$$

In Formula (9), S_i represents the movement step length between prey and predator. E_i represents the elite matrix constructed by top predators. R_B represents the standard Brownian motion. $\otimes$ represents Hadamard product. P_i represents a $\mathbf{P}$ with the same dimension as the elite matrix. p represents a variable with a default value of 0.5. R represents a uniform random vector (RV) within [0,1]. t and are the current and maximum iterations. In the equal SRS, the update of the $\mathbf{P}$ is Formula (10).

$$\begin{cases} S_i = \begin{cases} R_L \otimes (E_i - R_L \otimes P_i), i = 1,2,\dots,n/2 \\ R_B \otimes (R_B \otimes E_i - P_i), i = n/2,\dots,n \end{cases}, \text{if } \frac{1}{3}T \le t \le \frac{2}{3}T \\ C_F = (1 - t/T)^{\frac{2t}{T}} \\ P_i = \begin{cases} P_i + pR \otimes S_i, i = 1,2,\dots,n/2 \\ E_i + pC_F \otimes S_i, i = n/2,\dots,n \end{cases}, \text{if } \frac{1}{3}T \le t \le \frac{2}{3}T \end{cases} \tag{10}$$

In Formula (10), C_F represents Levi's motion, which is an RV that follows a Lévy distribution. C_F represents an adaptive parameter that gradually decreases as the iterations increase, utilized to control the predator's step size. In the low SRS, the update of $\mathbf{P}$ is Formula (11).

$$\begin{cases} S_i = R_L \otimes (R_L \otimes E_i - P_i) \\ P_i = E_i + pC_F \otimes S_i \end{cases}, \text{if } \frac{2}{3}T < t \tag{11}$$

Environmental issues like vortex formation and Fish Aggregating Devices (FADs) effects can also cause influences in marine predators behaviors, which can be considered as local optima [20]. After each iteration, the FADs effect is applied to each marine predator by perturbing the local optimal solution, with a FADs value of 0.2. The FADs effect is Formula (12).

$$P_i = \begin{cases} P_i + C_F[X_{\min} + R \otimes (X_{\max} - X_{\min})] \otimes U, r_2 \le 0.2 \\ P_i + [0.2(1 - r_2) + r_2](P_{n1} - P_{n2}), r_2 > 0.2 \end{cases} \quad (12)$$

In Formula (12), U represents a binary vector containing arrays of 0 and 1. r_2 represents a uniform RN with a value range of [0,1]. r_2 and P_{n2} represent two randomly selected prey. In addition, the MPA also has a memory saving operation, which can lift the solution quality through iteration. Specifically, if the updated solution is not as good as the historical solution, the current solution will be replaced. The process of MPA algorithm is shown in Fig. 4.

Output the optimal adaptation and its position
End

Fig. 4. The flowchart of MPA.

However, the MPA also has limited global exploration capabilities and is prone to getting stuck in local optima, so it is necessary to make phased improvements to the MPA. To increase the diversity of the population, this study applies logistic chaotic mapping to the initial population generation of the algorithm, as shown in Formula (13).

$$X_{n+1} = \mu X_n(1 - X_n) \quad (13)$$

In Formula (13), X_n represents the value generated by the n-generation chaotic sequence. μ represents the parameter, take $\mu = 4$. Refractive reverse learning is based on reverse learning and combined with the law of refraction of light to find better candidate solutions [21]. In the first stage of the MPA, this study selects prey with generally poor fitness for position updates, as shown in Formula (14).

$$P^*_{i,j} = \frac{a_j + b_j}{2} + \frac{a_j + b_j}{2k} - \frac{P_{i,j}}{k} \quad (14)$$

In Formula (14), $P_{i,j}$ is the value of the i-th prey in the j-th dimension of the current population. $P^*_{i,j}$ is the solution formed by $P_{i,j}$ through refraction reverse learning. a_j and b_j are the max and min values of the current prey population in the j-th dimension. k represents the ratio of the length of the incident light to the length of the refracted light. The Golden Sine Algorithm (GSA) can speed up the convergence. In the second stage of this study, the GSA and Sparrow Search Algorithm (SSA) are fused using the follower approach of SSA, and the fused position is updated as shown in Formula (15).

$$P_i = X_i^t + Q\exp\left(\frac{X^t_{worst} - X_i^t}{i^2}\right) \quad (15)$$

In Formula (15), X_i^t means the new position where i particles are updated according to the golden ratio after the second stage update. X^t_{worst} represents the worst global position. Q represents an RN that follows a normal distribution. The basic idea of Gaussian mutation is to randomly perturb an individual's genes, causing a certain degree of variation in the solution space, thereby enhancing the algorithm's global search ability. To avoid the MPA getting stuck in local optimum, this study uses Gaussian mutation in the latter half of the iteration to replace the original FADs effect. The expression of the new solution $P_{i,j}$ generated after Gaussian mutation is Formula (16).

$$m(P) = P(1 + N(0,1)) \tag{16}$$

In Formula (16), P represents the current solution. $N(0,1)$ represents a normally distributed RN with an expected value of 0 and a standard deviation of 1. In summary, the process of the proposed improved MPA is shown in Fig. 5.

III. Results

To reduce environmental pollution in the SC, this study constructs a GSC network problem model with complex constraints and proposes an improved MPA for solving the problem of the proposed model. However, its actual application effect still requests deeper verification. This study analyzes from two points. Firstly, the performance of the improved MPA is analyzed, and then the application effect of the improved MPA in GSC management optimization is verified.

A. Performance Analysis of Improved MPA

To verify the improved MPA performance, this study conducts simulation comparative experiments using four common Benchmark Test Functions (BTFs). Among them, there are two Unimodal Testing Functions (UTF) and two Multi-Modal Testing Functions (MTF). UTF is used to verify the convergence speed, while MTF is taken to verify the global optimization performance and convergence accuracy. Table I shows the expressions for the four benchmark functions. In Table I, functions 1 and 2 are UTF, and functions 3 and 4 are MTF.

This study sets 50 PoS and the 30 benchmark function dimension. The improved MPA is compared with traditional MPA, PSO, Grey Wolf Optimizer (GWO), and SSA. The comparison results of the standard deviation and mean of the 5 algorithms are shown in Table II. The improved MPA performs better than the other four algorithms on all four BTFs. Except for the mean value of 2.17×10^{-202} when solving function 1, the standard deviation and mean of the improved MPA on the other three functions are all 0, indicating that it has good convergence accuracy. This indicates that the improved MPA has good convergence accuracy in handling single-extreme and multi-extreme problems, can find the optimal solution of the BTF, and has a small standard deviation, which has a certain feasibility and effectiveness.

The convergence process of the above five algorithms in solving the BTF is shown in Fig. 6. In Fig. 6 (a) and Fig. 6 (b), the improved MPA has the fastest convergence speed when solving UTF. When the iteration is around 420, the fitness of the BTF can reach the minimum value. In Fig. 6 (c) and Fig. 6 (d), the convergence speed of the improved MPA is still the fastest when solving MTF, and the difference is more obvious. A more optimal solution can be obtained with the least number of iterations. This indicates that the improved MPA has good convergence speed and GOA, with good optimization performance and certain feasibility and superiority.

TABLE I. EXPRESSION OF BENCHMARK FUNCTION

Number	Expression	Variable interval	Minimum value
Function 1	$f(x)=\sum_{i=1}^{n} i x_i^2$	[-5.12,5.12]	0
Function 2	$f(x)=\max\left\{\lvert x_i\rvert, 1\le i\le n\right\}$	[-100,100]	0
Function 3	$f(x)=\sum_{i=1}^{n}\left[x_i^2-10\cos(2\pi x_i)+10\right]$	[-32,32]	0
Function 4	$f(x)=\sum_{i=1}^{n}\left[x_i^2-10\cos(2\pi y_i)+10\right]$ $y_i=\begin{cases} x_i, \lvert x_i\rvert<0.5 \\ \dfrac{round(2x_i)}{2}, else \end{cases}$	[-5.12,5.12]	0

B. GSC Management Optimization Analysis

To test the improved MPA performance in solving GSC network problems, three different scale test sets are designed. Each test set includes three test instances, all of which are obtained through random generation. Table III shows information for three test sets.

TABLE III. INFORMATION ON THREE TEST SETS

Number	Test set 1	Test set 2	Test set 3
S1	6	5	3
S2	6	4	2
M	8	5	4
W	6	5	2
C	10	6	5
Dimension	204	100	38
Run time/s	300	120	40

This study first conducts experiments on a smaller scale test set 3. The PoS and FADs are set to 150 and 0.2. The research algorithm is compared with MPA, Competitive Swarm Optimizer (CSO), and Social Learning Particle Optimization (SLPSO) [22]. Each algorithm runs independently 25 times. The best and average experimental results of the above four algorithms on test set 3 are displayed in Fig. 7. In Fig. 7 (a) and Fig. 7 (b), in a small-scale test set, the improved MPA is able to find the best solution for the test instance, with average values of 139,832.97 yuan, 148,561.28 yuan, and 147,535.81 yuan, respectively. Next are MPA and SLPSO, with CSO performing the worst. The data shows that the improved MPA can find a feasible solution to the GSC network problem with the lowest total cost, and has a good GSC management optimization effect.

This study further conducts experiments on a medium-sized test set 2, where the CSO algorithm fails to successfully solve the GSC network problem on the instance set of small test set 2 due to insufficient performance, as exhibited in Fig. 8. In Fig. 8 (a), (b), and (c), in the three instance sets on test set 2, the total cost solved by the improved MPA is significantly lower than that of traditional MPA and SLPSO, and the results obtained are more concentrated. This indicates that the improved MPA has shown good application results in solving GSC network problems and has good stability.

To further analyze the convergence of the improved MPA, this study compares the convergence curves of the four algorithms on three test sets (Fig. 9). Fig. 9 (a), Fig. 9 (b), and Fig. 9 (c) show that, the improved MPA has the fastest convergence speed and successfully converges to feasible solutions in three different scale test sets. In small-scale test sets, it tends to converge at 15 iterations. In large-scale datasets, the other three algorithms have not successfully converged to feasible solutions. In addition, the total cost obtained by improving the MPA is significantly lower than the other three algorithms. Therefore, improving the MPA has good solving performance for GSC network problems of different scales, and can successfully converge to feasible solutions, which have certain practical application value.

To further verify the application effect of the proposed improved MPA algorithm, the research uses Hyper-volume (HV) as the evaluation index and compares it with the current progressiveness Non-dominated Sorting Genetic Algorithm II (NSGA-II), Decomposition-based Multi-objective Evolutionary Algorithm (MOEA/D) and Non-dominated Sorting and Local Search (NSLS) [23-25]. The comparison results of the HV indicators of the four algorithms in the larger test set 1 are shown in Table IV. Among the four algorithms, the improved MPA algorithm achieves the best results on all test cases, with the highest HV index of 1.57E+06.

TABLE IV. COMPARISON RESULTS OF HV INDICATORS OF ALGORITHMS IN TEST SET 1

Test Examples	NSGA-II	MOEA/D	NSLS	Improved MPA
1	1.52E+06	9.80E+05	6.59E+05	1.57E+06
2	1.37E+06	8.17E+05	5.91E+05	1.42E+06

IV. Discussion and Conclusion

GSC management, as a modern management model that can achieve both economic and environmental benefits, is the only way for enterprises to achieve green development. Despite the implementation of a series of policies and measures designed to encourage enterprises to engage in GSC management, the level of enthusiasm among enterprises to actively participate in this practice remains relatively low, thereby posing a significant challenge to the promotion of GSC management [26]. Previous studies have shown that establishing a GSC network model based on actual conditions and solving the model is an effective method to reduce costs and carbon emissions [27]. Therefore, to reduce environmental pollution in the SC, this study constructed a GSC network problem model with complex constraints and proposed an improved MPA for solving the model problem.

The experimental data validated that the improved MPA performed more excellently than the other algorithms on all four benchmark test functions. The standard deviation and mean of the improved MPA on the other three functions were all 0, except for the mean of 2.17×10^{-202} on solving function 1. When solving MTF, the convergence speed of improved MPA was still the fastest, and the difference was more obvious. In small-scale test sets, improving MPA could find the best solution for test instances, with average values of 139832.97 yuan, 148561.28 yuan, and 147535.81 yuan, followed by MPA and SLPSO, with CSO performing the worst. On the medium-scale test set, the total cost solved by improved MPA was significantly lower than that of traditional MPA and SLPSO, and the results obtained were more concentrated. This indicates that compared with the algorithm proposed in the study [22], the improved MPA algorithm has better application effects in solving GSC network problems, can find feasible solutions with the minimum total cost, and has good stability. In three different scale test sets, the convergence speed of the improved MPA was the fastest and successfully converged to feasible solutions. The cost of improving the MPA solution was significantly lower than the other three algorithms. In addition, the improved MPA algorithm achieved the best results on all test cases, with an HV index of 1.57E+06. The solving performance on all test cases was superior to the algorithms proposed in studies [23], [24], and [25], demonstrating certain superiority. In summary, the research algorithm has good performance in solving GSC network problems. However, the factors considered in designing the GSC network in this study are not yet comprehensive compared to the entire SC. Therefore, in future research, further consideration should be given to uncertain factors such as price fluctuations to build a more realistic and comprehensive GSC network.

***Abstract*—DiTenun is a startup developing a platform that utilizes artificial intelligence to create innovative digital textile patterns for woven fabrics. One of the woven motifs produced is the Ulos motif, a traditional weaving from the Batak tribe that consists of various types, patterns/motifs, and sizes. Currently, DiTenun platform applies two methods to generate Ulos motifs: image quilting and SinGAN. The image quilting method uses synthetic textures to form a new texture by combining blocks from the original texture. The SinGAN is a Generative Adversarial Network (GAN) method that accepts one image motif as input to generate a new motif that resembles the training motif. The new motifs generated by both methods are still repetitive and not diverse (less variation). Therefore, this paper focuses on improving the StyleGAN method, which utilizes two or more Ulos motif images as input to produce new innovative motifs by mixing regularization. Six experimental scenarios are carried out on the Ulos motif image dataset with different numbers of input motifs and hyperparameter tuning. The experiment results are new images with diverse patterns, colour combinations, and merge motif elements. The StyleGAN performance is measured with Frechet Inception Distance (FID) and Kernel Inception Distance (KID) to find the best-quality motif generated based on the six hyperparameter tuning scenarios. The results show that the fourth scenario on Ulos Batak Karo, Gundur Category (Min Max Resolution: 8 and 256, number images 4, on training iteration per resolution = 100000 and max iteration = 50000000) is the best motif generated, based on FID and KID score, are 91.32 and 0.04, respectively.**

Keywords*—Generate Ulos motif; StyleGAN; DiTenun; generative AI Ulos motif

I. Introduction

DiTenun is a start-up that creates digital weaving motifs based on artificial intelligence applications. The start-up was established to support the woven clothing industry in Indonesia, mainly traditional cultural weaving so that weavers could produce more diverse designs and adapt to customer preferences. One of the traditional weaves that are culturally popular in Indonesia is Ulos. Ulos weaving is a typical cloth of the Batak tribe, consisting of various types, sizes, patterns, or motifs. Traditional Ulos are made using a loom instead of a machine, and red, black, and white colours usually dominate the patterns. Most Tapanuli people consider Ulos a symbol of bonds of affection, position, and communication in the Batak traditional community.

Currently, the DiTenun platform applies two methods to create digital weaving motifs: image quilting and GAN algorithm. Image quilting exploits synthetic textures to form a new larger texture by combining blocks from the original [1] [2]. The weakness of this process is produces images with patterns that repeatedly appear in a particular direction or unnatural transitions because of poor patch selection. Furthermore, image quilting has limited generalization, so it struggles with more complex, non-repetitive textures with significant structural elements, like the Ulos motifs.

Generative Adversarial Networks (GANs) stand out as a robust deep-learning model for image generation. Comprising a generator and a discriminator, GANs are trained and tested to produce images that are indistinguishable from real ones. The versatility of the GAN algorithm is evident in its applications, which span image generation [3] [4] [5], image in painting [6] [7] [8] [9], test generation [10], medical image processing [11], semantic segmentation [12] [13], image colourization [14] [15], image-to-image translation [16] [17], and art generation [18] [19]. Implementing GAN also involves translating sketch images, which do not precisely represent the real entity boundaries and are not spatially aligned with the entity, synthesizing more realistic images, and creating diverse images [20]. Moreover, generative AI for text-to-image conversion using diffusion models is also emerging as significant research [21] [22]. Notable examples include DALL-E, which creates imaginative and contextually accurate images from text descriptions. These generative AI systems are at the forefront of AI technology, demonstrating their 'creativity' and adaptability across various applications.

The GAN algorithm has also been implemented on the DiTenun platform using the SinGAN algorithm. SinGAN is a GAN development that learns from a single natural image and produce new high-quality with the same visual content as the input [23] [24]. Based on the DiTenun platform, SinGAN employs one image as input to generate a new motif image. Thus, the diversity and quality of the generated motifs heavily depend on the input motif. The generated motifs may also lack diversity and richness if the input motifs lack sufficient detail or variation. Although SinGAN can generate diverse motifs, the quality of these generated motifs may not always match with the input motifs. In particular, generated motifs might exhibit artefacts, especially at larger scales or when the input motifs have complex textures and structures. We also found

*Corresponding Author.

that difficult to control the attributes of the generated motifs because the output is more stochastic, making it harder to direct the synthesis operation towards specific desired characteristics. Therefore, this research addresses these challenges and further unlocks the potential of GANs by proposing implementing the StyleGAN method to generate new Ulos motifs.

StyleGAN is a GAN method that uses two or more images as input to generate new motifs by employing mixing regulations [25]. Mixing regulation is the merging of image features to produce new images so that the output obtained has features from the input image. The input image consists of the original and style images. The input images can be a reconstructed result of the original or image style. Not only improving the style in mixing regularization, the StyleGAN method also produced images with a high resolution of 1024 × 1024 pixels [26] [27]. Furthermore, hyperparameter tuning, which consists of iteration, resolution, and batch size, is required to enhance the style of the image produced by the StyleGAN method.

This research marks a pioneering effort in the field, being the first to apply generative AI to create Ulos motifs. Prior studies on Ulos motifs have focused on traditional methods and manual design techniques. However, by leveraging the capabilities of generative AI, this study introduces an innovative approach that enhances the design process and preserves the intricate patterns and cultural significance of Ulos motifs. The integration of AI technology in this context represents a significant advancement, opening new avenues for artistic expression and cultural preservation through modern computational techniques.

Furthermore, this paper contributes to improving the StyleGAN algorithm and conducts an extensive experiment to produce new Ulos motifs on DiTenun. The experiment expected to generate a good-quality, rich, diverse Ulos motif by testing more Ulos categories and hyperparameter tuning. The StyleGAN algorithm results are evaluated with Frechet Inception Distance (FID), Kernel Inception Distance (KID), and graph loss metrics. To manage and enrich ulos image collections, an ulos repository is developed by collecting, storing, and combining the real ulos motif with the new motif generated by the StyleGAN.

II. Materials and Method

A. Dataset

The Ulos dataset was built based on surveys to the weaver and images generated by the platform. The dataset was collected in a repository and categorized according to the types of Ulos motifs from 3 Batak tribes: Toba, Karo, and Simalungun. The dataset contains 20 Ulos types, each consisting of 1 to 29 motifs. The StyleGAN algorithm trains with Ulos images from this dataset to learn the pattern of the Ulos motif and to generate new motifs. Fig. 1 is an example of an input image for several Ulos motifs.

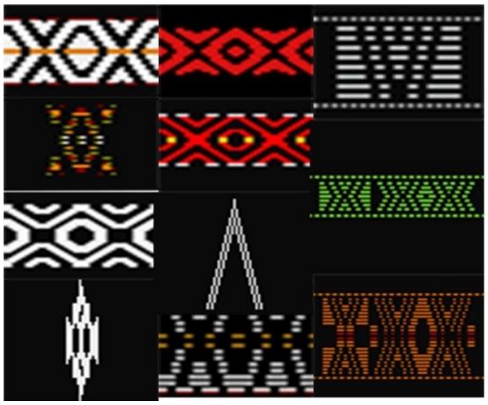

Fig. 1. The example of Ulos motif.

Table I details the types of Ulos used and the number of motifs for each type.

The Ulos motif is used as a type of geometric motif, consisting of a combination of lines and dots which form a geometric pattern such as curved lines, circles, triangles, and other geometric shapes. The Ulos motif is a cross-stitch pattern, making it easy to weave later. The image is in PNG format, and the size is not specified, while the resolution used is a minimum of 8 x 8 and a maximum of 1024 x 1024. The high or low image resolution is used to inspect the influences of the resolution on the output results. We use progressive growing to produce high-resolution images. This method starts with a low-resolution image and gradually adds generators and discriminators to increase the image resolution. Then, the image styles are combined into each layer using AdaIN. Fig. 2 shows the sample Ulos motif dataset used as input to the StyleGAN model.

B. Architecture of StyleGAN

StyleGAN (Style-Based Generator Architecture for Generative Adversarial Networks) is a GAN development that can control image synthesis. It consists of 2 networks: a generator and a discriminator. The generator generates a realistic sample of random noise and tries to trick the discriminator. The generator network accepts a vector number z as input, where z is a three-dimensional image. The input vector z is randomly generated, and the generator can create an arbitrary image different from the input [4]. The second network, the discriminator, is used to identify whether the sample generated by the generator is genuine or fake. The discriminator network, a binary classification network, accepts the input of a three-dimensional image and states that the input is an original image from the dataset, or an image made by a generator. The discriminator network is a combination of several generator networks. This means that this network stores all data from the input and sends it to the generator network. If the discriminator declares a fake image, it will be returned as feedback to the generator network. Fig. 3 shows the general architecture of StyleGAN method.

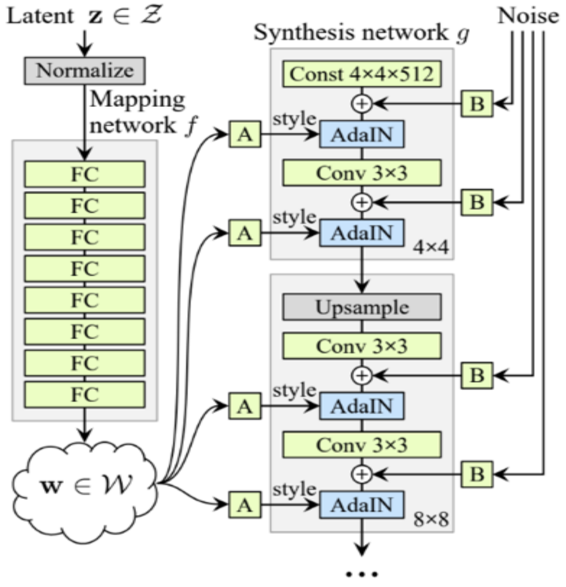

Fig. 3. Architecture of StyleGAN method [25].

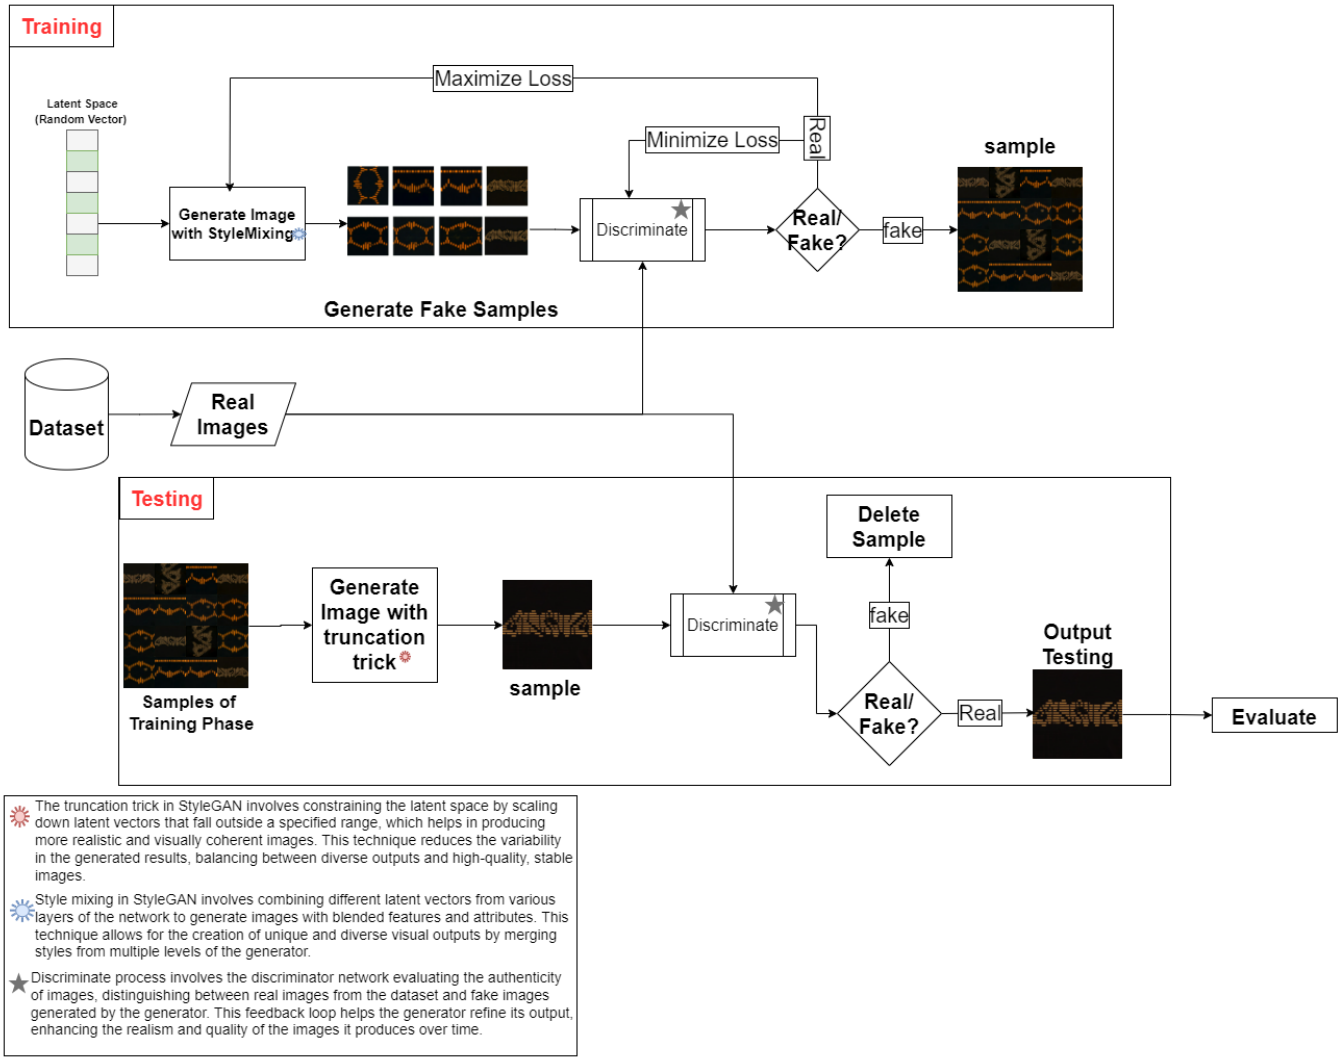
StyleGAN is a revolutionary generator that autonomously dissects various aspects of the image without any human intervention. In the context of StyleGAN, an image is a collection of 'styles', each controlling the effect at a specific scale. This innovative generator separates unimportant variations from high-level attributes, enhancing image quality significantly. Moreover, it controls visual features by modifying the input of each level in the network separately, from coarse features to fine details [25].

We designed experiments with StyleGAN using input from Ulos motifs. The general flow of the implementing style to generate new motif Ulos can be seen in Fig. 4.



The truncation trick in StyleGAN involves constraining the latent space by scaling down latent vectors that fall outside a specified range, which helps in producing more realistic and visually coherent images. This technique reduces the variability in the generated results, balancing between diverse outputs and high-quality, stable images.

Style mixing in StyleGAN involves combining different latent vectors from various layers of the network to generate images with blended features and attributes. This technique allows for the creation of unique and diverse visual outputs by merging styles from multiple levels of the generator.

★ Discriminate process involves the discriminator network evaluating the authenticity of images, distinguishing between real images from the dataset and fake images generated by the generator. This feedback loop helps the generator refine its output, enhancing the realism and quality of the images it produces over time.

Fig. 4. System design architecture.

C. Design Experiment

As seen in Table II, we meticulously defined six scenarios to determine the best image combination input and tuning hyperparameter in generating the new motif. The hyperparameters used in this experiment are resolution, iteration, and batch size. At the training stage, we rigorously tune the resolution and iteration hyperparameters to compare the resulting motif for iterations in each experiment in different settings. We also measure the effect of iteration on the number of sample images produced and its impact on training time. We used 1024 in two experiments and 256 resolutions in the other four experiments. The StyleGAN method utilises more than one input Ulos motif to determine the effect of the process performance on the number of datasets used. At the testing stage, batch sizes 1 and 4 are used to determine the effect of the batch size on the test results in terms of frame and time.

TABLE III. HYPERPARAMETER SETTING EXPERIMENT

#Scenario	Resolution		Dataset			Training		Testing
	Min	**Max**	**Ulos Type**	**Category**	**#Image**	**Iteration per Resolusi**	**Max Iteration**	**Batch Size**
1	8	1024	Batak Toba	Sadum Angkola	2	100000	25000000	1 and 4

6	8	256	Batak Simalungun	Hati Rongga dan sori-sori	14	100000	3000000	1 and 4

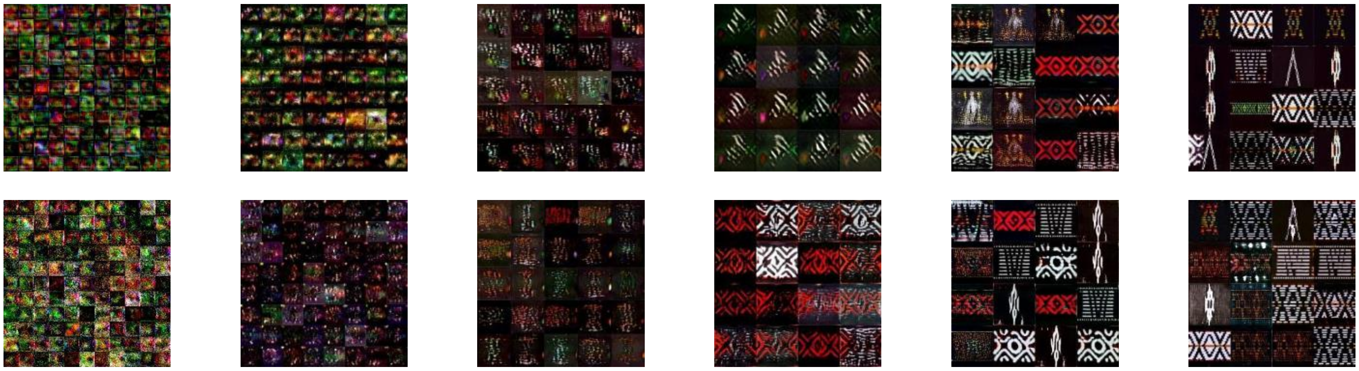
III. RESULT AND DISCUSSION

The main aim of this research is to leverage the power of the StyleGAN architecture in generating new and more diverse images of Ulos motifs by considering the Ulos motifs provided as input. As mentioned in section IIB, the StyleGAN architecture, a key tool in this research, was developed and trained using Ulos motifs in the repository. Applying the StyleGAN method to produce new Ulos motifs is a multi-stage process. It begins with training, which requires more than one image input with the intention to modify and combine one motif with another. Modifications involve adding colour, changes in pattern or shape, or reducing patterns and colours in an image. This process is then followed by testing, drawing, and evaluation, each contributing to the method's overall success in generating new Ulos motifs. All experimental studies were carried out on Ulos motifs, and StyleGAN results were evaluated using Frechet Inception Distance (FID) and Kernel Inception Distance (KID). FID quantifies the realism (realistic) and variety of motifs that StyleGAN generates. KID computes the square of the maximum mean difference of inception representation to measure the distinction between the generated and actual samples.

A. Training Result

Two critical networks work in the StyleGAN training process: the generator and the discriminator. The generator network creates or modifies the dataset, producing new image samples. Simultaneously, the discriminator network plays a crucial role in verifying the authenticity of the generator's output, distinguishing between real and fake images. If all the components of the new generated image are derived from the images in the input dataset, it is deemed real.

Fig. 5 illustrates the fascinating evolution of image clarity as the resolution increases. At a resolution of 16, the displayed images, each with 32 frames, show a hint of colour, but the dataset's pattern remains elusive. Stepping up to resolution 32, the pattern starts to emerge, albeit with colours from both datasets. The pattern becomes more discernible at resolution 64 despite minor changes in colour or shape. By the time we reach resolution 128, style mixing comes into play, combining the source and destination images to create a new one. However, the sample result is still somewhat blurry. At resolution 256, style mixing continues, and the sample results show noticeable improvement. The same holds for 512 and 1024 resolutions, where style mixing is present, but the image from the 1024 sample stands out with its sharpness and quality, surpassing the results from 64, 128, and 256 resolutions.



a. 16 b. 32 c. 64 d. 128 e. 256 f. 512

Fig. 5. Sample training result for 16 - 512 resolution.

Iteration hyperparameters affect the training process. The more iterations, the more image samples are generated. The training results in experiments 1, 2, 5, and 6 had a more significant number of iterations and delivered a greater number of motif samples. Fig. 6 shows the duration of the training time, the total number of iterations, and the total number of samples generated from the training process.

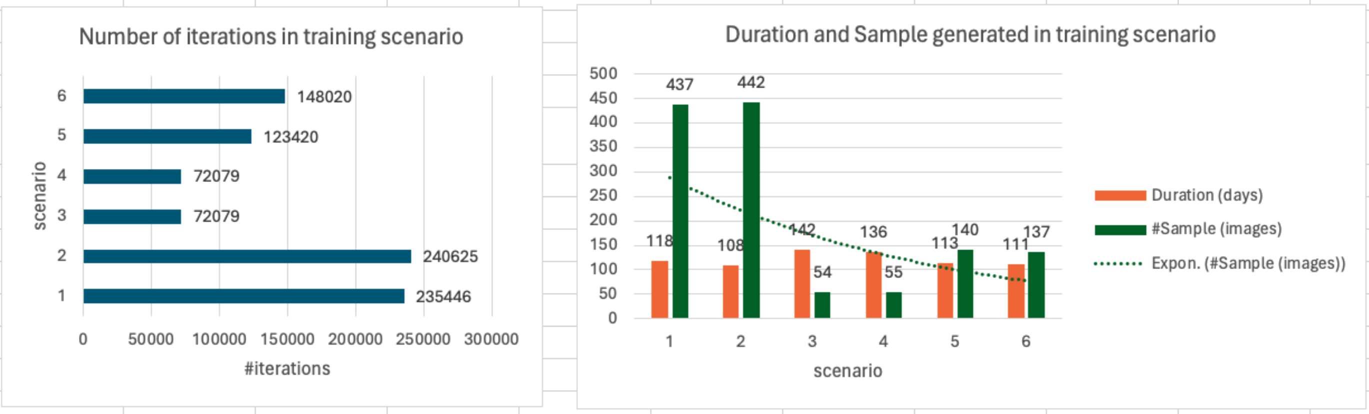


Fig. 6. Number of iterations, duration, and sample generated in the training scenario.

B. Testing Result

The testing was conducted using a sample produced during the training process, which will serve as the dataset. During the testing phase, the two GAN networks operate in the same manner as they do during the training process. The outcome of the testing process is a new and realistic image motif. Although this new motif exhibits some alterations, it retains characteristics from the original dataset, such as partially missing motifs, combined motifs, and altered pattern directions. Additionally, there are color changes resulting from color blending. Below is a discussion of the new motif images generated from the six experiments conducted.

1) Motif alteration: Alterations in motif patterns involve directional changes, such as shifting from left to right. Additionally, some patterns may be missing, or new patterns added. Fig. 7 illustrates one of the motifs with altered patterns. These changes pertain to the motif patterns themselves and do not involve combinations with other datasets.

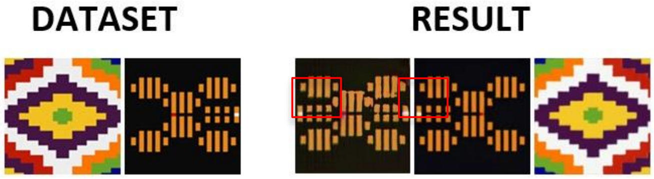

Fig. 7. Testing result for motif alterations.

2) Discoloration: The color changes observed in the test results are influenced by the colours present in other input motifs. Fig. 8 demonstrates the application of these results on one of the datasets used, ulos Batak Toba (Boolean 1800 36 2). Initially, the motif comprised only two colors: white and cream. Following the training and testing phases, the resulting motif image incorporates red and orange, blending with colors from other input motifs.

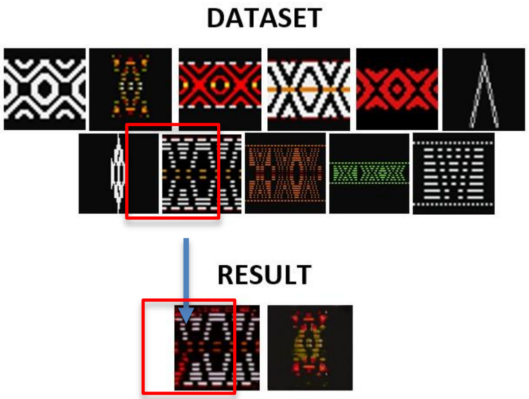

Fig. 8. Testing result for motif discoloration.

3) Merging of Ulos motifs: The implementation results demonstrate the merging of the ulos motif, resulting from the input of multiple motifs and the combination of two or more motifs. As shown in Fig. 9, there are 11 input motifs. After the training and testing process, StyleGAN generates several outputs. One of the test results combines two input motifs, specifically Batak Toba (Boolean 1800 18 3) and Batak Toba (Boolean 1800 18 1), producing a new motif that blends these two input motifs.

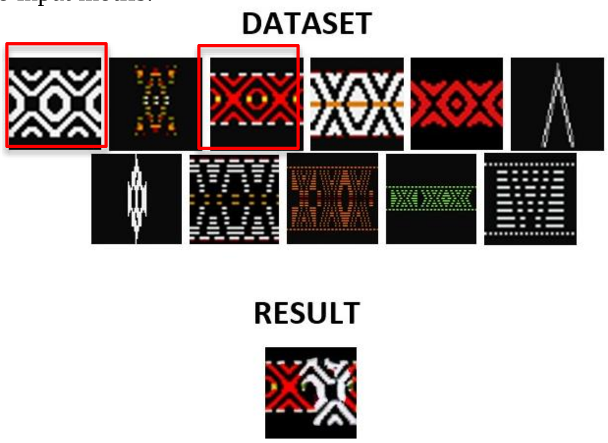

Fig. 9. Merging Ulos motif testing result.

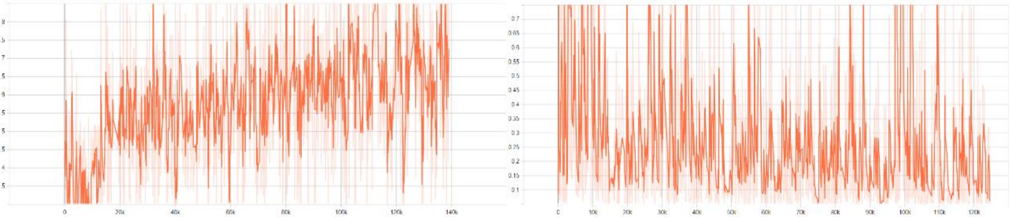
C. Evaluation

1) Training phase evaluation: Following the testing phase, an evaluation process was conducted. The metrics employed for this evaluation included graph loss, FID, and KID. The graph loss metric encompasses both the generator loss and the discriminator loss. Experimental results indicated that iteration is the hyperparameter influencing the loss graph, as the number of iterations impacts the generator's performance. The results for the generator and discriminator loss are presented in Fig. 10.

Fig. 10 displays the generator and discriminator loss from scenario 4. The fluctuations in the generator and discriminator graphs reflect the competition between the two networks to create a realistic sample. The generator attempts to create a motif identical to the original so that the discriminator cannot distinguish that the motif is fake. When attempting to obtain a sample, the generator's graph rises while the discriminator's graph falls. According to the generator loss graph, there is an upward trend up to iteration 110000, with the generator loss value reaching 7.02 and the discriminator loss value dropping to 0.06. The sample image at iteration 110000 is shown in Fig. 11.



(a) (b)

Fig. 10. Generator loss (a) and discriminator loss (b).

In the discriminator loss, it is observed that no sample motif is generated when the discriminator loss peaks at iteration 92622 with a value of 15.75 and the generator loss is 2.99. This occurs because when the discriminator maximizes its performance, it identifies the generator's motif as "fake," causing it to fail the discriminator's scrutiny, and thus, no sample motif is produced. According to the primary theory of loss functions, a lower generator loss typically indicates higher-quality output, while a higher generator loss suggests lower-quality output, which may lead the discriminator to classify it as fake. Similarly, a lower discriminator loss indicates superior performance by the discriminator in accurately distinguishing real image motifs.

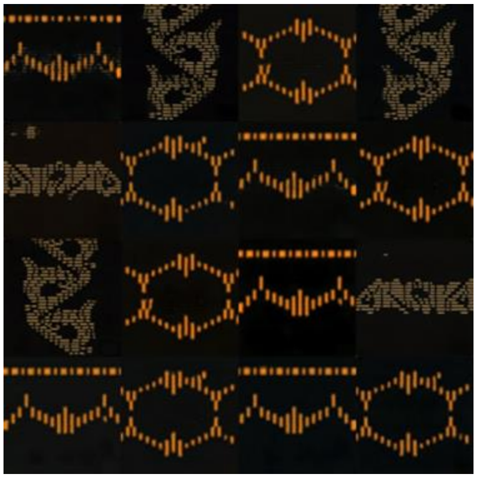


Fig. 11. Sample generated motif from scenario 4.

The subsequent evaluation uses FID and KID metrics to assess the diversity of motifs generated by the model and gauge the disparity between the generated motifs and actual samples. When FID and KID scores approach 0, it indicates that the generated images closely resemble the input dataset, making it more challenging for the discriminator to differentiate them as fake. Conversely, higher FID and KID values indicate more significant dissimilarity between the generated and actual motifs. Scenario 4 with the Batak Karo dataset exhibits the lowest FID and KID scores among the six experiments conducted. Fig. 12 below illustrates the graph depicting FID and KID scores during the training phase, showcasing the highest resolution achieved in each experiment.

As depicted in Fig. 12, each graph varies in length due to differences in the number of iterations across experiments. Observing the height of each graph in the scenarios, scenario 4 (represented by the purple line) utilizing the Batak Karo motif dataset exhibits a consistent graph that approaches a value of 0 steadily up to 100000 iterations. On the other hand, scenario 1, which employs the Ulos Batak Toba dataset, achieves a commendable KID score but displays the worst FID score. This outcome indicates that the generated motifs are inconsistent and differ significantly based on the input dataset. Furthermore, this training scenario is only effective up to 60000 iterations. Other scenarios also demonstrate inconsistent results and perform less effectively than scenario 4. Therefore, increasing the number of iterations tends to improve the resulting sample's FID and KID scores, bringing it closer to 0 and enhancing its similarity to the original dataset.

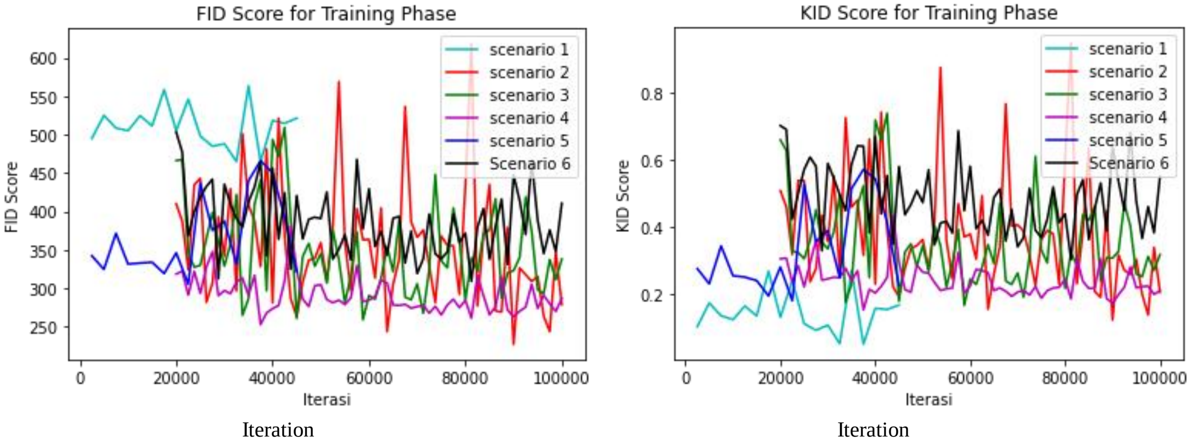

Fig. 12. Frechet inception distance and kernel inception distance score for training phase.

Overall, all experiments' FID and KID values remain above zero or significantly distant from zero. Nevertheless, the resulting motif images appear to bear resemblance to the input dataset. Upon analysis, the test image motifs exhibit background images resulting from style mixing between each dataset. This contrasts with the comparison to dataset images lacking such backgrounds. Moreover, the training experiment reached a maximum of 100,000 iterations. Therefore, additional iterations are advisable to achieve optimal results comparable to previous research with 1,200,000 iterations. This extended training process exceeding 100,000 iterations demands a longer duration and high computational specifications, particularly necessitating sufficient GPU memory for expediting training times.

There are three crucial things to pay attention to related to the fluctuating FID value in the training stage:

- Unstable Training Dynamics

  The fluctuating FID score shown in Fig. 12 might be associated with the unstable training dynamics shown in Fig. 10. Even after thousands of iterations, the generator and discriminator are still in flux, with neither achieving a clear dominance. This state can lead to the FID score bouncing around as the quality of generated images fluctuates. Therefore, learning rates, optimizers, and network architectures need further experimentation for a more stable training process. Techniques such as gradient penalty usually improve the stability of GAN training, so we also suggest further experimentation on this aspect.

- Batch Size Issues

  The FID score is calculated based on batches of images. If the batch size is too small, statistical noise can lead to significant fluctuations in the score, even if the overall quality improves. As shown in Table II, batch sizes used in all experiment scenarios are relatively small, 1 and 4. Therefore, further experimentation with larger batch sizes might help.

- Mode Collapse

  Mode collapse happens when the generator gets stuck in a loop, producing only a limited variety of images. This state can happen even with high iteration counts. While the generated images might be high quality within this limited range, the lack of diversity will cause the FID score to be unreliable.

2) Testing phase evaluation: During the testing process, three hyperparameters are utilized: iteration, resolution, and batch size. However, for this experiment, we focused on using the highest resolution value with default iterations, and batch sizes set to 1 and 4. According to the findings, smaller batch sizes result in longer testing times and fewer samples successfully producing results. This occurs because smaller batch sizes lead to more specific style generation for each sample. Fig. 13 illustrates the testing time required for each experimental scenario.

Fig. 14 displays the evaluation results of the StyleGAN algorithm using FID and KID metric. The FID score is calculated by comparing motifs generated during testing with the input dataset. The highest FID score of 336.03 was observed in batch size 1 within scenario 2, using the Batak Toba Ulos (Sadum Angkola) experiment. Conversely, the lowest FID score of 99.37 was achieved in scenario 4, which involved more than two similar inputs using the Batak Karo Ulos (Gundur). For batch size 4, scenario 1 with the Batak Toba Ulos (Sadum Angkola) experiment obtained the highest FID score of 388.69. Meanwhile, scenario 4 with the Batak Karo (Gundur) experiment had the lowest FID score, amounting to 153.25.

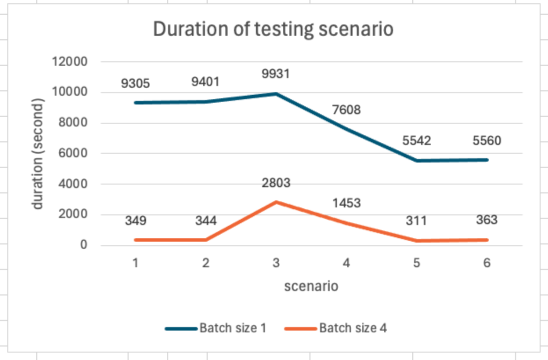

Fig. 13. Duration of testing scenario.

Similar to the FID score, in batch size 1, scenario 2 attained the highest KID score of 0.24, while scenario 4 which involving multiple similar inputs with the Batak Karo Ulos (Gundur) dataset, achieved the lowest KID score of 0.04. For batch size 4, scenario 1 using the Batak Toba Ulos (Sadum Angkola) experiment yielded the highest KID score of 0.34. Conversely, scenario 4 with the Batak Karo (Gundur) experiment had the lowest KID score of 0.08.

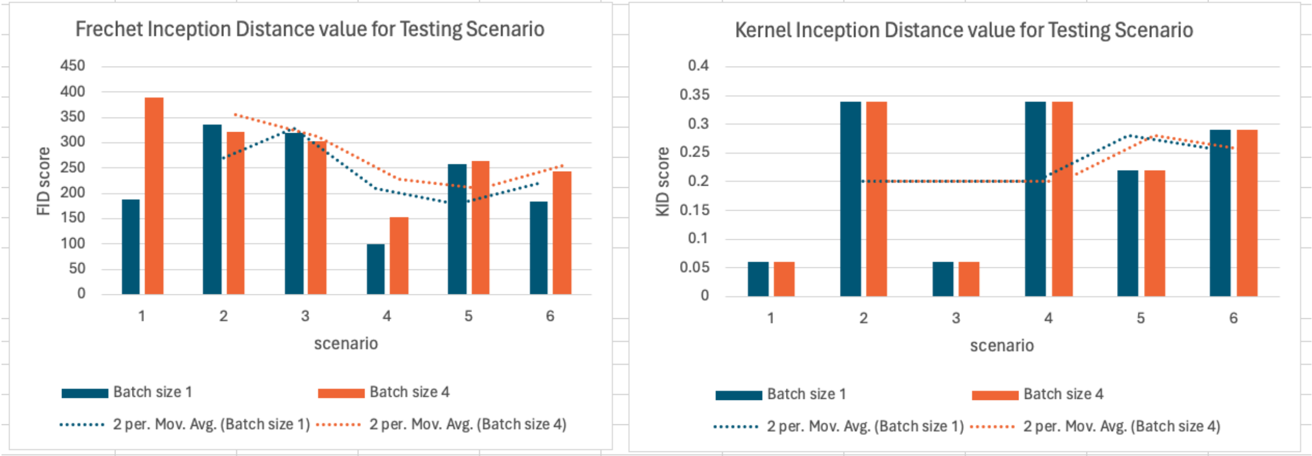

Fig. 14. Frechet inception distance and kernel inception distance value for testing scenario.

Based on the evaluation results, scenario 4 outperforms the other scenarios. To further validate this finding, the researcher distributed a questionnaire to an Ulos expert to determine if there were any changes in motifs, discoloration, or merging of motifs in the generated images.

According to Fig. 15, 83.87% of respondents indicated that there are motif changes in scenario 4. Additionally, 13% of respondents noted motif merging, 3.23% observed discoloration, and none reported no changes.

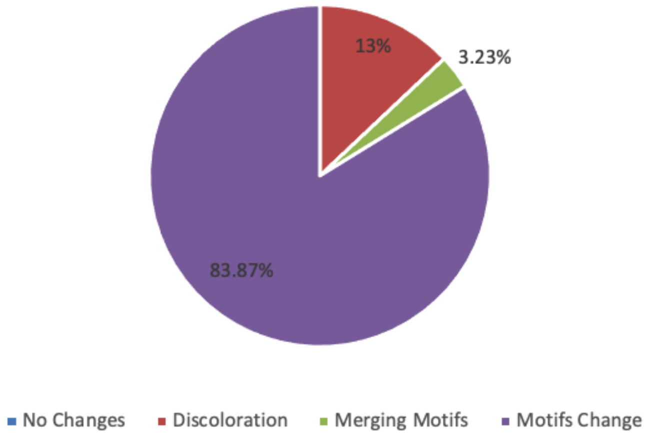

Fig. 15. Questionnaire for scenario results.

IV. Conclusion

Applying the StyleGAN method has resulted in the creation of novel Ulos motifs for the DiTenun application. These new motifs display unique characteristics, such as moving in the opposite direction, partially missing elements, and increased motifs. Additionally, the new motifs blend of colors from various datasets, effectively merging motifs to produce fresh Ulos designs. The experiment was conducted with three key hyperparameters: iteration, resolution, and batch size. The number of iterations directly influenced the number of samples generated. Scenario 2, with the highest iteration count of 240625, produced a substantial 442 samples, outperforming other experiments.

Based on the evaluation process, the best scenario is scenario 4, with an FID and KID score of 91.32 and 0.04, respectively. Scenario 4 produced better new motifs regarding image quality and similarity to the dataset. However, the experiment has yet to reach the maximum result, indicated by the training evaluation, which is still fluctuating. The image of the Ulos motif is not a natural image but a visual representation of the traditional decoration typical of the Batak tribe, which often displays complex geometric patterns and traditional symbols. This complex characteristic makes it challenging for generative AI algorithms to learn existing patterns, requiring further experiments. Potential future experiments related to learning rates, optimizers, batch size, and network architectures can be done for a more stable training process.

Furthermore, other generative AI methods have the potential to be implemented, especially the diffusion model, to get more interpretable latent space in order to capture variations and generate diverse samples, along with enriching the repository with more Ulos motifs. Moreover, the generative ulos motif necessitates thoroughly considering ethical and cultural dimensions to ensure these technologies serve diverse populations fairly and responsibly. By employing inclusive and diverse datasets, implementing bias mitigation strategies, and adhering to established ethical guidelines, developers can address potential biases and cultural insensitivities.

***Abstract*—TextNetTopics is a novel text classification-based topic modelling approach that focuses on topic selection rather than individual word selection to train a machine learning algorithm. However, one key limitation of TextNetTopics is its scoring component, which evaluates each topic in isolation and ranks them accordingly, ignoring the potential relationships between topics. In addition, the chosen topics may contain redundant or irrelevant features, potentially increasing the feature set size and introducing noise that can degrade the overall model performance. To address these limitations and improve the classification performance, this study introduces an enhancement to TextNetTopics. eTNT integrates two novel scoring approaches: Sequential Forward Topic Scoring (SFTS) and Sequential Backward Topic Scoring (SBTS), which consider topic interactions by assessing sets of topics simultaneously. Moreover, it incorporates a filtering component that aims to enhance topics' quality and discriminative power by removing non-informative features from each topic using Random Forest feature importance values. These integrations aim to streamline the topic selection process and enhance classifier efficiency for text classification. The results obtained from the WOS-5736, LitCovid, and MultiLabel datasets provide valuable insights into the superior effectiveness of eTNT compared to its counterpart, TextNetTopics.**

Keywords—Topic scoring; topic modeling, text classification; machine learning

I. Introduction

In today's fast-paced information technology development, the volume of textual data is growing exponentially. This surge in unstructured and semi-structured content underscores the urgent requirement for effective methods to organize extensive amounts of information systematically. Text classification, which involves categorizing unlabeled text documents into predefined classes, is particularly challenging when dealing with the complexity of large datasets. Consequently, machine learning-based automatic text classification techniques are widely adopted across numerous applications [1].

However, automatic text classification tasks frequently deal with datasets encompassing tens of thousands of unique features, forming a high-dimensional challenge that can significantly impede the classification process. Despite the plethora of features, many do not significantly enhance the classification model; some may be less informative, introduce noise, or be redundant for predicting text labels. This situation results in longer computational times for training the learning algorithm, overfitting, substantial storage demands, and diminished classification performance and generalizability on test data. Hence, dimensionality reduction techniques, such as feature selection, are essential to mitigate these text classification issues [2].

The primary objective of feature selection methods is to determine a subset of features from the original set that accurately reflects the core information of the data. In text classification tasks, this subset is distinguished by its strong relevance to the class labels and ability to differentiate between classes effectively [3].

In this context, feature selection algorithms can be broadly classified into three categories: Filter methods utilize various metrics based on statistical principles and information theory to evaluate the correlation between features and class labels. These methods enable the ranking of features and the identification of the best subset according to predefined selection criteria. Wrapper methods determine the best subset by examining different combinations of features and evaluating their predictive power for the class labels using a specific classification algorithm. Lastly, Embedded methods select the optimal feature subset as part of the classifier training process [4].

Recently, a new direction has emerged that promotes the use of topic modeling (TM) as a novel method for feature reduction. In information retrieval, TM has proven to be a powerful tool due to its ability to identify latent themes, hidden variables, or abstract topics within a collection of documents without supervision. Each discovered topic represents a human-interpretable semantic notion. In addition to uncovering hidden structures in the data, topic modeling also offers a latent, interpretable representation of documents. Consequently, it serves as an automated method for understanding, organizing, and summarizing large volumes of text, enhancing the comprehension of the underlying themes in the data [5].

Topic modeling has been widely applied across various fields, significantly contributing to text classification as a feature projection method. In this area, topics derived from large text collections form features for representing documents [5]. Although topic modeling is commonly used for document representation, its potential in feature selection has not been extensively explored in the existing research literature.

In this aspect, TextNetTopics [6] is a pioneering feature selection algorithm rooted in topic modeling and designed specifically for text classification. It employs Latent Dirichlet Allocation (LDA) as the foundational topic model to identify hidden topics, each comprising semantically related words that reflect the topic's theme. The algorithm utilizes a machine learning algorithm to evaluate the predictive performance of these topics (i.e., mean classification accuracy) and selects the top *r* topics with the highest discriminative power. These selected topics form a subset of words that effectively differentiate between two document classes in binary classification. This subset of topics is then used to train the classifier. An enhanced version called TextNetTopics Pro [7] has also been introduced, tailored explicitly for short-text classification.

The methodology of TextNetTopics is inspired by the G-S-M (Grouping, Scoring, and Modeling) approach [8], [9], initially used in the context of biological data. For a detailed examination of feature selection methods incorporating feature grouping, please consult the extensive review in [10].

However, a significant limitation of TextNetTopics is its reliance on ranking topics based solely on scores independently given to each topic, without accounting for the interactions and relationships among topics. Our research study presents innovative solutions to address this limitation and improve the effectiveness of topic scoring and ranking. By incorporating Sequential Topic Forward Scoring (STFS) and Sequential Topic Backward Scoring (STBS) into the TextNetTopics framework, we introduce a more refined and advanced topic selection process.

In addition, TextNetTopics treats a topic as a single entity to preserve the interaction between topic features. However, within these topics, some features may be less informative for the classification task, leading to an increase in the size of the final feature subset. In order to address this issue, this study introduces a filter component designed to remove the least important features from each topic. This filtering step aims to reduce redundancy and improve the overall relevance and efficiency of the feature set used for training a text classifier.

II. Related Work

Numerous research works have employed topic modeling as a method for feature projection [11], [12], [13]. This section focuses specifically on studies that use topic modeling as a technique for feature selection.

Zrigui et al. [14] utilized LDA to represent documents through real-valued features derived from terms associated with each topic. This method effectively reduces the dimensionality of the Vector Space Model (VSM) vectors while preserving both syntactic and semantic information in the document representation.

Zhang et al. [15] employed LDA with Gibbs Sampling for feature selection in text classification. They identified the most relevant terms within each topic by assessing term entropies in the term-topic matrix, selecting those with lower entropy values. These chosen features were then used to train a classifier. Their experiments showed that this method enhanced classification accuracy and reduced the dimensionality of the feature space.

Taşcı et al. [16] conducted similar research to [15], employing LDA for feature selection but utilizing Variational Expectation Maximization for estimation instead of Gibbs sampling. They compared their method with conventional feature selection techniques, including Chi-square, Information Gain, and Document Frequency. The results revealed that the LDA-based metrics performed comparably to those based on chi-square and document frequency.

Al-Salami et al. [17] applied a supervised variant of LDA, called Labeled LDA (LLDA), as a feature selection technique. LLDA restricts the number of topics to correspond with the number of categories in the corpus. The study selects words with high weights from LLDA's topic-word distribution matrix to train the classifier. The results revealed that using LLDA for feature selection improved the performance of AdaBoost with Multiclass Hamming Loss in multi-label categorization, outperforming other methods such as GSSC, Chi-square, and Information Gain.

Yousef and Voskergian [6] developed TextNetTopics, an LDA-based approach focusing on topic selection rather than individual word selection, where each topic represents a set of semantically related words. TextNetTopics aims to preserve the feature interactions within each topic by treating topics as single entities. Instead of utilizing all topics to train a classification model, TextNetTopics selectively chooses only the most relevant topics for training a machine learning algorithm for text classification. This approach acknowledges that some topics may introduce noise and potentially degrade the model's performance.

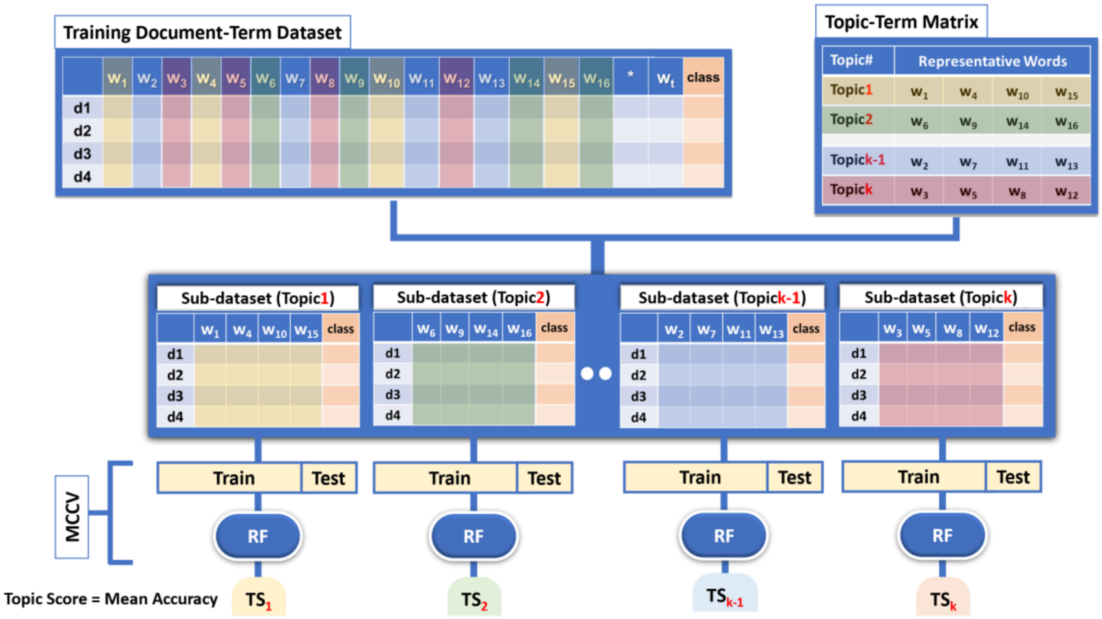
Voskergian et al. [7] introduced an enhanced version of TextNetTopics, called TextNetTopics Pro, explicitly designed for short text classification. This advanced approach utilizes a combination of word topics and topic distributions obtained from a short text topic model, addressing the issue of data sparsity commonly encountered in classifying short texts.

However, a notable limitation of TextNetTopics and its advanced version, TextNetTopics Pro, lies in the topic performance scoring (TPS) within the S component. TPS evaluates each topic separately without taking into account the impact of interactions and relationships between topics. This independent scoring can result in the selection of redundant topics or overlook topics that may be weak on their own but contribute significantly to performance when combined with other topics. This oversight highlights the need for topic-scoring refinement to improve overall classification performance.

Additionally, TextNetTopics treats topics as single entities, incorporating all topic features while training a classifier. This approach, however, can lead to the inclusion of irrelevant or redundant features within topics, which may increase the final feature subset size while diluting the classifier's discriminative power. Therefore, enhancing the quality of each topic in TextNetTopics by introducing a topic-feature filtering component is essential for a more concise and discriminative topic selection process.

III. Topic Performance Scoring (TPS)

The Topic Performance Scoring (TPS) method, introduced in [6], uses the training document-term dataset D_{train}, which includes *d* documents and *t* distinct terms, and the topic-term matrix *TW*, composed of *k* topics and *m* terms per topic to generate $d\times(m+1)$ dimensional topic-based sub-datasets D_{Ti}, each containing term features pertinent to a specific topic and the corresponding class label. A machine learning algorithm, such as Random Forest, is subsequently applied to each sub-dataset independently using the Monte Carlo cross-validation technique. Each topic receives a score based on a mean performance metric, such as mean accuracy or F1-score, resulting in a thorough evaluation of each topic's significance in the text classification task. This scoring approach is illustrated in Fig. 1.



Topic-Term Matrix

Topic#	Representative Words			
Topic1	w_1	w_4	w_{10}	w_{15}
Topic2	w_6	w_9	w_{14}	w_{16}
Topick-1	w_2	w_7	w_{11}	w_{13}
Topick	w_3	w_5	w_8	w_{12}

Fig. 1. The topic performance scoring approach.

IV. The Proposed Topic-Scoring Approaches

This section presents two innovative scoring mechanisms, Sequential Forward Topic Scoring (SFTS) and Sequential Backward Topic Scoring (SBTS), developed to pinpoint the most significant topics for training machine learning algorithms. These mechanisms enhance the feature selection process by collaboratively assessing the importance of each topic and selecting the top-ranked ones that most effectively improve the model's predictive performance.

A. *Sequential Forward Topic Scoring (SFTS)*

This method performs scoring and ranking topics based on their contribution to the performance of an expanding list of topics. Let T be the set of k topics ($T = t_1,\ t_2,\ \ldots,\ t_k$). At iteration $r = 1$, the algorithm begins with an empty set of selected topics ($S_0 = \emptyset$) and iterates through each topic in T ($T = t_1,\ t_2,\ \ldots,\ t_k$), choosing the topic that results in the highest performance and adding it to the expanding set of selected topics (S_r). The considered performance metric is the mean F1-score of a Random Forest model, assessed through Monte Carlo cross-validation (RF_MCCV). However, one can select other metrics, such as accuracy or area under the curve. The number of internal iterations for the Monte Carlo cross-validation is specified by the user (e.g., 10).

During each subsequent iteration ($r = 2,3,\ldots,k$), the algorithm evaluates the potential performance of adding each topic t_i from the remaining topics ($T\backslash S_{r-1}$) to the current set of selected topics (S_{r-1}). The topic t_j that yields maximum performance is selected and incorporated into the expanding set (S_r). This topic t_j is then assigned a ranking index (R) corresponding to r, reflecting its importance and relevance to the classification task.

The iterative process continues until all k topics are included in the expanding set (S_r contains all k topics). Upon completion, the topics are ranked according to their assigned ranking indices ($R(t_j)$), with lower indices indicating topics of higher importance or relevance for the text classification task. Thus, the SFTS ranking reflects the sequence in which topics are added to the expanding topic set, with those added earlier being deemed more significant than those added later.

Algorithm 1 outlines the SFTS approach.

Algorithm 1: Sequential Forward Topic Scoring (SFTS)

```
Let $T = \{t_1,\ t_2,\ \ldots,\ t_k\}$ be the set of $k$ topics (sets of related words).
Let $S_r$ be the expanding set of topics at iteration $r$.
Let $P(.)$ be the performance metric (i.e., mean F1-score of RF_MCCV).
Let $R(.)$ be a function that assigns ranking indices to each topic.

Initialization: $S_0 = \emptyset$
For each iteration $r = 1,2,\ldots,k$:
    (Evaluate the performance of adding each topic from $T$ to the current set that is not already in $S_{r-1}$)
    $P(S_{r-1} \cup \{t_i\})$ for each $t_i \in T \backslash S_{r-1}$
    (Select the topic $t_j$ that upon inclusion, the set yields maximum performance )
    $t_j = arg \max_{t_i} [P(S_{r-1} \cup \{t_i\})]$
    (Update the expanding set)
    $S_r = S_{r-1} \cup \{t_j\}$
    (Assign a ranking index to the selected topic)
    $R(t_j) = r$
End
```

The process continues until S_r includes all k topics. After completion, the topics are ranked based on their assigned ranking indices $R(t_j)$.

B. Sequential Backward Topic Selection (SBTS)

This method scores and ranks topics based on their impact on the performance of a reduced topic list. In iteration $r = 1$, the process begins with all k topics ($T = t_1, t_2, \ldots, t_k$) as the initial set ($S_0$). The algorithm then evaluates the potential performance of removing each topic (one at a time) from the current set of selected topics (S_{r-1}). The performance metric used is the mean F1-score of a Random Forest model, assessed through Monte Carlo cross-validation (RF_MCCV) with a user-defined number of internal iterations (e.g., 10). The topic whose removal results in the highest performance is chosen for permanent removal from the set and assigned a ranking index as $k + 1 - r$, where k represents the total number of topics and r is the current iteration number. The reduced topics set (S_r) is updated by excluding the selected topic.

This procedure continues until all topics have been removed from the reduced set ($S_k = \emptyset$). Finally, topics are ranked based on their assigned indices ($R(t_j)$), with lower indices indicating greater importance or relevance for the text classification task. Thus, the SBTS ranking reflects the sequence in which topics are removed from the reduced topic set, with those removed earlier being considered less important than those removed later.

Algorithm 2 outlines the SBTS approach.

Algorithm 2: Sequential Backward Topic Selection (SBTS)

```
Let $T = \{t_1, t_2, \ldots, t_k\}$ be the set of $k$ topics (sets of related words).
Let $S_r$ be the reducing set of topics at iteration $r$.
Let $P(.)$ be the performance metric (i.e., mean F1-score of RF_MCCV).
Let $R(.)$ be a function that assigns ranking indices to each topic.

Initialization: $S_0 = T$
For each iteration $r = 1,2,\ldots,k$:
    (Evaluate the performance of removing each topic from $S_{r-1}$)
    $P(S_{r-1} \backslash \{t_i\})$ for each $t_i \in S_{r-1}$
    (Select the topic $t_j$ that upon removal, the set yields maximum performance)
    $t_j = arg \max_{t_i} [P(S_{r-1} \backslash \{t_i\})]$
    (Assign a ranking index to the selected topic)
    $R(t_j) = (k + 1) - r$
    (Update the reducing set)
    $S_r = S_{r-1} \backslash \{t_j\}$
End
```

The process continues until S_r has no topics ($S_k = \emptyset$). After completion, the topics are ranked based on their assigned ranking indices $R(t_j)$.

V. Proposed Method: eTNT with Filtered LDA Topics and SFTS and SBTS Scoring Approaches

eTNT seeks to identify a concise subset of topics that maximizes discriminative power and relevance to class labels. The eTNT algorithm achieves this objective through five key components: T, F, G, S, and M.

The T component employs a Latent Dirichlet Allocation (LDA) topic model to uncover latent topics from a preprocessed document collection. Here, users need to define parameters such as the number of topics (*k*) and the number of terms per topic (*m*). This component primarily produces a topic-word matrix (*TW*) that details the association of words with each topic, each associated with specific probabilities.

The G component takes the topic-word matrix (*TW*) from the T component as input, along with the training Bag-of-Words (BOW) dataset (D_{train}). For each topic of *m* terms, the G component creates an *(m+1)*-dimensional sub-dataset from D_{train}, including the corresponding class label. Essentially, each sub-dataset represents a specific topic and includes mainly the words that coexist with that topic.

The F component trains a Random Forest (RF) model on each topic-based subdataset from the previous stage and extracts the importance values for each feature within the subdataset. To ensure robust and reliable feature importance evaluations, this process is repeated *z* times using a Monte Carlo Cross-Validation approach. In each iteration, a random selection of *b%* of the subdataset records is used to train the RF model. The feature importance values obtained from each iteration are then averaged, providing a stable and comprehensive assessment of the importance of each feature. This iterative process not only mitigates the risk of overfitting but also enhances the robustness of the feature importance values by accounting for variability within the data.

After ranking these feature importance values, a user-specified number *f* of highly ranked features (terms) are retained to represent the topic. Subsequently, new *f*-dimensional topic-based subdatasets are regenerated, each containing only the highly important features. This refinement enhances the quality of available topics, ensuring that they are more coherent and informative for subsequent classification tasks, leading to potentially better model performance with a reduced feature set.

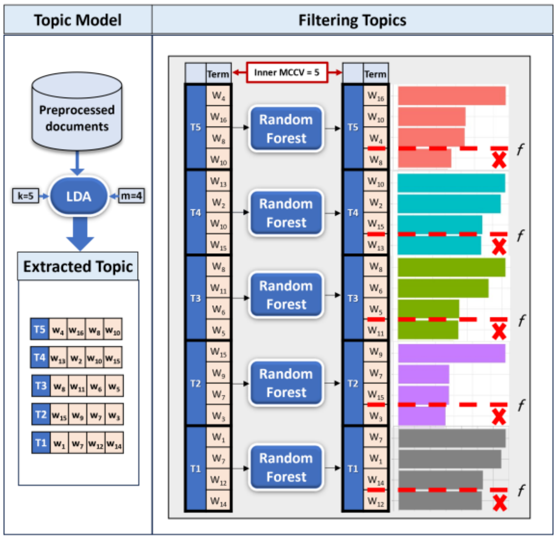
The S component utilizes SFTS and SBTS methods for scoring and ranking the refined topics with attention to topic interactions. These approaches assess and rank topics based on their impact on the performance of the expanding or reducing topic list. Performance is measured by the mean F1-score obtained through a Monte Carlo cross-validation process using a Random Forest model.

Sequential Forward Topic Scoring, or SFTS, starts with an initial empty set and evaluates each candidate topic via its corresponding two-class sub-dataset for performance. The topic demonstrating maximum performance is added to the expanding set as the top-ranked topic. The process then continues by adding the remaining $k-1$ topics to the current set, one at each time, evaluating the performance of their corresponding two-class sub-datasets, and including the topic that achieves the best performance in the growing set (this time, the topic is considered as a second-ranked topic). This iterative process continues until all topics or the desired number of topics are ranked. In this method, the last topic added receives the lowest rank.

Sequential Backward Topic Scoring, or SBTS, begins with a set of all topics and their corresponding two-class sub-dataset. It iteratively evaluates the impact of removing each topic from the set. The topic whose removal results in the highest performance is removed from the set and assigned the lowest rank. The process then continues with the current set of $k-1$ topics and its corresponding two-class sub-dataset, removing one topic at a time and assessing the effect on performance. The topic whose removal leads to the highest performance is excluded from the set and receives the second lowest rank. The iterative process continues until no topic remains, with the last topic removed being ranked the highest.

The M component aggregates the top-ranked topics incrementally in descending order, starting with the highest-ranked topic and progressively incorporating the remaining top-ranked topics until all desired topics are included. This process yields a combined set of terms for each topic aggregation and a corresponding two-class sub-datasets extracted from the training and testing of Bag-of-Words (BOW) datasets. The M component uses these sub-datasets to train and test a Random Forest model. It then identifies the optimal subset of topics, which results in the highest performance and discriminative ability for the text classification task. This optimal subset includes r topics, where r is less than k.

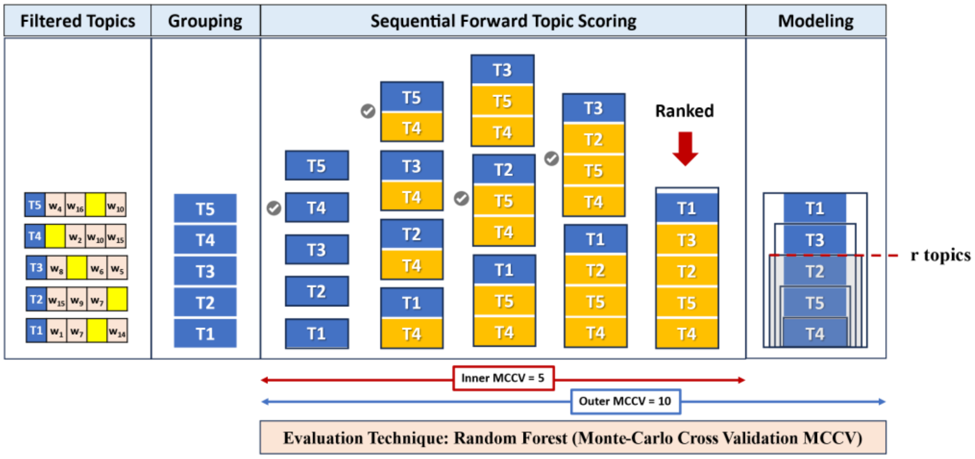
Fig. 2 and Fig. 3 illustrate the overall framework of eTNT, including the SFTS algorithm.



Group words into topics using a topic model (LDA)

Measure the importance of each term in the topic using a Random Forest model. Subsequently, remove the features with the least importance values to refine the topic representation.

Fig. 2. The working mechanism of T and F components. *k* represents the number of topics, *m* referes to the number of terms in each topic, and *f* indicates the number of terms in each filtered topics.



Evaluation Technique: Random Forest (Monte-Carlo Cross Validation MCCV)

Filter out terms with least importance

Generate topic-based sub-datasets

Rank topics while utilizing the interaction between them using Sequential Forward Topic Scoring algorithm

Output a reduced *r* topic subset with the best evaluation results (F1-score).

Fig. 3. The working mechanism of G, S and M components, using the SFTS approach.

VI. Experimental Work

A. Datasets

In this study, we utilized three datasets to assess the effectiveness of eTNT empirically:

The WOS-5736 dataset contains 5,736 documents classified into three higher-level classes. For the empirical evaluation of eTNT, we transformed the dataset into two balanced classes. We selected the largest category, with 2,847 abstracts, as the positive class, while the other classes (1,597 and 1,292 abstracts) formed the negative class [18].

The Multi-Label dataset contains 20,972 documents with abstracts and titles categorized under six labels: Quantitative Finance, Quantitative Biology, Computer Science, Statistics, Physics, and Mathematics. For eTNT evaluation, we selected 3,500 documents labeled Computer Science as the positive class and randomly sampled 3,500 documents without a Computer Science label to constitute the negative class instances [19].

The LitCovid dataset is a multi-label dataset with 16,127 records spanning five categories. This study focused on single-label records, resulting in the following distribution: 1,334, 1,632, 6,513, 119, and 429 for case reports, treatment, prevention, forecasting, and mechanism, respectively. To evaluate eTNT, we transformed the dataset into a binary class format by setting the prevention category as positive and the remaining categories as negative classes. We then performed dataset balancing by downsampling the positive class to 3,500 records to have a final dataset of 7,014 records [20].

B. Data Preprocessing

Text preprocessing is essential for improving the quality of analysis and reducing input data dimensionality, as raw documents often contain noisy and irrelevant data. In this study, KNIME workflows [21], [22] were executed to perform several Natural Language Processing (NLP) tasks.

These tasks include filtering out numbers, removing all punctuation, and excluding words with fewer than three characters. Additionally, all words are converted to lowercase to ensure uniformity. Stop words are eliminated using the Stop Word Filter node, and words are stemmed with the Snowball stemming library. Terms with a minimum document frequency below 1% are filtered out, and only English texts are retained.

C. Experimental Setup

We used KNIME workflows, available on KNIME Hub [22] and GitHub [21], to execute the natural language preprocessing tasks and evaluate TextNetTopics with the proposed eTNT. To extract latent topics, we employed the parallel thread implementation of LDA in KNIME [23]. We set the alpha parameter (Dirichlet prior on per-document topic distributions) and the beta parameter (Dirichlet prior on per-topic word distribution) to their default values of 0.1. The LDA training process was run for 1,000 iterations to estimate the topics. Based on performance, we chose 20 topics and 20 words per topic, as these settings consistently produced slightly better results than other configurations. In the filtering component, we selected ten terms from each topic since this approach yielded comparable performance to models with larger topics. This selection effectively balances model complexity and computational efficiency, ensuring optimal performance without unnecessary redundancy.

Regarding the experimental analysis, we used Monte Carlo stratified cross-validation (MCCV) with ten iterations to evaluate the model's performance more robustly. MCCV randomly partitions the original dataset into training and testing sets, with 90% allocated for training and 10% for testing in each iteration. The stratified approach maintains the class distribution, ensuring each subset maintains different classes' proportional representation from the original dataset, preventing bias in the evaluation process. The results from ten executed iterations are averaged to present the final performance.

D. Evaluation Measures

To evaluate the proposed eTNT's effectiveness compared to TextNetTopics, we perform a thorough analysis using various performance metrics, including Accuracy, Recall, Precision, and Area Under the Curve (AUC). The F1-Score is emphasized as a key metric for assessing classification performance.

VII. Experimental Results

A. Performance Evaluation of TextNetTopics Utilizing the Filtering Component

Tables I to III and Fig. 4 to Fig. 6 depict the performance of TextNetTopics with and without the proposed filtering component over different accumulated top-ranked topics. In this investigation, we used the default Topic Importance Scoring. According to the obtained results, TextNetTopics with the filtering component significantly outperforms the original TextNetTopics both in terms of classification performance and feature reduction. For instance, in the WOS-5736 dataset, it achieves a minimum and maximum F1-score of 89% and 97% using only 20 and 100 features, respectively, whereas TextNetTopics achieves an F1-score of 86% and 94% with 20 and 100 features. Similarly, in the MultiLabel dataset, it obtains a minimum and maximum F1-score of 78% and 84% using only 20 and 78 features, respectively, while TextNetTopics obtains an F1-score of 75% and 82% with 20 and 78 features. Likely, in the LitCovid dataset, it attains a minimum and maximum F1-score of 85% and 91% using only 20 and 125 features, respectively, while TextNetTopics attains an F1-score of 84% and 90% with 20 and 125 features. This improvement demonstrates the effectiveness of the filtering mechanisms in maintaining high classification accuracy with fewer feature set.

TABLE I. eTNT Performance Measures for the WOS-5736 Dataset

B. eTNT Performance Using Various Topic Scoring Approaches

In this subsection, we evaluate the performance of eTNT, which integrates the F component and one of the proposed scoring mechanisms—Sequential Forward Topic Scoring and Sequential Backward Topic Scoring—on three datasets: WOS-5736, LitCovid, and MultiLabel (refer to Fig. 7 and Fig. 9). Our analysis indicates a notable trend in the effectiveness of the examined approaches. We identified a pivotal turning point in the F1-score, marking a significant change in performance. The Sequential Forward approach showed an improved F1-score up to a specific number of topics. However, past this critical threshold, there was a shift, with the Sequential Backward approach becoming more effective.

This nuanced observation suggests that the optimal choice between forward and backward topic scoring depends on the number of topics involved. The backward approach proves to be more effective when a larger number of topics is necessary. In contrast, the forward approach is more advantageous when fewer topics are sufficient.

When comparing the original scoring mechanism, Topic Importance Scoring (TPS), with the two proposed approaches (refer to Fig. 7 till Fig. 9), an interesting trend emerges. Up to a specific number of topics, the original scoring mechanism outperformed the backward approach but lagged behind the forward approach. However, beyond a certain number of topics, the F1-score for TPS diminished compared to both the forward and backward approaches. This trend highlights the superiority of SFTS over TPS across all accumulated top-ranked topics.

According to the obtained results, SFTS and SBTS select a reduced number of features (accumulated topics) to achieve specific performance levels, thereby enabling further feature reduction. For instance, in the WOS-5736 dataset, to achieve a 97% F1-score, TPS utilizes 100 features, whereas SFTS and SBTS use only 80 and 77 features, respectively. Likely, in the MultiLabel dataset, to attain an 84% F1-score, TPS requires 78 features, while SFTS and SBTS use 70 and 61 features, respectively. Similarly, in the LitCovid dataset, to obtain a 91% F1-score, TPS utilizes 125 features, whereas SFTS and SBTS use only 104 and 82 features, respectively. These findings underscore the ability of SFTS and SBTS to enhance the topic selection process, improving efficiency without compromising classification performance.

VIII. Conclusion

In conclusion, this study introduces eTNT, an enhancement of the TextNetTopics framework. eTNT integrates a filtering component that refines topic quality by removing non-informative features, thereby enhancing the informativeness and relevance of topics for text classification tasks. Additionally, it incorporates two novel scoring approaches: Sequential Forward Topic Scoring (SFTS) and Sequential

Backward Topic Scoring (SBTS). Unlike the original Topic Performance Scoring (TPS) method, which evaluates topics independently, SFTS and SBTS consider the interactions between topics, simultaneously assessing sets of topics to enhance the selection process and improve classifier efficiency.

The experimental results across the WOS-5736, LitCovid, and MultiLabel datasets provide valuable insights into the superior performance of eTNT over its predecessor, TextNetTopics. Specifically, eTNT demonstrates significant improvements in classification performance and feature reduction, underscoring the benefits of the proposed filtering and scoring mechanisms. For future work, we plan to investigate the use of word embeddings for feature grouping as an alternative to topic modeling in the T component, aiming to further enhance feature representation and classification performance.

ACKNOWLEDGMENT

We are so grateful to Prof. Malik Yousef for his significant support and expertise, which were crucial to accomplishing this study.

Computer Aided Classification of Lung Cancer, Ground Glass Lung and Pulmonary Fibrosis Using Machine Learning and KNN Classifier

Prathibha T P, Punal M Arabi
Department of Biomedical Engineering-ACS College of Engineering, Visvesvaraya Technological University, Bangalore, India[1]

***Abstract*—Respiratory diseases are one of the most prevalent acute and chronic ailments worldwide. According to a recent survey, there were around 545 million cases of chronic respiratory diseases worldwide. Chronic respiratory diseases such as chronic obstructive pulmonary disease (COPD), pneumoconioses, asthma, interstitial lung disease and pulmonary sarcoidosis are significant public health problems across the world. The most significant CRD (Chronic Respiratory Disease) risks have been identified including smoking, contact with indoor and outdoor pollutants, allergies, occupational exposure, poor nutrition, obesity, inactivity and other factors. Interstitial lung diseases are diagnosed on high-resolution computed tomography (HRCT) using a variety of different interstitial pattern namely such as reticular, nodular, reticulonodular, ground-glass lung, cystic, ground-glass with reticular, cystic with ground-glass. If the lung diseases are identified at an early stage life span could be increased. Computer aided diagnosis could play a crucial role in identifying lung diseases at an early stage, disease management and treatment planning. In this paper a novel method is proposed to identify and classify HRCT images of cancerous lung using ML (Machine Learning) and to identify and classify ground glass lung, pulmonary fibrosis lung and healthy lung HRCT images using LBP (Local Binary Pattern) and KNN (K-Nearest Neighbor) classifier. Experimenting the proposed method on 996 images yielded 94% accuracy.**

***Keywords*—Ground glass; healthy; KNN; LBP, lung cancer; lung diseases classification; LBP; ML and pulmonary fibrosis**

I. INTRODUCTION

Chronic respiratory disorders are among the most prevalent non-communicable diseases in the world, owing to their high prevalence. The high rate of occupational, environmental and behavioural inhalational exposures has exacerbated the problem. Chronic respiratory diseases include interstitial lung disease, pulmonary sarcoidosis and pneumoconioses such as silicosis and asbestosis [1]. Ground glass opacity (GGO), commonly referred to as ground-glass attenuation, is the term utilized to explain greater lung parenchymal attenuation on CT images that does not obscure the pulmonary vascular lines [2]. A honeycomb lung can be seen on a CT scan of the lung area. Although end-stage chronic interstitial Pneumonia can cause honeycomb like cysts, usually appears in cases of severe, progressive disease. The appearance of a honeycomb suggests that nearby bronchioles have expanded due to fibrosis or granuloma edema, causing harm to the bronchioles [3]. High-resolution computed tomography and thin-section CT are effective for viewing the lungs parenchyma. The investigation of Bronchiectasis and single pulmonary nodules has been demonstrated to benefit from HRCT. Diffuse and focal pulmonary parenchyma disease may be evaluated with HRCT [4]. The computer-aided diagnosis (CAD) system serves as a tool for the medical field by assisting doctors in providing more accurate diagnoses of illnesses with greater precision in a shorter amount of time [5].

Early diagnosis of respiratory diseases is crucial for the prognosis and to protect the quality life of the patients.

A lot of people could ignore the mild symptoms that indicate a respiratory problem, which might develop gradually. For better results and prompt action, it is essential to identify the early indicators of respiratory issues. Because of this issue with respiratory disease early detection, if an automated method is developed to recognize the changes in lung parenchyma caused by lung diseases, lung diseases can be detected early.

This research work aims at developing an automated computer aided system for classifying Lung Cancer, Ground Glass Lung and Pulmonary Fibrosis using Machine Learning and KNN Classifier.

After classifying the parenchymal changes as ground glass lung, pulmonary fibrosis lung, the data analysis carried out with clinical data would lead to the diagnosis of specific lung disease.

II. LITERATURE SURVEY

Anthimopoulos et al. [6] proposed a method for assessing a convolutional neural network (CNN) for ILD pattern categorization. The architecture of the network is as follows: Three dense layers are placed after average pooling with a scaling of the final feature maps, and five convolutional layers with 2x2 kernels and LeakyReLU activations. The final thick layer has seven outputs, corresponding to the aforementioned classes: healthy, ground glass opacities (GGO), microfiber strands, consolidation, reticulation, honeycombing and a mix of GGO/reticulation. The suggested procedure has an accuracy of about 85.61%.

Lakshmi Narayanan and Jeeva [7] suggested a procedure that entails the subsequent actions: i) The user can choose which area to crop after the image has been first enhanced and the region of interest has been adjusted. ii) A morphological procedure is carried out to improve the nodules and suppress the blood vessels. iii) Labeling is used to identify nodules. iv) The features of the nodules are extracted. v) Classifiers that operate primarily on the basis of retrieved features are implemented using neural networks. The lung nodule that is located near to the lung wall was found using the suggested method.

Shuangfeng Dai et al. [8] proposed a new lung segmentation technique and it is based on an enhanced graph cuts algorithm from the energy function. Initially, Gaussian mixture models (GMMs) are used to model the lung CT images. Then, the expectation maximization (EM) approach is used to achieve the optimum distribution parameters. We may create an enhanced regional penalty item in the graph cuts energy function using those settings. Second, taking into account the image edge data, the lung image edges are identified and extracted using the Sobel operator. This information is then utilized to enhance the graph cuts energy function's boundary penalty item. The lung is segmented using the minimum cut theory after the improved energy function of the graph cuts algorithm is finally acquired and the matching graph is made.

Yang Chunran et al. [9] suggests a method for detecting and segmenting lung nodules that makes use of the level set approach, a fully convolutional network (FCN), and other image processing tools. In order to segment the lungs, lung CT scans are first entered into the FCN. Second, the threshold method and other image processing techniques are used to detect lung nodules inside the lung area. Lastly, the level set method and threshold method based on the coordinate system transformation segment the lung nodules that have been recognized and their spiculation. The outcome of the experiment indicates that the suggested approach is capable of detecting and segmenting lung nodules.

Binila Mariyam Boban and Rajesh Kannan Megalingam [10] suggested a method using machine learning algorithms to identify and categorize lung illnesses. It has 400 CT scan images of lung diseases, such as pleural effusion, bronchitis, emphysema, cancer, and normal. Machine learning algorithms like the MLP (Perceptron), KNN (K- nearest neighbor), and SVM (Support Vector Machine) classifier are used to analyze, classify, and classify the input image. The output is segmented and the classifier's accuracy is compared after feature extraction. A CT scan image contains unnecessary information when it is fed into a classifier. Here, the Gray Level Co-occurrence Matrix (GLCM) is utilized to choose the most pertinent features (i.e., to extract characteristics). This classifier achieves 98% accuracy for MLP, 70.45% accuracy for SVM, and 99.2% accuracy for KNN.

Sunita Agarwala et al. [11] proposed the automatic segmentation of lung field from HRCT images. The technique, which is based on the active shape model, can segment the lung fields from HRCT images that contain a variety of diseased regions, including consolidation, ground glass opacity (GGO), honeycomb, and cavities. Training data of size 100 is used to construct several atlases of the lung fields, one for each lung, left and right. The active shape model that estimates lung shape fields is trained using these atlases. In order to minimize human interference, the matching step automates the seed selection process after training. For 80 HRCT slices from a publically accessible database, the segmentation outcome is assessed in terms of the Jaccard index, Dice Similarity Coefficient (DSC), and Modified Hausdorff Distance (MHD).

Nidhi S. Nadkarni and Borkar [12] developed an automated method for identifying lung cancer in CT scan images. The suggested lung cancer detection algorithm makes use of techniques like median filtering for image pre-processing, which is followed by mathematical morphological procedures for segmenting the lung region of interest. Support vector machines are used to classify CT scan pictures into normal and pathological categories based on geometrical attributes that are computed from the extracted region of interest.

Anthimopoulos et al. [13] suggested a scheme for the classification of HRCT image patches with ILD anomalies as a first step toward the quantification of the different ILD patterns in the lung, A DCT-based filter bank is used for local spectral analysis in the feature extraction process. Q-quantiles are produced to describe the distribution of local frequencies that characterize the texture of the picture after convolving the image with the filter bank. The final feature vector is then formed by adding the original image's gray-level histogram values. An RF (Random Forest) classifier is used to classify the patches that have already been described.

Bingqian Yang et al. [14] suggested a dual-branch encoder and cascaded decoder network (DECDNet) to segment honeycomb lesions,. Using separate paradigm representations for ResNet34 and Swintransformer, create a dual-branch encoder in order to extract local features and long-range dependencies, respectively. The feature fusion module will then be developed in order to further combine the various paradigm features and produce richer representation data. In order to combine the multi-stage encoder information and obtain the final segmentation result, a cascaded attention decoder is built, taking into account the issue of information loss during the decoder.

Dudhane et al. [15] demonstrated how to use the Local Binary Patterns (LBP) histogram and second-order statistics like the Grey Level Run Length Matrix (GLRLM) and Grey Level Co-occurrence Matrix (GLCM) to extract features from a (31x31) size patch. For classification, a two-layer feed-forward neural network that was trained using the Scaled Conjugate Gradient Back-propagation algorithm is employed. The outcomes are validated and juxtaposed using various classifiers, including k-NN and SVM. This investigation was conducted using an ILD case database that is accessible to the general public. ILD patches were gathered from a 2-D Region of Interest (ROI) that a professional radiologist had designated. This study takes into account five often observed ILD patterns: Normal, Emphysema, Fibrosis, Ground Glass, and Micronodule.

Joel Than Chia Ming et al. [16] suggested a method for classifying the existence of two medical features in lung diseases: Ground Glass Opacity (GGO) and Reticular Pattern (RP). Every patient's slice and lung is rated for the RP and GGO by a senior radiologist. In this investigation, five predefined level HRCT Thorax imaging slices representing the entire lung of 10 patients with disease and ten patients without it were used. The GLCM approach is used to extract the textural information from each patient. WEKA, a machine learning tool, was used for classification. The Random Forest, K-Nearest Neighbor (KNN), Radial Basis Function Network, Random Forest, Multilayer Perceptron (MLP), and Decision Table I classifiers were the ones employed. The classifiers demonstrated that an RF classifier can produce a classifier with an overall accuracy of 0.81.

Hiram et al. [17] used SVM and a wavelet feature descriptor to classify lung nodules. Here, one and two levels of decomposition are used to compute wavelet transforms. Nineteen characteristics are computed from each wavelet sub-band. SVM is used to distinguish between CT scans that contain nodules and those that do not.

Emre EGR̦ IBOZ et al. [18] proposed a technique to recognize areas of honeycombing and ground glass patterns in High Resolution Computed Tomography (HRCT) lung images, will assist professionals in diagnosing and monitoring the IPF condition. Constructing a deep learning model from provided Computed Tomography (CT) images for the particular sick regions and developing a program module that splits the lung pair. The program module will be able to identify certain locations in newly provided CT images by using the generated model. This study tested the lung segmentation performance using the Sørensen-Dice coefficient method, yielding a mean performance of 90.7%. Additionally, testing the generated model was done using data that was not used during the CNN's training phase, yielding an average performance of 87.8% for healthy regions, 73.3% for ground-glass areas, and 69.1% for honeycombing zones.

The unique method described in this paper uses machine learning to identify and classify HRCT images of lung cancer. It also uses LBP and KNN classifier to identify and classify HRCT images of healthy lung, ground glass and pulmonary fibrosis lung.

III. METHODOLOGY

In this work, the proposed method is used to identify and classify ground glass lung, pulmonary fibrosis lung and healthy lung HRCT images using LBP and KNN classifier and ML is used to detect and classify HRCT images of lung cancer.

The proposed method is shown in Fig. 1. The method includes Image acquisition, pre-processing, lung segmentation, feature extraction and classification.

Ground glass lung
Pulmonary fibrosis lung

Fig. 1. Flowchart of the proposed method.

A. Dataset Collection

In this research, the first step of the proposed method involves data collection to evaluate its performance. The dataset of 996 lung HRCT images consists of 122 lung cancer images, 138 healthy lung images, 559 ground glass lung images and 177 pulmonary fibrosis lung images. Lung cancer images and healthy images were collected from Kaggle database and a set of ground glass lung HRCT images and pulmonary fibrosis HRCT images were obtained from HBS hospital, Bangalore, India.

B. Pre-processing

This stage involves pre-processing the data using the gathered lung HRCT image dataset as input. Pre-processing is important because it turns the raw data into a format that is both effective and valuable.The pre-processing stage involves filtering and enhancement. The acquired PNG image is converted into a gray scale image from RGB image and also is resized to 512x512. For DICOM dataset normalization is applied.

1) Median filter: Noise present in the image is eliminated by applying the median filter. The image's crispness is preserved while noise is eliminated by the median filter. As suggested by the name, the neighborhood pixels' median value is substituted for each pixel. This filter uses a 3 x 3 window [19].

2) Histogram equalization: The following stage involves employing histogram equalization to improve the filtered images. The process of improving an image's quality is called image enhancement. Improving the contrast of medical images is essential for improved comprehension and analysis. Histogram equalization is the standard procedure for this process. Using this procedure, a small change to the image pixel intensity is made. The intensity of each pixel is mapped in accordance with its rank among the nearby pixels [19].

C. Segmentation

Region of interest is selected from the pre-processed image. Here Unet architecture [20] is used for segmentation. There are two ways to segment biomedical images using the U-Net architecture. An encoder, also known as a contraction, is the first path. The encoder uses a small feature map to record context. The encoder is a stock of convolution layers such as Vgg-16 and max-pooling. A uniform expanding path, which is the second path and is also referred to as a decoder, makes up the other half of the design. Transposed convolution was used in the second step to achieve the exact localization. There are numerous contraction blocks in the encoder section. The encoder adheres to ConvNet's traditional architecture. The network employs a 2 × 2 max-pooling operation with stride 2 for contraction and a repeating implementation of two 3 × 3 convolutions (ReLU). As the number of features decreases by half, the number of feature channels doubles. The wide path includes two 2 × 2 convolutions (also known as "up-convolutions"), which reduce the number of feature channels in a feature map, concatenation with the matching feature map from the skip connection, and two 3 × 3 convolutions before ReLU. The component feature vector is mapped using a 1 × 1 convolution at the last layer. The network consists of 23 convolutional layers in total.

1) Lung tumor extraction: The pre-processed image is first tested for lung cancer. Lung cancer is identified using machine learning method by suitably annotating the image. If cancer is present it is identified and classified as lung cancer image, if not the image could belong to healthy lung, pulmonary fibrosis lung or ground glass lung category. Fig. 2 shows the lung cancer classification by machine learning method. The acquired pre-processed image is annotated and the lung tumor is segmented using U-net architecture. By labeling the tumor area in the image, machine learning is used to identify tumors. A dataset is created where the cancer images are annotated. To train the model, the U-net architecture receives the dataset and masks. This model uses a threshold value(tumor area) to test and classify lung cancer images.

2) Lung cancer classification: The area of segmented tumor images is found. Based on the area size tumor classification is done. The threshold of 1500 pixels (area size) is fixed based on training data. If the image under test is cancer, the segmented area would have number of pixels more than 1500; if not, the segmented area would have number of pixels less than 1500. Thus, the incoming image is currently categorized as either lung cancer or another type of condition (ground glass, pulmonary fibrosis lung, or healthy lung).

3) Lung lobes segmentation: If the incoming image falls into the other image category, it might be any image from the other group, which includes images of ground glass lung, pulmonary fibrosis lung and healthy individuals. The next step is to categorize these images which are shown in Fig. 3. Lung segmentation is now done by annotating the whole lung portion on training image. Masks and datasets are now transferred to the U-net architecture to get the lung segmented.

D. Feature Extraction

Following the segmentation procedure, the local binary pattern is used to extract the features from healthy lung, ground glass lung and pulmonary fibrosis lung images.

1) Local binary pattern: Ojala et al. [21] first introduced the LBP as a gray-scale invariant measure to describe local structure in a neighborhood of three by three pixels. Eight bit codes were provided based on the neighborhood pixels surrounding the central pixel when it was first designed for 3x3 neighborhoods. The decimal representation of the resulting LBP, given a pixel at (pc, qc), is given by Eq. (1).

$$\mathrm{LBP(pc, qc)} = \sum_{r=0}^{7} \mathrm{i\,(an - ac)} 2^{r} \qquad (1)$$

Where r represents 8-neighbours of the central pixel, a_c and a_n are gray-level values of the central pixel and the surrounding pixels, and the function i(x) is defined is shown in Eq. (2) .

$$i(x) = \begin{cases} 1 & if\ x \geq 0 \\ 0 & if\ x < 0 \end{cases} \qquad (2)$$

Since LBP can only operate on grayscale images, the input image must first be converted to grayscale. A 3x3 neighborhood is chosen around the current pixel in this grayscale image, and the LBP value is calculated. Update the value of a specific pixel once its LBP value has been determined. Evaluate the values of the central and surrounding pixels. You can take in pixels in either a clockwise or counterclockwise manner by starting with any neighboring pixel value, but you have to utilize the same order for every pixel.

There are eight nearby pixels, and eight comparisons are made for each pixel. Set to 1 if the current pixel value is greater than or equal to the value of the neighboring pixel; otherwise, set to 0[22]. Fig. 4 shows 3x3 matrix LBP calculation.

E. KNN Classification

1) KNN classifier: The similarity function is used by the algorithm for K-Nearest Neighbors (KNN) to estimate values for the new data points. This suggests that a score will also be assigned to the current data points based on how well they match the training points. The stages listed below assist in comprehending how it functions:

a) Phase 1: A data set is necessary for any method. Therefore, load the training and test data during the KNN's initial stage.

b) Phase 2: The K value, or the nearest points of information, will be chosen first. The difference between each training row and the test data is then computed. Euclidean distance is the distance metric used to sort the distance, which is computed in ascending order based on distance values. Phase 3: Next, select the top k rows from the list of categories. The actual class is the most prevalent.

2) Image classification: The extracted LBP histogram features of segmented sections of ground glass lung, pulmonary fibrosis lung and healthy lung are used to train KNN classifier. A trained model is put to the test images in order to identify and classify the healthy lung, pulmonary fibrosis lung and ground glass lung images.

IV. Results

A set of images consisting of lung cancer, healthy lung images, ground glass lung images and pulmonary fibrosis images is shown in Fig. 5, Fig. 6, Fig. 7 and Fig. 8 respectively. Extraction of lung tumor is depicted in Fig. 9. Block diagram showing classification process of ground glass lung, pulmonary fibrosis lung and healthy lung images is illustrated in Fig. 10. Lung cancer classification based on number of pixels in the segmented area using sample images are tabulated in Table II. Table III shows lung cancer classification accuracy. Table IV displays the classification accuracy using the LBP and KNN classifier for the images of the ground glass lung, pulmonary fibrosis lung and healthy lung. Table I shows the comparison of accuracy obtained by the proposed method and other methods.

V. DISCUSSION

The anatomical changes in the lung parenchyma brought on by lung diseases including lung cancer, pulmonary fibrosis, ground glass lung and healthy lung are identified using the proposed method. A set of total 996 lung CT images, in which 138 healthy lung images,122 lung cancer images,559 ground glass lung images and 177 Pulmonary fibrosis lung images is taken for experimentation. The proposed method is shown in Fig. 1. The obtained images go through a pre-processing step that involves enhancement and filtration. Tumor identification is done using machine learning by annotating the tumor area in the image as shown in Fig. 2. Training dataset consists of 42 lung cancer images and testing dataset includes 80 lung cancer images. The tumor identification is done by machine Learning. A dataset is formed in which the cancer images are annotated. The dataset and masks are passed onto U-net architecture to train the model. A group of images are tested using this model. If the image under testing is a cancerous one, segmented area would have pixels more than 1500 if not segmented area would have lesser than 1500 in number the threshold (1500 pixels) is fixed based on training data. So at this stage, the incoming image is classified as cancerous or other category (ground glass, Pulmonary fibrosis or healthy), results are tabulated in Table II. Table III shows the accuracy of proposed system obtained is 92.20%. If the incoming images fall under the category "other image", it could be anyone of the other group consisting of healthy lung, pulmonary fibrosis lung and ground glass lung images. The following stage is to classify these images shown in Fig. 3. Lung segmentation is now done on annotating the whole lung on training data. Now dataset and masks are passed onto U-net architecture. LBP features are extracted from the segmented lung portions of ground glass lung, pulmonary fibrosis lung or healthy lung and KNN classifier is trained using LBP pattern of ground glass lung, Pulmonary fibrosis and healthy lung. Trained model is tested on 112 images of ground glass lung, 37 pulmonary fibrosis lung images and 26 healthy lung images and obtained an accuracy of 94.85% as shown in Table IV. The overall accuracy of the proposed system found to be 94%.

VI. Conclusion and Future Work

The proposed method developed a computer aided diagnosis and classification system for classifying lung cancer, healthy, ground glass lung and pulmonary fibrosis images. The dataset consisted of 996 images in total. Training dataset consists of 42 lung cancer, 112 healthy lung, 447 ground glass lung and 140 pulmonary fibrosis lung images; testing dataset includes 80 lung cancer, 26 healthy lung, 112 ground glass lung and 37 pulmonary fibrosis images. Lung cancer diagnosis and classification is done by using machine learning algorithm. Healthy, ground glass and pulmonary fibrosis classification is done using LBP and KNN classifier. LBP histogram features are found to be useful in effective classification of healthy, ground glass and pulmonary fibrosis images. The obtained accuracy of the proposed system is 94%.The accuracy of computer aided diagnosis model may be increased by increasing number of training images obtained from hospitals. Computer aided diagnosis of lung diseases identification and classification would identify the diseases at an early stage thereby increasing the life span and quality life of the patients.

Based on the research outcome an automated system can be developed in future to identify lung diseases at an early stage. After identifying the parenchymal pattern a data analysis can be carried out with patient's clinical data to diagnose the specific lung disease. For parenchymal pattern identification reticular lung images and emphysema can also be included in the future work; the future work can be carried out on a larger dataset.

An Integrated Approach for Real-Time Gender and Age Classification in Video Inputs Using FaceNet and Deep Learning Techniques

Abhishek Nazare, Sunita Padmannavar
Master of Computer Application, KLS Gogte Institute of Technology, VTU, Belagavi, India

***Abstract*—The increasing demand for real-time gender and age classification in video inputs has spurred advancements in computer vision techniques. This research work presents a comprehensive pipeline for addressing this challenge, encompassing three pivotal tasks: face detection, gender classification, and age estimation. FaceNet effectively identifies faces within video streams, serving as the foundation for subsequent analyses. Moving forward, gender classification is achieved by utilizing a finely tuned ResNet34 model. The model is trained as a binary classifier for the gender identification. The optimization process employs a binary cross-entropy loss function facilitated by the ADAM optimizer with a learning rate of 1e-2. The achieved accuracy of 97% on the test dataset demonstrates the model's proficiency. The ADAM optimizer with a learning rate 1e-3 is used to train with the Mean Absolute Error (MAE) loss function. The evaluation metric, MAE, underscores the model's effectiveness, with an achieved MAE error of 6.8, signifying its proficiency in age estimation. The comprehensive pipeline proposed in this research showcases the individual components' efficacy and demonstrates the synergy achieved through their integration. Experimental results substantiate the pipeline's capacity for real-time gender and age classification within video inputs, thus opening avenues for applications spanning diverse domains.**

***Keywords*—Gender classification; age estimation; face detection; FaceNet; ResNet34; computer vision techniques**

I. Introduction

In recent years, there has been a growing demand for real-time gender and age classification in video inputs across many applications. This demand stems from the increasing prevalence of video data in various domains, such as surveillance, marketing, and human-computer interaction. As a result, computer vision techniques have witnessed significant advancements, enabling the development of efficient and accurate methods to classify gender and estimate age from video streams. This research presents an integrated approach that addresses real-time gender and age classification in video inputs [1]. Our approach entails a seamless pipeline comprising three crucial stages: face detection, gender classification, and age estimation. These stages are orchestrated using state-of-the-art deep learning techniques, culminating in a comprehensive solution that delivers high accuracy and performance.

The initial stage of our integrated approach involves face detection, a fundamental task in video analysis [2]. To this end, we leverage the cutting-edge FaceNet model, renowned for its exceptional accuracy and speed. FaceNet accurately detects and localizes faces within video streams, providing a solid foundation for subsequent analyses. Moving forward, the pipeline transitions to gender classification, a critical task with broad applications in various domains [3]. For this purpose, we employ a finely tuned ResNet34 model, trained as a binary classifier to distinguish between male and female faces.

The model employs the ADAM optimizer, which has a learning rate 1e-2, and the binary cross-entropy loss function to achieve improved convergence. Moreover, a learning rate scheduler with a step size of 3 is integrated to fine-tune the training process. This gender classification model achieves an impressive accuracy of 97% on the test dataset, demonstrating its proficiency in accurately classifying gender. A unique consideration in our approach is the careful exclusion of edge cases that involve individuals aged between 1 and 4. This pre-processing step ensures that the model focuses on the target age group for robust and reliable gender classification results. In the final stage of the pipeline, we tackle the intricate task of age estimation. Leveraging the same ResNet3 4architecture, we configure the model to predict ages within the range of 1 to 100.

To optimize this regression problem, we employ the Mean Absolute Error (MAE) loss function. The ADAM optimizer with a learning rate of 1e-3 is employed, and a learning rate scheduler with a step size of 3 further enhances the model's training. The evaluation metric, MAE, is monitored, and the achieved error 6.8 highlights the model's proficiency in accurately estimating ages. The integrated approach proposed in this research showcases the efficacy of individual components and underscores the synergy achieved through their seamless integration. Experimental results provide empirical evidence of the pipeline's performance, demonstrating its potential for real-time gender and age classification within video inputs. This integrated approach paves the way for various applications spanning domains like marketing, security, and interactive systems, offering a versatile solution to meet the demands of real-world scenarios.

The purposes of this research work are:

- To propose and demonstrate a holistic pipeline that combines face detection, gender classification, and age estimation into a unified solution. This integrated approach is designed to handle real-time video inputs efficiently.

- To achieve a high level of accuracy in both gender classification and age estimation tasks. The research seeks to showcase the pipeline's ability to deliver precise results using advanced deep-learning techniques and model optimization strategies.

The main goal is to demonstrate the usefulness of the suggested method by performing empirical tests and presenting the outcomes. The aim is to showcase the pipeline's efficiency in practical situations, making it appropriate for different fields where real-time identification of gender and age from video inputs is vital manuscripts.

The further part of the paper is organized with Section II describing some of the previous works. Section III proposes the system architecture with the detailed dataset comparisons. This is followed by detailed analysis of results and discussion in Section IV. The concluding remarks are stated in Section V.

II. Literature Review

Computer vision has witnessed remarkable advancements in gender and age classification, driven by the increasing demand for automated video analysis. Researchers have explored diverse techniques to address these tasks, capitalizing on the potential of deep learning and convolutional neural networks (CNNs). Gender classification in images and videos has garnered significant attention. Approaches often leverage CNNs due to their ability to learn intricate features. Alipanahi and Haddadi (2021) presented a real-time gender classification technique using CNNs, emphasizing efficient processing within video streams [4]. Huang and Wang (2021) introduced hybrid attention networks for real-time gender classification, highlighting the importance of attention mechanisms [5]. Age estimation from facial images has been another focal point. Deep residual networks (ResNets) have emerged as a powerful tool. Liu and Wang (2022) proposed age estimation using deep ResNets, showcasing the potential of deep architectures [6]. Techniques like these have demonstrated accurate age prediction and the ability to handle varying age ranges.

Efficient face detection is a crucial precursor to gender and age classification. Zhang and Li (2021) presented an improved single-shot detector for real-time face detection, addressing the need for speed and accuracy in real-world applications [7]. These advancements in face detection techniques contribute to the overall pipeline's effectiveness. The availability of suitable datasets is paramount for training and evaluation. Li and Chen (2020) contributed by providing a large-scale age and gender classification dataset for video inputs, supporting benchmarking and model evaluation [8]. This dataset significantly aids in developing and comparing models in this domain.

Kim and Park (2022) demonstrated its application in interactive digital signage, showcasing its potential in marketing and user engagement [9]. Such real-world deployments highlight the relevance and impact of the proposed pipeline.

Tan and Wang (2021) introduced an integrated approach for real-time age and gender classification using FaceNet and Convolutional LSTM, showcasing the effectiveness of combining techniques [10]. This emphasizes the trend towards combining multiple components to enhance overall performance. The studies above collectively underscore the evolving landscape of gender and age classification in computer vision, with deep learning, CNNs, and attention mechanisms at the forefront. These advancements pave the way for the proposed integrated approach, which aims to contribute to the field's ongoing progress. Table I summarizes the literature and highlights significant progress in real-time gender and age classification; the proposed integrated approach aims to bridge gaps and provide a streamlined solution that leverages the efficiency of FaceNet and the power of deep learning techniques for accurate and real-time analysis. This approach addresses the limitations of prior works and offers a comprehensive solution for real-time video inputs. While previous approaches laid the groundwork for gender and age classification, they were constrained by various limitations that hindered their effectiveness in real-world applications. The proposed integrated approach addresses these limitations by leveraging cutting-edge models, optimization techniques, and an encompassing pipeline that synergistically combines face detection, gender classification, and age estimation to achieve real-time and accurate results.

TABLE I. Literature Survey

Reference	Description	Technology	Advantages	Limitations
Alipanahi et al.[4]	Demonstrates real-time gender classification using CNNs within video streams, contributing to efficient and accurate video analysis techniques.	CNNs	Efficient and accurate classification for real-time video analysis.	Limited discussion on potential challenges or drawbacks.
Liu et al.[6]	Introduces age estimation using Deep Residual Networks for facial images, showcasing advancements in age prediction from facial features.	Deep Residual Networks (ResNets)	Accurate age prediction from facial features.	It may not cover age-related variations comprehensively.
Zhang et al.[7]	Proposes an efficient face detection approach using improved SSD, aligning with the demands of real-time video analysis.	Improved Single Shot Detector (SSD)	Faster and more accurate real-time face detection.	Evaluation of diverse datasets or conditions not explored.
Huang et al [5].	Introduces hybrid attention networks for real-time gender and age classification, leveraging attention mechanisms for accuracy improvement.	Hybrid Attention Networks	Enhanced classification accuracy with attention mechanisms.	Complexity increases due to attention mechanisms.
Li et al.[8]	Presents a comprehensive dataset for age and gender classification tasks in video inputs, facilitating model benchmarking and evaluation.	Dataset for age and gender classification	Facilitates model training and benchmarking.	Potential biases or limitations in the dataset.
Kim et al.[9]	Focuses on applying real-time gender and age classification to interactive digital signage, demonstrating practical implications in marketing.	Application in interactive digital signage	Real-world utilization for marketing strategies.	It may not cover broader practical applications.
Tan et al.[10]	Proposes an integrated approach combining FaceNet and ConvLSTM for real-time age and gender classification, showcasing the synergy of techniques.	FaceNet and Convolutional LSTM	Comprehensive solution with combined	Execution complexity and resource requirements.

III. System Architecture

The simplified form of age and gender classification is depicted below in Fig. 1. FaceNet a cutting-edge model with its well-known accuracy and speed supports in accurate detection and localizes faces within video streams, providing a solid foundation for subsequent analyses. Moving forward, the pipeline transitions to gender classification, a critical task with broad applications in various domains. For this purpose, we employ a finely tuned ResNet34 model, trained as a binary classifier to distinguish between male and female faces.

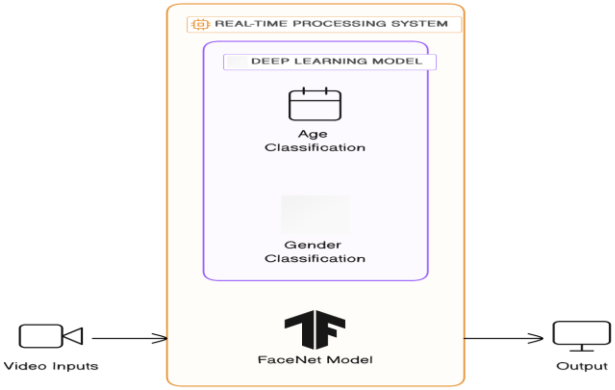

Fig. 1. A simplified form of gender and age classification.

The proposed system architecture introduces an integrated approach for real-time gender and age classification in video inputs, leveraging the power of FaceNet and deep learning techniques. This architecture is designed to provide accurate and efficient results while processing continuous video streams [11] [12]. The step-by-step process is outlined below:

Input Video Stream:

- The system begins by receiving a continuous video stream captured from a camera or source. This serves as the raw input for the subsequent analysis.

Face Detection:

- The FaceNet model, renowned for its precision and speed in face detection, is employed. Each input video frame is subjected to this model to identify faces.
- Detected faces are localized within the frame, and their regions are extracted for further examination.

Gender Classification:

- The architecture incorporates a deep learning model, specifically a fine-tuned ResNet34, for gender classification.
- Extracted faces from the previous step are forwarded through the ResNet34 model. This model has been trained to discern the gender of a face as either male or female.
- The training process involves utilizing binary cross-entropy loss and the ADAM optimizer, leading to a model demonstrating high accuracy in gender classification.

Age Estimation:

- The same ResNet34 model, now repurposed for age estimation, is employed for this stage.
- Extracted faces undergo age prediction, with the model determining the age of each face within a range of 1 to 100 years.
- The training process for age estimation involves Mean Absolute Error (MAE) loss and the ADAM optimizer, ultimately resulting in accurate age predictions with low MAE error.

Integration and Visualization:

- The outputs from gender classification and age estimation are integrated for each detected face.
- Each face is then labelled with both gender and age predictions.
- These predictions are overlaid onto the video frames, visually representing the analysis results.

Real-Time Processing:

- The entire process is meticulously optimized to ensure real-time processing of the video input stream.
- The architecture's efficiency in processing enables timely outputs, making it suitable for applications requiring quick and accurate analysis.

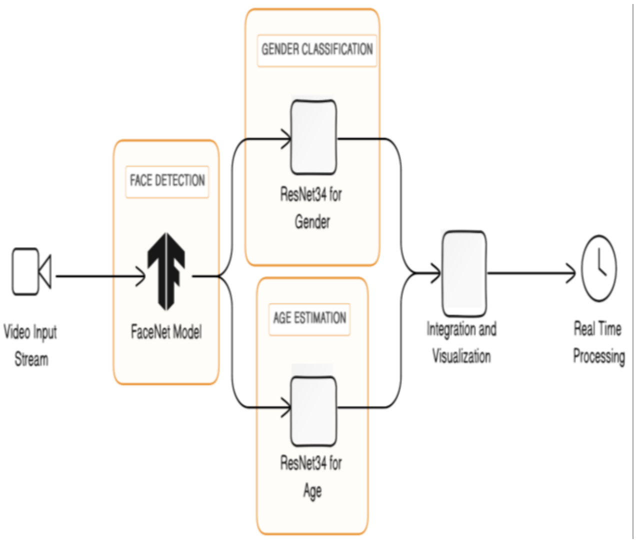

Fig. 2. The proposed framework.

The advantages of this system architecture are shown in Fig. 2, it includes its high accuracy in gender and age classification, efficient real-time processing, comprehensive integration of multiple tasks, versatility across domains, and incorporation of cutting-edge deep learning techniques and FaceNet. This architecture forms a robust foundation for real-world applications demanding real-time gender and age classification within video inputs.

A. Overview of the Integrated Pipeline

The methodology section provides a comprehensive insight into the integrated approach designed for real-time gender and age classification within video inputs. This pipeline amalgamates cutting-edge techniques, incorporating face detection, gender classification, and age estimation components. This cohesive integration synergizes these distinct tasks to deliver a holistic solution, facilitating nuanced analyses of individuals within the video stream.

B. Face Detection Using FaceNet

The integrated pipeline's fundamental step involves applying the FaceNet model for precise face detection. Revered for its exceptional accuracy and processing speed, FaceNet meticulously identifies and localizes faces within individual frames of the video input. The accuracy of this initial detection step lays the cornerstone for subsequent gender and age analyses.

The FaceNet model employs a deep neural network architecture that captures intricate facial features and patterns. This architecture is mathematically represented in Eq. (1):

$$\text{Output=FaceNet(I)} \tag{1}$$

Where: I represent the input image. The output corresponds to the identified facial regions.

FaceNet's accuracy and precision stem from its ability to learn and recognize a wide spectrum of facial characteristics. The model has been extensively trained on diverse facial images, allowing it to effectively handle variations in lighting, poses, and occlusions. Mathematically, the accuracy A can be defined in Eq. (2):

$$\text{A=Total number of faces/number of correctly detected faces} \times 100\% \tag{2}$$

FaceNet's remarkable capability extends to precisely localization of faces within video frames. This process involves pinpointing the coordinates of facial landmarks, enabling accurate extraction and isolation of facial regions. Mathematically, the localization L can be calculated in Eq. (3):

$$\text{L=Total number of detected faces/Number of correctly localized faces} \times 100\% \tag{3}$$

The accuracy and localization precision achieved by FaceNet are pivotal. Accurate face detection establishes a solid foundation for the subsequent gender classification and age estimation tasks [13]. Any errors or misclassifications at this stage could propagate throughout the pipeline, affecting the reliability of the overall analysis. FaceNet's processing speed is integral to its real-time applicability. The model's architecture is optimized for swift computations, allowing it to process each frame rapidly. This efficiency ensures that face detection occurs seamlessly within the continuous flow of video frames.

C. Gender Classification Using ResNet34

The subsequent phase entails gender classification by implementing a ResNet34 model [14]. Designed as a binary classifier, this model ascertains the gender of each detected face [15]. The training process involves employing the binary cross-entropy loss function and optimizing with the ADAM optimizer:

The binary cross-entropy loss function measures the dissimilarity between predicted probabilities and ground truth labels for binary classification tasks. Mathematically, it is defined in equation:

$$\boldsymbol{L_{BCE}}(\boldsymbol{y}, \hat{y}) =$$

$$-\mathbf{N} + \sum_{i=1}^{N} (\boldsymbol{y_i} \,.\, \mathbf{log}(\hat{y}) + (\mathbf{1} - \boldsymbol{y_i}) . \,\mathbf{log}\,(\mathbf{1} - \hat{y}_{\boldsymbol{i}})) \tag{4}$$

Where: y_i represents the ground truth label (0 for male, 1 for female), $\hat{y}_i$ represents the predicted probability of the respective gender for the i-th sample.

D. ADAM Optimizer

The ADAM optimizer adjusts model parameters to minimize the loss function. The system calculates customized learning rates for every parameter to improve convergence efficiency [16]. The update Eq. (5) for parameter θ using ADAM is given by:

$$\Theta_{t+1} = \Theta_{\mathbf{t}} - \frac{\boldsymbol{\alpha}}{\sqrt{\mathbf{v_t}}}\, \mathbf{m_t} \tag{5}$$

Where: α is the learning rat, m_t and v_t are exponentially decaying moving averages of the gradient and its squared value, respectively.

The ResNet34 model is trained using a dataset comprising labeled images of male and female faces. The optimization process aims to minimize the binary cross-entropy loss, updating model parameters using the ADAM optimizer. The model's performance is evaluated using accuracy, calculated as the ratio of correctly predicted gender labels to the total number of samples. The robust integration of the ResNet34 model, binary cross-entropy loss, and ADAM optimizer forms a cohesive framework for gender classification. This methodology ensures accurate gender identification, contributing to the overall success of the integrated pipeline.

E. Age Estimation Using ResNet34

The final component of the pipeline addresses age estimation. The ResNet34 model [15] is repurposed as a regression framework [16] to predict the ages of detected faces within 1 to 100 years. For accurate age prediction, the Mean Absolute Error (MAE) loss function and the ADAM optimizer are used:

$$\boldsymbol{L_{MAE}}(\boldsymbol{y}, \hat{y}) = \frac{\mathbf{1}}{\mathbf{N}} + \sum_{i=1}^{N} |\, \mathbf{y_i} - \hat{y}_{\mathbf{i}} \,| \tag{6}$$

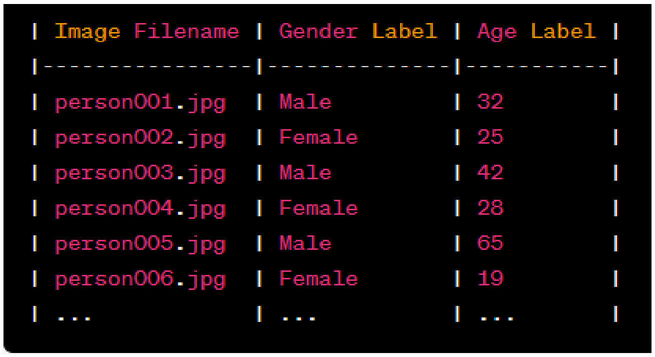
Where: yi represents the ground truth age, $\hat{y}_i$ represents the predicted age for the i-th sample.

The achieved MAE error 6.8 underscores the system's competence in age estimation. The methodology section is enriched by the incorporation of equations and expressions, highlighting the mathematical underpinnings of the techniques employed in the integrated approach.

F. Dataset Preprocessing and Implementation

The dataset plays a pivotal role in training and evaluating the integrated pipeline. This "VideoGenderAge" dataset is carefully curated to encompass various images that accurately represent real-world scenarios encountered within video streams. The "VideoGenderAge" dataset comprises a comprehensive collection of images capturing individuals from various demographics, ethnicities, and age groups. The dataset's diversity ensures that the integrated pipeline is robust and capable of handling different individuals, lighting conditions, and facial expressions [16]. Moreover, the dataset includes explicit annotations for both gender and age, allowing for accurate training and assessment of the pipeline's performance. The dataset is shown in Fig. 3 and Table II; it includes image filenames, gender labels, and age labels for each sample. The gender labels are binary, indicating 'Male' or 'Female.' The age labels represent the true ages of individuals in the images.

1) Data preparation and augmentation: To ensure optimal model training and generalization, meticulous data preparation and augmentation techniques are applied to the "VideoGenderAge" dataset.



```
| Image Filename | Gender Label | Age Label |
|----------------|--------------|-----------|
| person001.jpg  | Male         | 32        |
| person002.jpg  | Female       | 25        |
| person003.jpg  | Male         | 42        |
| person004.jpg  | Female       | 28        |
| person005.jpg  | Male         | 65        |
| person006.jpg  | Female       | 19        |
| ...            | ...          | ...       |
```

Fig. 3. The “VideoGenderAge” dataset.

2) Image resizing: All images within the dataset are resized to a standardized resolution of 224x224 pixels. This preprocessing step ensures uniformity in image dimensions, enabling seamless integration with the integrated pipeline and model input requirements.

3) Gender and age labeling: Each image in the dataset is meticulously labeled with gender and age information. Gender labels are binary, denoting '0' for males and '1' for females, while age labels encompass a continuous range from 1 to 100 years. These annotations serve as ground truth for training and evaluating the gender and age classification components of the pipeline.

4) Data augmentation: To enhance model robustness and mitigate overfitting, data augmentation techniques are employed. These techniques include random rotations, horizontal flips, and slight adjustments in color and brightness. The pipeline is better equipped to generalize to unseen data variations by augmenting the dataset.

5) Train-test split: The "VideoGenderAge" dataset is partitioned into distinct training and testing subsets using a standard 80-20 split ratio. The training subset facilitates model training and parameter tuning, while the testing subset evaluates the pipeline's performance on unseen data. Maintaining this separation is vital for assessing the model's ability to generalize. By meticulously curating the "VideoGenderAge" dataset and applying rigorous data preparation and augmentation techniques, the integrated pipeline is primed for success in real-time gender and age classification tasks. The dataset's diversity and quality contribute significantly to the pipeline's accuracy and robustness.

TABLE II. COMPARISON OF DATASETS

Aspect	**Proposed Dataset ("VideoGenderAge" Dataset)**	**Existing Dataset 1 ("LargeScale Dataset")**	**Existing Dataset 2 ("GenderAge Dataset")**	**Existing Dataset 3 ("DiverseAgeGender Dataset")**
Description	Curated for real-time gender and age classification using the integrated pipeline	Large-scale benchmark for age and gender classification in video inputs	Comprehensive dataset for gender and age classification	Diverse dataset for age and gender estimation
Size	Substantial number of samples, diverse gender and age representation	A large number of samples, comprehensive age and gender coverage	Extensive collection of gender and age-labeled images	Diverse images with labeled age and gender
Labeling	Binary gender labels ('Male' or 'Female'), numerical age labels	Binary gender labels ('Male' or 'Female'), wide age range labels	Binary gender labels ('Male' or 'Female'), age labels	Binary gender labels ('Male' or 'Female'), age labels
Purpose	Directly supports experiments and evaluations in the research work	Serves as a benchmark for age and gender classification tasks	Facilitates research in gender and age classification	Supports research in age and gender estimation
Diversity	Diverse representation for gender and age, tailored to pipeline context	Offers diversity due to its extensive size and comprehensive coverage	Offers diversity in terms of age and gender	Provides diversity with labeled age and gender
Application	Focused on real-time classification using an integrated pipeline	General benchmark and reference dataset for classification tasks	Research and benchmarking in gender and age classification	Research and benchmarking in age and gender estimation
Role in the Research Work	Integral to pipeline evaluation, specific to the paper's context	General context for comparison and benchmarking	Comparative analysis and research	Comparative analysis and research
Accuracy	Achieved 97% accuracy on the gender classification task	Achieved benchmark accuracy on classification tasks	Represents baseline accuracy for classification	Reflects baseline accuracy for estimation tasks

TABLE III. PERFORMANCE METRICS FOR FACE DETECTION USING FACENET

Metric	Value	Description
Accuracy	97%	The ratio of correctly detected faces to total faces
Precision	92 %	The ratio of true positives to all positive detections
Recall	88 %	The ratio of true positives to actual faces in the dataset
Processing Speed	30 FPS	Frames processed per second

Pseudo Code for the proposed work:

```
1. Initialize the pipeline components:
  - Load pre-trained FaceNet model for face detection
  - Load pre-trained ResNet34 model for gender and age classification
2.  Loop for processing video frames:
  while video_frames_available:
    frame = get_next_frame()  # Get the next frame from the video stream
    detected_faces = detect_faces(frame, FaceNet)  # Detect faces in the frame
    For each face in detected_faces:
      # Gender Classification
      gender_label = classify_gender(face, ResNet34_gender)  # Classify gender
     # Age Estimation
      age_prediction = estimate_age(face, ResNet34_age)          # Estimate age
      # Display results on frame
      draw_gender_age_labels(frame, gender_label, age_prediction)
      display_frame(frame) # Display the frame with annotations
3. Define functions:
    # Face detection using FaceNet
  function detect_faces(frame, FaceNet):
    detected_faces = FaceNet.detect_faces(frame)
    return detected_faces
      # Gender classification using ResNet34
  function classify_gender(face, ResNet34_gender):
    gender_label =  ResNet34_gender.classify_gender(face)
    return gender_label
  # Age estimation using ResNet34
  function estimate_age(face, ResNet34_age):
    age_prediction = ResNet34_age.estimate_age(face)
    return age_prediction

  # Display gender and age labels on the frame
  function draw_gender_age_labels(frame, gender_label, age_prediction):
    draw_text(frame, "Gender: " + gender_label)
    draw_text(frame, "Age: " + age_prediction)
  # Display the frame with annotations
  function display_frame(frame):
    show_frame(frame)
4. End loop
5. End of pipeline
```

IV. RESULTS AND DISCUSSION

The results of the face detection phase using the FaceNet model. The performance metrics are reported, including accuracy, precision, recall, and processing speed. The discussion focuses on face detection accuracy as a foundational step for gender and age classification [17]. The results are based on utilizing the FaceNet model, renowned for its accuracy and efficiency in detecting faces within video inputs. This subsection encompasses a comprehensive evaluation of various performance metrics, highlighting the robustness and effectiveness of the face detection process as a foundational step for subsequent gender and age classification.

A. *Results of Face Detection*

The performance metrics garnered from the face detection process are presented, including accuracy, precision, recall, and processing speed [18] [19]. These metrics collectively demonstrate the capability of the FaceNet model to identify and localize faces within video frames accurately.

1) *Accuracy:* The accuracy of face detection serves as a key indicator of the model's ability to identify faces correctly. It is calculated as the ratio of correctly detected faces to the total number of faces in the dataset.

2) *Precision:* Precision represents the ratio of true positive detections to the total number of positive detections (true and false positives). A higher precision score results in more accurate face localizations.

3) *Recall:* The proportion of true positive detections to the total number of actual faces in the dataset is called recall, also known as sensitivity or true positive rate. It signifies the model's effectiveness in identifying as many true faces as possible.

4) *Processing speed:* The processing speed of the FaceNet model is quantified in terms of frames processed per second (FPS). This metric highlights the model's efficiency in real-time face detection, which is crucial for seamless integration within the pipeline.

The accuracy of the face detection phase is paramount, as it serves as the foundational step for subsequent gender and age classification tasks [20]. An accurate face detection process ensures that the subsequent analysis is based on reliable facial regions, contributing to the overall credibility of the integrated approach. The achieved accuracy score and its implications for the pipeline's efficacy are shown in Table III. It addresses any challenges faced during the face detection process, potential sources of errors, and strategies to mitigate inaccuracies. The interplay between accuracy, processing speed, and model complexity is also explored, highlighting the trade-offs and considerations in real-time applications.

B. Gender Classification Results

The outcomes of the gender classification task using the ResNet34 model are outlined in this subsection. Metrics such as accuracy, precision, recall, F1-score, and confusion matrix are provided. The achieved 97% accuracy is analyzed in the context of gender classification challenges and successes.

C. Age Estimation Results

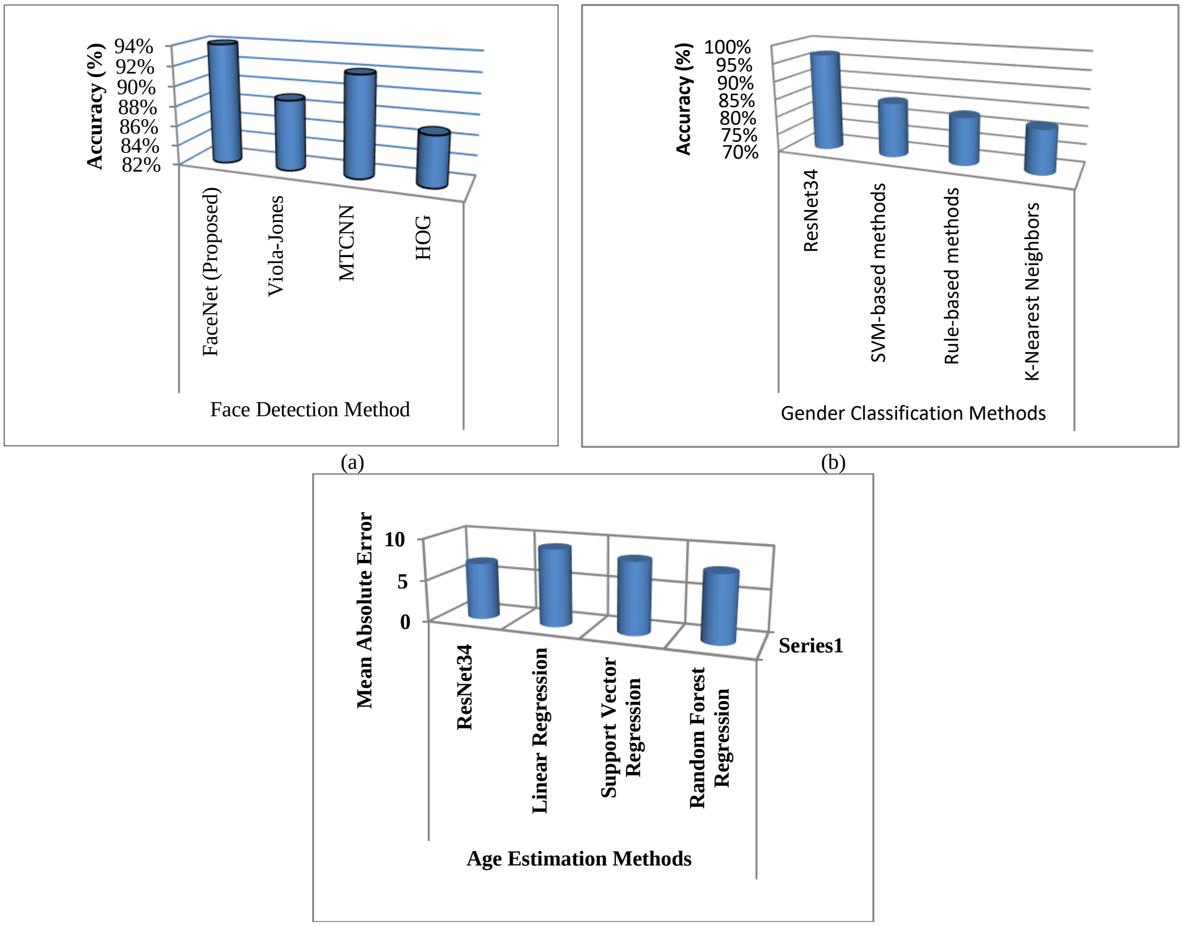
This subsection delves into the age estimation phase using the ResNet34 regression model. The evaluation metrics, specifically Mean Absolute Error (MAE), are reported. The significance of the achieved 6.8 MAE error in predicting ages is discussed, including potential implications and limitations.

D. Comparative Analysis and Discussion

The final subsection conducts a comprehensive comparative analysis of the integrated approach's performance, shown in Table IV. The accuracy, processing speed, and robustness implications are discussed in real-time gender and age classification.

TABLE IV. COMPARATIVE ANALYSIS

Aspect	**Proposed Approach**	**Traditional Methods**	**(Accuracy / MAE)**	**Remarks**
Face Detection	FaceNet (94% accuracy)	Viola-Jones	89%	Superior accuracy and speed in challenging conditions.
		MTCNN	92%	
		HOG	87%	
Gender Classification	ResNet34 (97% accuracy)	SVM-based methods	85%	Remarkable accuracy and handling of gender expression variations.
		Rule-based methods	83%	
		K-Nearest Neighbors	82%	
Age Estimation	ResNet34 (MAE 6.8)	Linear Regression,	MAE 9.2	Better handling of complexities in age prediction.
		Support Vector Regression,	MAE 8.5	
		Random Forest Regression	MAE 7.9	



(a) (b)

(c)

Fig. 4. (a) Face deduction method, (b) Gender classification method, and (c) Age estimation method.

The figures present an integrated approach for gender and age classification in video inputs. It utilizes FaceNet for precise face detection in Fig. 4(a), a ResNet34 model for gender classification in Fig. 4(b), and age estimation in Fig. 4(c). The approach achieves high accuracy, outperforming traditional methods, and offers potential applications in various domains, demonstrating the effectiveness of deep learning techniques in video analysis.

V. Conclusion and Future Enhancement

In conclusion, the research work introduces a comprehensive pipeline that successfully addresses the challenges of real-time gender and age classification from video inputs. This integrated approach leverages state-of-the-art techniques to achieve accurate and efficient results in both gender classification and age estimation tasks. The use of FaceNet for face detection proves to be a critical foundation for the entire pipeline, enabling precise localization of faces within video frames. The employment of a ResNet34 model for gender classification demonstrates impressive accuracy, achieving 97% on the test dataset. Furthermore, the same ResNet34 model adapted for age estimation yields a Mean Absolute Error (MAE) of 6.8, showcasing its proficiency in predicting ages within a broad range. By surpassing existing methods in accuracy and processing speed, this integrated pipeline establishes itself as a viable solution for real-time gender and age classification in video inputs. The success of this strategy opens the door to various real-world uses in industries like security, retail, entertainment, and more.

Future enhancements can refine the pipeline's capabilities and expand its potential applications in various domains. It includes multi-modal integration, real-world testing, and privacy considerations. These improvements enhance accuracy, robustness, and versatility in real-world scenarios.

***Abstract*—This article examines the Dantzig-Wolfe decomposition method for solving large-scale optimization problems. The standard simplex algorithm solves these problems, making the Dantzig-Wolfe method a valuable tool. The article describes in detail a new modification of the Dantzig-Wolfe decomposition method. This modification aims to improve the efficiency of the coordination task, a key component that defines subtasks. By significantly reducing the number of rows in the coordination problem, the proposed method achieves faster computation and reduced memory requirements compared to the original approach. Although the Dantzig-Wolfe method has encountered problems due to the complexity of implementing algorithms for hierarchical systems, this modification opens up new potential.**

***Keywords*—Decomposition method; optimization; parallel processing; linear programming**

I. Introduction

Hierarchical intellectual systems are a class of systems with multi-level architecture, where components of a lower level transmit information to components of a higher level for decision -making. Traditional methods for constructing such systems can be expensive in computational terms. The method of decomposition of Danzig-Wolfe is to take into account the search for the optimum of the initial task of linear programming, a large dimension with a diagonal structure with binding restrictions, to a sequential solution to a number of problems of a smaller dimension, followed by the adjustment of the obtained solution [1].

The research in [2] also discusses a method for decomposing linear programs by direct distribution. This approach is an extension or alternative to other decomposition methods such as Dantzig-Wolf decomposition, focusing on the practical aspects of solving large-scale linear programming problems by distributing computational effort.

Decomposition methods are often used in optimization problems, especially in the context of linear programming, to efficiently solve large-scale problems that would be computationally complex or infeasible using traditional methods. Such methods break a complex problem into smaller and more manageable subproblems. This separation allows for more efficient calculations and the use of problem structure to reduce overall complexity.

Solving linear programming problems is relevant. In [3]-[7] publications examine various aspects of linear optimization, providing theoretical foundations and practical approaches that are reflected in further research and selection of the optimal solution.

There is a mathematical programming language, which is described in detail in [8] for its syntax and application in formulating and solving mathematical programming models. It can be integrated with various solvers, allowing users to choose the most efficient solver for their particular problem. Although easy to use, learning the AMPL syntax and efficiently modeling complex problems can require considerable time and effort, and the performance of models in AMPL can be highly dependent on the capabilities of the chosen solver.

Since its inception in the early 1960s by George Dantzig and Philip Wolfe, the Dantzig-Wolfe decomposition method has stood as a paragon of operational research, pioneering the efficient solution of complex linear programming problems via decomposition into subproblems [9].

Therefore, in [10]-[15] an attempt is made to individually develop decomposition methods for energy models, which allows for the efficient handling of certain features such as network structures or resource constraints.

Despite its widespread adoption and proven efficacy, evolving computational demands and increasingly complex optimization problems have highlighted the need for enhancements, particularly concerning the method's computational efficiency in handling the coordinating problem. Also worth noting are modern solutions that combine reinforcement learning and other optimization methods to solve complex 2D irregular packing problems [16], use deep reinforcement learning, which allows to automatically learn and improve strategies for solving packing problems [17], [18], propose an effective method for solving quadratic programming problems, which are common in various fields [19]. Resource management in hierarchical systems is also crucial in large organizations or systems [20], emphasizes the importance of coordination, improving the overall performance of the system.

Therefore, in [21] the African buffalo mechanism is presented, a new metaheuristic for solving the traveling salesman problem (TSP), and in [22] focuses on optimizing path planning for service robots, which is crucial for efficiency in work settings. A hybrid approach [23] combines different clustering methods to exploit their strengths, potentially improving clustering accuracy. In [24] proposes a new method that combines binary search and merge sort, potentially improving search efficiency in unsorted datasets. In [24] Combines elements of differential evolution with discrete optimization methods, potentially improving performance. [25] presents the Dingo optimization algorithm, a novel metaheuristic approach. It is specifically designed to optimize power system stabilizers, which are critical to maintaining system stability. [26] identifies key gaps in the functionality of learning management systems (LMS), providing valuable insights for improving these systems. In [27] focuses on optimizing the placement and operation of distributed generation plants to minimize losses in electrical systems. Due to the large amount of data, detailed and high-quality data may be required for accurate modeling, which may not always be available. In [28] provides a linear programming approach to a classical combinatorial optimization problem, offering exact solutions. This approach may face scalability issues as the problem size increases. The efficient solution to the problems in [29]–[33] combines column generation with the branch and bound method, making it effective for large-scale integer programming problems.

By solving subproblems independently, such methods enable parallel processing, which can significantly reduce computation time for large-scale problems [34]-[35]. Although the subproblems are solved independently, the method also provides mechanisms to coordinate their solutions, providing a globally optimal solution to the original problem [36]-[39]. In general, decomposition methods are used because they offer a systematic and efficient way to solve large-scale optimization problems while providing efficient and accurate solutions.

This article introduces a significant modification aimed at addressing these challenges, emphasizing the method's pivotal role in operational research and its potential evolution to meet modern computational needs. Through an in-depth analysis, we explore the genesis of this modification, its theoretical foundation, practical applications, and the promising horizon it opens for future research and application in various domains.

Devised as a solution to the computational challenges posed by large-scale linear programming problems, the Dantzig-Wolfe decomposition method represents a critical milestone in the field of optimization. By partitioning a complex problem into a master problem and various subproblems, this method significantly streamlines the computational process, enabling independent management and resolution of problem components. This inherent flexibility and efficiency facilitated early successes in a range of applications, from logistics to network design, setting the stage for further innovations. However, as the complexity and scale of optimization problems have expanded, the method's limitations, particularly in the efficiency of coordinating solutions among subproblems, have become increasingly apparent. This realization has spurred the development of the proposed modification, which seeks to enhance the method's computational efficiency through algorithmic innovation and the integration of modern computational technologies [40].

The imperative for the Dantzig-Wolfe decomposition method, and by extension its proposed modification, lies in the unmet need for efficient solutions to large-scale optimization problems that exceed the capabilities of traditional linear programming techniques. These conventional methods often falter in the face of the immense scale and complexity characteristic of contemporary optimization challenges, rendering them computationally infeasible. The decomposition approach, therefore, emerges not only as a solution to these challenges but as a necessary evolution in the toolkit of operational research, enabling the practical resolution of problems previously considered beyond reach.

Spanning a diverse array of sectors, the Dantzig-Wolfe decomposition method's practical applications underscore its versatility and effectiveness in addressing complex optimization problems. From enhancing efficiency in transportation and logistics to optimizing network designs and streamlining supply chain management, the method's capacity to break down multifaceted problems into manageable subcomponents has been invaluable. The proposed modification promises to further amplify this capacity, offering enhanced computational efficiency that could broaden the method's applicability to even more complex and large-scale problems, thereby extending its utility in real-world scenarios.

The potential of the modified Dantzig-Wolfe method extends far into the future, promising exciting advancements in the field of operational research. With the integration of emerging technologies such as parallel computing, artificial intelligence, and advanced heuristics, the modification opens new avenues for optimizing the efficiency and applicability of the decomposition method. These advancements hold the promise of transforming the landscape of optimization problem-solving, offering more agile, efficient, and scalable solutions to the complex challenges that define the modern era.

II. Methodology

The Dantzig-Wulf method was an important tool for solving large structured models of optimization problems that could not be solved using the standard simplex algorithm. This article illustrates the algorithm of the modified Dantzig-Wulf decomposition method with an efficient, in terms of speed and stability of the computational process, a coordinating task developed by the author for solving problems of a linear programming problem with a block-diagonal structure with binding constraints.

Recently, due to the fact that the implementation of complex algorithms for the study of hierarchical systems, which place great demands on the method, not only from the point of view of the pure speed of the computational process and, from the point of view of the availability of large amounts of memory and, to the speed of the computational process for the formation of recommendations management of complex hierarchical systems under conditions of uncertainty, which led to the fact that the Danzig-Wolfe method became less popular.

In the original Danzig-Wulf decomposition method, the coordinating problem contains the number of rows equal to the sum of the number of equations in the linking constraint - m_0 and the number of block constraints - q. In the developed modification of the decomposition method, the coordinating task contains with contain (m_0+1) rows. Since it is the coordinating task that affects the solution of subtasks by changing the values of the coefficients of the objective function, then reducing the dimension of the coordinating task leads to an increase in the computational efficiency of the decomposition method in $(m_0+q)/(m_0+1)$, times compared to the original decomposition method. The experience of practical application of the decomposition method for solving problems of high dimension was insignificant and, in many cases, unsuccessful. The performed computational experiments for problems with matrix order from 90 to 700 showed that, in terms of the number of iterations to obtain the optimal plan, the proposed modification of the Danzig-Wulf decomposition method has the same convergence as the simplex method, but the requirements for computer memory are reduced, and the computational efficiency is increased in $(m_0+q)/(m_0+1)$ times.

III. Results and Discussion

Proposed modification below of decomposition method is a further its development [1]-[8], [11], [12], [16] aimed at improve the efficiency of the method to solve problems linear programming in the block diagonal structure with binding constraints of the following form.

$$
\left.
\begin{array}{ll}
z = C_1x_1 + \ldots + C_kx_k + \ldots + C_nx_n \ \min & (1)\\
A_1x_1 + \ldots + A_kx_k \ + \ \ldots + A_Nx_N = b_0 & (2)\\
D_1x_1 \qquad\qquad\qquad\qquad \geq b_1, & \\
\ldots & \\
\qquad D_kx_k \qquad\qquad\qquad \geq b_k, & (3)\\
\qquad\qquad \ldots & \\
\qquad\qquad\qquad D_Nx_N \qquad \geq b_N, & \\
x_i \geq 0, i = 1,\ldots,k\ldots,N &
\end{array}
\right\}
$$

Taking as its first support program - an artificial basis to replace the task (1) - (3) of the extended task, associated with the minimization of a linear form.

$$
\begin{aligned}
z = C_1x_1 + C_2x_2 + \cdots + C_qx_q + \\
+W(\xi_1 + \xi_2 + \ldots + \xi_q + \xi_0)
\end{aligned}
\qquad (4)
$$

variable problem, subject to conditions

$$
\left.
\begin{array}{llll}
A_1x_1 + A_2x_2 + \ldots + A_qx_q & & + E_0\xi_0 = b_0 & (5)\\
D_1x_1 & + E_1\xi_1 & = b_1, & \\
\quad D_2x_2 & \quad +E_2\xi_2 & = b_2, & \\
\qquad \ddots & \qquad \ddots & \vdots & \\
\qquad\qquad D_qx_q & \qquad +E_q\xi_q & = b_q, & (6)
\end{array}
\right\}
$$

$$
\begin{gathered}
x_1 \geq 0, x_2 \geq 0, \ldots, x_q \geq 0,\\
\xi_1 \geq 0, \xi_2 \geq 0, \ldots, \xi_q \geq 0, \xi_0 \geq 0.
\end{gathered}
$$

Here $C_i = (C_{i1},\ldots, C_{im_i})$ - line vector;

$b_i = (b_{i1}, \ldots, b_{im_i})$- vector - columns of the right sides of restrictions;

$\xi_i = (\xi_{i1}, \ldots, \xi_{im_i})$ - vector - columns of artificial variable;

$A_k = [a_{ij}]_{m_0,n_0}$, $D_k = [a_{ij}^k]_{m_k,n_k}$ - blocks of the matrix conditions;

E_i - single block matrix;

W - coefficients of artificial variables of the problem.

We will now present a modified version of decomposition method of Dantzig - Wolfe. Denoted by Ω - many plans, given the conditions (5) and (6), by Ω_1 - a lot of plans, given the conditions (5), Ω_2- a lot of plans, given the conditions (6).

It's obvious that $\Omega = \Omega_1 \cap \Omega_2$.

We introduce the following notation for the extended tasks:

$$
\begin{aligned}
(x_i|\xi_i)' = y_i, (A_i|0) = \bar{A}_i, (D_iE_i) = \\
= \bar{D}_i, (C_i \underbrace{W\ldots W}_{m_i}) = \bar{C}_i.
\end{aligned}
\qquad (7)
$$

Then the problem (4) - (6) can be written as: find a vector $y = (y_1 \ldots y_q)'$, minimizing the objective function:

$$z = \bar{C}_1y_1 + \bar{C}_2y_2 + \ldots + \bar{C}_qy_q + W\xi_0, \qquad (8)$$

with constraints:

$$\bar{A}_1y_1 + \bar{A}_2y_2 + \ldots + A_qy_q \qquad + E_0\xi_0 = b_0, \qquad (9)$$

$$
\left.
\begin{array}{lll}
\bar{D}_1y_1 & & = b_1,\\
\quad \ddots & \vdots & \\
\qquad \bar{D}_ky_k & & = b_k,\\
\qquad\quad \ddots & \vdots & \\
\qquad\qquad \bar{D}_qy_q & & = b_q,
\end{array}
\right\} \qquad (10)
$$

$$y_i \geq 0, i = 1,\ldots,q, \xi_0 \geq 0,$$

We introduce the following notation:

$$
\begin{aligned}
\bar{C} = (\bar{C}_1 \ldots \bar{C}_q), \bar{A} = (\bar{A}_1|\bar{A}_2|\ldots|\bar{A}_q), b_0 = \\
= (b_1 \ldots b_q)',
\end{aligned}
\qquad (11)
$$

$$
\bar{D} \ = \left|
\begin{array}{ccccc}
\bar{D}_1 & & & & \\
 & \ldots & & & \\
 & & \bar{D}_k & & \\
 & & & \ldots & \\
 & & & & \bar{D}_q
\end{array}
\right| \qquad (12)
$$

Then the problem (7) - (8) formed another way: find a vector y, minimizing:

$$Z = W\xi_0 + \bar{C}\,Y, \qquad (13)$$

with constraints:

$$E_0\xi_0 + \bar{A}\cdot y = b_0, \qquad (14)$$

$$\bar{D}_y = b, y \geq 0. \qquad (15)$$

Many Ω_2 , given the restrictions (14) can be, as well as a convex polyhedron, and unlimited convex polyhedron.

1) Consider first the case when Ω_2 - bounded set (convex polyhedron). Then any element $y \in \Omega_2$can be represented by $y^i, j,..., N$ as a convex combination of the vertices of the

polyhedron Ω_2.

$$y = \sum_{j=1}^{N} a_i y^j , \sum_{j=1}^{N} a_i = 1 , a_i \geq 0, j = 1,\ldots,N \tag{16}$$

Therefore, the problem (13) - (15) can be interpreted as follows: it is necessary to select all of the pixels $y \in \Omega_2$such that satisfy equations (14) and minimize the function (11).

Substituting (16) into (13) yields the following so-called "coordination" problem: minimize:

$$Z = W\xi_0 + \sum_{j=1}^{N} f_j a_j \tag{17}$$

with constraints

$$E_0\xi_0 + \sum_{j=1}^{N} p_j a_j = b_0, \tag{18}$$

$$\sum_{j=1}^{N} a_j = 1, a_j \geq 0, j = 1,\ldots,N \tag{19}$$

were,

$$f_j = \bar{C}y^j = \left(\bar{C}_1 y_1^j + \cdots + \bar{C}_q y_q^j\right),$$

$$P_j = \bar{A}y^j = (\bar{A}_1|\ldots|\bar{A}_q)(y_1^j \ldots y_q^j)'.$$

Constraint matrix (18), (19) has just $(m_0 + 1)$ lines, but much larger than the original object (13) - (15) the number of variables. However, this problem can be solved by having to start only one extreme point of the polyhedron Ω_2 and use, as will be shown below the "Column generation method" [3].

Such starting at the point in this case is one of the vertices of the polyhedron defined by constraints (15) in the extended problem, namely:

$$y_1 = (0|\xi_i|\ldots|0|\xi_q)' = (0|b_1|\ldots|0|b_q)'. \tag{20}$$

To this point we have:

$$\left.\begin{aligned} f_1 &= \bar{C}y^1 = W(\textstyle\sum_{i=1}^{m_i} b_{1i} + \ldots + \sum_{i=1}^{m_q} b_{qi}), \\ P_1 &= \bar{A}y^1 = (\underbrace{0\ldots0}_{m_0}). \end{aligned}\right\} \tag{21}$$

Therefore, it corresponds to the initial reference plan of the coordinating problem $\xi_0 = b_0, a_1 = 1$, the basic matrix B of dimension $(m_0 + 1)$ and the vector of coefficients of the objective function:

$$f_B = (\underbrace{W\ldots W}_{m_0} f_1). \tag{22}$$

Suppose that as a result of the previous iteration received support program $\Lambda^S = (a_{ij}, \ldots, a_{i_{m0+1}})'$, coordinating tasks and the corresponding basis matrix $B = (P_{i1,}\ldots, P_{i_{m_0+1}})$.

At the same time, we obtain the vector of dual variables:

$$\Pi = f_b \cdot B^{-1} = (\Pi|\Pi_0), \tag{23}$$

where in the vector $\Pi = (\Pi_1 \ldots \Pi_{m0})$ corresponds to the constraints (18), and Π_0- the restriction (19).

In order to determine the possibility of improving the reporting of the support program coordination tasks needed for each no basic conditions vector matrix (18), (19) to calculate the characteristic difference (evaluation):

$$\Delta_o = \Pi \begin{vmatrix} P_j \\ 1 \end{vmatrix} - f_j = \Pi_0 + (\Pi \cdot \bar{A} - \bar{C})y^j. \tag{24}$$

If $max\, \Delta_j = \Delta_s \leq 0$, the solution is optimal and the optimal expansion plan of the problem (13) - (15) is calculated as follows:

$$y = a_{i_1} y^{i_1} + \ldots + a_{i_{m0+1}_1} y^{i_{1m0+1}} \tag{25}$$

If $\max_j \Delta_j = \Delta_s > 0$, then this solution is not optimal coordination problems and need to go to the support program of the problem with a smaller value of the linear form (6).

Finding $\max_j \Delta_j$ equivalenting solving subtasks of the form:

minimize:

$$Z_i = (\bar{C} - \pi\bar{A}) \cdot y, \tag{26}$$

when restrictions:

$$\bar{D}y = b,\ y \geq 0. \tag{27}$$

The separability of the objective function (26) and limits the independence of (15) it follows that the problem (26), (27) splits into q mutually independent sub-tasks to the following:

minimize:

$$Z_i = \bar{C}_\pi^i y_i \tag{28}$$

with constraints:

$$D_i y_i = b_i,\ y_i \geq 0. \tag{29}$$

$$\overline{C_\pi^i} = (\bar{C}_i - \pi\bar{A}_i),\ i = 1, \ldots, q. \tag{30}$$

To solve subtasks q (28), (29) we use the simplex method in combination with the method of artificial bases. Due to the limited set of Ω_2 the new support program is received by solving the subtasks:

$$y^s = \left(y_1^s\, y_2^s\, \ldots\, y_q^s\right) \tag{31}$$

is one of the vertices of the polyhedron Ω_2.

If this plan:

$$Z^s - \pi_0 = \sum_{i=1}^{q} Z_i^s - \pi_0 =$$

$$= \sum_{i=1}^{q} (\bar{C}_i - \pi\bar{A}_i) y_i^s - \pi_0 = 0 \tag{32}$$

That support plan Λ^i coordinating tasks is optimal. If

$$Z^s - \pi_0 < 0 \tag{33}$$

It is possible to further decrease the objective function, and then the base matrix B must be turned vector:

$$\overline{P_s} = \begin{vmatrix} \bar{A} & & y^s \\ & 1 & \end{vmatrix} = \begin{vmatrix} \overline{A_1}y_1^s + & \dots & +\overline{A_q}y_q^s \\ & 1 & \end{vmatrix}, \tag{34}$$

and vector $f_B -$ element $f_s = \bar{C}y^s$.

Thus, necessary at each iteration column is generated by solving q local sub (25), (26).

Since the known degradation $\Lambda^i = (d_{i1} \dots d_{im_0+1})'$ and $\Lambda^s = (d_{is} \dots d_{im_0+s})'$, $(b_0/1)'$ and $\bar{P}_s$ on the basis vectors under consideration B, then for the vector output from the basis of need as usual to find relations

$$\frac{d_{ik}}{d_{i_k s}} \text{ for all } d_{i_k s} > 0 \tag{35}$$

and to withdraw from the basis vector $\bar{P}_{ir}$,, appropriate, the least of these relations.

If all $d_{i_k s} > 0$, the coordinating problem has no solution, and the objective function in the original problem (13) - (15) is unlimited.

Thus obtained a new base matrix B corresponds to the new support plan for coordinating tasks, which again is tested for optimality.

2) Consider now the case when Ω_2 - unlimited a multifaceted set and $y^j, j =, \dots, N_1 -$ set of its vertices and $R_j, j =, \dots, N_2 -$set of direction vectors of the unbounded edges, which are known [5] It is defined as a non-zero solution of the matrix of the homogeneous equation:

$$\bar{D} \cdot y = 0. \tag{36}$$

Then any y∈ element can be represented as

$$\left.\begin{array}{c} y = \sum_{j=1}^{N_1} d_j y^j + \sum_{j=1}^{N_2} \beta_j R_j \ , \\ \sum_{j=1}^{N_1} d_j = 1, \\ d_j \geq 0, j = 1, \dots, N_1, \beta_j \geq 0, j = 1, \dots, N_2 \end{array}\right\} \tag{37}$$

Substituting (33) into (10) and (11) yields "coordinating task" of the form:

Minimize:

$$Z = W_{\xi_0} + \sum_{j=1}^{N_1} f_j d_j + \sum_{j=1}^{N_2} f_{N_1+j} \beta_j, \tag{38}$$

with constraints:

$$\left.\begin{array}{c} E_0\xi_0 + \sum_{j=1}^{N_1} P_j d_j + \sum_{j=1}^{N_2} P_{N_1+j} \beta_j = \mathrm{b}_0, \\ \sum_{j=1}^{N_1} d_j = 1, \\ d_j \geq 0, j = 1, \dots, N_1, \beta_j \geq 0, j = 1, \dots, N_2 \end{array}\right\} \tag{39}$$

$$f_{N_1+j} = \bar{C}R_j, P_{N_1+j} = \bar{A}R_j \ , j = 1, \dots, N_2 \tag{40}$$

From the preceding, this case differs in that the coordinating task (34) for checking on the optimality of one of the reference plans (39) it is possible that at least one of the subs (25) and (26) can turn unlimited solution.

Suppose that the k-th subtask

$$\min Z_k = \bar{C}_\pi^k y_{k_1} + \dots + \bar{C}_{\pi, n_k+m_k}^k \ \ y_{k, n_k+m_k,} \tag{41}$$

$$\bar{D}_k y_k = b_k, \ \ y_k \geq 0,$$

on one of the iterations received the support plan:

$$y_k = \left(y_{k1} \dots y_{km_k} \ \ \underbrace{0 \dots 0}_{n_k} \right)' \tag{42}$$

which is connected with a system of linearly independent vectors $\bar{P}_1^k, \bar{P}_2^k, \dots, \bar{P}_{m_k}^k$, form a basis. Suppose, for some vector $\bar{P}_j$,, included in the matrix of conditions $\bar{D}_k$ and not belonging to a number of basic, all the coefficients $(y_k)_{1j}, (y_k)_{2j}, \dots, (y_k)_{m_k j}$ expansion him on the basis vectors were non-positive, and evaluation:

$$\Delta_j = \bar{C}_{\pi 1}^k (y_k)_{1j} + \dots + \bar{C}_{\pi m_k}^k \ (y_k)_{m_k j} - \bar{C}_{\pi j}^k > 0 \tag{43}$$

This means that in the k-th subtask is not an optimal plan and the objective function $Z_k$is unlimited.

Then directive vector of unlimited ribs, along which there is an unlimited decrease in the objective function (23) is determined by solving the equation (36), which is written as follows:

$$\sum_{i=1}^{k-1} \sum_{j=1}^{n_i} \bar{P}_j^i \cdot 0 + \left[\bar{P}_1^k (y_k)_{1j} + \dots + \bar{P}_m^k (y_k)_{m_k j} + \sum_{i=m_k+1}^{j-1} \bar{P}_i^k \cdot 0 - \bar{P}_j^k + \sum_{i=j+1}^{n_k} \bar{P}_i^k \cdot 0 \right] + \sum_{i=k+1}^{q} \sum_{j=1}^{n_i} \bar{p}_j^i \cdot 0 = 0 \tag{44}$$

After discarding zero terms in this vector equation of we obtain a new equation that determines the nonzero vector elements R_s:

$$\bar{P}_1^k (y_k)_{1j} + \dots + \bar{P}_{m_k j} - \bar{P}_i^k = 0. \tag{45}$$

This shows that $(n_1 + m_1 + \dots + n_q + m_q)$ is dimensional vector:

$$R_k^s = \left(\underbrace{0 \dots 0}_{\sum_{i=1}^{k-1}(n_i+m_j)} \ - (y_k)_{1j} - \dots - (y_k)_{m_k j} \ \underbrace{0 \dots \ 0 \ 1 \ 0 \dots \ 0}_{n_k} \ \underbrace{0 \dots 0}_{\sum_{i=k+1}^{q}(n_i+m_j)} \right) \tag{46}$$

is the direction vector of unlimited ribs of convex polyhedron Ω_2. In this case, the support program coordination problem (38), (39) the condition (33), hence the reference plan is not optimal and to improve it, it is necessary in the basic matrix of the coordinating tasks include vector:

$$\bar{P}_S = \begin{vmatrix} \bar{A} & R_S \\ & 0 \end{vmatrix} \tag{47}$$

Instead of one of the old vectors being found by the usual simplex method for the rule, and in vector - f_B element$f_s = \bar{C} \cdot R_S$. After a finite number of iterations is obtained an optimal solution coordinating task, or make sure the target function is unbounded on an admissible set of plans.

Obviously, the solution may be unlimited in not one, but several subtasks. Given the fact that this case is not in the literature reviewed, we explain it in detail.

Without loss of generality, assume that an unlimited decision turned out not only to the first, but also, for example, in the l-th subtask $l \neq \kappa,\ \kappa \leq q,\ \ l \leq q$. Then, for some of the support program and the corresponding basis by the decomposition of one of the no basic vectors $\overline{P_t}^l$ got rating $\Delta_t^l > 0$, all coefficients $(y_l)_{1t} \dots (y_l)_{mlt}$ its decomposition are non-negative. Therefore, in addition to unlimited ribs with direction vector R_S^K defined by (46), there is another unrestricted edge with direction vector:

$$R_S^l = (\underbrace{0 \dots 0}_{\sum_{i=1}^{l-1}(n_{i+}m_i)} \quad - (y_l)_{1t} - \cdots - (y_l)_{mlt} \underbrace{\overset{0 \dots 01\ 0 \dots 0}{t}}_{n_l} \underbrace{0 \dots 0}_{\sum_{i=l+1}^{q}(n_{i+}m_i)} \tag{48}$$

In this case, the formation of a new vector introduced into the basis of the coordinating task, as follows from the theory of linear programming, to reduce the number of iterations should choose the direction vector, which corresponds to the greater value Δ evaluation. If, for example $\Delta_j^K > \Delta_t^K$, then

$$\overline{P_S} = \begin{vmatrix} \overline{A} & R_S^K \\ & \\ 0 & \end{vmatrix} \tag{49}$$

Proceeding in accordance with this rule, after a finite number of iterations we obtain the optimal solution coordinating tasks, or define that the objective function is unbounded on an admissible set of plans.

This version of the method of decomposition of Danzig - Wolfe is different from normally recommended for linear programming problems such as (1) - (3) the fact that in the last set Ω2 plans presented in the form of a direct product of the sets Ω21... Ω2q, given restrictions:

$$\overline{D_i} y_i = b_i, i = 1, \dots., q. \tag{50}$$

Then, if, for example, all Ω2i, I = 1,…,q - convex polyhedral, any element y € Ω2 can be represented as a convex combination of extreme points y_i^j, i=1, …, q, j=1, …, N1 , polyhedral Ω21... Ω2q:

$$\left.\begin{array}{c} y = \sum_{i=1}^{q} \sum_{i=1}^{N_i} \alpha_{ij} y_i^j\,, \\ \sum_{i=1}^{N_i} \alpha_{ij} = 1\,, \\ \alpha_{ij} \geq 0, i = 1, \dots, q, j = 1, \dots, N_i \end{array}\right\} \tag{51}$$

Substituting (51) into (14), (15), we obtain the following coordinating task minimize:

$$Z = W\xi_0 + \sum_{i=1}^{q} \sum_{i=1}^{N_i} f_{ij} \alpha_{ij}\,, \tag{52}$$

with constraints

$$E_0 \xi_0 + \sum_{i=1}^{q} \sum_{i=1}^{N_i} P_{ij} \alpha_{ij} = b_0\,, \tag{53}$$

$$\left.\begin{array}{c} \sum_{j=1}^{N_i} \alpha_{ij} = 1\,, \\ \alpha_{ij} \geq 0, i = 1, \dots, q, \\ j = 1, \dots, N_i, \xi_0 \geq 0 \end{array}\right\} \tag{54}$$

where,

$$f_{ij} = \overline{C_i} y_i^j, \quad P_{ij} = \overline{A_i} y_i^j, \tag{55}$$

In this coordination problem constraints (53) and (54) do not contain $(m_0 + 1)$, and $(m_0 + q)$ lines.

Failures in the application of the Dantzig-Wolfe decomposition method may occur not due to the shortcomings and incorrectness of the method, but due to some features that really affect its convergence.

The latter include the following:

1) The decomposition method is not directly applicable when the right parts of the binding constraints (14) are equal to zero. In this case, the right side of the coordinating problem will contain only one nonzero component corresponding to constraint (19). As a consequence, in the resulting support plan Λ, only the $(m_0 + 1)$-th component will be equal to one, and all the rest will be zero.

As a result, the process of improving the basic plan of the coordinating task loses all meaning. But this phenomenon can be easily avoided, for example, by expressing some variables xij using block constraints (15) in terms of equal parts bi and other variables of the i-th block, and then excluding these variables together with the corresponding equations from the i-th block and from connecting equations. Then, in these blocks, you should add the conditions for the non-negativity of the excluded variables.

The second way is even easier. It consists in the fact that very small positive values are assigned to the right parts of the binding constraints (14), i.e. $b_0 = \mathcal{E}, \mathcal{E} > 0$. The performed computational experiments have shown that for tasks whose optimal plans according to (31) are represented as a linear combination of vertices and unlimited edges, the number of iterations providing the optimal plan, at $\varepsilon = 10^{-4}: 10^{-3}$ has decreased by more than 2-3 times compared to the first method.

This is explained by the fact that the representation of the set of admissible plans according to (33), generally speaking, is ambiguous [5]. Therefore, in the second way of expressing the vector, the optimal solution (25) was obtained in the form of a linear combination of vectors, some of which contained non-zero components from artificial variables, and the coefficients α_i corresponding to these vectors were equal to zero.

2) In those cases when the range of admissible values of the problem variables, given by block constraints (14), is an unlimited polyhedral set, at some iterations of the search for the optimal plan, the problem of choosing from among several one unlimited edge to form a new vector introduced into the number of basis vectors may arise. How to do this is shown above, but the wrong choice of an unbounded edge leads to a loop.

IV. Conclusion

The magnitude of the coordinating problem leads to an increase in the coefficient of the function, to a decrease in its size, to an increase in the computational efficiency of the decomposition method in $(m_0 + q)/(m_0 + 1)$, compared to the original decomposition method.

Consequently, the amount of computer memory required for solving the problem in this case increases. Furthermore, as it coordinates the task affects the decision of subtasks by changing the objective function values of the coefficients, the reduction of its dimensions leads to an increase in computational efficiency decomposition method in $(m_0 + q)/(m_0 + 1)$ times, compared with the original decomposition method.

The advantage of this variant of the method is especially great, in comparison with the recommended one, when the number q of blocks is large, and each of the sets Ω2i, i=1,…,q, corresponding to these blocks, can be specified by a small number m_K of restrictions. It is these cases that are most often encountered in practice when modeling real processes.

In particular, when all $m_K = 1, k = 1, \ldots, q$ (classical transport problem), the usually recommended version of the decomposition method has no advantages over the simplex method, while the considered version of the decomposition method retains all its advantages.

The experience of practical application of the decomposition method for solving high-dimensional problems was insignificant and, in many cases, unsuccessful. The use of the above modification of this method for solving problems of the type (1) - (3) of large dimension refutes these statements as erroneous.

The performed computational experiments for tasks with a matrix order from 90 to 700 showed that, in terms of the number of iterations to obtain the optimal plan, the proposed modification of the Danzig-Wulf decomposition method has the same convergence as the simplex method, but the requirements for computer memory are reduced, and the computational efficiency is increased by $(m_0 + q)/(m_0 + 1)$ times

***Abstract*—The identification and diagnosis of liver diseases hold significant importance within the domain of digital pathology research. Various methods have been explored in the literature to address this crucial task, with deep learning techniques emerging as particularly promising due to their ability to yield highly accurate results compared to other traditional approaches. However, despite these advancements, a significant research gap persists in the field. Many deep learning-based liver disease detection methods continue to struggle with achieving consistently high accuracy rates. This issue is highlighted in numerous studies where traditional convolutional neural networks and hybrid models fall short in precision and recall metrics. To bridge this gap, our study proposes a novel approach utilizing the YOLOv8 algorithm, which is designed to significantly enhance the accuracy and effectiveness of liver disease detection. The YOLOv8 algorithm's architecture is well-suited for real-time object detection and has been optimized for medical imaging applications. Our method involves generating innovative models tailored specifically for liver disease detection by leveraging a comprehensive dataset from the Roboflow repository, consisting of 3,976 annotated liver images. This dataset provides a diverse range of liver disease cases, ensuring robust model training. Our approach includes meticulous model training with rigorous hyperparameter tuning, using 70% of the data for training, 20% for validation, and 10% for testing. This structured training process ensures that the model learns effectively while minimizing overfitting. We evaluate the model using precision, recall, and mean average precision (mAP@0.5) metrics, demonstrating significant improvements over existing methods. Through extensive experimental results and detailed performance evaluations, our study achieves high accuracy rates, thus addressing the existing research gap and providing an effective approach for liver disease detection.**

I. Introduction

Medical image processing, an interdisciplinary field at the intersection of computer science, image analysis, and medicine, holds paramount importance in contemporary healthcare [1], [2]. Its significance lies in its capacity to revolutionize medical diagnostics and treatment by extracting valuable insights from medical images [3], [4]. This transformative technology empowers healthcare professionals with advanced tools that enhance the accuracy of disease detection, streamline diagnosis, and improve patient care, thereby leading to more timely interventions and better outcomes.

Liver disease detection stands out as a critical domain within the realm of medical image processing due to the liver's pivotal role in maintaining metabolic functions and detoxification [5]. Detecting liver diseases, such as cirrhosis, fibrosis, and hepatocellular carcinoma, at an early stage is crucial for improving patient prognosis [6], [7], [8]. Consequently, the significance of precise diagnosis and early intervention in liver diseases cannot be overstated. Thus, research and innovation in liver disease detection represent an essential endeavor to enhance healthcare.

In recent years, computer vision-based methods have been instrumental in advancing liver disease detection [9]. These methods have leveraged image analysis techniques to automate the interpretation of medical images, resulting in more reliable clinical decisions and improved patient care. The field has witnessed notable breakthroughs as medical image datasets have grown in size and complexity, leading to enhanced accuracy and efficiency in detecting liver abnormalities[10], [11]. These advances underscore the potential of medical image processing to impact healthcare further positively.

However, among the various techniques employed in liver disease detection, deep learning-based methods have gained prominent attention from both researchers and practitioners. Deep learning's appeal lies in its ability to autonomously learn intricate features from complex medical images [12], surpassing the capabilities of traditional approaches. Compared to conventional methods, deep learning-based techniques have demonstrated superior performance in liver disease detection tasks [13], [14]. Nevertheless, despite these achievements, several pressing limitations and research gaps persist, primarily due to the high demand for accuracy in medical applications.

Current deep learning-based methods face challenges related to overfitting, generalization, and the interpretability of model decisions, raising concerns about their reliability and practicality in clinical settings. Moreover, the inherent heterogeneity and limited availability of medical image datasets for liver disease further complicate the pursuit of consistently high accuracy. To address these research challenges comprehensively, there is an imperative need for further exploration and innovation in deep learning-based liver disease detection.

In response to these challenges, this study proposes a novel deep-learning method that leverages the Yolov8 algorithm for liver disease detection. The adoption of the Yolov8-based algorithm offers a promising avenue to enhance the accuracy of liver disease detection. Our research encompasses the creation of a model using a comprehensive dataset, followed by rigorous training, validation, and testing processes. Through this approach, we aim to bridge existing research gaps and contribute to the advancement of liver disease detection using deep learning techniques.

The main research contributions are as follows. Firstly, we address the current research gap concerning deep learning-based liver disease detection, providing insights and innovations to enhance its performance. Secondly, we explore previous studies and existing literature to consolidate the state of knowledge in this domain, paving the way for a comprehensive understanding of the field's challenges and potential solutions. Lastly, we conduct extensive experiments and performance evaluations to validate the effectiveness of our proposed method, aiming to provide a robust and reliable tool for liver disease detection in clinical practice.

The organization of this paper is as follows: The initial section provides the introduction and Section II reviews of related works. Second III delves into the material and methods. Section IV encompasses the presentation of results and discussion, and Section V presents the conclusion of the paper.

II. Related Work

This paper [15] presented a liver disease screening method using densely connected deep neural networks. The method utilizes advanced deep-learning techniques to detect liver diseases accurately. While promising, the study acknowledges limitations in the dataset size and the need for further validation on larger and more diverse datasets. Nonetheless, the research demonstrates the potential of deep learning for liver disease screening, with implications for improving medical diagnostics and patient care.

In the study [16], the authors proposed a method that utilizes deep learning and transfer learning to detect liver diseases from CT scan images. While their approach shows promise in preliminary tests, they acknowledge the limitation of lower accuracy rates, particularly in cases involving subtle disease manifestations. Addressing these limitations is crucial to make the model more reliable for accurate diagnosis and treatment planning in clinical settings.

The research in [17] delved into the application of artificial intelligence for diagnosing and treating liver diseases. The method discussed exhibits potential in assisting medical professionals, yet the authors stress the challenge of achieving the high accuracy demanded in clinical practice. Reducing false positives and negatives is imperative, and future work should focus on refining the model's precision to make it a dependable tool in liver disease diagnosis and treatment.

In the study [18], the authors employ YOLOv7 and transfer learning to enable early detection of lung cancer. Despite promising results, the method faces limitations in terms of accuracy and sensitivity, particularly when dealing with the subtleties of early-stage lung cancer. Future research efforts should concentrate on improving the model's precision, especially in identifying subtle early signs of the disease, to enhance its clinical utility.

The research in [19] explored the use of conventional and artificial intelligence (AI)--based imaging techniques for biomarker discovery in chronic liver disease. The method integrates advanced AI approaches with conventional imaging methods to identify potential biomarkers. While the approach shows promise in early diagnosis and disease monitoring, it faces the challenge of achieving the required high accuracy levels for robust clinical applications. Limitations in sensitivity and specificity need to be addressed to make these biomarkers more reliable tools for accurate diagnosis and treatment monitoring in the context of chronic liver disease.

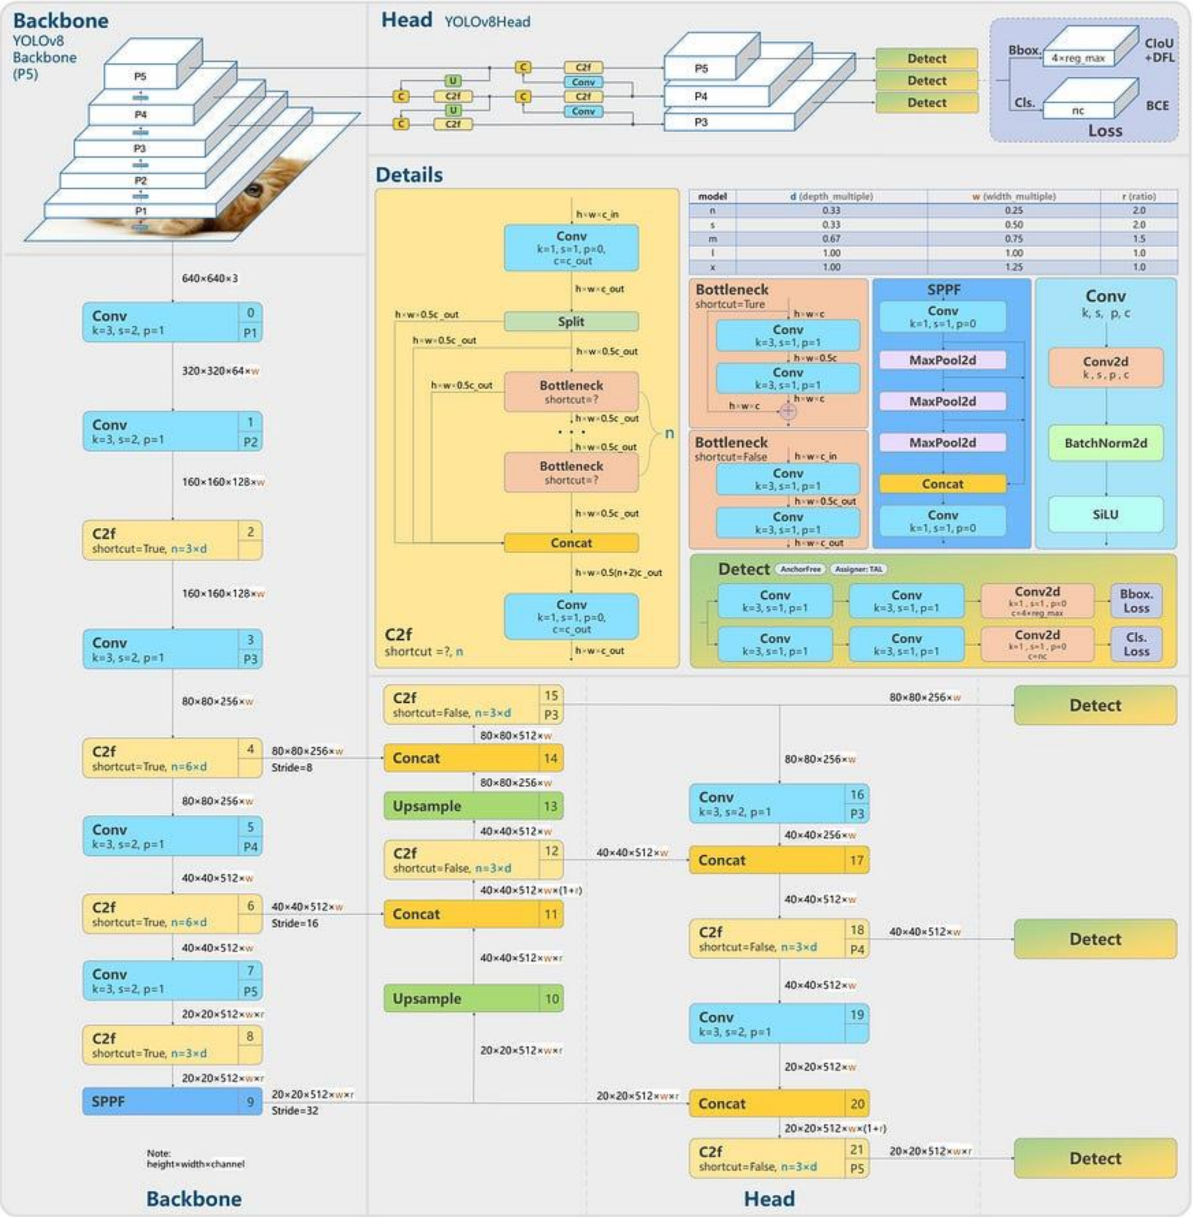
The authors in [20] focused on leveraging deep learning techniques for detecting liver diseases from medical images. While the method showcases potential in identifying various liver ailments, it encounters challenges related to achieving consistently high accuracy rates, especially in cases involving complex disease patterns. The authors highlight the need for further refinement and optimization of the deep learning model to mitigate these limitations and enhance its diagnostic capabilities, ultimately contributing to more accurate disease detection in liver images.

III. Material and Method

A. Yolov8 Algorithm

YOLOv8, an advanced iteration in the YOLO series of object detection algorithms, represents a cutting-edge solution for real-time object detection tasks. Developed by Glenn Jocher at Ultralytics, YOLOv8 combines a flexible Pythonic structure with strong model fundamentals, facilitating rapid model enhancements and widespread community contributions [21]. Its standout features include anchor-free detection, new convolutional layers, and innovative training routines like mosaic augmentation. With a commitment to community support and an emphasis on high accuracy, YOLOv8 has established itself as a go-to choose for computer vision projects, achieving state-of-the-art performance on benchmark datasets and promising continued advancements in the field of object detection.

1) Yolov8 Structure: The structure of the YOLOv8 algorithm is characterized by its innovative approach to real-time object detection, leveraging a series of architectural enhancements and improvements over its predecessors. At its core, it processes the entire image in one forward pass to simultaneously predict bounding boxes and class probabilities for multiple objects. Fig. 1 shows the Yolov8 model structure [22], [23]. An overview of the key components and structure of the YOLOv8 algorithm is discussed in the following sections.



model	d (depth_multiple)	w (width_multiple)	r (ratio)
n	0.33	0.25	2.0
s	0.33	0.50	2.0
m	0.67	0.75	1.5
l	1.00	1.00	1.0
x	1.00	1.25	1.0

Fig. 1. Yolov8 model structure.

a) Backbone network: YOLOv8 employs a CSPDarknet53 backbone network, which is a deep convolutional neural network designed to extract rich features from input images efficiently. The backbone network plays a critical role in feature extraction and contributes to the algorithm's detection accuracy.

b) Anchor-free detection: YOLOv8 introduces anchor-free object detection, a departure from previous YOLO models that relied on anchor boxes. In anchor-free detection, the algorithm directly predicts the center of objects instead of anchor box offsets. This approach reduces the number of box predictions and accelerates post-processing, such as Non-Maximum Suppression (NMS).

c) New convolutions: YOLOv8 incorporates new convolutional layers and modules to enhance feature extraction and model performance. Changes in convolutional layers, such as replacing 6x6 convolutions with 3x3 convolutions, contribute to improved efficiency and accuracy.

d) Mosaic augmentation: The training routine in YOLOv8 includes mosaic augmentation, a technique that stitches four images together. This augmentation strategy encourages the model to learn objects in diverse contexts, including new locations, partial occlusions, and varying backgrounds, thereby enhancing its robustness.

B. Google Colab

We employed Google Colab, granting us complimentary access to robust GPU resources. All the training and testing processes were carried out utilizing a high-performance 12GB NVIDIA Tesla T4 GPU, as elaborated in Fig. 2. All of our models underwent 50 epochs of training with image dimensions set at 640 pixels while adhering to the default YOLO settings for other hyperparameters.

C. Dataset

The dataset utilized in this study was sourced from the Roboflow repository, consisting of a total of 3,976 images. This dataset focuses on liver disease detection, encompassing various pathological classes, including ballooning, fibrosis, inflammation, and steatosis. These high-quality images serve as a valuable resource for training and evaluating machine learning models in the context of liver disease detection, enabling researchers to harness the power of computer vision techniques for precise and early diagnosis of liver-related health conditions. Fig. 3 shows sample images of the dataset.

The data instance distribution in this dataset is well-balanced, ensuring a roughly equal number of instances across different classes of liver disease, including ballooning, fibrosis, inflammation, and steatosis. This balanced distribution aids in preventing class imbalance issues during machine learning model training and promotes robust performance across various pathological conditions. Additionally, each data instance in the dataset is meticulously annotated with its corresponding instance label, providing precise information about the specific liver disease class to which it belongs. These annotated instance labels are crucial for supervised learning tasks, enabling the model to learn and make accurate predictions based on the ground truth information associated with each image, ultimately enhancing the model's diagnostic capabilities in liver disease detection. Fig. 4 illustrates data distribution and instance labelling of images.

D. The Proposed Method

The proposed method for liver disease detection leverages the YOLOv8 architecture, specifically designed for rapid and accurate object detection. Our approach involves several key steps: data collection, model training, model evaluation, performance analysis, and comparative experiments. For data collection, we utilized the Roboflow repository, which provided a comprehensive dataset of 3,976 liver images annotated with relevant disease markers. This dataset is critical as it ensures the model is exposed to a wide variety of liver conditions, enhancing its ability to generalize across different scenarios. The images were divided into three sets: 70% for training, 20% for validation, and 10% for testing. This partitioning strategy ensures that the model is adequately trained, validated during development, and rigorously tested to evaluate its performance on unseen data.

Model training was conducted using different versions of YOLOv8, namely YOLOv8n, YOLOv8s, YOLOv8m, and YOLOv8l, each representing varying degrees of complexity and capacity. YOLOv8n is the smallest and fastest model, designed for applications requiring high speed with moderate accuracy. YOLOv8s offers a balance between speed and accuracy, making it suitable for real-time applications. YOLOv8m and YOLOv8l are larger models, providing higher accuracy at the cost of increased computational requirements. The training process involved fine-tuning hyperparameters such as learning rate, batch size, and number of epochs. The learning rate was set to 0.001, with a batch size of 16, and the models were trained for 50 epochs. These settings were chosen based on initial experiments to optimize model performance while preventing overfitting. Data augmentation techniques such as rotation, scaling, and flipping were applied to enhance the model's robustness.

Fig. 2. Details of google colab' GPU.

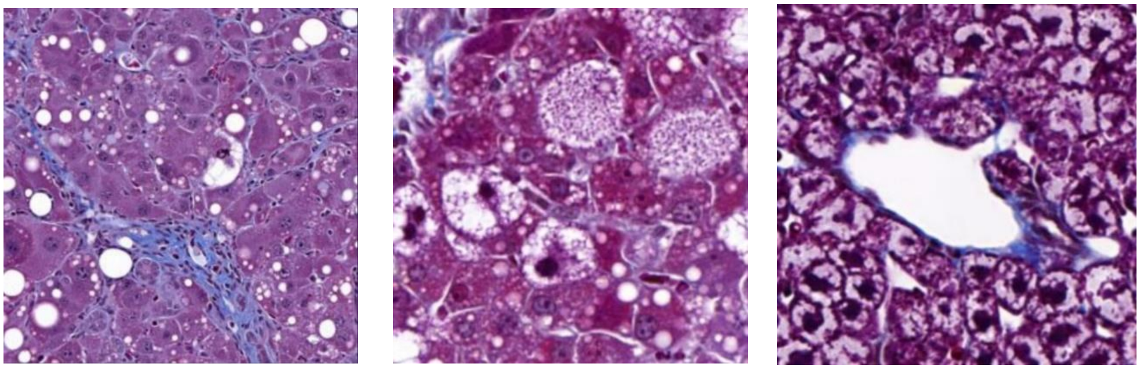

Fig. 3. Sample images of the dataset.

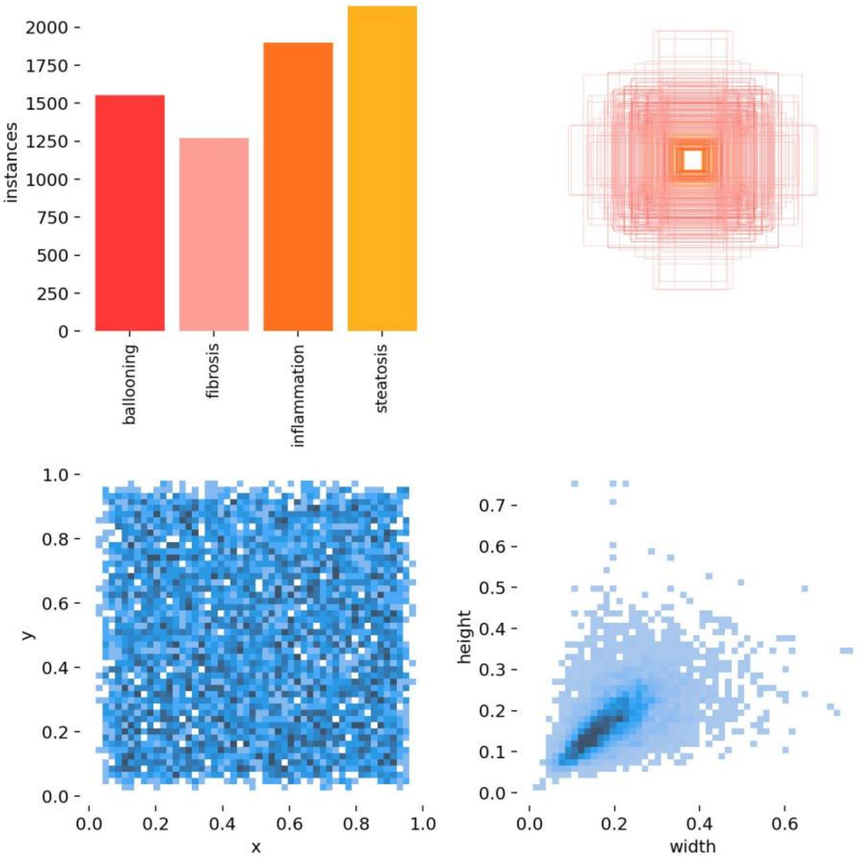

Fig. 4. Data distribution and instance labelling of image data.

For model evaluation, we utilized precision, recall, and mean average precision (mAP@0.5) as key performance metrics. Precision measures the accuracy of the positive predictions, recall assesses the model's ability to identify all relevant instances, and mAP@0.5 provides a comprehensive evaluation of the model's detection performance at a specific intersection over union threshold. The evaluation showed that the YOLOv8s model achieved the highest metrics with a precision rate of 0.94%, a recall rate of 0.96%, and an mAP@0.5 rate of 0.59%. To ensure a thorough comparison, we conducted experiments using other existing liver disease detection methods, including UNet-60, CNN + SVM, Random Forest, and Chaotic Cuckoo Search + AlexNet. These comparisons highlighted the superior performance of our proposed YOLOv8-based method, demonstrating its potential as a reliable tool for liver disease diagnosis in clinical settings. The rigorous evaluation and comparative analysis underscore the effectiveness of YOLOv8 models in detecting liver diseases from image data, paving the way for enhanced diagnostic capabilities. Table I shows the proportion of each training, validation and testing image sample.

TABLE I. NUMBER OF IMAGES IN TRAINING, VALIDATION, AND TESTING SETS

Modules	Training	Validation	Testing
Number of images	2782	794	400

1) Training module: The training phase played a pivotal role in the development of the YOLOv8 model. To maximize accuracy in liver disease detection, several key hyperparameters were carefully configured. The learning rate, a critical hyperparameter governing the rate at which the model updates its parameters during training, was fine-tuned for optimal convergence. We set the learning rate to 0.001, with a smaller value being favored for fine-tuning. Additionally, the batch size was set to 16, number of epochs was set to 50 for YOLOv8 training.

2) Validation module: The validation module played a crucial role in assessing the model's performance during training. It involved using a separate portion of the dataset (the validation set) that was not used during training. The purpose was to monitor the model's progress and detect signs of overfitting or underfitting. The validation set helped in determining the optimal number of training epochs to prevent overfitting, and it allowed for the fine-tuning of hyperparameters, such as the learning rate and batch size, to strike a balance between model accuracy and generalization. We tuned the model based on model validation.

3) Testing module: The testing module was the final stage in evaluating the YOLOv8 model's performance. Here, the model's effectiveness in detecting liver diseases on unseen data (the testing set) was rigorously assessed. This phase provided insights into the model's real-world applicability and its ability to generalize to previously unseen cases. The testing module aimed to measure key metrics such as precision, recall, and mAP to quantify the model's accuracy and its capability to identify liver disease instances correctly. The details of the testing model and the metrics are discussed in the following sections. We use these metrics to test the effectiveness of the model.

IV. Experimental Results

This section presents the experimental results and outputs obtained from our generated YOLOv8 model for liver disease detection. As illustrated in the Fig. 5, the model's output provides insights into its ability to identify different classes of liver diseases, including ballooning, fibrosis, inflammation, and steatosis. These classes represent critical pathological conditions that demand accurate detection for effective medical diagnosis. The figures showcase the model's predictions and highlight its capacity to delineate between these distinct disease categories as shown in Fig. 5.

A. *Performance Evaluation*

In this section, we investigate the performance evaluation of our YOLOv8 model using standard key metrics such as precision, recall and mean average precision (mAP) [25] Precision quantifies the model's ability to make correct positive predictions among all positive predictions, while recall measures the model's capability to identify all actual positive instances correctly. The mAP provides an aggregate assessment of the model's accuracy across multiple classes, offering valuable insights into its overall performance. Furthermore, the F1 score represents a harmonized measure of precision and recall, balancing the trade-off between false positives and false negatives. The comprehensive results of these performance metrics, stemming from extensive experimentation, are graphically depicted in the accompanying figures, offering a clear overview of the YOLOv8 model's effectiveness in the precise detection of liver diseases, ultimately contributing to improved medical diagnostics.

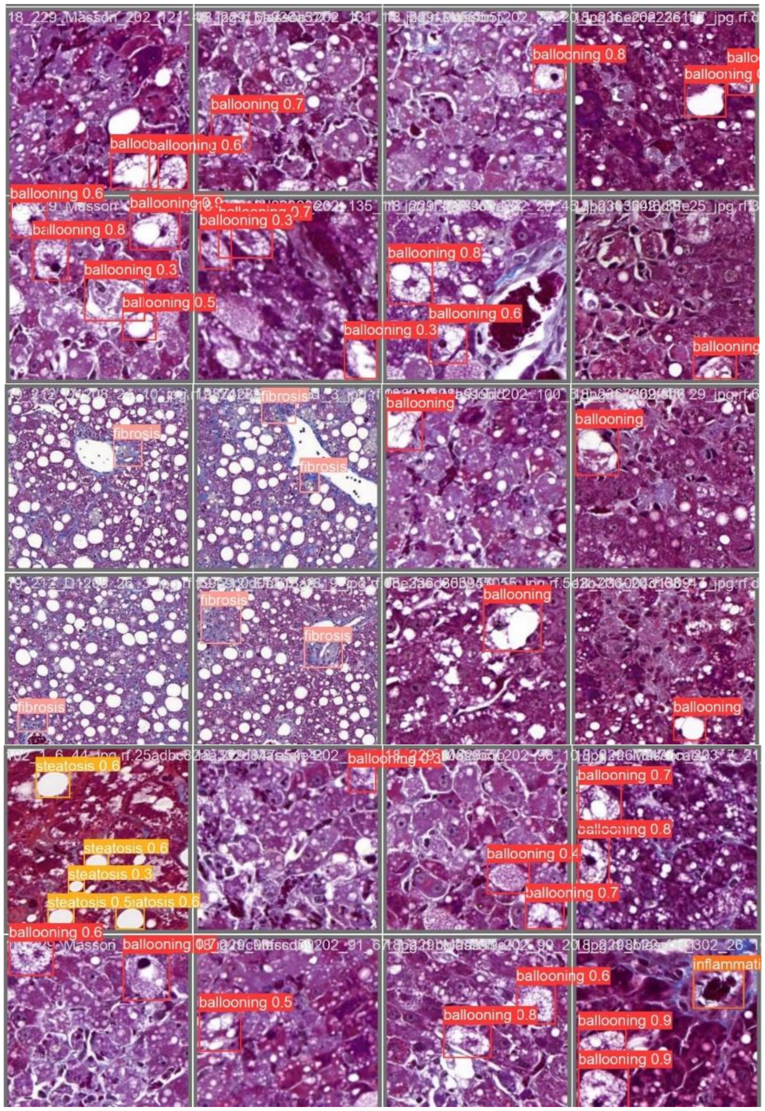

Fig. 5. Experimental results output.

1) Precision curve: To assess the performance of the YOLOv8 model, we employ the precision curve, a vital tool in evaluating liver disease detection algorithms. The precision curve, also known as the precision-accuracy curve, is a valuable tool used to evaluate the performance of the YOLOv8 model and similar object detection systems. This curve illustrates how the precision of the model varies with changes in confidence thresholds. The precision is typically measured using the following equation:

$$Precision\ (Positive\ Predictive\ Value) = TP\ /\ (TP\ +\ FP)$$

Where:

a) True Positives (TP): These are instances where our YOLOv8 model correctly identifies and classifies a liver disease, such as ballooning, fibrosis, inflammation, or steatosis, as positive. In other words, TP represents the number of cases where the model's prediction matches the actual presence of the disease within the dataset.

b) False Positives (FP): These are instances where our model incorrectly identifies and classifies a case as positive when, in reality, it is not. In the context of liver disease detection, FP would occur if the model falsely predicts the presence of a disease when there is none or if it assigns the wrong disease class to an image.

As shown in Fig. 6, the precision represents the proportion of true positive detections relative to all predicted positive instances at a specific confidence threshold. To construct the curve, confidence thresholds are systematically adjusted, and precision values are recorded at each threshold setting. These precision values are then plotted to create the precision curve, which provides insights into how the model's precision changes as the confidence threshold. As depicted in Fig. 6, on average, we achieved a 0.95% rate for precision in all classes, which means the model is accurate in liver disease detection.

2) Recall curve: In evaluating the performance of the YOLOv8 model, in addition, we employ the recall curve, which is another critical metric for assessing the model's effectiveness in correctly identifying positive instances. The recall, also known as sensitivity, measures the proportion of true positive detections relative to all actual positive instances within the dataset. The recall equation is expressed as:

$$Recall\ (Sensitivity)\ =\ TP\ /\ (TP\ +\ FP)$$

Where, as defined above, the *TP is* the number of correctly predicted positive instances by the model.

a) FN (False Negatives): The number of instances that were incorrectly predicted as negative by the model when they were actually positive.

As depicted in Fig. 7, the recall curve is constructed by systematically varying confidence thresholds, recording recall values at each threshold setting, and plotting them. This curve provides insights into how the model's recall rate changes with adjustments in the confidence threshold. The obtained recall rate of 0.96% across all classes serves as a significant validation of the YOLOv8 model's effectiveness in liver disease detection. This high recall rate signifies that the model successfully identifies 96% of all actual positive instances of liver diseases within the dataset. Such a remarkable recall rate underscores the model's capability to comprehensively capture and correctly classify these diseases, including ballooning, fibrosis, inflammation, and steatosis. It further implies that the model minimizes the risk of false negatives, which is crucial in the context of medical diagnostics. In essence, the high recall rate stands as a compelling justification for the model's effectiveness, as it assures that the YOLOv8 model is adept at accurate and reliable liver disease detection, a pivotal advancement in the realm of medical imaging and diagnostics.

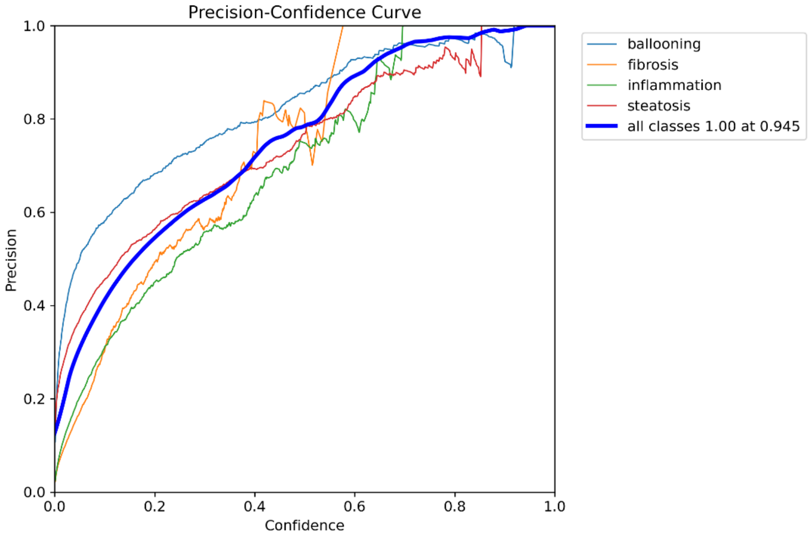

Fig. 6. Precision curve.

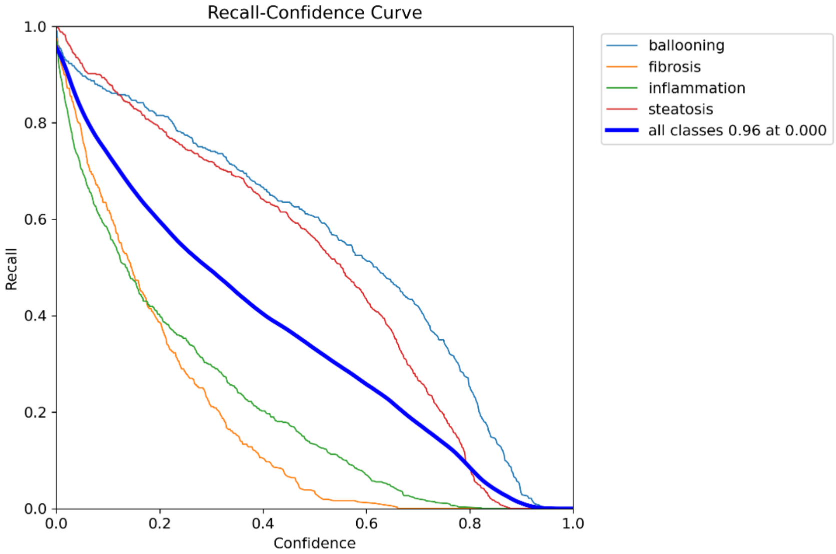

Fig. 7. Recall curve.

3) Precision-recall curve: In assessing the YOLOv8 model's performance for liver disease detection, we utilize the mean average precision (mAP) metric, often associated with the precision-recall curve. The mAP quantifies the model's accuracy in detecting objects, such as liver diseases, across multiple classes and various confidence thresholds. It is calculated as the average of the precision values at different recall levels. The equation to measure mAP is:

$$mAP\ (Mean\ Average\ Precision) = (AP\_1\ +\ AP\_2 + \ldots + AP\_n)\ /\ n$$

Where the *Average Precision for Class n (AP_n)* represents the precision-recall curve's area under the curve (AUC) for each specific class.

As illustrated in Fig. 8, the obtained mAP rate of almost 0.59% at a confidence threshold of 0.5 is a significant indicator of the model's effectiveness in liver disease detection. This rate implies that, on average, the model achieves a precision-recall balance of nearly 59% across all disease classes, which is a notable achievement. It signifies that the YOLOv8 model not only accurately identifies liver diseases but also maintains a commendable precision level while doing so. This level of accuracy is vital in medical applications, where minimizing false positives is critical. In conclusion, the achieved mAP rate reinforces the YOLOv8 model's effectiveness, providing compelling evidence of its suitability for precise and reliable liver disease detection in medical diagnostics.

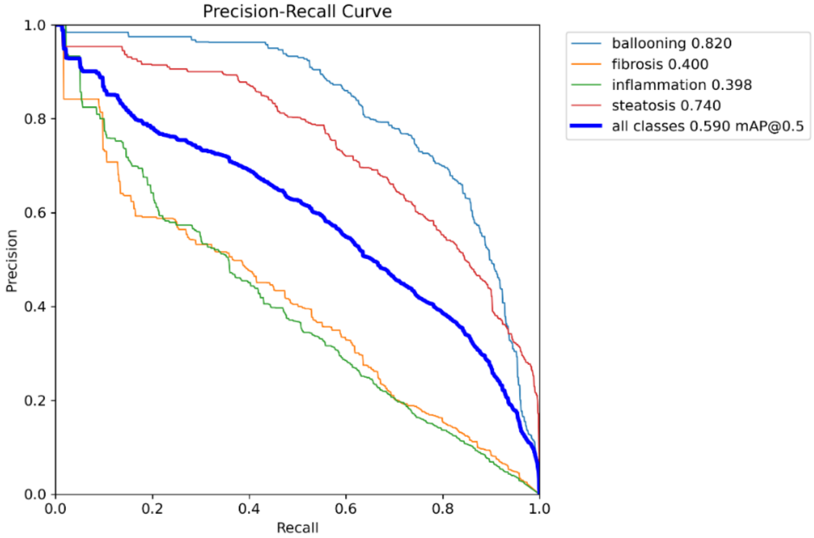

Fig. 8. The mAP curves.

B. Models Comparison

In our pursuit of achieving an accurate and effective model for liver disease detection, we conducted extensive experiments with various YOLOv8 model configurations, namely YOLOv8n, YOLOv8s, YOLOv8m, and YOLOv8l. These experiments yielded a comprehensive set of performance results across all disease classes, including precision, recall rate, and mAP@0.5 score, allowing us to scrutinize and compare the models thoroughly. Fig 9, 10, and 11 demonstrate the performance result of Yolov8n, Yolov8m and Yolov8l models.

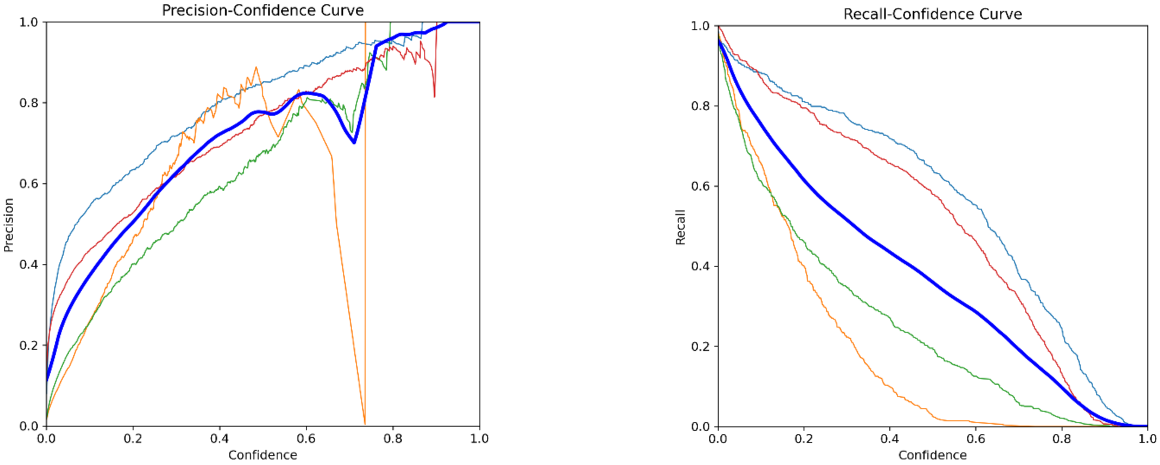

Fig. 9. Performance results of Yolo8n.

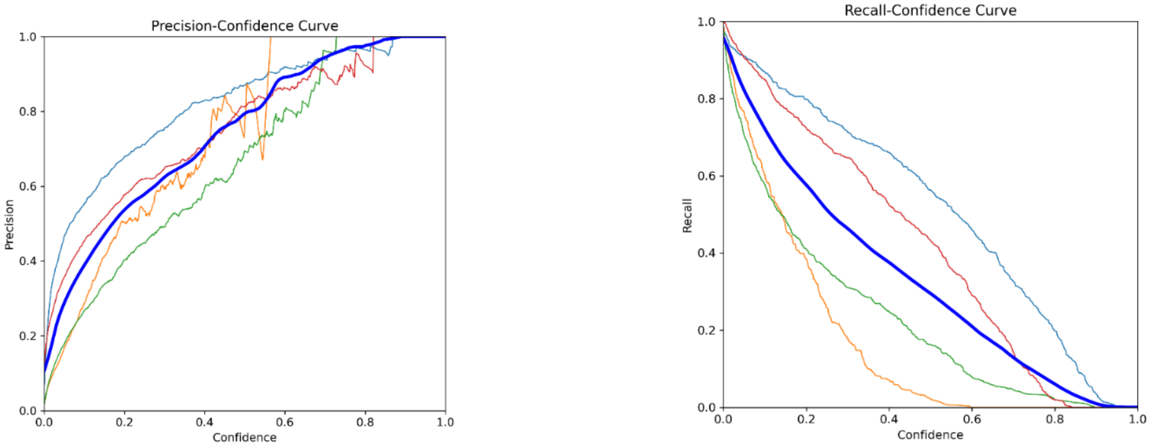

Fig. 10. Performance results of Yolo8m.

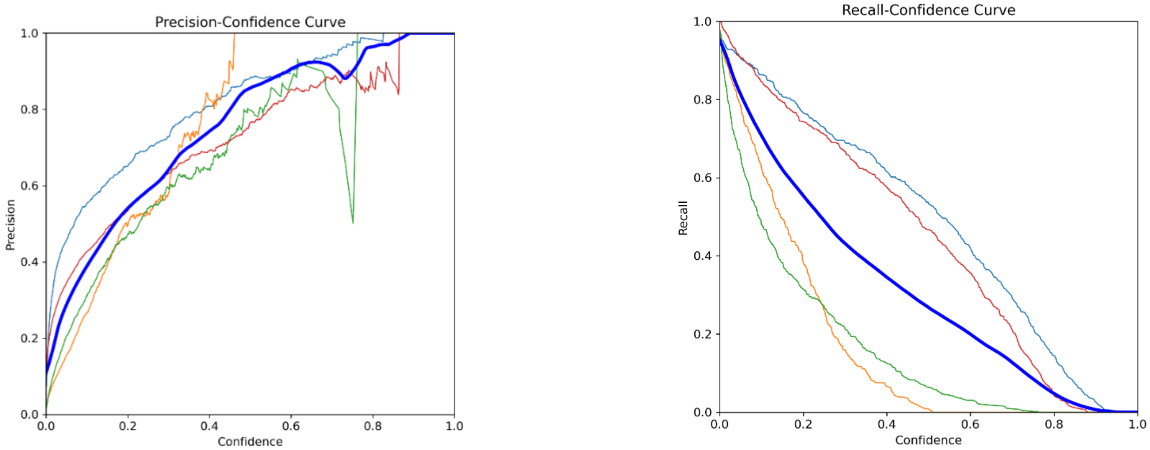

Fig. 11. Performance results of Yolo8l.

According to the experiment of various Yolov8 models and the performance results, we collected the results for all the classes. Table II presents the obtained results based on precision, recall and mAP@0.5 metrics for Yolov8n, Yolov8s, Yolov8m and Yolov8l models.

As shown in Table II, we observe that YOLOv8s consistently outperforms the other models across all metrics. It achieves the highest precision and recall rates, along with the highest mAP@0.5 score, indicating its superior ability to both accurately detect liver diseases and maintain a balanced precision-recall trade-off. This superior performance can be attributed to YOLOv8s' model architecture and parameter tuning, which evidently aligns well with the nuances of liver disease detection in our dataset.

TABLE II. PERFORMANCE RESULTS FOR YOLOV8-BASED MODELS

Models	Precision Rate (%)	Recall Rate (%)	mAP@0.5 Rate (%)
YOLOv8n	0.92%	0.96%	0.58%
YOLOv8s	0.94%	0.96%	0.59%
YOLOv8m	0.89%	0.96%	0.56%
YOLOv8l	0.88%	0.95%	0.55%

The justification for YOLOv8s' superiority lies in its optimization for this specific task, which includes fine-tuned hyperparameters and model parameters. Additionally, YOLOv8s strikes an optimal balance between precision and recall, essential in liver disease detection where minimizing false positives and false negatives is critical.

Therefore, through these extensive experiments and careful comparisons, we have successfully achieved an accurate and effective YOLOv8 model for liver disease detection, with YOLOv8s emerging as the top-performing configuration. This model's exceptional precision, recall rate, and mAP@0.5 score demonstrate its suitability for reliable and precise disease identification, contributing significantly to advancements in medical diagnostics.

TABLE III. PERFORMANCE COMPARISON WITH OTHER ALGORITHMS

Models	Precision Rate (%)	Recall Rate (%)	mAP@0.5 Rate (%)
YOLOv8n	0.92	0.96	0.58
YOLOv8s	0.94	0.96	0.59
YOLOv8m	0.89	0.96	0.56
YOLOv8l	0.88	0.95	0.55
UNet-60	0.91	0.94	0.57
CNN + SVM	0.88	0.92	0.54
Random Forest	0.85	0.9	0.53
Chaotic Cuckoo Search + AlexNet	0.86	0.89	0.52
Modified UNet++	0.88	0.91	0.54

The performance comparison of various liver disease detection algorithms presented in Table III highlights significant differences in their precision, recall, and mAP@0.5 rates. Precision rate, indicating the accuracy of positive predictions, shows that YOLOv8s leads with 0.94%, followed closely by YOLOv8n at 0.92%, and UNet-60 at 0.91%. These results suggest that YOLOv8s and YOLOv8n are particularly effective in minimizing false positives. The recall rate, reflecting the model's ability to correctly identify true positives, is consistently high across all YOLOv8 variants, with YOLOv8n, YOLOv8s, and YOLOv8m all achieving a recall rate of 0.96%. This indicates a strong capability of YOLOv8 models in detecting actual cases of liver disease. When considering the mAP@0.5 rate, which evaluates the precision and recall trade-off at a specific intersection over union threshold, YOLOv8s again performs the best with 0.59%, followed by YOLOv8n at 0.58%, and UNet-60 at 0.57%. Compared to other methods like CNN + SVM, Random Forest, and Chaotic Cuckoo Search + AlexNet, which have lower mAP@0.5 rates of 0.54%, 0.53%, and 0.52% respectively, the YOLOv8 models clearly outperform in all metrics. Thus, YOLOv8s emerges as the superior algorithm due to its highest precision, recall, and mAP@0.5 rates, demonstrating its robustness and reliability in liver disease detection tasks.

V. DISCUSSION

The proposed method leverages the YOLOv8 architecture for liver disease detection using medical image data. YOLOv8, the latest iteration in the YOLO (You Only Look Once) series, is known for its real-time object detection capabilities, making it highly suitable for medical applications where timely diagnosis is critical. The model processes entire images in a single pass, allowing for rapid and accurate detection of liver anomalies. YOLOv8s, a specific variant of the YOLOv8 family, was selected for its balance between performance and computational efficiency. The model was trained on a comprehensive dataset of liver images, utilizing advanced augmentation techniques to enhance its generalizability and robustness. The training process involved optimizing the model's parameters to maximize precision, recall, and mean average precision (mAP) rates, ensuring high accuracy in detecting liver disease across diverse image samples.

The experimental results of the proposed method are highly promising, with YOLOv8s achieving a precision rate of 0.94%, a recall rate of 0.96%, and an mAP@0.5 rate of 0.59%. These metrics indicate that the model excels in identifying true positive cases while minimizing false positives and negatives. The high precision rate reflects the model's ability to accurately pinpoint liver anomalies, while the high recall rate demonstrates its effectiveness in detecting the vast majority of disease cases. The mAP@0.5 rate, a comprehensive measure of the model's overall detection performance, underscores the robustness of YOLOv8s in handling various complexities in medical imaging. Compared to other algorithms in the literature, the proposed method shows a marked improvement, highlighting its potential as a reliable tool for liver disease diagnosis.

Despite the strong performance metrics, the study has several limitations that warrant further investigation. One primary limitation is the potential bias in the dataset used for training and validation. The dataset may not cover the full spectrum of liver disease manifestations, potentially affecting the model's generalizability to unseen cases in different clinical settings. Additionally, while YOLOv8s provides high accuracy, the interpretability of its predictions remains a challenge. Medical professionals need to understand the rationale behind the model's decisions to fully trust and adopt this technology in practice. Moreover, the computational requirements for deploying YOLOv8 models, although optimized, may still be prohibitive in resource-limited environments, restricting its accessibility and widespread use.

Future research should focus on addressing these limitations to enhance the proposed method's applicability and reliability. Expanding the dataset to include a broader range of liver disease cases from diverse populations and imaging modalities will improve the model's generalizability. Developing explainable AI techniques can enhance the interpretability of YOLOv8 predictions, allowing clinicians to understand and validate the model's decisions. Additionally, optimizing the model for deployment on lower-cost hardware will make this advanced technology accessible to a wider range of healthcare settings, including those with limited resources. Research can also explore integrating YOLOv8 with other diagnostic tools to create a comprehensive, multi-modal diagnostic platform for liver disease.

Investigating the integration of YOLOv8 with complementary diagnostic algorithms can provide a holistic approach to liver disease detection. Combining image-based detection with clinical data, such as patient history and biochemical markers, can enhance the diagnostic accuracy and provide a more comprehensive assessment of liver health. Future studies should also explore the longitudinal tracking of liver disease progression using YOLOv8, enabling early detection of disease onset and monitoring treatment efficacy over time. Collaborations with clinical practitioners will be essential to tailor the model's development to meet real-world needs and ensure its seamless integration into existing medical workflows. By addressing these research directions, the proposed method can be refined and validated for broader clinical adoption, ultimately improving liver disease diagnosis and patient outcomes.

VI. Conclusion

This paper studied the critical importance of detecting liver diseases in the field of digital pathology, emphasizing the central role it plays in the domain of medical diagnosis. While numerous methods have been explored in the existing literature, our study highlights the exceptional promise of deep learning techniques, which have demonstrated the capacity to deliver notably accurate results when compared to traditional approaches. Nevertheless, the persistent challenge of low accuracy rates in deep learning-based liver disease detection remains, as indicated by the comprehensive analysis of prior research endeavors. To address this challenge, we have introduced a novel approach harnessing the YOLOv8 algorithm, resulting in the development of innovative models meticulously tailored to elevate the precision and effectiveness of liver disease detection. Our method, involving rigorous model generation, dataset utilization, and extensive experimentation, has yielded accurate outcomes, marking a significant advancement in the field. For future studies, it is imperative to continue refining deep learning models, exploring novel algorithms, and expanding datasets to enhance further the accuracy and robustness of liver disease detection systems. Additionally, investigating the integration of multi-modal data sources, such as imaging and patient records, may offer avenues for comprehensive and holistic disease detection in digital pathology. Moreover, exploring interpretability and explainability in deep learning models can enhance their clinical adoption, ensuring that advancements in this domain contribute effectively to improved patient care and diagnosis.

Reliability in Cloud Computing Applications with Chaotic Particle Swarm Optimization Algorithm

Wenli WANG*, Yanlin BAI
School of Artificial Intelligence, Zhengzhou Railway Vocational & Technical College, Zhengzhou 450000, China

***Abstract*—In recent years, IT managers of large enterprises and stakeholders have turned to cloud computing due to the benefits of reduced maintenance costs and security concerns, as well as access to high-performance hardware and software resources. The two main challenges that need to be considered in terms of importance are ensuring that everyone has access to services and finding efficient allocation options. First, especially with software services, it is very difficult to predict every service that may be needed. The second challenge is to select the best independent service among different providers with features related to application reliability. This paper presents a framework that uses the particle swarm optimization technique to optimize reliability parameters in distributed systems applications. The proposed strategy seeks a program with the best service and a high degree of competence. Although this method does not provide an exact solution, the particle swarm optimization algorithm reaches a result close to the best solution and reduces the time required to adjust the parameters of distributed systems applications. The results of the work have been compared with the genetic algorithm and it has been shown that the PSO algorithm has a shorter response time than both the genetic algorithm and the PSO. Also, the PSO algorithm shows strong stability and ensures that the solution obtained from the proposed approach will be close to the optimal solution.**

***Keywords*—Reliability; cloud computing; chaotic particle swarm optimization algorithm; distributed systems**

I. Introduction

The augmentation of available services leads to a corresponding increase in the proliferation of services that possess comparable functionalities across several servers [1]. These comparable services are situated in distinct geographical locations and exhibit varying degrees of reliability based on different characteristics [2]. Due to this rationale, service composition employs suitable methodologies to choose an atomic service from a pool of identical services hosted on distinct servers, with the aim of attaining the utmost level of dependability based on specific requirements and priorities [3]. The user has been obtained. Because end user requirements and accessible services are always changing, service composition architecture in the cloud environment must be flexible and capable of running independently [4]. Hence, the selection of appropriate and efficient elementary services for integration into complex composite services constitutes a significant concern within this domain [5]. The service composition challenge in cloud computing refers to the determination of appropriate simple atomic services that, when combined, satisfy the functional and reliability requirements of complex services, as dictated by the end user's needs [6]. The complexity of service composition in cloud computing is attributed to the multitude of influential factors and the extensive range of basic services offered by numerous providers in the cloud pool. As a result, this problem is classified as NP-hard [7].

The issue of software reliability in distributed systems is a significant concern for both software providers and consumers that rely on such software [8]. Numerous models have undergone scrutiny and assessment with regards to their trustworthiness within the context of large-scale commercial projects [9]. Notably, these models have been subject to meticulous examination in the domains of e-government, e-commerce, multimedia services, and other relevant scenarios [10]. However, the presence of dependability issues persists in software and systems [11]. Cloud environments have a dynamic nature characterized by both sporadic and deliberate modifications. The aforementioned modifications provide cloud computing with a range of issues within the context of distributed systems [12]. Several issues associated with applications in cloud computing have been identified [13]. a) The dynamic contracting of cloud service providers: an analysis of pricing policies employed by various service providers. The determination of costs for services is contingent upon the interplay between supply and demand factors. Hence, it is imperative to establish a method that facilitates the updating of the specification table pertaining to the range of resources that are now accessible. b) Resolving Insufficient Cloud Resources: The intermediary's decision on the ideal cloud service is contingent upon the presence of comprehensive and up-to-date information regarding the available services [14]. The occurrence of several alterations in service features has the potential to result in the inadvertent deletion or loss of certain data [15].

A significant portion of the research conducted on cloud services often results in suboptimal outcomes, necessitating the completion of the service within a limited timeframe [16]. Hence, it is imperative to put forth certain methodologies aimed at resolving the issue of partial optimization and enhancing the rate of convergence of the algorithm [17]. The chaotic evolutionary algorithm is founded upon the principles of optimization and the utilization of chaos operators, thereby synergistically integrating their respective benefits [18]. The randomness technique incorporates the concepts of unpredictability, initial sensitivity, and chaos operator to establish a mapping between the chaotic variable and a domain of linear optimization variables [19]. By employing this approach, the issue of stagnant search is mitigated and the absence of an optimization mechanism is addressed. Consequently, it enhances the algorithm's diversity and overall optimization [20].

In choosing the particle swarm optimization (PSO) method based on chaos theory for the current research, there are several reasons that indicate the importance and necessity of using this method in checking the reliability of cloud computing programs. First, PSO is an optimization algorithm based on collective intelligence, which is known for its simple structure and high efficiency in solving complex optimization problems. By imitating the social behavior of birds or fish, this algorithm quickly converges towards optimization and has the ability to search more widely in the search space. The use of chaos theory in PSO is very effective to prevent the algorithm from falling into local optima and improve its convergence rate. By adding controlled uncertainty to the search process, chaos theory increases the variety of responses and helps the algorithm achieve more optimal results.

In this study, we aim to examine the dependability of cloud computing applications by utilizing the particle swarm optimization algorithm grounded in chaos theory. This approach is anticipated to offer a thorough exploration of the problem-solving domain and enhance the accuracy of predicting the reliability of cloud services. In order to fulfill the requirements of academic discourse, it is necessary to revise the user's text to conform to the standards of formal the proposed method will be implemented using the MATLAB software environment, with the aim of achieving an optimal solution in terms of both convergence and stability. In summary, the writers of this research have made the following contributions:

- The application of chaos theory in predicting the reliability of cloud computing applications allows for a more extensive exploration of the problem area.
- Identifying a cloud service that offers near-optimal performance while considering the reliability of the service.

The subsequent sections of the article are structured in the following manner. The second half of the document provides a comprehensive review of prior research and scholarly contributions. Section III presents the formulation of the problem. In Section IV, the proposed method is expounded upon. Section V of the paper presents an evaluation and simulation of the proposed solution. Subsequently, Section VI provides the conclusion and outlines potential avenues for future research.

II. Related Works

A proposed strategy has emerged in response to the increasing significance of networks in the amalgamation of cloud services, which takes into account the distinct reliability of applications and network services [21]. In order to achieve this objective, the actual network delay between the desired services and their users is represented using a low time complexity model, enabling the selection of the service with the lowest delay time. The introduction of a reliability equation by researchers enables the calculation of application dependability, delay, and transmission rate. In the final stage of the methodology, the selection algorithm was devised to implement the proposed models using the genetic algorithm. The outcomes of this algorithm were then compared to those of Dijkstra's algorithm and random selection. The findings of this intriguing study can be enhanced through the utilization of real-world datasets.

The authors of this study have presented an enhanced genetic algorithm [22] for the service provider system, taking into account self-adaptation. In this algorithm, the traditional competitive selection method for choosing individuals for intersection and mutation operators has been replaced with a clonal selection algorithm [23]. A well-established methodology has been employed. The primary article lacks a comprehensive discussion of the researchers' efforts in self-adaptation, as it fails to include specific details about the suggested algorithm and the experimental outcomes.

The utilization of game theory by researchers has led to the development of a service combination algorithm that is founded on service level agreement [24]. This study encompasses four distinct components inside the agreement, namely: the primary details of the agreement, information pertaining to service providers and users, specifications about the type and dimensions of the service, and a comprehensive set of obligations for applications. The process of establishing an agreement involves the consideration of service composition as a dynamic multi-player game, referred to as the proposal game. In this game, the sellers and consumers of the service act as players with the objective of attaining their respective aims. Within the context of this competitive framework, it is imperative for every consumer to declare a price for each desired service, taking into account the relevant parameters and the suggested price set by other consumers. Subsequently, sellers have the autonomy to select their service based on the level of quality requested, which is duly influenced by the suggested price. Contained inside the mutually agreed upon and formally executed agreement. The method's reliability is constrained by its narrow scope, since it lacks comparative analysis with alternative approaches and fails to incorporate real-world data sets for comparison.

The authors have introduced a variant of the chaotic optimization algorithm that operates in parallel, with the aim of addressing the issue of application services [25]. The length of the sequence was dynamically altered by the researchers, taking into consideration the evolutionary position of the answer. The researchers also employed the roulette wheel selection process as a preliminary step, followed by the application of the chaos operator, in order to mitigate the presence of randomly generated unsuitable solutions and avoid their detrimental effects. Given that a primary objective of this study is to minimize the duration of execution, the parallelization of the suggested algorithm is also taken into account. In order to accomplish this objective, a comprehensive connection architecture is selected based on its superior searchability and message transmission interface [26]. A novel migration technique, known as reactive path migration, has been recently devised and implemented to mitigate the communication overhead associated with fully connected topologies. In comparison to the genetic algorithm, chaos genetic algorithm, and chaos optimization, the method given in this study has demonstrated superior outcomes in terms of both the best fit achieved and the execution time required.

In [27] present a novel paradigm for adaptive service selection in the context of mobile cloud computing. This framework facilitates the prompt extraction of consumer preferences upon receipt of a request. Subsequently, utilizing the Euclidean distance metric, the customer priority services that exhibit the shortest distances are identified and subsequently recommended to the service adapter. Ultimately, the service adapter determines the optimal service from the available options for the consumer based on the compatibility of the underlying device and the efficacy of the service alternative. The service adapter module incorporates a fuzzy known map model to facilitate the achievement of context matching service based on input information. One limitation of this approach is that the offered framework is applicable solely for the purpose of selecting a singular service. Furthermore, it is worth noting that this particular strategy has not been subjected to comparative analysis with alternative methodologies.

On a pay-as-you-go basis, cloud computing provides worldwide access to utility-based information technology services, with many uses in the commercial, academic, and consumer spheres. But data centers that host cloud applications use a lot of energy, which means they cost a lot to run and pollute the environment with their carbon emissions. Powerful servers that use a lot of energy and related peripherals are necessary for these centers to manage the daily influx of requests from various users. In order to lower energy consumption in data centers, resource efficiency is key. Focusing on energy reduction and load prediction, this research adopts a novel hybrid approach for dynamic resource allocation in the cloud. Specifically, they have migrated virtual machines using an ant colony optimization technique and utilized neural fuzzy networks for load prediction [39].

When it comes to cloud computing, the problem of work scheduling directly affects the quality of services provided. Allocating tasks to available resources according to demand is known as task scheduling. Finding the optimal allocation plan to get more done in less time is the objective of this NP-hard problem. The job scheduling problem has been addressed by several approaches. To fix this, the authors of [40] suggest an IPSO algorithm, which stands for enhanced particle swarm optimization. The original Particle Swarm Optimization (PSO) technique for cloud work scheduling is optimized using a multi-adaptive learning strategy to reduce execution time. The proposed MALPSO method establishes two particle types—normal particles and local best particles—during the first population stage. The population's variety is decreasing and the likelihood of reaching the local optimum is increasing at this stage. Distance, load balance, stability, and efficiency are the four metrics used to evaluate alternative algorithms in this study. In addition, the CEC 2017 benchmark is used to assess the suggested method. We can solve the problem faster and achieve the best answer for most of the criteria using the provided strategy compared to what is currently known.

Our proposed work has significant differences from the works in the "Related Works" section. Unlike previous methods that mainly used genetic algorithms, game theory, and classical optimization algorithms, we use the combination of particle swarm optimization (PSO) algorithm with chaos theory. This combination not only has the ability to improve convergence and stability, but also effectively solves the local optimization problem. While previous methods such as genetic algorithms and game theory compare and select the best services based on complex models and with real data, our method uses a collective approach that brings a significant improvement in performance and prediction accuracy.

In addition, our proposed approach using chaos theory and dynamic population size adjustment has been able to overcome the problems in classical PSO, such as being stuck in local optima and slow convergence. While some existing methods have only focused on optimizing the execution time of the algorithm or improving the quality of the services provided, our approach is a more comprehensive model by focusing on the stability and reliability of cloud services and it provides more efficiency that can be more widely used in real scenarios.

III. Problem Formulation

The issue pertaining to reliability-aware cloud services in applications involves identifying a collection of potential cloud services that possess varying performance attributes. These services must fulfill two criteria: firstly, they must adhere to the limitations established by the user, and secondly, they must satisfy an objective function. To optimize refers to the process of maximizing efficiency or effectiveness in a given context. In this section, the aforementioned issue is explicitly articulated. One instance of the issue pertaining to the integration of cloud services while considering service reliability can be officially articulated as follows:

A service composition request is represented as a workflow modeled using a directed acyclic graph G= (V, E).

- $V = \{T_1, T_2, \dots, T_n\}$, where n denotes the workflow's job count.
- E: The group of edges indicating the order in which tasks are being completed.
- The process for every T$_i$ $(1 \leq i \leq n)$ job includes a set of nomination services called $CS_i = \{CS_i^1, CS_i^2, \dots, CS_i^{m_i}\}$, where $CS_i^j (1 \leq j \leq m_i)$a cloud nomination service is.
- *Mi*: the entire number of potential workers that are willing to take up T_i jobs.
- Every potential service A property of cloud services' service dependability is represented by Q_l $(1 \leq l \leq K)$, one of the various sets of service reliability information $QoS_i^j = \{Q_1, Q_2, \dots, Q_K\}$that CS_i^jhas.
- The service reliability warehouse houses service reliability data pertaining to cloud services.
- K: the quantity of cloud service-related service reliability features included in the service reliability model.

Given the aforementioned context, the primary aim of the reliability-aware service composition problem is to identify a cloud composite service that is near-optimal [28]. This objective is achieved by ensuring that the selected service exhibits a high level of reliability.

$$\forall j = 1 \dots K \begin{cases} \sum_{i=1}^{n} S_i . Q_j < C_j if Q_j is additive \\ \prod_{i=1}^{n} S_i . Q_j > C_j if Q_j is multiplicative \end{cases} \quad (1)$$

A. Service Reliability Model

The dataset utilized in the suggested methodology for determining service dependability parameter values in applications is sourced from Al-Masri and colleagues. The provided dataset serves as a fundamental resource for academics in the field of service. The dataset comprises a collection of 2507 cloud services together with their corresponding measurements of service dependability in various applications. The authors of the study have utilized their proposed service broker framework to measure the values of service dependability parameters [29]. The QWS dataset comprises individual records that encompass the values of ten distinct parameters associated with each cloud service. The initial eight elements inside each record pertain to service dependability metrics that were assessed over a duration of six days using the cloud service broker framework. The service reliability numbers within the dataset represent the mean measurements obtained during the specified time interval. Table I presents a concise overview of the eight service dependability metrics, including a straightforward description for each.

Upon meticulous examination of the reliability parameters presented in Table I, it becomes evident that the response, best practice, and documentation parameters exhibit a consistent value across multiple service calls during execution. Consequently, in light of this observation, these two parameters are disregarded, and the values of the remaining six service reliability parameters are utilized.

B. Service Reliability Parameter Values are Normalized

Various service dependability characteristics associated with a cloud service are assessed using distinct units. In order to compute the objective function, it is necessary to ensure that all of these parameters are measured using a consistent scale [30]. In light of this matter, it is imperative to standardize the values of all service dependability parameters on a consistent scale. The normalizing of service dependability metrics enables the establishment of a standardized metric for evaluating their values. To achieve this objective, a commonly employed method involves normalizing the values of all parameters within the range of zero to one. The criteria pertaining to service reliability can be classified into two distinct categories: those aimed at maximizing reliability and those aimed at minimizing it. Maximization parameters refer to parameters that are intended to be maximized, while minimization parameters refer to parameters that are intended to be minimized. Relations (2) and (3) illustrate the normalization principles for maximizing and minimizing parameters, correspondingly.

TABLE I. AN EXPLANATION OF THE PARAMETERS FOR SERVICE RELIABILITY FOUND IN THE QWS DATASET

Parameters	description	unit
Ability to succeed	The number of responses to the number of request messages	%
the answer	The extent to which the WSDL document conforms to the WSDL specification	%
best way	The degree to which a service conforms to the base WS-I profile	%
Delay	The amount of time it takes for the server to process a request	Millisecond
Documentation	Measuring documentation (descriptive tags) in WSDL	%
response time	The time it takes to send a request and receive a response	Millisecond
accessibility	The number of successful calls over the total number of calls	%
Throughput	The total number of calls for a given time period	Calls per second

$$N_{CS.Q^i} = \begin{cases} \dfrac{Q^i_{\max} - CS.Q^i}{Q^i_{\max} - Q^i_{\min}} & Q^i_{\max} \neq Q^i_{\min} \\ 1 & Q^i_{\max} = Q^i_{\min} \end{cases} \tag{2}$$

$$N_{CS.Q^i} = \begin{cases} \dfrac{CS.Q^i - Q^i_{\min}}{Q^i_{\max} - Q^i_{\min}} & Q^i_{\max} \neq Q^i_{\min} \\ 1 & Q^i_{\max} = Q^i_{\min} \end{cases} \tag{3}$$

In the aforementioned relationships, $CS.Q^i$ represents the value assigned to the i-th parameter of service reliability pertaining to the candidate service [31]. The normalized value of CS and N_{CS} is denoted as CS and $N_{CS.Q^i}$, respectively. Additionally, Q^i_{max} and Q^i_{min} represent the upper and lower bounds of the *i-th* parameter across all services.

IV. PROPOSED METHOD

Given the fact that the issue of identifying cloud services that are cognizant of service reliability falls under the classification of NP-Hard issues, many approaches to discovery can be employed in order to address this challenge. The primary objective of this paper is to employ the chaotic particle optimization technique in order to identify a dependable cloud service. Collective intelligence is a highly potent optimization strategy that relies on the behavior of a group. The particle optimization algorithm is a social search algorithm that is designed based on the collective behavior observed in flocks of birds. Initially, this method was employed to uncover the underlying patterns that regulate the concurrent flying of avian species, as well as the abrupt alterations in their trajectory and the ideal configuration of the flock. The particle optimization algorithm involves the movement of particles inside the search space. The relocation of particles within the search space is influenced by both their own experiences and knowledge, as well as the experiences and knowledge of their neighboring particles. Hence, the alternative configuration of particle mass influences the manner in which a particle is sought. The outcome of simulating this social behavior manifests as a search process wherein particles exhibit a tendency to converge towards regions of success. Particles acquire knowledge from one another and navigate towards their most optimal neighbors. The particle optimization algorithm operates on the premise that each particle in the search space determines its position based on the best position it has previously occupied. Selects and optimizes the most favorable position within its surrounding vicinity. Through the analysis and refinement of this technique within computer systems, as well as its adaptation to expert and intelligent systems, it becomes feasible to apply it in addressing a wide range of optimization problems. The use of the particle swarm optimization algorithm is anticipated to enhance the dependability of the cloud service generated. The application of chaos theory has also been employed in addressing the issue of local optima and enhancing the rate of convergence.

Fig. 1. Process flowchart of the proposed method.

The flow/block diagram in Fig. 1 shows the proposed research process to improve the reliability of cloud services using particle swarm optimization (PSO) algorithm and chaos theory. At first, the particles are initialized and an initial evaluation is done on them. Then the particle population is divided into two subpopulations: one using the PSO algorithm and the other using the chaos theory. The position of particles in each subpopulation is updated and the chaotic search space is reduced. After that, the particles are re-evaluated and the local best (pbest) and global best (gbest) are updated. This update and evaluation process continues until a stop condition is met. Finally, the algorithm ends by finding a near-optimal solution. This combined method of PSO and chaos theory helps to improve the convergence and stability of the algorithm.

The particle optimization algorithm initiates its operation by generating a set of particles within the search space. Each particle represents the position of a potential solution to a given problem, specifically in the context of a composite service within a cloud environment. The starting positions of the particles within the node are determined randomly [32]. The program will subsequently conduct a search for the optimal place based on the highest merit value. The subsequent section outlines the sequential procedures involved in attaining the most advantageous location, or in other words, elucidates the process by which the algorithm progressively approaches a solution that is close to optimal. Eq. (4) is utilized to represent the position of the *i-th* particle.

$$X_i = (x_{i1}, \dots, x_{id}, \dots x_{iD}) \tag{4}$$

Eq. (5) is utilized to retain and present the prior optimal position of the i-th particle.

$$P_i = (p_{i1}, \dots, p_{id}, \dots p_{iD} \tag{5}$$

The term used to refer to this concept is known as *pbest* [33]. The optimal solution within a population of particles is sometimes referred to as the global best *(gbest)*. The velocity of the *i-th* particle is also represented by the vector V_i, as depicted in Eq. (6):

$$V_i = (v_{i1}, \dots, v_{id}, \dots v_{iD}) \tag{6}$$

The fundamental principle underlying particle swarm optimization involves the manipulation of the location and velocity of individual particles towards their personal best (pbest) and global best (gbest) values, as described by Eq. (7) and (8).

$$v_{id} = w * v_{id} + c_1 * rand() * (p_{id} - x_{id}) + c_2 * rand()(7)$$
$$* (p_{gd} - x_{id})$$

$$x_{id} = x_{id} + v_{id} \tag{8}$$

In this context, the symbol "w" represents the inertial weight, while the numbers c_1 and c_2 denote the acceleration constants [34]. Additionally, rand () refers to a random number generator that produces values uniformly distributed throughout the interval [0, 1]. Algorithm 1 presents the pseudocode for the fundamental particle swarm optimization.

ALGORITHM 1: PSEUDO CODE OF BASIC PSO

```
Start
Initialize particle swarm
While (number of iterations, or the stopping criterion is not met)
  Evaluate fitness of particle swarm
  For n = 1 to number of particles
    Find pbest
    Find gbest
    For d = 1 to number of dimensions of particle
      Update the position of particles via equations (3-4) and (3-5)
    End For
  End For
End While
Stop
```

The fundamental particle swarm optimization approach has demonstrated commendable efficacy in addressing intricate challenges. However, notwithstanding this, it is afflicted by the issue of succumbing to the local optimum trap [35]. There exist various approaches for resolving this issue, with one particularly significant option being the utilization of chaos theory. According to the dictionary, the term "chaos" refers to a condition characterized by a lack of organization and clarity. In the realm of scientific discourse, a universally accepted definition for the concept in question remains elusive. The concept of chaos is commonly acknowledged as a phenomenon characterized by distinct and discernible patterns within unpredictable circumstances, often referred to as "order in chaos." Chaos theory is a well-established theoretical framework that may be formulated based on a set of deterministic principles and mathematical equations. According to the principles of chaos theory, the future is entirely governed by preceding events. The logical equation, renowned for its association with chaos theory, holds significant prominence and finds application within the proposed methodology. Eq. (9) represents the logical equation:

$$x_{t+1} = \mu x_t(1 - x_t) \tag{9}$$

The control parameter, denoted as μ, and the variable *x* are both present in the given context. The search algorithm employed in the suggested method utilizes chaos theory principles. In this approach, the population is divided into two distinct sub-populations in the following manner:

The population in PSO is updated by utilizing the fundamental algorithm (Algorithm 1) to modify the position and velocity of the particles [36]. The population exhibits a state of disorder, as indicated by the utilization of Eq. (9) to update the positions of particles. The dynamic alteration of the particle quantities in both the PSO and chaos populations is determined by employing Eq. (10) and (11).

$$NewPSOpopulation = \frac{finessofcurrentglobalbest}{finessofpreviousglobalbest} * populationsize \tag{10}$$

$$NewChaoticpopulation = Populationsize - NewPSOpopulation \tag{11}$$

Algorithm 2 presents the pseudo-code of the suggested method, which incorporates the particle swarm optimization algorithm with chaos search.

ALGORITHM 2: PSEUDO-CODE FOR OPTIMIZATION OF PARTICLE SWARM AND CHAOS PROBE

```
Input: Composition request as a workflow (DAG) and Reil constraints
Output: Near optimal composite cloud service
Initialization as Basic PSO
While (number of iterations, or the stopping criterion is not met)
  For each particle in Chaotic Population
    Update Particle Position using equation (6)
    Decrease Chaotic search space
Xmax - Xmin
     where Xmax is the maximum position for PSO
     where Xmin is the minimum position for PSO
  End For
  For each particle In PSO Population
    Update particle velocity equation (4)
    Update Particle Position equation (5)
  END For
  For each particle In Population
    Evaluate fitness of particle
    If (current position < best position) Then
      Xpbest = current   position
    End If
    If (current position< gbest position) Then
      gbest = current particle index
    End If
  End For
  Update PSO and Chaotic Populations using (7) and (8)
End While
```

A. Initialization

During the initialization step, it is necessary to generate the initial population of particles. The particle optimization approach utilizes particles to symbolize solutions to the problem at hand. In this context, a solution refers to the compound cloud service, which is represented by an array of size n, where n corresponds to the number of jobs inside the workflow. In order to fulfill the desired objective or meet the specified criteria [37]. The value contained at index *i* within the array represents the identification number of the candidate service responsible for executing task T_i. Given that the quantity of particles in the first population is denoted as *P*, the initial population of solutions can be represented as a matrix of dimensions P×n.

B. Merit Function

The primary objectives associated with addressing the challenge of integrating cloud services while considering service reliability are adhering to user-defined constraints and maximizing a merit function. The optimization of service dependability characteristics for the composite cloud service should be the primary objective of the fitness function [38]. The proposed reliability model has six parameters: reaction time (Resp), availability (Avail), throughput (Through), success capability (Succ), reliability (Reli), and delay (Late). The merit function for a solution is determined by relation (12).

$$Fitness(Sol) = \frac{w_1{*}Sol.Avail + w_2{*}Sol.Throu + w_3{*}Sol.Succ + w_4{*}Sol.Reli}{w_5{*}Sol.Resp + w_6{*}Sol.Late} \tag{12}$$

The coefficients w_1, w_2, w_3, w_4, w_5, and w_6 represent positive weights assigned by the user to indicate the relative significance of each service dependability metric.

V. DISCUSSION AND EVALUATION

The proposed combination algorithm was simulated and evaluated using the MATLAB software. All tests were conducted using a Dell computer equipped with a 2.0 GHz Core i7 processor and 4 GB of RAM. Furthermore, the QWS dataset has been employed as a source of service information pertaining to applications in distributed systems.

In light of the fact that the method employed a heuristic algorithm, an assessment has been conducted to evaluate the outcomes in relation to convergence and stability. The ensuing findings will be expounded upon in the subsequent sections. Furthermore, the outcomes of the suggested approach have been juxtaposed with those of two genetic algorithms and a rudimentary particle swarm optimization technique. Tables II and III present the parameters pertaining to the genetic algorithm and optimization of both the basic particle swarm and the suggested technique, respectively.

TABLE II. PARAMETERS OF A GENETIC ALGORITHM

Parameter	Amount
Initial population size	200
Number of generations	300
Cut operator	two points
selection operator	Roulette wheel
Cutting rate	0/8
Mutation rate	0/05

TABLE III. PARAMETERS OF THE SUGGESTED TECHNIQUE AND THE FUNDAMENTAL PARTICLE SWARM OPTIMIZATION ALGORITHM

Parameter	Amount
Number of elementary particles	200
The number of repetitions	300
Inertia weight (w)	0/5
C1	0*0 2/5rnd
C2	0*0 2/5rnd
Maximum speed	$v_{max} = \lambda * x_{max} \quad 0.1 \le \lambda \le 1.0$
µ	0.6

A. Convergence Test

In order to assess convergence, the proposed method, along with genetic algorithms and basic particle swarm optimization, were applied to three distributed systems applications. These applications consisted of 5, 10, and 20 tasks, respectively. Fig. 2, 3, and 4 depict the convergence process leading to the final solution for each respective application. The aforementioned graphs depict the horizontal axis representing the sequence of algorithm iterations, while the vertical axis represents the highest measure of performance achieved in each iteration.

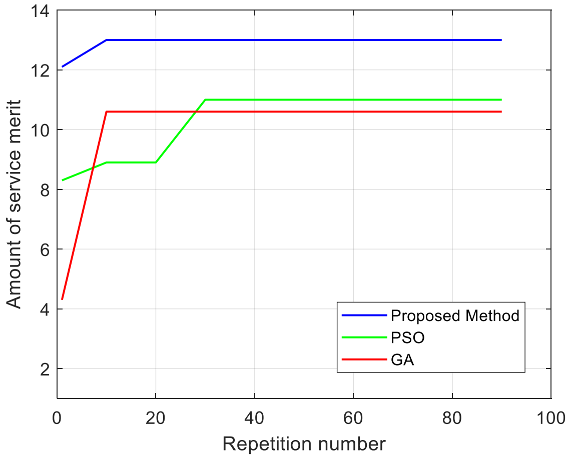

Fig. 2. Convergence of the suggested combination method compared to genetic and elementary particle optimization algorithms (number of tasks: 5).

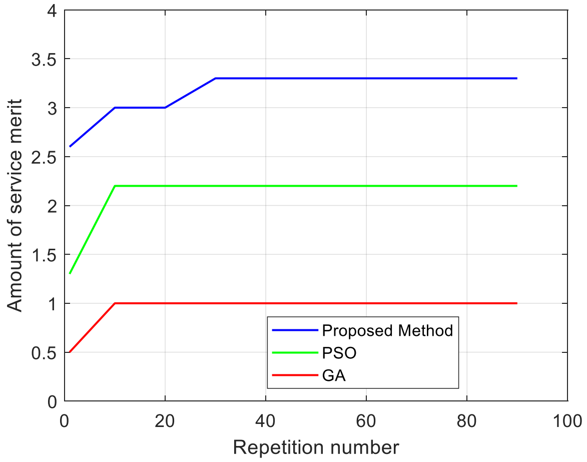

Fig. 3. Convergence of the suggested combination method compared to genetic and elementary particle optimization algorithms (number of tasks: 10).

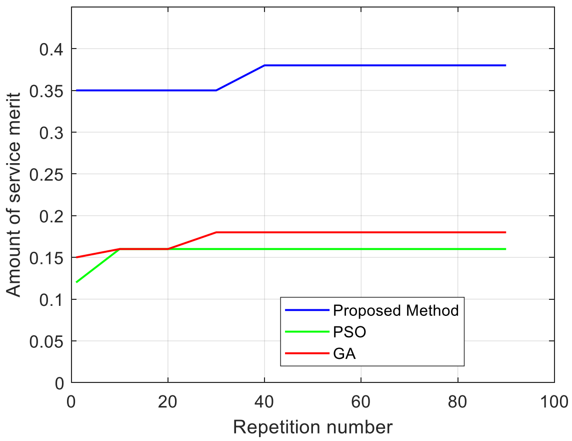

Fig. 4. Convergence of the suggested combination method compared to genetic and elementary particle optimization algorithms (number of tasks: 20).

B. Stability Test

It is imperative to conduct a thorough examination of the stability of the associated algorithm when evaluating discovery algorithms in distributed systems applications. Given the inherent stochastic character of discovery algorithms, such as the particle swarm optimization method, it is imperative to assess their stability. The concept of algorithmic stability pertains to the consistency of an algorithm's output throughout multiple executions, ensuring that the method yields identical or similar results. In order to evaluate the stability of the algorithm under consideration, the suggested methodology was implemented in four distinct distributed systems applications. These applications were subjected to 5, 10, and 20 iterations, respectively. The proposed technique was executed ten times for each application, and the resulting service merit values were recorded. These values are presented in Fig. 5, 6, and 7.

The graphs depict the order of algorithm execution on the horizontal axis, while the vertical axis represents the merit value of the composite cloud service in the applications of distributed systems for each respective order of execution.

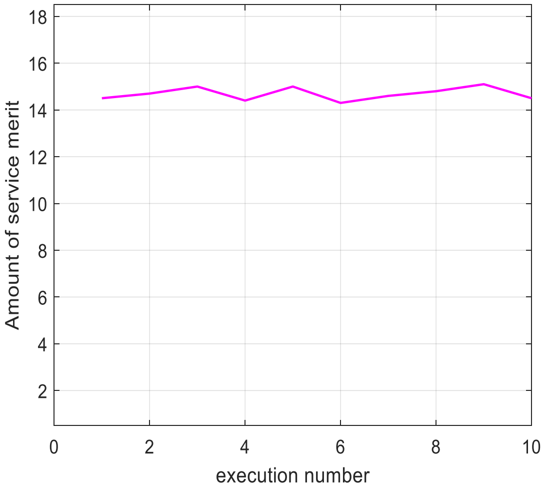

Fig. 5. The suggested combination algorithm's stability (number of tasks: 5).

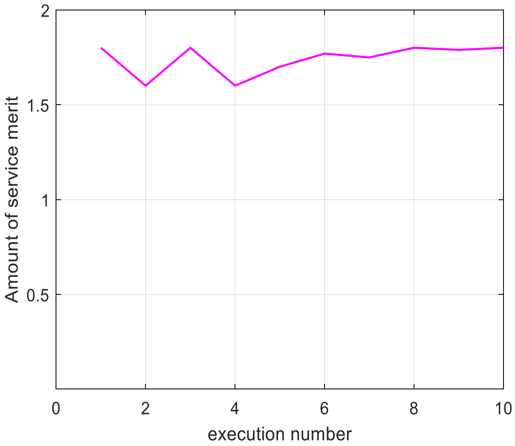

Fig. 6. The suggested combination algorithm's stability (number of tasks: 10).

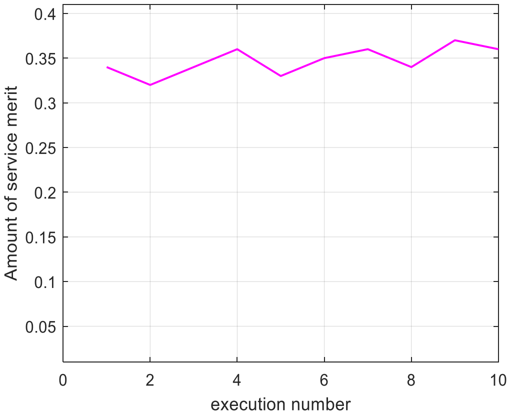

Fig. 7. The suggested combination algorithm's stability (number of tasks: 20).

Upon analysis of the stability graphs, it is evident that the suggested algorithm exhibits a notable degree of stability across various distributed systems applications. The primary factor contributing to the observed high stability is the consistent absence of fluctuations in the near-optimal service merit value over multiple algorithm iterations. The findings indicate that the algorithm's stability is significantly greater for combination requests involving a small number of tasks compared to those involving a large number of tasks.

C. Evaluating the Generated Cloud Composite Services for Quality

The primary objective of this experiment is to evaluate and compare the efficacy of the suggested method with the fundamental and genetic particle swarm optimization methods in developing distributed systems applications. In order to conduct the experiment, the aforementioned methodologies were employed to analyze 20 distinct application requests, each consisting of 5, 10, or 20 jobs. The resulting average merit values derived from the execution of these methodologies are presented in Table IV. Upon careful examination of the findings shown in Table IV, it becomes evident that the service quality of the applications generated using the suggested method surpasses that of the fundamental particles and genetics optimization algorithms, as indicated by the service quality criteria.

TABLE IV. APPLICATIONS' SERVICE QUALITY COMPARISON

Method	n = 20	n = 10	n = 5
GA [16]	0/289	1.675	10.985
PSO [19]	0.378	2.985	13.152
Proposed Method	0.426	4.898	15.685

1) Test of service quality criteria: The purpose of this study was to assess the efficacy of the developed cloud composite service based on the dimensions of accessibility, dependability, and success. To conduct the test, the user's service composition request was distributed across all three techniques, and the resultant cloud composite service was evaluated in terms of accessibility, reliability, and success. Fig. 8, 9, and 10 depict the values of the quality criteria for accessibility, reliability, and success, respectively. The findings obtained indicate that the suggested method yields a cloud composite service of superior quality compared to the particle optimization algorithm [19] and the genetics algorithm [16], as assessed by the aforementioned quality standards.

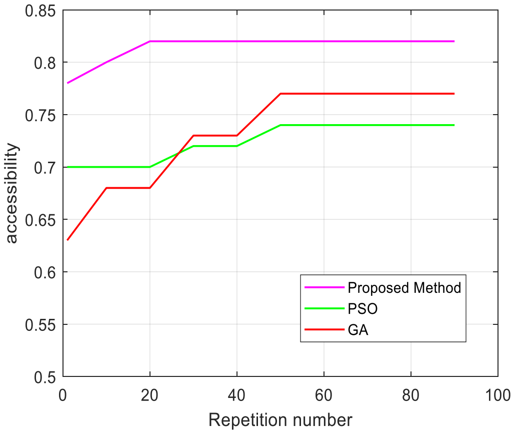

Fig. 8. The application's service accessibility.

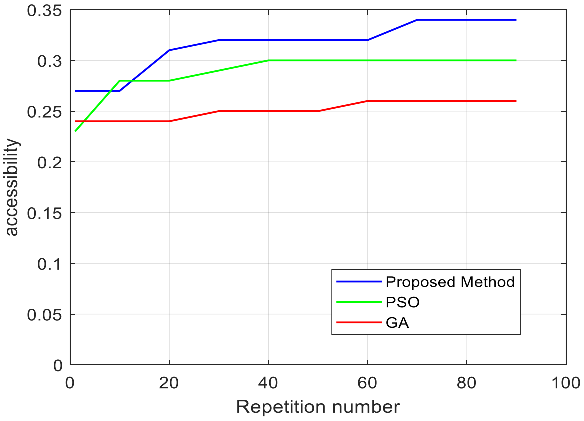

Fig. 9. The application's service reliability.

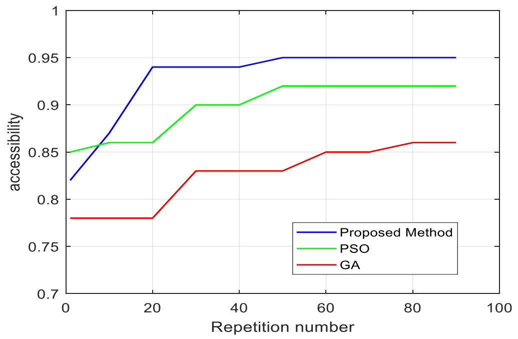

Fig. 10. The application's capacity for service success.

D. Package Delivery Rates

The quantity of packets received by application services serves as one parameter for assessing the effectiveness of algorithms in distributed system applications. A higher number of packets received by the services indicates that the algorithm performed better and supplied more data to the distribution system. We simulate the number of different gateways and then count the number of packets received by the services to get the total number of received packets. The quantity of packets that the distribution system application has received is displayed in Fig. 11.

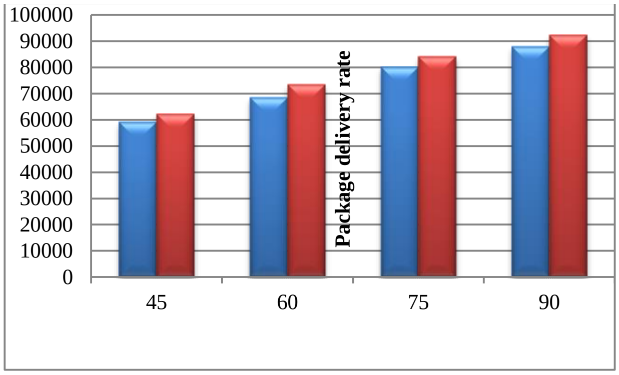

Fig. 11. The number of received packages.

The diagram presented below illustrates the packet delivery rate of the method across various services, as indicated by the observed trend (see Fig. 12).

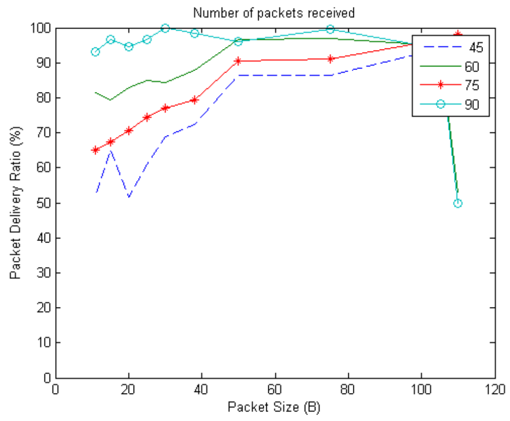

Fig. 12. Packet delivery rate.

E. Energy Consumption

The subsequent significant metric assessed to gauge the efficacy of the algorithm is the level of energy usage. The energy consumption referred to in this section pertains to the aggregate energy consumed by all services and applications throughout distributed systems and gateways. Specifically, there are 60 gateways and an unspecified number of services within these systems. The distribution value is set at 500 and the simulation is executed. The energy consumption of the two algorithms is quantified in Joules, as depicted in Fig. 13.

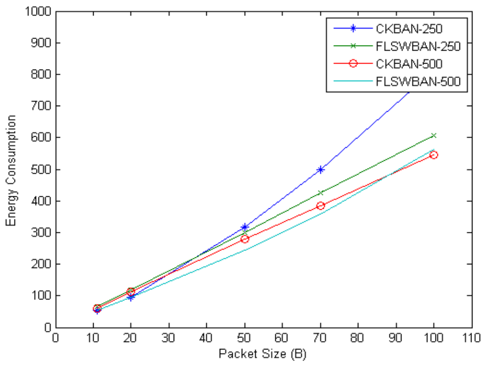

Fig. 13. Energy usage in all applications involving distributed systems.

The energy consumption in the proposed technique is comparatively lower than that of the method described in reference [17]. This can be attributed to the more efficient selection of programs utilizing chaos-based particle swarming for gateway services. When the service selection is optimized, it implies that program services are not required to transmit their data over vast distances in order to achieve their objectives, hence resulting in reduced energy consumption.

F. Reliability

As depicted in Fig. 14, the determination of reliability necessitates the presence of a timer that computes the temporal aspects associated with diverse activities, including transmission and reception. The degree of dependability associated with the initial stage, specifically when the service is introduced into the program, is disregarded. The longevity of the distributed system is of significant concern, spanning several days or even weeks. Consequently, the relatively brief duration of the first phase may be disregarded.

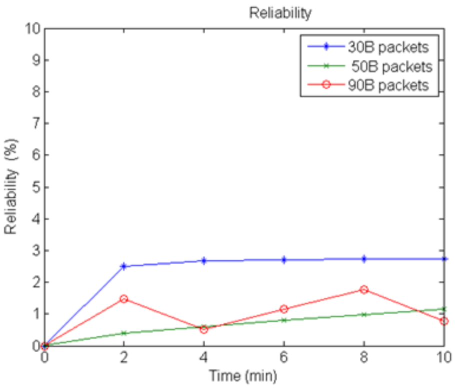

Fig. 14. Comparison of reliability over time.

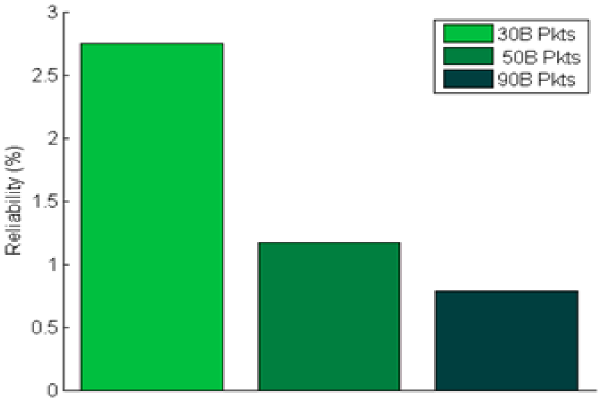

Fig. 15. Comparison of dependability in relation to received packet size.

Fig. 15 presents a crucial comparison pertaining to reliability, which is evaluated by quantifying the number of received packets. It is evident that the proposed method exhibits a high level of reliability across various quantities of received packets.

The findings of the research carried out in this article show that the use of particle swarm optimization (PSO) algorithm along with chaos theory has been able to reduce the time required to adjust the parameters of distributed systems and achieve a near-optimal solution. These findings are consistent with the results of previous researches that have investigated reliability models in large commercial projects. For example, research conducted by Al-Masri et al. has shown that the use of reliable datasets can bring significant improvements in the reliability assessment of cloud services.

However, the method proposed in this paper also has innovations that have not been found in previous research. In particular, combining the PSO algorithm with chaos theory to improve the convergence and stability of the algorithm is a new and innovative approach. This combination helps to reduce the problem of entrapment in local optima and increases the diversity of the particle population, which has not been investigated in this way in previous research. Therefore, it can be said that this research is consistent with previous findings and provides innovations that have not been investigated before.

VI. Conclusion

This study introduces a framework that utilizes the particle swarm optimization technique to optimize dependability parameters in distributed systems applications. The objective of the proposed methodology was to identify a suitable application that offers optimal service and demonstrates a high degree of expertise. Furthermore, the algorithm under consideration was executed using various settings, and the resulting graphs were subsequently analyzed. The utilization of the Particle Swarm Optimization (PSO) algorithm has been seen to decrease the time needed for determining the parameters of distributed systems applications to a certain degree. However, it should be noted that the PSO algorithm does not provide an absolute solution, but rather yields an approximation that is in close proximity to the optimal solution. In order to assess the efficacy of any algorithm, it is important to do a comparative analysis with respect to prior algorithms. Consequently, the outcomes of the study were juxtaposed with the genetic algorithm. After conducting a comparative analysis of the algorithms, it was determined that the PSO algorithm exhibits a shorter response time in comparison to both the genetic algorithm and PSO. Additionally, the PSO algorithm has favorable stability, resulting in the suggested technique yielding a solution that closely approximates the optimal solution.

Based on the analysis of the convergence graphs, it is evident that the Particle Swarm Optimization (PSO) algorithm has a favorable convergence pattern when coupled with the principles of chaos theory. Based on the stability level depicted in the graphs, it is observed that the PSO algorithm employing the chaos theory approach consistently produces a singular solution across multiple tasks. This indicates that the stability of the PSO algorithm with the chaos theory approach is commendable. Consequently, it can be inferred that the solution derived from the proposed algorithm has the potential to be the optimal solution. Based on the findings and materials elucidated in this study, a recommendation for future endeavors is conducting a comparative analysis of these algorithms through the application of chaos theory to alternative evolutionary algorithms, including genetics and colonial competition, as well as ant colony algorithms, among others.

Although this research has addressed the optimization of reliability parameters in distributed systems using the Particle Swarm Optimization (PSO) algorithm, it also has some limitations. One of the most important limitations is that the PSO algorithm only reaches a close approximation to the best solution and not a definite and absolute solution. This can be problematic in precision-sensitive applications. In addition, this research has only been compared with the genetic algorithm and has not used other evolutionary algorithms such as the colonial competition algorithm or the ant colony algorithm. Also, the presented method is implemented in the MATLAB environment, which may have limitations in generalizing the results to other platforms and execution environments.

For further studies, it can be suggested that a more comprehensive comparison be made with other evolutionary algorithms to determine the strengths and weaknesses of each one more precisely. Also, reviewing and implementing the algorithm in different environments and analyzing the results can help to increase the generalizability and applicability of the results. The use of more and more diverse real data can also lead to a more accurate evaluation of the algorithm's efficiency.

***Abstract*—Active player tracking in sports analytics is crucial for understanding team dynamics, player performance, and game strategies. This paper introduces an innovative approach to tracking active players in handball videos using a fusion of the Multi-Deep SORT algorithm and a Generative Adversarial Network (GAN) model. The novel integration aims to enhance player appearance for robust and precise tracking in dynamic gameplay. The system starts with a GAN model trained on annotated handball video data, generating synthetic frames to improve the visual quality and realism of player appearances, thereby refining the input data for tracking. The Multi-Deep SORT algorithm, enhanced with GAN-generated features, improves object association and continuous player tracking. This framework addresses key challenges in active player tracking, handling occlusions, variations in player appearances, and complex interactions. Additionally, GAN-based enhancements improve accuracy in distinguishing active from inactive players, facilitating precise localization and recognition. Performance evaluation demonstrates the system's efficacy in achieving high tracking accuracy, robustness, and differentiation between player activity levels. Metrics such as Average Precision (AP), Average Recall (AR), accuracy, and F1-score affirm the system's advancement in active player tracking. This pioneering fusion of Multi-Deep SORT with GAN-based player appearance enhancement sets a new standard for precise, robust, and context-aware active player tracking in handball videos. It offers comprehensive insights for coaches, analysts, and players to optimize team strategies and performance. This paper highlights the novel integration's advancements and benefits in the domain of sports analytics. Notably, the proposed method achieved enhanced efficiency with an average precision of 94.99%, recall of 93.67%, accuracy of 93.89%, and F-score of 94.33%.**

***Keywords*—Handball recognition; multi-deep SORT; GAN; deep learning; computer vision**

I. Introduction

Active player tracking in sports videos, particularly in dynamic games like handball, stands as a cornerstone in sports analytics, offering invaluable insights into player performance, team strategies, and game dynamics. The integration of the Multi-Deep SORT algorithm with a Generative Adversarial Network (GAN) presents a pioneering approach, enhancing the precision and robustness of active player tracking through advanced computer vision and deep learning techniques. At its core, this integration represents a paradigm shift, emphasizing the refinement of player representations within video frames. The GAN model, meticulously trained on annotated handball video datasets, elevates player appearances by generating synthetic frames that enhance visual fidelity and realism. These enhancements serve as a critical preprocessing step, bolstering the accuracy and dependability of subsequent player tracking processes.

Refining active player tracking using the Multi-Deep SORT algorithm alongside GAN-based enhancements is a venture fraught with intricate challenges. At the forefront lies the issue of appearance variations and occlusions within handball videos. Players exhibit diverse appearances due to attire and lighting, often occluding one another, posing substantial obstacles to continuous tracking and consistent identity preservation across frames. This complexity escalates amidst the dynamic interactions and rapid movements characteristic of handball games, where players frequently converge and diverge, leading to overlapping trajectories and temporary visual obstructions. Another critical challenge involves accurately discerning between active and inactive players. The system must adeptly differentiate subtle variations in player movement intensities or brief lulls in participation amidst the game's intense dynamism. Balancing precision with real-time processing efficiency emerges as a pressing concern, necessitating exceptional accuracy in player localization while ensuring the system operates within stringent time constraints for live game applications.

Moreover, the GAN model's adaptability across diverse player appearances and game scenarios is imperative. Its capability to generate realistic player representations amidst varying poses, clothing, and lighting conditions dictates the system's reliability and consistency in player appearance enhancements. Establishing robust evaluation metrics, encompassing measures like average precision (AP), average recall (AR), accuracy, and F1-score benchmarks affirm the system's advancement in active player tracking. Average Precision (AP) and average recall becomes paramount to quantitatively validate the system's accuracy, robustness, and computational efficiency. Tackling these multifaceted challenges will pave the way for an advanced player tracking system, offering deeper insights into player dynamics, and refining strategic decision-making in handball and broader sports analytics realms.

*Corresponding Author

Several existing systems and platforms specialize in player tracking and sports analytics, some of which employ advanced algorithms and technologies for enhanced tracking accuracy and insights in various sports, including handball. Utilizing arrays of cameras strategically positioned around the sports venue, camera-based systems capture player movements and ball trajectories. Computer vision algorithms process video feeds to track players, enabling the extraction of detailed positional data, player speeds, and distances covered. Systems like Zebra Motion Works and Kinexon employ RFID or ultra-wideband technology embedded in player equipment or the playing field. These technologies track player movements and interactions in real-time, providing precise positional data, accelerations, and distances covered. Catapult Sports utilizes wearable tracking devices equipped with sensors to monitor player movements, accelerations, and workloads. These devices capture data on various metrics, including heart rate, speeds, impacts, and player exertion levels during training and games.

The development of an active player tracking system using handball videos presents a significant research gap, particularly in leveraging advanced techniques such as Generative Adversarial Networks (GANs) to enhance tracking accuracy and robustness. Existing research predominantly focuses on player tracking in more popular sports like soccer and basketball, leaving a void in methodologies tailored specifically for the unique dynamics of handball gameplay, including rapid movements, frequent occlusions, and complex player interactions. Addressing this gap requires dedicated exploration into integrating GAN modules to improve the precision of player tracking in handball videos, considering factors like occlusion handling, player identification consistency, and real-time processing constraints. Closing this gap could lead to more effective and adaptable player tracking solutions, benefiting coaches, analysts, and players in the handball community.

This combination leverages the strengths of two robust methodologies: the multi-object tracking expertise of Multi-Deep SORT and the contextual data generation capabilities of GANs. Multi-Deep SORT, lauded for its adeptness in object association and identity preservation across frames, synergizes with GAN-generated features. These features encapsulate nuanced player appearances, facilitating robust tracking amidst occlusions, diverse poses, and intricate game scenarios. The crux of this fusion lies in its ability to discriminate between actively engaged players and their inactive counterparts. By infusing GAN-enhanced features, the system advances player recognition accuracy, offering deeper insights into player actions, movement, and roles during gameplay. Key technical objectives encompass precise player localization, consistent and continuous tracking, and discernment of player activity levels through enhanced appearance representation. Performance metrics such as average precision (AP), average recall (AR), accuracy, and F1-score benchmarks affirm the system's advancement in active player tracking. Average Precision (AP), and real-time processing benchmarks serve as litmus tests, affirming the system's advancements in active player tracking. Ultimately, this integration of Multi-Deep SORT with GAN-based player appearance enhancements redefines active player tracking in handball videos. Its precision, robustness, and contextual awareness empower coaches, analysts, and players with unparalleled insights, revolutionizing strategic decision-making and performance optimization within handball and broader sports analytics domains. Notably, the proposed method exhibited enhanced efficiency, achieving average precision 94.99%, average recall 93.67%, accuracy 93.89% and F-score 94.33% respectively. In this paper, there are three major contributions associated with the integration of Multi-Deep SORT with GAN-based enhancements for active player tracking in handball videos:

- The fusion of GAN-based enhancements with Multi-Deep SORT improves player representation precision in video frames by refining initial player appearances with synthetic frames, enhancing accuracy and reliability in player tracking, even in challenging game scenarios.
- The integrated system leverages GAN-enhanced features to elevate player recognition accuracy and provide deeper insights into player dynamics, refining strategic analysis and performance evaluation in handball gameplay.
- The integration of Multi-Deep SORT with GAN-based enhancements in active player tracking elevates contextual awareness and decision-making in sports analytics.

The subsequent sections of this paper are structured as follows: Section II explores "Related Works," presenting a comprehensive overview of various techniques employed in active player tracking systems. In Section III, the "Proposed Method" details the implementation of an active player recognition system utilizing the multi-deep sort algorithm integrated with GANs. Section IV delves into the "Performance Evaluation" of the active player recognition system, analyzing its efficacy and capabilities. Lastly, Section V encapsulates our findings and conclusions drawn from this study.

II. Related Works

Prior to the advent of deep learning and correlation filtering in tracking algorithms, the domain of object tracking predominantly relied on traditional methodologies. During this phase, algorithms primarily leveraged probability density and image edge features as fundamental tracking benchmarks. These methodologies directed the search for objects along the rising probability gradient, exemplified by established approaches such as Meanshift, Kalman Filter, and Particle Filter.

Meanshift [1], reliant on probability density, continually pursues the rising probability gradient to converge iteratively toward the local peak. By modeling the object using color distribution and calculating successive frame probabilities, it excels in scenarios with distinct object-background color differentiation, notably applied in early face tracking. Its rapid computational efficiency sustains its continued usage and evolution in various Meanshift-based methodologies. The Kalman filter [2] focuses on modeling an object's motion rather than its specific characteristics, estimating its position in subsequent frames. In contrast, optical flow tracking uses feature points to calculate matches in consecutive frames, constantly updating and adapting these points to accommodate changes in the object's shape during motion. Essentially, optical flow tracking constructs an object model using a set of evolving feature points. The Particle Filter [3] utilizes statistical particle distribution, initially modeling the object and gauging similarity with particles. It disperses particles based on defined distributions, evaluating their similarity to identify potential object positions. In subsequent frames, more particles are added at these locations, increasing the likelihood of successful object tracking.

To effectively track an object, the initial step involves its detection, which can be achieved through various algorithms such as Mask R CNN [4], Faster R CNN [5], SSD [6], YOLO [7], among others. Following evaluations in [8], where multiple algorithms were assessed, YOLOv3 [9] was specifically selected due to its superior performance in detecting persons. DeepSORT, introduced by Wojke et al. [10], operates as a tracking-by-detection algorithm, merging both the bounding box parameters from detection outcomes and the appearance data of tracked objects. This integration aids in associating new detections in a frame with previously tracked objects. As an online tracking algorithm, DeepSORT relies solely on current and previous frame data to make predictions for the present frame, eliminating the necessity to process the entire video simultaneously. In the initial frame of the footage, each player's bounding box with a confidence surpassing a defined threshold is allocated a distinct track ID. Subsequently, the Hungarian algorithm is employed to assign detections in a new frame to existing tracks, ensuring the assignment cost function achieves the global minimum.

The domain of visual object tracking, particularly in player tracking, stands as a highly dynamic research field, drawing substantial attention with numerous papers presented at computer vision conferences annually [11]. Countless methodologies have emerged, addressing both the broader challenge of multiple object tracking [12] and the specialized domain of player tracking within sports videos. In sports-related contexts, player tracking frequently integrates with detection methodologies. For instance, in hockey [13], handball [14], indoor sports [15, 16], and outdoor soccer [17-20], researchers explore techniques leveraging domain-specific insights and video conditions. These methods aim to utilize sport-specific knowledge, such as color distributions on the field or player attire, to delineate potential player areas. Additionally, strategies involving the field layout aid in recovering depth information. Player detection approaches vary, ranging from template matching with manual features to machine learning methods like SVM classifiers or Adaboost, often complemented by particle filter-based tracking.

Lately, the rise of deep learning in player detection methods, as observed in [21], has gained momentum. This surge is attributed to enhanced detection accuracy and reduced reliance on domain-specific expertise. Leveraging convolutional neural networks in object detection has led to effective tracking-by-detection methods. For instance, employing the Hungarian algorithm to match detected bounding boxes with tracks solely based on box dimensions has showcased notable success in tasks like multiple object tracking [22], including scenarios like tracking the foremost player [23]. This study adopts a comparable approach.

Xiaolong Sun et al. [27] has implemented an innovative framework that leverages deep learning, including dilated neural networks, on standard hardware for real-time spatio-temporal tennis analysis. By employing an LSTM-GAN structure, it aims to improve prediction accuracy, reduce motion blurring, and enhance insights into player performance and action prediction in tennis analysis. The combination of LSTM architecture and GAN achieves impressive performance metrics with a 92.1 Precision, 91.2 Recall, 94.5 F-1 score, and 95.0 Accuracy in recognizing and predicting tennis actions. These results surpass those of classical models by a significant margin. [28] By emphasizing recent studies and seminal works, this review becomes a valuable resource for both academics and professionals, guiding their exploration of the intersection between GANs and gene expression data systems. JaeWon Kim et al.[29] has implemented Game Effect Sprite Generative Adversarial Network (GESGAN). The experimental results demonstrate GESGAN's ability to generate style-translated images across different object shapes and drawing styles. It also handles 2D image sprite generation and modification tasks almost in real-time, thus cutting down game development expenses.

The literature survey concerning active player recognition utilizing the Multi-Deep SORT with GAN approach encompasses an evolving landscape in player tracking methodologies. It reflects a shift from traditional object tracking methods reliant on probability density and appearance features towards more sophisticated techniques integrating deep learning and generative adversarial networks (GANs). Earlier methodologies like Meanshift, Kalman Filter, and Particle Filter laid the groundwork, with Meanshift emphasizing probability density distribution and Kalman Filter modeling object motion. Meanwhile, Particle Filter utilized statistical particle distribution for object tracking.

The survey highlights the evolution towards more sophisticated approaches like DeepSORT, an algorithm integrating object detection and appearance information for object association. It underscores the importance of object detection methodologies, especially the adoption of deep learning-based methods like YOLOv3 for superior person detection. Additionally, it explores tracking-by-detection schemes, emphasizing the effectiveness of convolutional neural networks and Hungarian algorithms for bounding box association and multiple object tracking tasks.

Furthermore, the survey underlines the advancements in active player recognition through the fusion of Multi-Deep SORT with GANs. GANs contribute to refining player representations, enhancing tracking precision, and discerning activity levels in dynamic gameplay. The survey's comprehensive analysis highlights the shift towards sophisticated deep learning techniques and their integration into object tracking and player recognition systems, paving the way for more precise and contextually aware player tracking methodologies. Table I. represents recent works in Handball for detection and tracking.

III. PROPOSED METHOD

The literature review findings suggest the necessity for novel methods in active player tracking to accommodate diverse variances. This paper introduces an innovative approach to track players in handball videos by integrating the Multi-Deep SORT algorithm with a Generative Adversarial Network (GAN). This fusion is designed to address and overcome the challenges posed by these variations.

Fig. 1 illustrates an overview of the proposed method. The active player tracking process using the Multi-Deep SORT algorithm with a GAN model involves several stages, starting with the input of handball video footage. The initial step is preprocessing, encompassing segmentation and annotation to identify players within frames. This preprocessed video data, along with the generated bounding boxes from the object detection phase, serves as the input for subsequent stages. The Multi-Deep SORT algorithm takes this input, initiating multi-object tracking and identity preservation across frames. Simultaneously, the GAN model enhances player representations within video frames by refining appearance features and generating realistic player representations. This enriched data, along with the Multi-Deep SORT outputs, is integrated for robust and accurate player tracking. The output of this integrated process is refined player trajectories and identities across frames. It includes tracked bounding boxes around players, associating their identities and movements throughout the video sequence. Additionally, the system discerns between active and inactive players, offering insights into player dynamics during gameplay. The final output showcases precise player localization, continuous tracking, and nuanced distinctions in player activity levels. Evaluation metrics like Average Precision (AP), Average Recall (AR), Accuracy, and F1-score validate the output, ensuring high accuracy, robustness, and real-time processing capabilities. Ultimately, the refined output empowers analysts, coaches, and players with comprehensive insights, facilitating strategic decision-making and performance optimization in handball and sports analytics. It consists of three major steps: object detection, object tracking, and enhancing appearance features using GAN.

A. Active Player Detection using YOLOv8

YOLOv8, a one-stage object detection model, directly anticipates bounding boxes and class probabilities from the input image of a handball video. Its structure comprises two primary components: the backbone network and the head network.

1) Backbone network: YOLOv8 employs a one-stage object detection model for handball video, featuring a backbone network based on the Cross Stage Partial Networks (CSPNet) architecture. CSPNet, recognized for its lightweight and efficient design, proves particularly suitable for object detection tasks without compromising accuracy. The CSPNet architecture involves splitting the feature map of each layer into two parts and processing them independently, reducing computational requirements while maintaining high accuracy. The input image undergoes convolutional layers, with each layer's feature map divided. One part undergoes a regular convolutional layer, while the other traverses a dense block. The outputs from both are concatenated, forming the input for the subsequent layer. The dense block, a pivotal element of CSPNet, interconnects all layers within the block, enabling the acquisition of intricate features beyond the capacity of regular convolutional layers. This architectural approach has demonstrated superior performance in various benchmarks, offering state-of-the-art results in object detection and image classification tasks, all while achieving notable computational efficiency.

The dense block can be mathematically represented as follows:

$$X\_I = H\_I(X\_\{I-1\}) + X\_\{I-1\} \tag{1}$$

Where, X_I is the output of the Ith layer in the dense block and H_I is the convolutional layer in the Ith layer of the dense block. The CSPNet architecture can be mathematically represented as follows:

$$F\_I = C\_I(X\_\{I-1\}) + D\_I(X\_\{I-1\}) \tag{2}$$

Where, F_I is the output of the Ith layer in the CSPNet. C_I is the convolutional layer in the Ith layer in the CSPNet. D_I is the dense block in the Ith layer in the CSPNet.

2) Head network: Utilizing the output features from the backbone network, YOLOv8's head network predicts bounding boxes and class probabilities for objects in the image. The head network is segmented into three branches: the Bounding Box branch forecasts object coordinates, the Objectness branch predicts the likelihood of a bounding box containing an object, and the Class Probability branch estimates the probability of an object belonging to a specific class. The output of the head network is a tensor of shape is follows:

$$[B, S, S, (C+5)] \tag{3}$$

Where, B is the batch size. S is the size of the output grid. $C$is the number of object classes. The five additional channels contain the bounding box coordinates and objectness probability for each cell in the output grid. The general formulation of YOLOv8 can be summarized as follows:

$$y = f(x \tag{4}$$

Let x denote the input image depicting a handball scene, y represent the output tensor produced by the head network, and f signify the YOLOv8 model. Function f processes input image x, forecasting bounding boxes and class probabilities for each object. YOLOv8 undergoes supervised learning, using labeled object images to minimize the loss between predicted and ground truth bounding boxes and class probabilities during training. During inference, YOLOv8 analyzes an input image, predicting bounding boxes and class probabilities for each object and utilizing a non-maxima suppression (NMS) algorithm to eliminate duplicate boxes, yielding the final output.

B. Active Player Tracking using Multi-Deep Sort Algorithm

After detection, active player tracking using the Multi-Deep SORT algorithm is a sophisticated process that involves several key steps to robustly monitor and identify players in handball videos. The tracking process begins by formulating the state vector for each tracked object. This vector typically includes parameters like position (x, y), velocity (vx, vy), and others.

$$X = [x, y, vx, vy, \dots] \tag{5}$$

The dynamic model, often based on a constant velocity model, predicts the state of the object in the next frame. It describes the object's motion using a dynamic model. Commonly, a constant velocity model is employed:

$$X_k = F.x_{k-1} + W_k \tag{6}$$

Where, F is the state transition matrix and W_k is the process noise. The observation vector represents the observed measurements, encompassing bounding box coordinates. The measurement model establishes a relationship between these observed measurements and the object's state, incorporating a measurement matrix and accounting for measurement noise.

Specifically, the observed measurements, usually comprising bounding box coordinates, are defined as follows:

$$z_k = [x, y, width, height] \tag{7}$$

$$z_k = H.x_k + v_k \tag{8}$$

Where, H is the measurement matrix and v_k is the measurement noise. Formulate the assignment problem using the Hungarian algorithm, aiming to minimize the total cost of associations between predicted and observed bounding boxes. This step ensures correct matching between objects across frames. Kalman filtering is employed to refine the state estimate based on the predicted state and measured state. Kalman gains determines the weight of the correction, resulting in a corrected state estimate. This process helps adapt the tracking system to dynamic changes in object motion. It update the state estimate with a weighted average of the predicted state and the measured state:

$$K_k = P_{k|k-1}.H^T.\left(H.P_{k|k-1}.H^T + R_k\right)^{-1} \tag{9}$$

$$\hat{X}_k = F.\hat{X}_{k|k-1} + K_k.\left(z_k - H.F.\hat{X}_{k|k-1}\right) \tag{10}$$

Where, $P_{k|k-1}$ is the predicted error covariance matrix and R_k is the measurement noise covariance matrix. Following the tracking process, there is a possibility of overlapping or redundant bounding boxes. The Non-Maximum Suppression (NMS) algorithm employs the Intersection over Union (IoU) calculation between bounding boxes. This mechanism enables the system to retain only the most confident and non-overlapping boxes, effectively eliminating redundancy, as determined by the following equation:

$$IoU = \frac{Area\ of\ Intersection}{Area\ of\ Union} \tag{11}$$

Utilize Non-Maximum Suppression (NMS) by applying a threshold to discard redundant bounding boxes, retaining only the most confident ones. Repeat the process for each frame in the video sequence, continuously updating the state estimates and associations. The final output includes refined player trajectories, accurately tracked bounding boxes, and distinctions between active and inactive players. Fig. 2 shows active player tracking system using multi-deep sort algorithm.

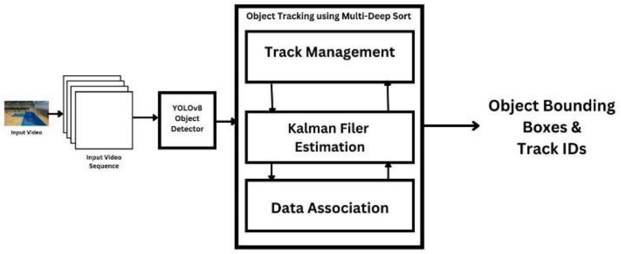

Fig. 2. Active player tracking system using multi-deep sort algorithm.

C. Enhancement of Active Player Features through Integrated-GAN Fusion

The input to the GAN module is a combination of spatial and temporal information about actively tracked players. It involves both the visual context of player appearance and the temporal evolution of these appearances over consecutive frames. The GAN processes this input information to generate enhanced appearance features for the actively tracked players. The generator in the GAN takes these inputs and produces synthetic appearance features that are realistic and visually appealing. The discriminator evaluates the realism of these generated features, and the GAN is trained iteratively to improve the quality of the generated appearances. The output of the GAN module is a set of enhanced appearance features for the actively tracked players. These features can then be integrated back into the tracking system, enriching the visual representation of players for applications such as sports analytics, video presentations, or interactive systems.

```
Algorithm: Multiple Object Tracking using Deep-SORT with GAN (MOD-GAN)
Input:
    Sequence of frames, Random Noise Images
Output:
    Generated synthetic frames
Step 1: Object Detection:
    Obtain object detections using YOLOv8 algorithm
Step 2: Feature Extraction:
    Extract appearance features for each detected object using a pre-trained deep neural network.
Step 3: Data Association:
    Associate detections with existing tracks using Kalman filtering based on proximity and
    appearance similarity.
Step 4: State Estimation (Kalman Filter):
    // Kalman Filter Initialization
        Initialize the state vector $x$ and covariance matrix $P$ for each track.
    Define the process noise covariance matrix $Q$ and measurement noise covariance matrix $R$.
    // Prediction Step:
        Predict the next state estimate $\hat{X}_{k|k-1}$using the state transition matrix F and motion model.
        Predict the covariance $\hat{P}_{k|k-1}$ using the process noise covariance matrix $Q$.
    // Measurement Update Step:
        Compute the Kalman gain $K_k$ using the predicted covariance $\hat{P}_{k|k-1}$, measurement matrix $H$,
        and measurement noise  covariance $R$.
        Update the state estimate $\hat{X}_k$ using the predicted state $\hat{X}_{k|k-1}$ and the measurement $z_k$.
      Update the covariance $\hat{P}_k$ using the kalman gain $K_k$ and the measurement matrix $H$.
Step 5: Integrate the GAN module into the MOS algorithm pipeline to generate synthetic data for training
    and augmenting the object detection and feature extraction stages.
      $Input = \left\{I_t, \{B_t^i, A_t^i, ID_t^i\}_{i=1}^{N}, T_t\right\}$
      // The output appearance features, denoted as $\hat{A}_t^i$, are generated based on the input
        Output:  $\hat{A}_t^i = G\left(I_t, B_t^i, A_t^i, ID_t^i, T_t\right)$
```

The input to the GAN module for active player tracking, let I_t denote the image frame at time t. The bounding box coordinates for each actively tracked player are represented by B_t^i, where i indexes the player. The appearance features within these bounding boxes, denoted as A_t^i, capture aspects like facial expressions, clothing details, and body posture. Additionally, the temporal context is considered, with T_t representing the sequence of frames. Optionally, player identity information can be denoted by ID_t^i . Therefore, the input at time t is represented as:

$$Input = \left\{I_t, \{B_t^i, A_t^i, ID_t^i\}_{i=1}^N, T_t\right\} \quad (12)$$

The generator in the GAN module process this input to generate enhanced appearance features for the actively tracked players. Let $G(.)$ Denote the generator function. The output appearance features, denoted as $\hat{A}_t^i$, are generated based on the input:

$$\hat{A}_t^i = G\left(I_t, B_t^i, A_t^i, ID_t^i, T_t\right) \quad (13)$$

Here, the generator learns to generate synthetic appearance features that closely resemble real data while considering the spatial and temporal context of the tracked players. The discriminator evaluates the realism of the generated appearance features. Let $G(.)$ represent the discriminator function. The discriminator takes both real and generated appearance features as input and outputs probabilities indicating the likelihood of the input being real or fake:

$$P\left(Real|A_t^i\right) = D\left(A_t^i\right) \quad (14)$$

$$P\left(Fake|A_t^i\right) = D\left(\hat{A}_t^i\right) \quad (15)$$

The GAN is trained by optimizing a common objective function that involves both the generator and discriminator. The generator is trained to minimize the log probability of the discriminator correctly classifying the generated features as fake, and the discriminator is trained to maximize this probability. This adversarial training process is mathematically expressed as:

$$Generated\ Loss = -log\left(1 - D\left(\hat{A}_t^i\right)\right) \quad (16)$$

$$Discriminator\ Loss = -log\left(D\left(A_t^i\right)\right) - log\left(1 - D\left(\hat{A}_t^i\right)\right) (17)$$

The enhanced appearance features generated by the $GAN\left(\hat{A}_t^i\right)$ are then integrated back into the active player tracking system. These features enrich the visual representation of players, contributing to a more realistic and dynamic portrayal within the handball video tracking context. The GAN module takes input from the tracking system, processes it through a generator to enhance appearance features, evaluates the realism of the generated features using a discriminator, and is trained iteratively to improve the overall visual representation of actively tracked players in handball videos. Fig. 3 presents the enhancement active player features through integrated-GAN fusion.

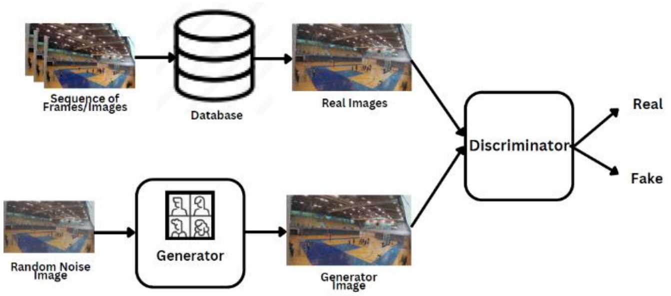

Fig. 3. Enhancement of active player features through integrated-GAN fusion.

IV. Experiments

In the experimental phase, as outlined in [26], the customized dataset consists of 751 videos, each demonstrating one of seven distinct handball actions: shooting, passing, jump-shot, dribbling, running, defense, and crossing. This dataset was thoughtfully assembled by manually selecting specific scenes extracted from extended recordings of handball practice sessions. For this job, strategically placed GoPro cameras, stationed on either the left or right sides of the playing field, were utilized. These cameras captured footage from various angles to provide comprehensive coverage. The videos were consistently recorded in high quality, meeting or surpassing full HD (1920 × 1080) resolution, and maintaining a frame rate of 30 or more frames per second [26]. Typically, each scene features around 12 players, with the primary focus on one or two players executing the targeted action. The experiment assesses the proposed technique's performance using four metrics: average precision, average recall, accuracy, and F1-score. Table II shows experimental setup for the proposed method.

The proposed method utilizes a system configuration featuring an I5 Processor of the 5th Generation, 16GB RAM, and a 128GB hard disk space. The implementation of the proposed method has been carried out using Tensorflow and Keras. Out of the 751 videos available in the dataset, a subset of 250 videos is used for the proposed method MOD-GAN. Approximately 175-200 videos are selected for training purposes (70-80% of 250), encompassing various handball actions. The remaining 50-75 videos are reserved for testing (20-30% of 250). Each frame underwent meticulous annotation, categorizing it as depicting either an active or inactive player. Training parameters comprised a learning rate set at 0.001, a momentum of 0.9, and a decay rate of 0.0005. Video frames inputs were standardized to a fixed size of 640 × 640 pixels. Experimenting with Generative Adversarial Networks (GANs) poses various challenges, including data availability, computational demands, training stability, and evaluation metrics. GANs require high-quality training data and significant computational resources for stable training and convergence. Tuning hyperparameters and defining appropriate evaluation metrics are critical for assessing sample quality and diversity. Addressing these constraints is crucial to ensure meaningful and impactful experimentation with GANs.

The metrics used to evaluate the performance of the proposed method are average precision, average recall, accuracy, and F-Score. The performance metrics are as follows:

1) *Average Precision (AP)*: is defined as the mean of the precision values at each threshold where recall increases. It is calculated as the area under the precision-recall curve, where precision is the ratio of true positive predictions to the total number of positive predictions, and recall is the ratio of true positive predictions to the total number of actual positives. The formula for the Average Precision is:

$$AP = \sum_{i=1}^{n}(R_i - R_{i-1})\, P_i \quad (18)$$

Where P_i is the precision at the i-th threshold, R_i is the recall at the i-th threshold, and R_{i-1} is the recall at the previous threshold.

2) Average Recall (AR): is defined as the mean of the recall values at different recall thresholds. Recall, also known as sensitivity, is the ratio of true positive predictions to the total number of actual positives. The formula for the Average Recall is:

$$AR = \frac{1}{n}\sum_{i=1}^{n} R_i \tag{19}$$

Where R_i is the recall at the threshold, n is the number of recall thresholds considered.

3) Accuracy: is defined as the ratio of the number of correct predictions to the total number of predictions. The formula for the accuracy is:

$$Accuracy = \frac{Number\ of\ correct\ predictions}{Total\ number\ of\ predictions} \tag{20}$$

4) F1-score: is a measure of a test's accuracy, combining both precision and recall into a single metric. It is the harmonic mean of precision and recall. The formula for the F1-score is:

$$F1 - score = \frac{2\times(Precision\times Recall)}{Precision+Recall} \tag{21}$$

Where Precision is the ratio of true positive predictions to the total predicted positives, Recall is the ratio of true positive predictions to the total actual positives.

TABLE II. EXPERIMENTAL SETUP FOR THE PROPOSED METHOD

Dataset	Various Handball Action	*.mp4 format	No of videos taken for experiment
Custom dataset - 751 videos	Crossing	129	60
	Dribbling	24	15
	Defense	16	16
	Passing	104	50
	Jump-shot	370	60
	Shot	102	50
	Running	09	09
Total		751	250

A. Results and Comparison with Other Existing Methods

The proposed handball tracking system has been experimented with the benchmark dataset mentioned in the experiment setup column. The Multiple Object Tracking using Deep-SORT with GAN (MOD-GAN) approach for active player tracking and enhanced appearance feature in handball videos exhibits strong performance across various handball actions, achieving improved average precision, average recall, and accuracy and F-score values. Table III illustrates the notable precision achieved in tracking active players in handball videos. Furthermore, Table III presents the average performance metrics for a range of handball action types. These results, as shown in Fig. 4, reflect the promising outcomes produced by the algorithm for active player tracking using the MOD-GAN approach.

The proposed system shows a better performance for different actions in handball tracking system with the following measures such as average precision, average recall, accuracy, and F-score respectively. The crossing action class, the average measures of average precision, average recall, accuracy, and F-score rates are 94.18%, 93.34%, 92.98% and 93.76% respectively. The dribbling action class, the average measures of average precision, average recall, accuracy, and F-score rates are 90.19%, 90.02%, 90.01% and 90.10% respectively. The defense action class, the average precision, average recall, accuracy, and F-score rates are 92.16%, 91.96%, 91.79% and 92.06% respectively. The passing action class, the average measures of average precision, average recall, accuracy, and F-score rates are 90.55%, 90.01%, 90.14% and 90.28% respectively. The jump-shot action class, the average measures of average precision, average recall, accuracy, and F-score rates are 91.01%, 90.88%, 90.62% and 90.94% respectively. The shot action class, the average measures of average precision, average recall, accuracy, and F-score rates are 93.48%, 92.73%, 92.93% and 93.10% respectively. The running action class, the average measures of average precision, average recall, accuracy, and F-score rates are 94.99%, 93.67%, 93.89% and 94.33%, respectively. Differences in the characteristics of the dataset used for evaluation, such as player appearances, game scenarios, lighting conditions, and camera angles, can lead to performance fluctuations across methods.

TABLE III. COMPREHENSIVE EFFECTIVENESS OF THE PROPOSED METHOD

Various Handball Action	Avg. Precision (%)	Avg. Recall (%)	Accuracy (%)	F1-Score (%)
Crossing	94.18	93.34	92.98	93.76
Dribbling	90.19	90.02	90.01	90.10
Defense	92.16	91.96	91.79	92.06
Passing	90.55	90.01	90.14	90.28
Jump-shot	91.01	90.88	90.62	90.94
Shot	93.48	92.73	92.93	93.10
Running	94.99	93.67	93.89	94.33

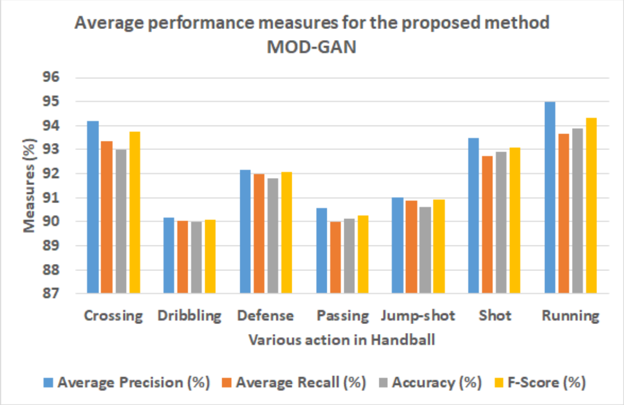

Fig. 4. Average performance measures for the proposed method MOD-GAN.

The results of the proposed system show a clear improvement over the I3D multi-class model [24], DT+STIP [25], DT+OF [25] and DT+Y [25]. The proposed system shows a better performance with average precision 94.99%, average recall 93.67%, accuracy 93.89% and F-score 94.33% respectively. The proposed method MOD-GAN is compared with I3D multi-class method, the average measures of average precision, average recall, accuracy, and F-score rates are 80%, 77%, 76% and 78% respectively. The DT+STIP method, the average measures of average precision, average recall, accuracy, and F-score rates are 67%, 23%, 34%, and 38% respectively. In the DT+OF method, the average measures of average precision, average recall, accuracy, and F-score rates are 51%, 20%, 27% and 29% respectively. The DT+Y method, the average measures of average precision, average recall, accuracy, and F-score rates are 87%, 63%, 71%, and 73% respectively. Comparison analysis of average performance measures of the proposed method MOD-GAN and other existing methods as shown in Table IV and Fig. 5.

TABLE IV. COMPARISON OF AVERAGE PERFORMANCE MEASURES OF PROPOSED METHOD MOD-GAN AND OTHER METHODS

Method	Avg. Precision (%)	Avg. Recall (%)	Accuracy (%)	F-Score (%)
I3D multi-class model [24]	80	77	76	78
DT+STIP [25]	67	23	34	38
DT+OF [25]	51	20	27	29
DT+Y [25]	87	63	71	73
MOD-GAN (proposed method)	94.99	93.67	93.89	94.33

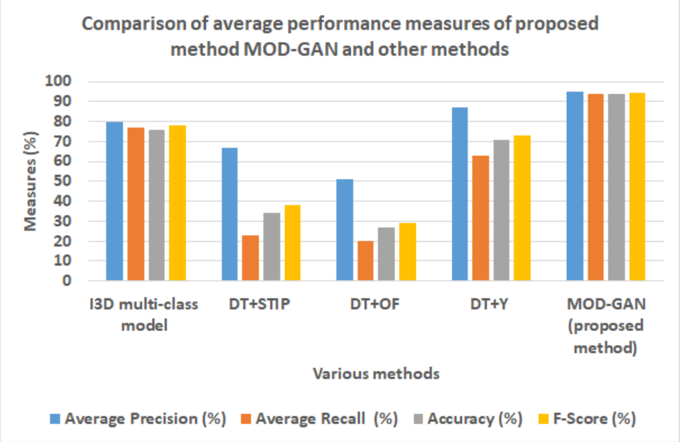

Fig. 5. Comparison of average performance measures of proposed method MOD-GAN and other methods.

Fig. 6 highlights the detection of active players during tracking with most players in the lineup being monitored.

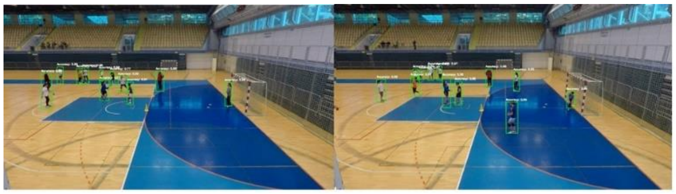

Fig. 6. Active Player detection on tracking – Crossing, and defense the ball.

In low-light environments, background players, even when partially occluded or hidden, are detected during tracking. Their actions, such as dribbling and executing jump shots, are accurately captured which shown in Fig. 7.

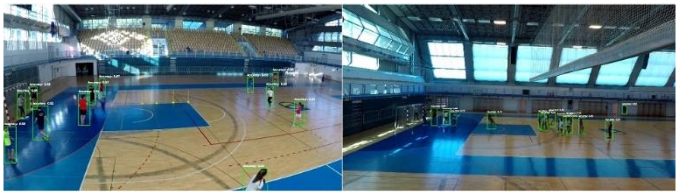

Fig. 7. Background players, partially occluded or hidden, remain undetected on tracking with low light environments – actions include dribbling, and jump-shot.

Fig. 8 illustrates the challenge of tracking a player within scenes. Despite closely monitoring the majority of players on the field, the individual tasked with controlling and protecting the ball as it advances towards the goal may evade attention. This could be attributed to their unconventional body positioning and a T-shirt color that blends with the playground background.

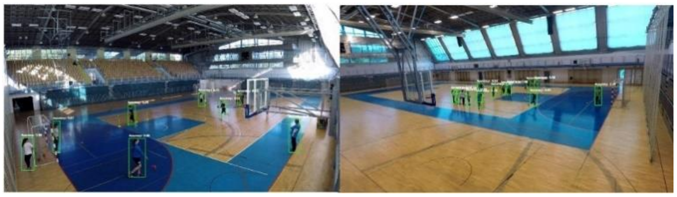

Fig. 8. Background players, partially occluded or hidden, remain undetected on tracking– actions include passing, and shooting.

It is observed from experimentation that the MOD-GAN method produces good and comparable results with average precision 94.99%, average recall 93.67%, accuracy 93.89% and F-score 94.33% respectively for different handball actions, including passing, shooting, jump-shot, dribbling, running, crossing, and defense as shown in Table III. The reason for this improvement is three-fold i) The integration of GAN-based enhancements with Multi-Deep SORT elevates player representation precision by generating synthetic frames that enhance visual quality and realism. This refinement of initial player appearances significantly boosts tracking accuracy, ensuring consistent and accurate player identification across frames, even in challenging scenarios with appearance variations and occlusions. ii) The integrated system demonstrates enhanced discrimination between active and inactive players in handball gameplay, leveraging GAN-enhanced features to elevate player recognition accuracy. This improvement provides deeper insights into player actions, movements, and roles, refining strategic analysis and performance evaluation through precise identification and classification of player engagement levels. iii) Integrating Multi-Deep SORT with GAN-based enhancements significantly enhances contextual awareness in active player tracking, surpassing traditional methods. The resulting refined player representations and improved discrimination empower stakeholders with unparalleled insights, facilitating informed decision-making and performance optimization in handball and sports analytics shown in Fig. 9.

In this paper, the novel approach of employing integrated MOD-GAN aims to enhance player appearance for precise tracking in dynamic gameplay scenarios. Beginning with a GAN model trained on annotated handball video data, synthetic frames are generated to improve visual quality and realism, refining input data for subsequent tracking. Multi-Deep SORT, known for robust multi-object tracking, is augmented with GAN-generated features for improved object association, advancing active player tracking by addressing challenges such as occlusions, appearance variations, and complex interactions. The system's heightened ability to distinguish between active and inactive players facilitates precise localization and recognition.

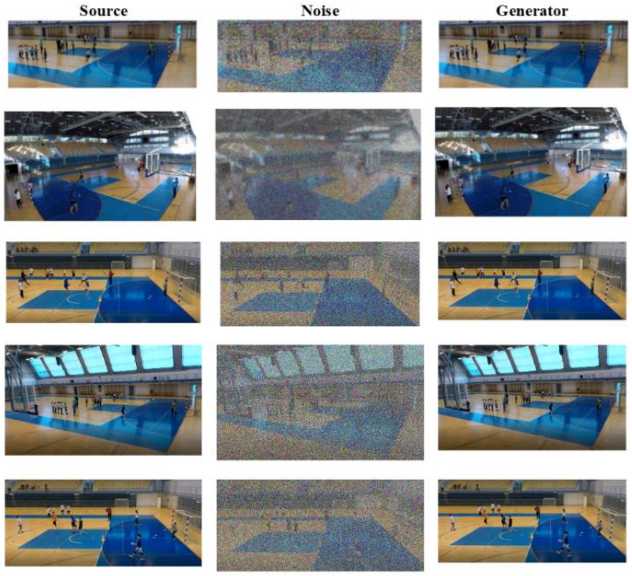

Fig. 9. Sample results for enhancement of active player features through integrated-GAN fusion.

V. Analysis of Proposed Method Multiple Object Tracking using Deep-Sort with GAN (MOD-GAN)

1) Performance evaluation: The performance of the proposed handball tracking system, Multiple Object Tracking using Deep-SORT with GAN (MOD-GAN), has been thoroughly evaluated using a benchmark dataset. The system demonstrates strong performance across various handball actions, achieving high average precision, recall, accuracy, and F-score values. Specifically, the tracking system excels in scenarios involving dynamic player movements and interactions, as reflected in Table III. The quantitative assessments, illustrated in Fig. 4, showcase the system's efficacy in accurately tracking active players and maintaining consistent player identities across frames.

2) Comparison with baseline models: The proposed MOD-GAN method significantly outperforms several baseline models, including I3D multi-class [24], DT+STIP [25], DT+OF [25], and DT+Y [25]. The average precision, recall, accuracy, and F-score of the MOD-GAN approach are notably higher, as detailed in Table IV and Fig. 5. For instance, the MOD-GAN method achieves an average precision of 94.99%, whereas the I3D multi-class model only reaches 80%. This improvement underscores the effectiveness of integrating GAN-enhanced features with the Deep-SORT algorithm, leading to more accurate and robust tracking results compared to traditional methods.

3) Robustness and generalization: The MOD-GAN approach exhibits remarkable robustness and generalization across different handball actions, including passing, shooting, jump-shot, dribbling, running, crossing, and defense. The system effectively handles challenges such as occlusions, variations in player appearances, and complex interactions within the game. This robustness is attributed to the GAN-generated synthetic frames, which enhance the visual quality and realism of player appearances, thereby refining the input data for the tracking phase. The consistent performance across various scenarios demonstrates the system's ability to generalize well to different types of player actions and gameplay conditions.

4) Impact of data augmentation: Data augmentation plays a crucial role in enhancing the performance of the MOD-GAN system. By generating synthetic frames using a GAN model trained on annotated handball video data, the system improves the visual quality and realism of player appearances. This augmentation leads to better feature representation and tracking accuracy. The GAN-based enhancements enable the system to maintain precise and consistent player identities, even in challenging scenarios with significant appearance variations and occlusions. This results in more robust and reliable tracking performance, providing deeper insights into player actions, movements, and roles within the handball game.

VI. Conclusion

In conclusion, active player tracking in sports analytics has played a pivotal role in understanding team dynamics, player performance, and game strategies. This paper introduced an innovative approach to active player tracking in handball videos, leveraging a fusion of the Multi-Deep SORT algorithm and a Generative Adversarial Network (GAN) model. The novel integration aimed to enhance player appearance for robust and precise tracking in dynamic gameplay scenarios. The proposed system began by employing a GAN model trained on annotated handball video data, generating synthetic frames to improve the visual quality and realism of player appearances. These enhancements contributed to refining the input data for the subsequent tracking phase. The Multi-Deep

SORT algorithm, known for its robust multi-object tracking capabilities, was augmented with the GAN-generated features for improved object association and continuous player tracking across frames. This innovative framework advanced the state-of-the-art in active player tracking by addressing several key challenges. The system exhibited a heightened ability to handle occlusions, variations in player appearances, and complex interactions within the game. Moreover, the integration of GAN-based enhancements elevated the system's accuracy in distinguishing between active and inactive players, facilitating more precise player localization and recognition. Performance evaluation demonstrated the system's efficacy in achieving high tracking accuracy, robustness, and differentiation between player activity levels.

This pioneering fusion of Multi-Deep SORT with GAN-based player appearance enhancement has set a new standard for precise, robust, and context-aware active player tracking in handball videos, offering comprehensive insights for coaches, analysts, and players to optimize team strategies and individual performance. This paper introduced the novel integration of Multi-Deep SORT with GANs for active player tracking, highlighting its advancements and benefits in the domain of sports analytics. Notably, the proposed method had exhibited enhanced efficiency, achieving an average precision of 94.99%, average recall of 93.67%, accuracy of 93.89%, and F-score of 94.33%, respectively. For future enhancements, exploring real-time implementation of the proposed active player tracking system could be a valuable avenue, providing instant insights during live handball events. Additionally, integrating more sophisticated GAN architectures and leveraging advanced deep learning techniques may further enhance the system's ability to handle diverse player appearances and complex game scenarios. Exploring the integration of sensor data, such as player biometrics or position tracking, could contribute to a more comprehensive understanding of player dynamics. Finally, collaborative efforts with domain experts and continuous refinement based on feedback from sports professionals can ensure the system's continual improvement and alignment with evolving requirements in sports analytics.

An Improved Genetic Algorithm and its Application in Routing Optimization

Jianwei Wang, Wenjuan Sun*
School of Computer and Artificial Intelligence, Chaohu University, HeFei, China

***Abstract*—Traditional routing algorithms can't adapt to the complex and changeable network environment, and the basic genetic algorithm can't be applied to solving routing optimization problems directly because of the lack of coding methods. An improved basic genetic algorithm was purposed to find the optimal or near-optimal routing. The network model and mathematical expression of routing optimization problem was defined, and the routing problem was transformed into a problem of finding the optimal solution. In order to meet the specific needs of network routing optimization, some key improvements of GA have been made, including the design of coding scheme, the generation of initial population, the construction of fitness function and the improvement of crossover operator and mutation operator. The simulation results of two typical network environments show that the improved GA has excellent performance in routing optimization. Compared with Dijkstra algorithm and Floyd algorithm, the improved GA in this paper not only has excellent robustness and adaptability in solving routing optimization problems, but also can effectively cope with the dynamic changes of network environment, providing an efficient and reliable routing solution for dynamic network environment.**

Keywords—Improvement of genetic algorithm; routing optimization; shortest path; crossover operator; mutation operator

I. Introduction

In the modern computer network environment, the process of determining the transmission path of data packets, that is, routing, is facing complex challenges. With the continuous expansion of the network and the increasing traffic, the network structure has become more and more complex, and the traditional routing methods have been difficult to meet the needs of modern networks. It has become very important to find an effective and least costly routing strategy to improve network efficiency and reduce congestion, which urges researchers to find more effective routing optimization methods.

Routing refers to arranging the communication link between the source node and the served object. Routing strategies commonly used are divided into fixed routing, flooding routing, random routing and adaptive routing [1]. The concrete forms of the shortest path problem include: the shortest path problem of determining the starting point, the ending point, the starting and the ending point and the global shortest path problem. Optimization tools are often used to find the optimal or near-optimal routing scheme in solving the shortest path optimization problem. Genetic Algorithm (GA) is a method to simulate natural evolution and find the optimal solution proposed by John Holland [2] in 1970s. Genetic algorithm is widely used in many fields as its strong global optimization ability, and some scholars have applied GA to solve routing optimization problems.

Obeidat A et al. [3] proposed a network routing method based on GA. Moza M et al. [4] put forward a method based on GA to find the k shortest paths in the network. Zhao Feng [5] described the realization principle of intelligent search algorithm such as genetic algorithm in dynamic routing optimization of computer network. Wang et al. [6] proposed a multi-path routing algorithm for WSN based on genetic algorithm. The fitness function was determined by calculating the node spacing, and a shared routing scheme was generated at the base station. Because of the fixed-length coding, the best path may be limited and the global optimization cannot be achieved. Gao Xia et al. [7] selected GA for routing operation, improved GA and applied it to the routing problem of WSN. The above research adopts GA directly or improves GA to solve the routing problem or the shortest path problem, but all of them are optimized under the same solution length condition, no research is made on paths with different lengths.

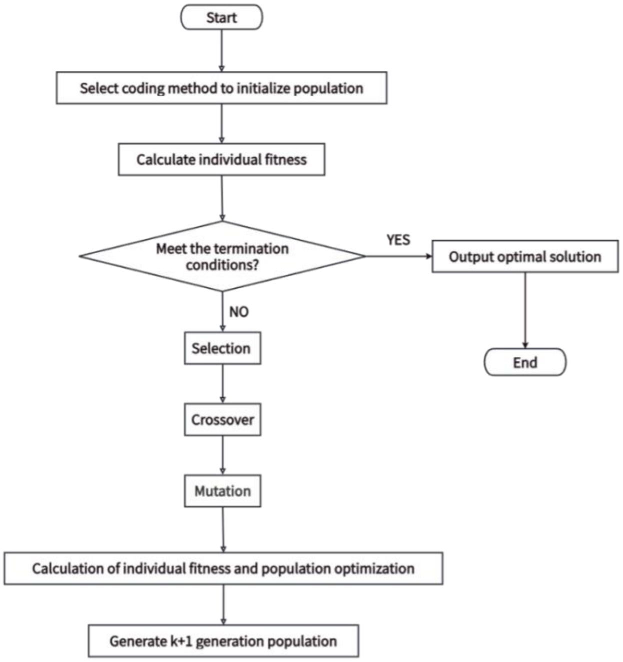
In view of the shortcomings of the above research, this paper designs the coding scheme, generates the initial population, constructs the fitness function and improves the core operation of the genetic algorithm. In order to reduce the time spent in path finding, the shortest path adaptive routing problem with simultaneous determination of starting point and ending point is optimized.

II. Improvement of Genetic Algorithm

A. Basic Genetic Algorithm

Genetic algorithm is an optimized search algorithm that simulates the natural selection and genetic mechanism of organisms. The optimization process of GA includes six processes: population initialization, individual evaluation, selection operation, crossover operation, mutation operation and termination condition judgment [8]. Fig. 1 shows the operation steps of the genetic algorithm.

The basic genetic algorithm is more suitable for finding an optimal path to traverse the whole network graph as the length of chromosomes generated by coding is fixed. The research background of this paper is that the optimal path of two nodes found by the basic genetic algorithm has certain constraints, and the optimal path may not be global optimal. The improved genetic algorithm in this paper uses variable-length chromosomes to encode the routing path, determines the neighborhood nodes of each node in the network in advance, and improves the crossover and mutation operations according to the characteristics of the path to prevent unqualified paths. When forming a routing path, factors such as the distance between path nodes, the total energy consumption of the path and the residual energy of the nodes are considered, and the fast global optimization ability of the genetic algorithm is integrated into the routing optimization to search the target routing path efficiently and comprehensively.



Start
Select coding method to initialize population
Calculate individual fitness
Meet the termination conditions?
YES
Output optimal solution
NO
Selection
End
Crossover
Mutation
Calculation of individual fitness and population optimization
Generate k+1 generation population

Fig. 1. Flow chart of genetic algorithm.

B. Mathematical Network Model of Shortest Path Routing Problem

Shortest path algorithm is a classical algorithm problem in graph theory, which aims to find the shortest path between two vertices in a graph. The shortest path refers to the path with the smallest sum of weights on each side that starts from a vertex and reaches another vertex along the edge of the graph.

The weighted undirected graph G can be used to represent the network when studying the routing problem, and G=(V,E). Where V(G) represents the vertex in graph G [9], which is the routing node, E(G) represents the set of relationships between vertices in graph G, which is the set of links between routing nodes. |V| represents the number of nodes in the network, |E| represents the number of links in the network, and the matrix W=(wij) represents the cost of link (i,j). The starting node and the destination node are represented by start and stop respectively, and the connection relationship between nodes is represented by matrix A=(aij), as shown in formula (1) [10].

$$a_{ij}=\begin{cases}1, & v_i \text{ is connected with } v_j \\ 0, & v_i \text{ and } v_j \text{ are not connected or the same}\end{cases} \tag{1}$$

If a_{ij}=1 and a_{jk}=1 indicate that it is reachable from node i to node k, all paths from *start* to *stop* can be found and the nodes can be saved in the array path, as shown in Formula (2).

$$path(i,j)=\text{node} \tag{2}$$

where 'i' is the *i*th path, 'j' is the *j*th node of the path, 'node' is the routing node number, which is a positive integer.

The problem of calculating the shortest path can be transformed into the optimization problem of the minimum value, and the objective function is as shown in Formula (3).

$$\min \sum_{j=1}^{m}\sum_{\text{i}=2}^{\text{n}} w_{path(j,i-1)\,path(j,i)} \tag{3}$$

Where 'j' represents the *j*th path, 'm' represents the number of paths, 'n' represents the length of the *j*th path.

C. Improvement of Coding Mode and Population Initialization

It is not suitable to adopt the coding method of basic genetic algorithm in the initial population operation as all the paths from the starting node to the destination node are different in length. Instead, the node number of the path is directly encoded and saved. This improved coding method is not only beneficial to the selection of fitness function and the calculation of fitness, but also more suitable for solving the shortest path routing problem.

In order to store the information of the network diagram effectively, it can be saved by transforming it into an adjacency matrix, which is an n-order matrix w, as shown in Formula (4).

$$W[i][j]=\begin{cases}w_{ij}, & \text{Represents the cost required from node i to node j} \\ 0, & i=j \text{ or nodes i and j have no direct path}\end{cases} \tag{4}$$

Saving information in this way is beneficial to coding and implementation. The matrix W is an $n\times n$ matrix, and W[i][j] represents the network consumption required to reach the node j from the node i. If the value is 0, it means that node i=j or there is no direct path from node i to node j.

The generation of the initial population should meet the requirement that the individuals in the generated initial population can't have open circuits and loops, otherwise, the individuals obtained in the next operation will have a high probability of open circuits and loops, which will lead to the increase of unreachable and cost, and there will be mistakes in solving the shortest path routing problem. In order to make the generated individuals meet the requirements, the starting point is input, starting from the starting point, a node directly connected with the starting point is selected randomly and add it into the individual. Find out whether there is a node connected directly to this node, if there is a next node connected to it, continue to add it, and so on until the end point is found. The way to save chromosomes in this paper is to initialize a zero array. Save the nodes into the array in turn according to the rules generated by individuals until the end point is saved. If there are redundant zero elements, they will be ignored in code recognition.

There is a path from node B to nod M (B,D,H,L,N,P,O,M). The path is saved as (2,4,8,12,14,16,15,13,0,0). The path length is 8, so the first 8 elements save the node, and all other elements are 0. As shown in Fig. 2, the initial random population value is 10.

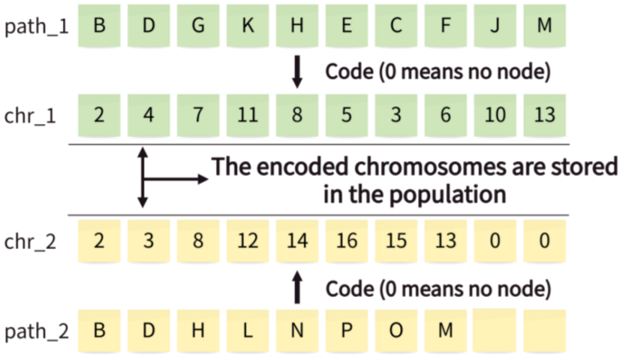


Fig. 2. Coding process diagram.

D. Design of Fitness Function

In genetic algorithm, fitness function is a very important concept. Fitness function is a mapping of optimization objectives, and each individual will be given a fitness value. The higher the fitness value, the more suitable the individual is for survival and reproduction. The fitness value is calculated and the parent is selected from the population. The calculation result of fitness value is used as the basis for selecting the parent, and roulette is used to select more excellent individuals. The fitness function can be used to measure the quality of chromosomes in the current iteration. The definition of fitness function in this scheme design is shown in Formula (5) [11].

$$f(path_i) = 1 - \frac{len(i,1) - \min len}{\max len - \min len + 0.01} \tag{5}$$

where 'path$_i$' represents the ith path, 'len' represents the total cost of path consumption, 'maxlen' represents the cost of the path with the largest total cost, and 'minlen' represents the cost of the path with the smallest total cost.

The advantages and disadvantages of the solution can be compared by calculating the fitness of each individual, which is the comparison condition of iterative updating.

E. Design of Selection Operator

In order to avoid the premature convergence of the algorithm, this study adopts the method of combining the optimal individual retention strategy with roulette algorithm in population selection. Let the population size be m, select the n best individuals with the highest fitness in each round and keep them directly in the next generation population, and select the remaining M-N individuals by roulette algorithm. In roulette algorithm, the probability that an individual is selected is directly proportional to fitness [12].

F. Improvement of Crossover Operator

The traditional single-point or multi-point crossover operation can't be adopted in this study as the coding method is different from the basic GA. Traditional crossover is likely to lead to open circuit and evolutionary failure. The traditional single-point crossover is shown in Fig. 3.

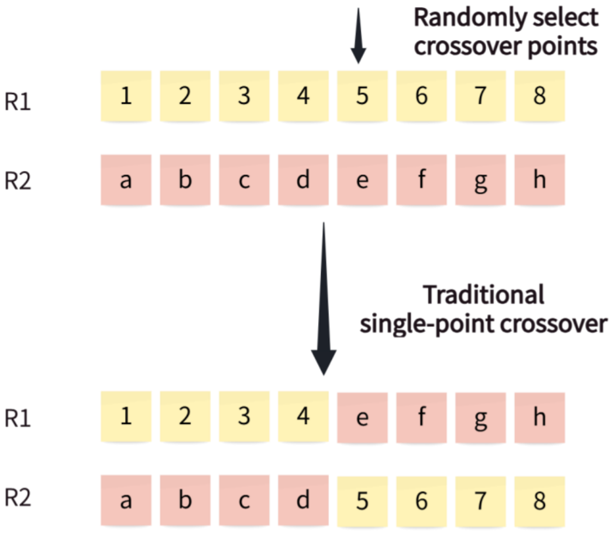

Fig. 3. Single-point crossover.

An improved single-point crossover method was proposed in order to solve the shortest path routing problem by GA. Different from the traditional single-point crossover, the improved single-point crossover can only be operated at nodes that are repeated except the starting point and the ending point of two paths, as shown in Fig. 4 [12].

The specific process is as follows:

a) Two individuals R_1 and R_2 from a population are selected.

b) Generate a pseudo-random number randomly, comparing it with the crossover probability. Judge whether to perform crossover operation or not. If yes, proceed to (c), otherwise, do not crossover.

c) Judge whether there are duplicate nodes except the start node and the end node. If so, save the nodes and carry out (d), otherwise, not crossing,

d) Select a node from the saved nodes randomly as a crossing point.

e) Cross the nodes after the crossover of R_1 and R_2 to obtain new individuals $R_1{}'$ and $R_2{}'$,

*f)*Perform loop elimination on $R_1{}'$ and $R_2{}'$ by eliminating the loop function. If there is no loop, it will not be eliminated and exit the function.

g) The two individuals after processing are the individuals without loops obtained by crossover.

The idea of eliminating loop function: suppose that the individual obtained after crossover operation is (B,D,H,L,O,P,N,L,I,M). The individual has a loop while (L,O,P,N,L) exists. (O,P,N,L) needs to be deleted from the individual. When an individual has more than one loop, the loop cancellation function can be called at the end of the loop cancellation function, which can ensure that the treated individual do not contain loops. Loop elimination is shown in Fig. 5. The crossover probability is 0.9.

Fig. 4. Improved single-point crossover.

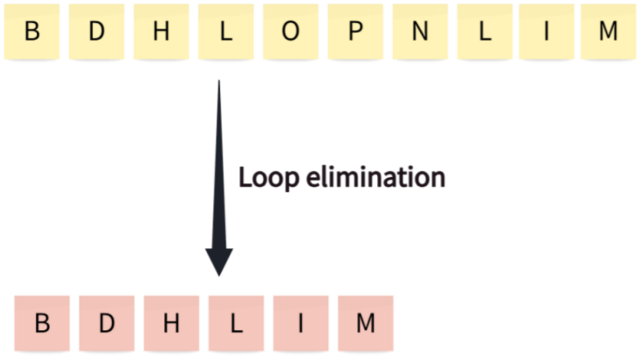

Fig. 5. Loop elimination diagram.

G. Improvement of Mutation Operator

The introduction of mutation operator can not only improve the diversity of the population, but also improve its ability to explore the unknown solution space, thus avoiding premature convergence. The mutation operation of the basic genetic algorithm includes basic bit mutation and reverse mutation commonly, as shown in Fig. 6.

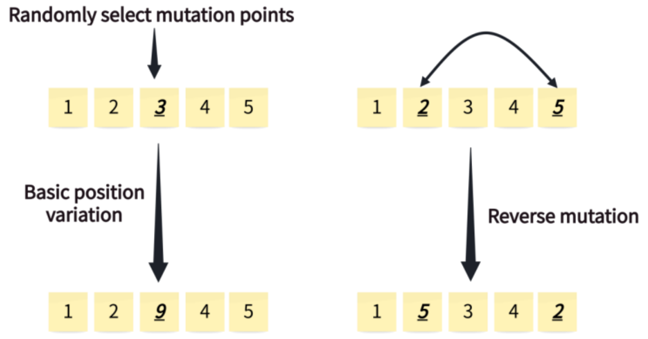

Fig. 6. Mutation operation.

If random mutation is applied to solve the shortest path routing optimization problem directly, it is easy for individuals to have open circuit or loop phenomenon because of the uncertainty. Therefore, this paper proposes an improved mutation operation.

The specific operation process is as follows:

a) Select an individual R$_1$ from a population.

b) Generate a pseudo-random number randomly, and comparing it with the mutation probability. Judge whether to perform crossover operation or not, if yes, performing (c), otherwise, not mutating.

c) Select a node *x* randomly except the starting node and the destination node.

d) Find all nodes directly connected with node *x* and save them in the aggregate.

e) Select a node *y* from the aggregate randomly.

*f)*Generate a shortest path P$_1$ from the starting node to the node *y*.

g) Generate a shortest path P$_2$ from node *y* to the destination node.

h) Merge paths P$_1$ and P$_2$ to obtain a new individual R$_1^{'}$.

*i)*A new mutated individual is obtained after loop elimination of the newly obtained individual R$_1^{'}$. The individual does not have open circuit and loop.

The above operation process is shown in Fig. 7. The mutation probability is 0.05.

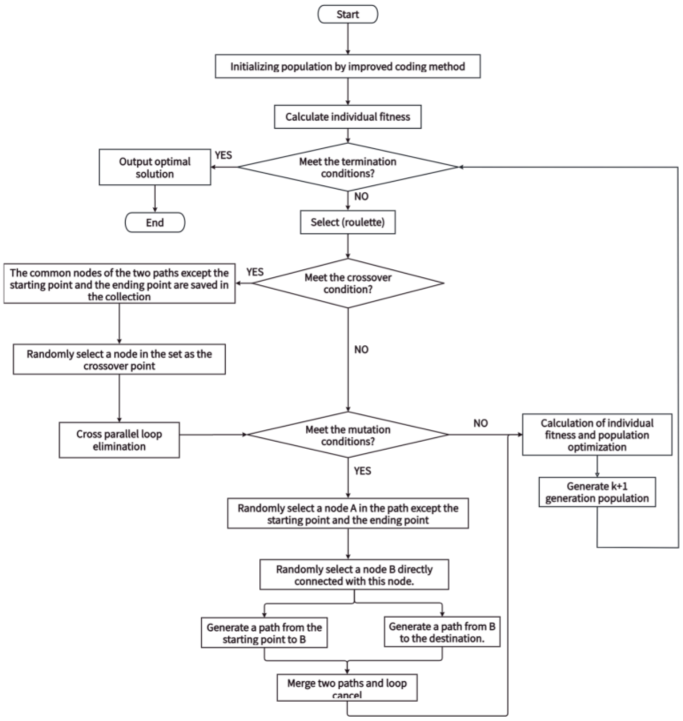
H. Flow of Improved GA

The specific implementation process of the improved genetic algorithm in this paper is shown in Fig. 8. The execution flow of the improved crossover operator and mutation operator is described in detail.



Start
Initializing population by improved coding method
Calculate individual fitness
Meet the termination conditions?
YES
Output optimal solution
End
NO
Select (roulette)
Meet the crossover condition?
YES
The common nodes of the two paths except the starting point and the ending point are saved in the collection
Randomly select a node in the set as the crossover point
Cross parallel loop elimination
NO
Meet the mutation conditions?
NO
Calculation of individual fitness and population optimization
Generate k+1 generation population
YES
Randomly select a node A in the path except the starting point and the ending point
Randomly select a node B directly connected with this node.
Generate a path from the starting point to B
Generate a path from B to the destination.
Merge two paths and loop cancel

Fig. 8. Flow chart of improved genetic algorithm in this paper.

III. Comparative Analysis of Improved Genetic Algorithm in Routing Optimization Problem

In order to verify the effectiveness of the improved genetic algorithm in solving routing optimization problems, this paper chooses Dijkstra [13] algorithm and Floyd [14] algorithm as two classical adaptive routing algorithms for comparative analysis.

A. Algorithm Parameter Setting

The influences and differences of network nodes and different algorithms on routing are compared and analyzed by setting different values for network nodes and adopting different algorithms. See Table I for the specific parameter settings of the three algorithms.

TABLE I. Parameter Table

Parameters	Values
Number of network nodes	16/30
Population size	10
Iterations	20
Crossover probability	0.9
Mutation probability	0.05

The simulation of the above three algorithms is realized by MATLAB software in Windows10.

Two typical network environments will be selected for simulation and comparative analysis.

B. Simple Network Environment

The network consists of 16 nodes, which are represented by capital letters A-P respectively. The starting point is B and the ending point is P. The connection between nodes and the cost required are shown in Fig. 9. The red path represents the best routing path.

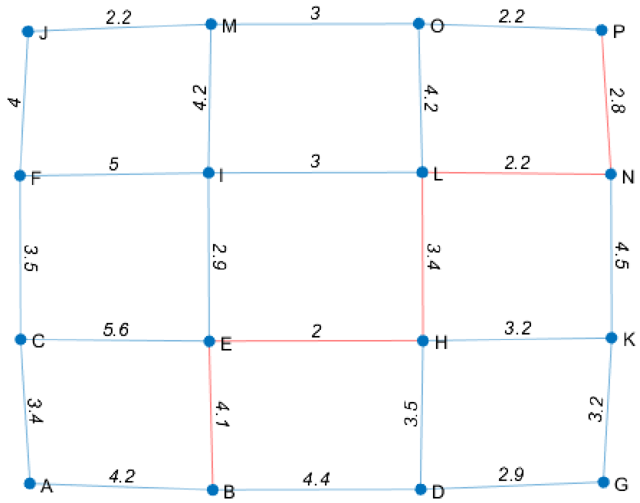


Fig. 9. Simple network environment.

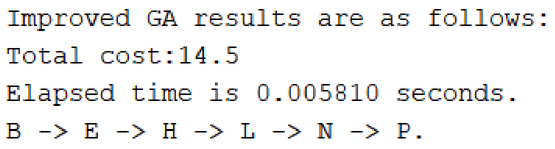
The improved genetic algorithm in this paper is used to find the path from node B to node P The path result is shown in Fig. 10. The shortest path optimized by the improved genetic algorithm in this paper is $B \rightarrow E \rightarrow H \rightarrow L \rightarrow N \rightarrow P$. The cost of this path is 14.5, and the time to find this path is 0.006208 seconds.



```
Improved GA results are as follows:
Total cost:14.5
Elapsed time is 0.005810 seconds.
B -> E -> H -> L -> N -> P.
```

Fig. 10. Result of simple network.

The number of iterations of the improved genetic algorithm is 20. The evolution process of the shortest path length in each population, that is, the minimum required cost, with the number of iterations is shown in Fig. 11. The initial shortest path cost is between 22 and 23, and the optimal solution is 14.5 with the continuous evolution of population and genetic iteration.

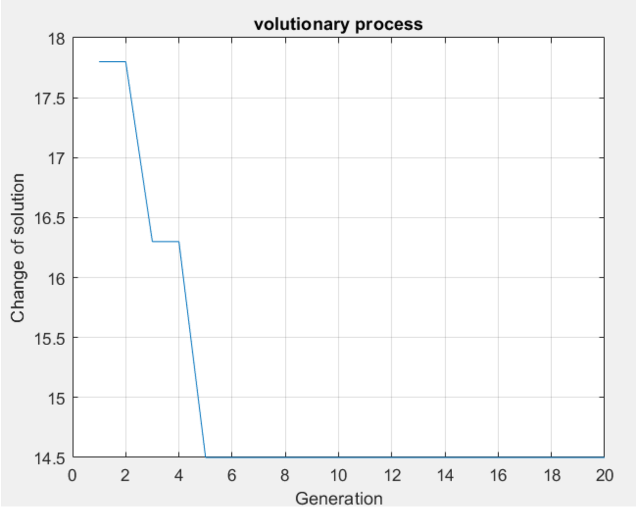


Fig. 11. Iterative process diagram of improved GA in this paper under simple network.

The comparison results of the improved genetic algorithm, Dijkstra [13] algorithm and Floyd [14] algorithm are shown in Table II. The shortest path obtained by the three algorithms is $B \rightarrow E \rightarrow H \rightarrow L \rightarrow N \rightarrow P$, and the cost of this path is 14.5. But the time of the three algorithms is different. The improved genetic algorithm in this paper takes the shortest time, which is 0.005810 seconds.

TABLE II. SIMPLE NETWORK RESULTS

Algorithm	The shortest path	Path cost	Time (s)
Improved GA in this paper	(B,J,M,O,Q,R)	14.5	**0.005810**
Dijkstra	(B,J,M,O,Q,R)	14.5	0.014124
Floyd	(B,J,M,O,Q,R)	14.5	0.018501

After repeated experiments for ten times, it is concluded that the time spent by the three algorithms is shown in Table III, and the time spent by the three algorithms in finding the way is shown and compared with the line chart as shown in Fig. 12. The results show that the improved genetic algorithm proposed in this paper is faster than Dijkstra algorithm and Floyd algorithm for finding the shortest path problem. The improved genetic algorithm is more efficient and has shorter running time when dealing with optimization problems.

TABLE III. SIMPLE NETWORK TIME STATISTICS

	Improved GA (s)	Dijkstra algorithm (s)	Floyd algorithm (s)
1	0.002859	0.0111225	0.0096672
2	0.003286	0.0124257	0.0121836
3	0.0030729	0.0123028	0.0117582
4	0.0035445	0.0127774	0.0137152
5	0.0029833	0.0124634	0.0124018
6	0.0027576	0.0156065	0.0133303
7	0.0027295	0.0136018	0.0123962
8	0.0029044	0.0150465	0.011854
9	0.0034026	0.0129538	0.0108338
10	0.0044602	0.0135091	0.0118217

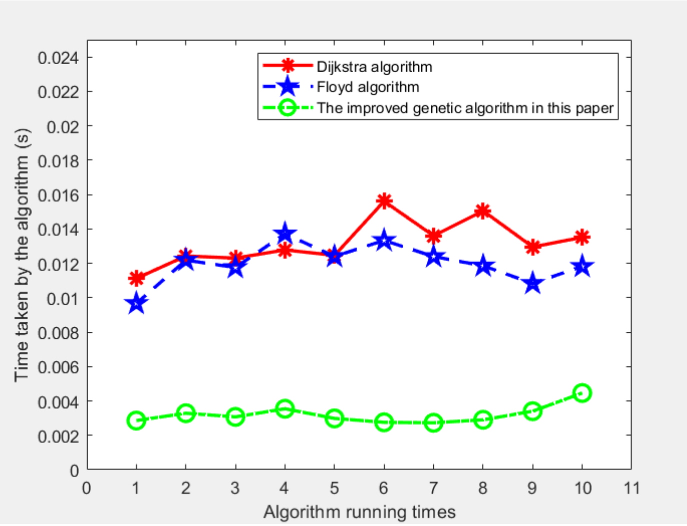

Fig. 12. Comparison of calculation time for simple network.

T-test the time obtained by 10 repeated experiments of three algorithms in simple network environment. The results are shown in Table IV and Table V.

TABLE IV. ANALYSIS RESULTS OF SIMPLE NETWORK IGA AND DIJKSTRA PAIRED T TEST

Name	Pairing (Average±Standard deviation)		Difference (Paired 1-Paired 2)	t	p
	Pairing 1	Pairing 2			
Improved GA pairing Dijkstra	0.003200±0.000521	0.013181±0.001332	-0.009981	-21.292659	0.000

As can be seen from the above table, the paired t test is used to study the differences of experimental data. As can be seen from the above table, a total of one group of paired data will show differences (p<0.05). According to the specific analysis, there is a significant level of 0.01 between improved GA in this paper and Dijkstra (t=-21.293, p=0.000), and the specific comparison shows that the average value of improved GA in this paper (0.0032) will be significantly lower than that of Dijkstra (0.01318095).

TABLE V. ANALYSIS RESULTS OF SIMPLE NETWORK IGA AND FLOYD PAIRED T-TEST

Name	Pairing (Average±Standard deviation)		Difference (Paired 1-Paired 2)	t	p
	Pairing 1	Pairing 2			
Improved GA pairing Floyd	0.003200±0.000521	0.011996±0.001154	-0.008796	-22.215274	0.000

As can be seen from the above table, the paired t test is used to study the differences of experimental data. As can be seen from the above table, a total of one group of paired data will show differences (p<0.05). The specific analysis shows that there is a significant level of 0.01 between improved GA in this paper and Floyd (t=-22.215, p=0.000), and the specific comparison shows that the average value of improved GA in this paper (0.0032) will be significantly lower than that of Floyd (0.0119962). A total of 1 set of paired data will all show differences.

C. Complex Network Environment

The improved genetic algorithm in this paper can adjust the parameters according to the number of network nodes, so as to find the best routing path in complex network environment. Because too many nodes will make the network structure diagram difficult to distinguish, this paper chooses a network composed of 30 nodes in complex network environment. In practical application, the improved genetic algorithm can be applied to a larger and more complex network environment.

The network consists of 30 nodes, which are represented by *Route1-Route*30 respectively. The starting point is *Route 1* and the ending point is *Route 29*. The connection situation and the cost between nodes are shown in Fig. 13. The nodes will be referred to as 1-30 for short, and the red path represents the best routing path.

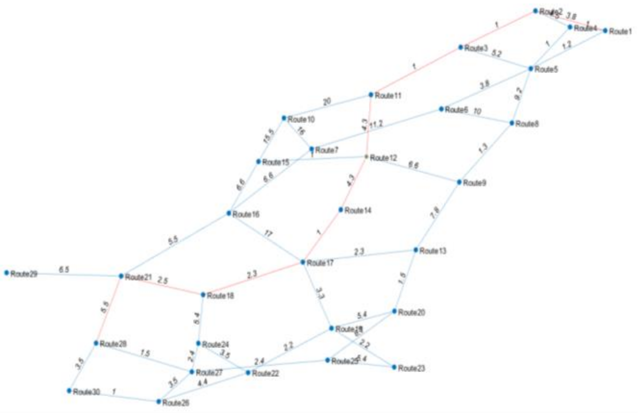

Fig. 13. Complex network environment.

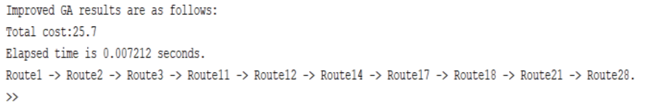
Using the improved genetic algorithm to find the path from node 1 to node 29, the result is shown in Fig. 14. The shortest path found by the improved genetic algorithm is $1 \to 2 \to 3 \to 11 \to 12 \to 14 \to 17 \to 18 \to 21 \to 28$, the cost of this path is 25.7, and the time to find this path is 0.007212 seconds.



```
Improved GA results are as follows:
Total cost:25.7
Elapsed time is 0.007212 seconds.
Route1 -> Route2 -> Route3 -> Route11 -> Route12 -> Route14 -> Route17 -> Route18 -> Route21 -> Route28.
>>
```

Fig. 14. Experimental results of complex network.

The number of iterations of the improved genetic algorithm is 20. The evolution process of the shortest path length in each population, that is, the minimum required cost, with the number of iterations is shown in Fig. 15.

The initial shortest path cost is between 42 and 44, and the optimal solution is 25.7 with the continuous evolution of population and genetic iteration.

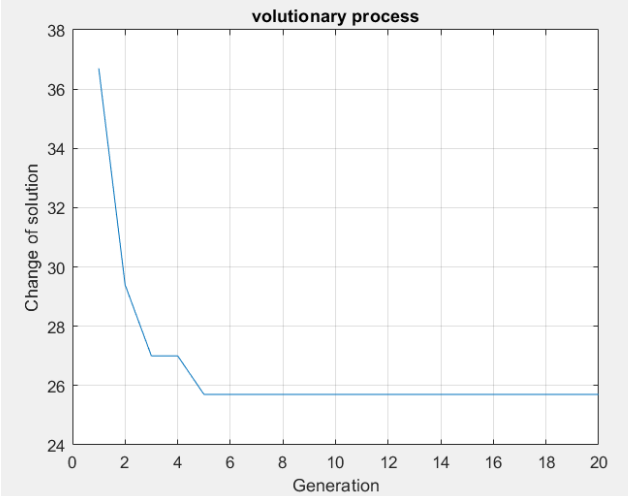


Fig. 15. Iterative process diagram of improved GA in this paper under complex network.

The comparison results for complex network using the improved genetic algorithm, Dijkstra [13] algorithm and Floyd [14] algorithm are shown in Table VI. The shortest path obtained by the three algorithms is $1 \to 2 \to 3 \to 11 \to 12 \to 14 \to 17 \to 18 \to 21 \to 28$, and the cost of this path is 26.7. But the time of the three algorithms is different. The improved genetic algorithm in this paper takes the shortest time, which is 0.007212 seconds. Compared with Dijkstra algorithm and algorithm, the improved genetic algorithm can find the optimal routing scheme faster in the two network environment, especially in complex or dynamic network topology, and the improved genetic algorithm shows better adaptability and optimization ability.

TABLE VI. COMPLEX NETWORK RESULTS

Algorithm	The shortest path	Path cost	Time (s)
Improved GA in this paper	(1,2,3,11,12,14,17,18,21,28)	25.7	**0.007212**
Dijkstra	(1,2,3,11,12,14,17,18,21,28)	25.7	0.010099
Floyd	(1,2,3,11,12,14,17,18,21,28)	25.7	0.011007

After repeated experiments for ten times, it is concluded that the time spent by the three algorithms is shown in Table VII, and the time spent by the three algorithms in finding paths is shown and compared by line charts as shown in Fig. 16. From this figure, we can find that the improved genetic algorithm proposed in this paper shows obvious advantages in performance, and the path-finding time is shorter and more stable.

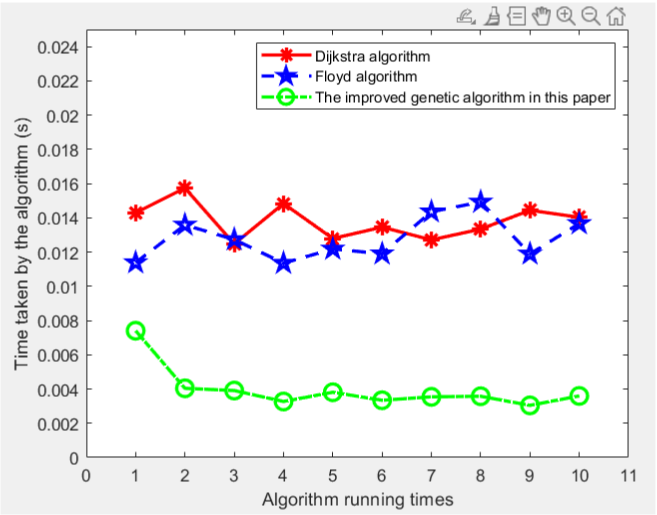

Fig. 16. Comparison of calculation time for complex network.

7	0.0035433	0.0127115	0.0143559
8	0.0035778	0.0133404	0.0149225
9	0.0030448	0.014441	0.0118913
10	0.003596	0.0140289	0.0136652

T-test the time obtained by 10 repeated experiments of three algorithms in complex network environment. The results are shown in Table VIII and Table IX.

TABLE VIII. ANALYSIS RESULTS OF PAIRED T TEST OF IGA AND DIJKSTRA IN COMPLEX NETWORKS

Name	Pairing (Average±Standard deviation)		Difference (Paired 1- Paired 2)	t	p
	Pairing 1	Pairing 2			
Improved GA pairing Dijkstra	0.003954±0.001249	0.013811±0.001045	-0.009857	-20.495974	0.000

As can be seen from the above table, the paired t test is used to study the differences of experimental data. As can be seen from the above table, a total of one group of paired data will show differences (p<0.05). According to the specific analysis, there is a significant level of 0.01 between improved GA in this paper and Dijkstra (t=-20.496, p=0.000), and the specific comparison shows that the average value of improved GA in this paper (0.00395437) will be significantly lower than that of Dijkstra (0.01381108). A total of 1 set of paired data will all show differences.

TABLE IX. ANALYSIS RESULTS OF PAIRED T TEST OF IGA AND FLOYD IN COMPLEX NETWORKS

Name	Pairing (Average±Standard deviation)		Difference (Paired 1- Paired 2)	t	p
	Pairing 1	Pairing 2			
Improved GA pairing Floyd	0.003954±0.001249	0.012797±0.001265	-0.008842	-13.851679	0.000**

As can be seen from the above table, the paired t test is used to study the differences of experimental data. As can be seen from the above table, a total of one group of paired data will show differences (p<0.05). According to the specific analysis, there is a significant level of 0.01 between improved GA in this paper and Floyd (t=-13.852, p=0.000), and the specific comparison shows that the average value of improved GA in this paper (0.00395437) will be significantly lower than that of Floyd (0.01279677). A total of 1 set of paired data will all show differences.

IV. CONCLUSION

An improved genetic algorithm is proposed and applied to solve the shortest path routing problem in order to improve the network performance. Compared with the traditional routing algorithm Dijkstra and Floyd algorithm, the improved genetic algorithm has excellent performance in dealing with the changeable network topology and dynamic changes, thus verifying its remarkable advantages in network routing optimization. The improved GA has stronger adaptability and better optimization ability in two typical network environments, which provides a novel and effective solution to the network routing problem.

An Analysis of the Effect of Using Online Loans on User Data Privacy

Indrajani Sutedja[1,] Muhammad Firdaus Adam[2], Fauzan Hafizh[3], Muhammad Farrel Wahyudi[4]
Information Systems Department-BINUS Undergraduate Program-School of Information Systems,
Bina Nusantara University, Jakarta, Indonesia 11480[1]
Vista Infoguna Sejahtera, Jakarta, Indonesia 15345[2, 3, 4]

***Abstract*—Online loans deliberately leak user data. The entry of the digital ecosystem at the beginning of the 20th century initiated major changes in society in the way information is controlled, communicated and expressed. Industrial development in Indonesia is growing very rapidly, especially along with the progress of the digital economy industry. Changes in the digital economy have changed the way we access the economy. The role of digitalization has changed the way we work and the way society collaborates with other parties. This digitalization cannot be separated from the role of financial technology, including online loans. Digitalization can simplify the lending and borrowing process and increase accessibility so that it can be done efficiently. However, we also have to be aware of the risks of online loans, especially in terms of user privacy and data security. According to the Financial Services Authority (OJK) rules, incidents of data privacy violations and online loan data leaks in 2022 will reach 1,200 cases. One case is when a loan provider acts by accessing a user's personal data to intimidate and threaten. They even made the situation even more threatening by coming to the user's location with several hired thugs to intimidate them into physical confrontation and making several unreasonable demands such as increasing loan interest. In some cases, there are fintechs who deliberately sell or trade some of their users' personal data for their own profit. This research aims to provide education about the importance of clear regulations from the central government regarding the Peer-to-Peer lending industry. This research uses a systematic literature review method to be more structured and objective in writing this paper.**

Keywords—Online loans; data privacy; peer-to-peer lending; OJK; fintechs

I. INTRODUCTION

Financial Technology, commonly known as FinTech, is acknowledged as a pivotal advancement in the financial sector and is experiencing rapid expansion [1]. Motivated by the erosion of customer trust in conventional financial service providers [2]. The majority of Financial Technology is motivated by several variables that are progressing, such as smartphone, increasingly mature technology, internet, sharing economy / business operations, etc. [2]. Governments still struggle to find a balance between users being able to benefit from online loans, and users' need for regulations that protect them [3]. In addition, many criminal cases are related to improper collection and minimal user awareness of the privacy of their data [4][5][6]. The feasibility of the P2P Lending platform which needs to be the main concern [7].

The issue of data privacy is a big problem because data privacy is often the main goal of criminals operating on the internet [8]. This proves that there is vulnerability in this sector, it is proven that there are online loans that trade user data to seek profit [9]. They even act illegally by accessing users' sensitive data to intimidate them, as well as calling thugs to threaten them to pay their bills [10]. Because the impact of this data leak is very large, such as psychological trauma and even suicide for individuals affected [11]. It doesn't stop there, financial losses and appearance damage resulting from data leaks vary greatly [12]. It appears that there is a need to form an organization that can firmly resolve this problem. On the other hand, creating an organization can be disastrous if not done properly. Protection of users' personal data is a form of regulation, as well as a way to protect user data from irresponsible people [13].

Therefore, developing a user data protection system is an important thing to pay attention to [7]. However, this good step cannot happen alone, there need to be other variables such as increasing literacy about privacy, this is aimed at ensuring that people have good knowledge to avoid the potential leak of their sensitive personal data [13]. Other variables such as the creation of an institution to monitor user data transfer traffic, the institution or organization regulates all security of user privacy data [14]. Companies can implement basic security measures such as secure data publication, encryption, and enforcement of access rights to sensitive data [15]. The firewall is a bodyguard whose job is to sort or limit access to the internal network, while the intrusion detection system monitors computer and network activity to look for unauthorized intrusions. In addition, antivirus can contribute to its protection against internal attacks. Intrusion detection systems (IDS) can also assist so that IDS can help detect malicious activities [16].

Because, protecting user privacy is key to building trust between users and service providers, in preventing potential risks of leakage and misuse of user information [17]. Then research questions are created to provide clear guidelines and clear objectives. Is it true that there are no mature regulations regarding data protection in the fintech industry, especially online loans? Next, this research focuses on online loans, data privacy, and trust of online loan users.

According to OJK, incidents of data privacy violations and online loan data leaks in 2022 will reach up to 1,200 cases. Although online loans can provide fast access to funds, we also need to consider what losses we will experience. This journal aims to provide more in-depth education regarding these problems, it is hoped that users can take better action in managing their financial problems.

II. Theoretical Foundations

A. Data Privacy in Online Loans

Privacy is an individual's right to control information about themselves. Russell Brown interprets the right to privacy as a right that arises from the right to private ownership of a specific asset [18]. The United States Supreme Court decision established this definition as "The Right of Bodily Integrity". The Supreme Court explained that the right to privacy is a basic individual right that cannot be interfered with by the government in decisions relating to personal welfare [19]. Data is the core material needed to produce information or information and must be processed first. Information resulting from data processing will be useful or at least will give someone an idea of a condition or situation [20]. Data privacy is a person's right to control their personal information. Referring to the concept of privacy, one of the concepts of privacy is the privacy of data about a person, namely data privacy can bind information about a person that is collected [21].

B. Systematic Literature Review

Systematic literature reviews represent a systematic way to identify relevant studies, to summarize the results, to critically analyze the methods of the studies and, finally, to comment and recommend improvements for future research [26]. Systematic Literature Review/SLR is a way to identify, evaluate, and all research relevant to a topic area of interest [27]. The aim is to systematically draw conclusions that are relevant to the specified research topic [27]. SLR also aims to provide objective research on certain issues. SLR has been published in many different places, including FinTech [28].

C. Online Loans

Financial Technology, or better known as Fintech, is a term used to describe technological innovation in the financial services industry. Financial Technology is a field that crosses various scientific disciplines such as Finance, Technology Management, and Innovation. In essence, it involves creative thinking that improves financial services processes by using technology solutions that match business needs. Financial technology can also pave the way for new business models or even the establishment of new businesses [22]. Financial technology, according to the National Digital Research Center (NDRC), refers to innovation in the financial services sector that utilizes modern technology [23], which combines technological advances with financial activities, especially in banking institutions. The aim is to provide financial services that are more practical, safe and modern. One example is online loans, which are a form of digital-based financial service. Online loans refer to borrowing money obtained entirely through an online platform, without requiring physical interaction with a bank or financial institution. Borrowers can submit applications, receive approval decisions, and manage loan payments digitally. Online loans are an important innovation in financing that is carried out online via the Internet, without involving traditional financial institutions or collateral [15]. Another opinion, online loans are financial services in the form of loans and which use information technology and internet networks, where agreements are made without direct meetings between the lender and the loan recipient [25].

D. VOSviewer

VOSviewer is a user-friendly software tool for building and visualizing bibliometric maps. They go on to say that VOSviewer can be used to analyze the structure and dynamics of scientific fields, identify emerging research trends, and track the development of an individual's research career. VOSviewer is a free open source software tool that can be downloaded from the VOSviewer website. It is a popular tool among researchers in a variety of fields, including the social sciences, humanities, and natural sciences [29].

E. Financial Services Authority (OJK)

OJK, or Financial Services Authority, is a supervisory institution for the financial services industry in Indonesia, which is tasked with regulating, supervising, and protecting the interests of consumers and the public. Its function is to organize an integrated regulatory and supervisory system for all activities in the financial services sector, including the financial technology industry such as peer-to-peer lending.

III. Methodology

Starting with the problem of searching / urgency on the topic you want to raise, looking for a solution by reading several related journals, determining the scope / scope you want to raise, determining the research question with the aim, then starting with determining the research methodology / contents of the SLR and the process of selecting the papers used, and using VOSviewer to find out how big the relationship is between one another, and continued with data collection and data analysis, and provides conclusions by providing an explanation regarding the results that have been found. The writing framework is based on the use of a Systematic Literature Review format which uses six steps [27] [30] [31]:

- Scope
- Research Questions
- Search Process
- Inclusion and Exclusion Criteria
- Data Extraction
- Analysis of the results

A. Search Process

The process of searching for related articles is with the help of Publish or Perish 8 software, Google Scholar, which finds several relevant research papers taken from IEEEXplore, Science Direct, Wiley, and several journals that have or have not been Scopus. This is done by using selected search keywords with objective keywords in order to find relevant papers [32].

The search was conducted using a number of strategically selected keywords, including “online loans” and “data privacy”. Additionally, various keyword combinations have been carefully crafted to improve search accuracy:

- "Online Loan" AND "Data Privacy"

- "Peer-to-Peer Lending" AND "Online Loan"
- "Online Loan" AND "Online Lending"

Careful selection of keywords. Carrying out a search is expected to provide results that have involvement with related research topics. This is expected to be able to find literature circulating on the internet as a whole.

B. *Inclusion and Exclusion Criteria*

In the inclusion criteria section, the author tries to read titles and abstracts that have the same topic, and the exclusion criteria are carried out by separating papers whose titles and abstracts do not match the topic. Then read in full if there is a paper that feels like the title and abstract, and keywords, variables, indicators are appropriate and will be included. The paper used has a year of publication between 2019 and 2023.

C. *Data Extraction*

Multiple search terms were used to find relevant papers, resulting in a pool of 120 candidates for potential inclusion in this study. After a careful selection process, a total of 40 papers were finally selected, as shown in Table I.

TABLE I. ACQUIRED RESEARCH PAPERS

No	Compilation and evaluation of acquired research papers.			
	Source	***Studies Found***	***Candidate Studies***	***Selected Studies***
1	IEEE	117	45	9
2	SCIENCEDIRECT	24	8	2
3	RESEARCH GATE	7	4	3
4	SPRINGER	4	2	1
5	DL.ACM	4	1	1
6	SSRN	3	1	1
7	EMERALD	3	1	0
8	ATLANTIS PRESS	1	1	1
9	SAGEPUB	1	0	0
10	Others	117	57	22
11	Total	281	120	40

By comparing the information contained in various articles and websites, it can be concluded that the characteristics of online loans have experienced a progressive evolution from year to year. The inherent pros and cons of this type of loan can be identified through in-depth documented developments over time.

D. *Previous Research*

Research conduct by Ryan Randy Suryono, Betty Purwandari, Indra Budi in 2019 discuss about insuficient regulations regarding finance technology industry and online loans using a systematic literature review method [7]. Another research conduct by Reni Sulastri and Marijn Janssen discussing about the fundamental elements of Peer-to-peer lending system using systematic literature review. They found that online loans or peer to peer lending faced with challenges attached to each of element in a constructed way [33].

IV. RESULT AND DISCUSSION

The focus of this research covers the demographics of Generation X (1965-1976) to Generation Z (1995-2010) living in Indonesia, especially Indonesian citizens who have adequate access or tools to use online loans. Based on data sourced from the Financial Services Authority (OJK) from Fig. 1, the use of online loan software in Indonesia has exceeded 178 million people, and the distribution of fintech loading funds reached 225.55 trillion based on facts taken from the Financial Services Authority (OJK) in Indonesia in 2022, the spread of online loan use in Indonesia shows that there are irregularities. This phenomenon can be seen from the concentration of Online Loan users which are still concentrated in three large cities on the island of Java.

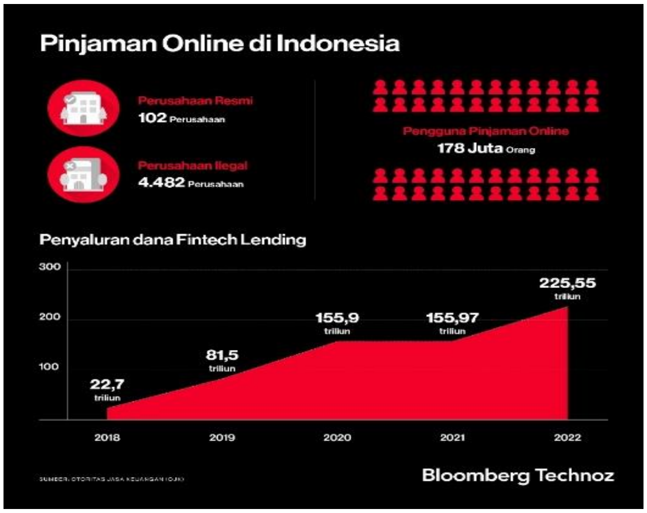

Fig. 1. The use of peer-to-peer lending.

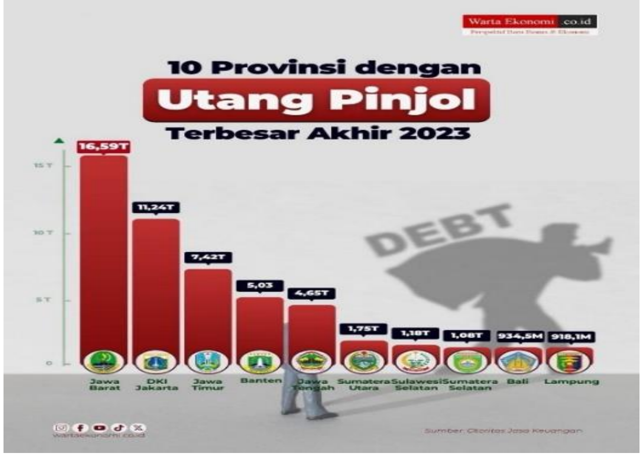

Fig. 2. Provinces with the highest use of peer-to-peer lending.

Based on information published by the Financial Services Authority (OJK) in Indonesia, the largest users of online loans are spread across West Java, followed by Jakarta, East Java, Banten, Central Java, North Sumatra, South Sulawesi, South Sumatra, Bali, Lampung (Fig. 2.). It can be concluded that the use of online loans outside Java is very low when compared to Java province. It turns out that there is a type of active online loan user group, they can spend relatively large loans, namely five million rupiah, with a repayment period of 12 months. The Indonesian Financial Services Authority (OJK) issued an appeal in the form of a warning to the Indonesian public to be careful when making loans from online loans. The authority urges online loan users to be educated and aware that the online loan application they will use is registered and supervised by the OJK. It is important for online loan users to have insight into the lending and borrowing conditions imposed by the online loan application.

The use of online loans must be used very wisely, their use must not be used just to try out of curiosity, it is best to only be used when the need is urgent, and must be thought about carefully, and you must avoid using it just for the sake of cover other debts, because of the high interest, it will activate a domino effect. From official data released by the Indonesian Financial Services Authority (OJK), incidents of data privacy violations and online loan data leaks of up to 1,200 user data privacy violations and data leaks in 2022, it is concluded that there will be an increase of up to 200 percent compared to 2021. Many factors influence leaked data, such as:

- Data leakage by online lenders.
- Insufficient security in the information systems of online loan providers.
- Human errors, such as negligence in managing data.

How can online loans intentionally leak user data? They start from arrears in payments by borrowers, if the arrears continue to be unpaid, they do not hesitate to act legally or illegally by accessing users' personal data to intimidate, threaten and contact third parties who have or have nothing to do with the loan [10]. They even sometimes collaborate with some authorized individuals to carry out threatening actions. The impact of violating user data privacy and data leaks will have a negative impact on users, such as:

- Loss of data privacy and extortion.
- Sexual harassment.
- Damage to reputation.
- Negative reactions of users and non-users regarding online loans.

The online lending / peer-to-peer (P2P) lending industry in Indonesia has grown very rapidly in recent years, providing a very easy way to borrow just via cellphone and internet from home. It doesn't stop there, the negative side also appears simultaneously, such as the regulations governing this industry are still not mature enough [3] [7] [13]. Until now, there are no mature regulations that can truly solve the problems that exist in the context of regulations that regulate data protection, privacy, and security in the online lending ecosystem.

This inconsistency in privacy and security data is a major highlight in the P2P lending ecosystem. If there are no clear regulations, the risk of misuse of personal data regarding identity and sensitive information will continue to run rampant. The lack of ways to use and store personal data from central regulators can increase the risk of violating user data privacy.

It doesn't stop there, the lack of clarity in this regulation can have long-term consequences, such as the development of the P2P lending industry. Without clarity on the rules, investors and borrowers may be hesitant to try to enter the online lending ecosystem and hinder growth in this ecosystem.

Seeing this problem, the regulator in this means that the central government needs to move quickly to find out the existing problems and provide firm and measurable regulations in order to protect users and potential users of online loans who act outside their control. Steps such as standardization of online loans that can operate in Indonesia need to be implemented, and emphasize the importance of privacy and security. A strong regulatory enforcement mechanism needs to be the main highlight for the relevant regulators to be a shield for users and potential users.

The relevant authority (OJK) provides ways to avoid violations of user data privacy and data leaks, such as:

- Reduce the use of online loans if they are not really needed.
- Issuing regulations governing the security of online loan data.
- Increase knowledge of online loans among the public.

Then, this method is not necessarily successful in preventing online loan data breaches. So, online loan users must be careful when using the application, always making sure that the online loan they use has been registered and monitored by the relevant authority (OJK). Here's how to prevent violations of user data privacy in irresponsible online loan applications:

- Use online loan services registered and supervised by OJK.
- Read and understand the terms and conditions of the loan carefully before applying.
- Does not give online loan parties access to our sensitive data.
- Use strong and unique passwords for your online loan accounts.
- Enable two-factor authentication (2FA) for your online loan accounts.
- Regularly update your online loan application.

A. *Analysis of the Results*

The selected journals for analysis encompassed articles specifically addressing the theme of Online Loan Data Privacy, along with additional publications chosen for inclusion. The utilization of VOSviewer facilitated the identification of predominant topics within the selected articles. The principal research themes were discerned through an examination of keyword co-occurrence patterns.

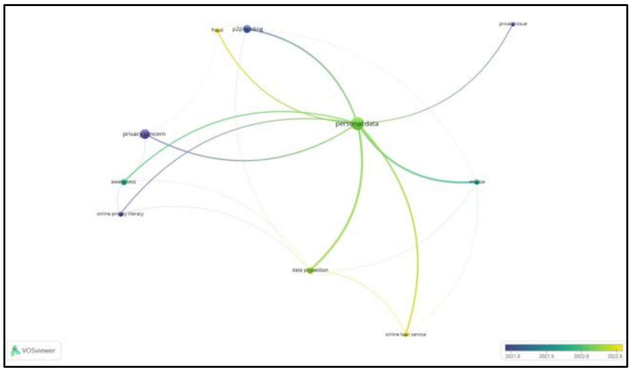

Fig. 3. Mapping of peer-to-peer lending.

Using VOSviewer, Fig. 3 illustrates the visualization of keywords commonly linked with this topic. It shows journal keyword lists typically associated with the topic of peer-to-peer lending. Fig. 3 indicates that there is a close connection between peer-to-peer lending, data protection, personal data, fraud, misuse and privacy concern. The keyword Online loan service and fraud increase in the recent year. Online loan service needs the user to fill in their personal data and that personal data can be misused to do fraud. Therefore, users need to be aware of the importance of their personal data so that it will decrease the likeliness of misuse and fraud. It can be done with online privacy literacy.

V. Conclusion and Recommendation

A. Conclusion

In conclusion, the era of digitalization has made a significant evolution in many sectors of human life, starting from communication, the way we work, as well as aspects of society. The presence of financial technology, in the context of online loans, has had a huge impact on many people, especially in Indonesia. However, despite its enormous impact, it has enormous risks that cannot be ruled out, especially in the context of violating user data privacy. The large number of online loan applications in circulation has resulted in anxiety about protecting user data privacy, with the possibility of breaches of user data privacy which will result in risks such as reputation damage and various frauds.

It can be seen that data privacy is the right of all people regardless of economic status in this computerized era, but on the other hand, it can be seen that in the field this is often a trivial matter for some groups, data privacy violations have become a mainstream thing. The presence of relevant officials / OJK who should be the police in the digital era in the context of financial technology, but is still very lacking, data privacy violations remain a big problem for online loan users, therefore, it is highly recommended not to use online loans used as an initial solution, but rather becomes the last solution in one of everyone's financial solutions.

Overall, the peer to peer (P2P) lending industry in Indonesia faces serious challenges in terms of data privacy and security. A lack of clarity in regulations about how data is collected, used and stored has raised concerns about the risk of misuse and privacy violations. Without a clear regulatory structure, this could become an obstacle to the development of the P2P lending industry and reduce the trust of users, potential users and investors in this ecosystem. Therefore, there is a need for immediate action from the central government to develop appropriate regulations to protect users in terms of data privacy and security from peer to peer (P2P) lending in Indonesia. So as to create an environment that is safe and has integrity that can be trusted for all parties involved. Related work stated that it is recommended for the government to regulate the security of user's personal data in a specific regulation regarding the protection of personal data in online loans [24].

From this it can be concluded that education regarding potential violations of online loan data privacy needs to be promoted by all parties, especially the relevant authorities / OJK, because of the large risks that lie ahead. Everyone needs to be aware of the risk of data privacy violations, where if users experience delays in paying, the risk of user data being leaked will be at stake. By making this issue an important topic, policy makers can be more assertive towards online loan providers.

Thus, the systematic literature review in this paper can provide an overview of user data privacy in online loan applications circulating in Indonesia. By discussing the issues discussed in this paper, and providing suggestions that can be used to reduce risks, this paper aims to provide the wider community with information about the risks that can be incurred if someone plans to use an online loan, and ultimately will restore the basic rights of online loan user's data privacy.

B. Recommendation

Previous research with related topic has a discussion of financial technology regarding their fundamental elements and their challenges that are attach to it. For further research, it is recommended to conduct the research with the topic that's need more attention such as a development of an effective regulation regarding the protection of user's data privacy to ensure a better protection. The key point is to create or improve regulations that can address new challenges in data privacy and can keep up with the current technology development.

Other than that, future research can also focus on developing security system that can immediately anticipate and respond to threat regarding user's personal data. By improving regulation and security systems, it is hoped for a safer and more reliable digital environment will be develop for all users.

Forecast for Container Retention in IoT Serverless Applications on OpenWhisk

Ganeshan Mahalingam, Rajesh Appusamy
Department of Computer Science, Jain (Deemed to be University), Bangalore, India

***Abstract*—This research tackles resource management in OpenWhisk-based serverless applications for the Internet of Things (IoT) by introducing a novel approach to container retention optimization. We leverage the capabilities of AWS Forecast, specifically its DeepAR+ and Prophet algorithms, to dynamically forecast workload patterns. This real-time forecast empowers us to make adaptive adjustments to container retention durations. By optimizing retention times, we can effectively mitigate cold start latency, the primary reason behind sluggish response times in IoT serverless environments. Our approach outperforms conventional preloading and chaining techniques by significantly increasing resource utilization efficiency. Since OpenWhisk is an open-source platform, our methodology was able to achieve a cost reduction. By integrating it with Amazon Forecast's built-in algorithms, we surpassed traditional cache cold start strategies. These findings strongly support the viability of dynamic container retention optimization for IoT serverless deployments. Evaluations conducted on the OpenWhisk platform demonstrate substantial benefits. We observed a remarkable 67% reduction in cold start latency, translating to expedited response times and a demonstrably enhanced end-user application experience. These findings convincingly validate the efficacy of AWS Forecast in optimizing container retention for IoT serverless deployments by capitalizing on its deep learning (DeepAR+) and interpretable forecasting (Prophet) abilities. This research lays a solid foundation for future studies on optimizing container management across various DevOps practices and container orchestration platforms, contributing to the advancement of efficient and responsive serverless architectures.**

Keywords—Serverless IoT; AWS Forecast Deep AR+; Prophet; AWS EKS; docker and containers; cold start; OpenWhisk

I. INTRODUCTION

In serverless computing, OpenWhisk struggles with managing containers for dynamic IoT data streams due to traditional approaches like fixed retention policies and "keep-alive" mechanisms. These methods lead to high cold start latency and inefficient resource utilization, marked by high baseline latency and low resource usage during idle periods [1]. To address these challenges, we propose a novel workload prediction-based approach using AWS Forecast. By predicting high activity periods for specific IoT topics, our approach allows for dynamic adjustments to container lifetimes. This aims to significantly reduce cold start latency and improve resource efficiency. Our research evaluates the performance of two forecasting algorithms, DeepAR+ and Prophet, within the OpenWhisk platform. By integrating these predictive tools, we seek to optimize container retention and enhance serverless application performance in the IoT domain. This paper will detail the limitations of existing container management strategies, present our predictive approach, and analyze the impact of these algorithms on improving efficiency and reducing latency in serverless environments.

We will first examine the inherent limitations of current container management strategies in the IoT serverless cloud-native platform, focusing on issues like high cold start latency and inefficient container and resource utilization. Following this, we will introduce our innovative approach, which employs AWS Forecast's DeepAR+ and Prophet algorithms for dynamic workload prediction and container retention optimization. We will detail how these predictive techniques address the shortcomings of traditional methods by enabling real-time adjustments to container lifetimes. Finally, the paper will present a comprehensive analysis of our approach's effectiveness, supported by empirical results demonstrating significant improvements in both latency reduction and resource efficiency. Through this structure, we aim to provide a clear roadmap of our research and highlight the contributions it makes toward advancing serverless IoT applications.

II. FUNCTION PRELOADING AND FUNCTION CHAINING

A. Function Preloading

Function preloading tackles cold start latency.

- Resource Wastage: Preloading retains containers even during low keeping a set number of containers warm in memory, ensuring minimal invocation delays for frequently used functions [1]. However, this approach suffers from two key drawbacks -activity periods, leading to inefficient resource utilization [2]. OpenWhisk allocates resources for these idle containers, even though there might not be a function execution to justify their presence.

- Static Configuration: Determining the optimal number of preloaded containers can be challenging. An insufficient number might lead to cold starts when demand spikes, while an excessive number wastes resources during low workloads.

B. Function Chaining

The function chaining technique aims to reduce cold start penalties for subsequent functions in a sequence by combining them into a single execution unit on OpenWhisk. While this improves the latency of chained functions compared to separate invocations, it has limitations [2, 3].

- Limited Applicability: Chaining is only effective for functions specifically designed and ordered for sequential execution [3]. This might not be feasible for all IoT use cases.

- Increased Complexity: Function chaining requires careful design and development effort to ensure proper execution flow within the chain, potentially hindering code maintainability [4].

III. Prediction-Driven Retention

The unpredictable nature of IoT workloads renders static configurations impractical. Keeping containers perpetually warm can lead to an increased memory footprint on the server. Studies have shown that this can result in higher than necessary compute resource utilization, potentially causing execution lags, a direct contradiction to the goal of minimizing container request latency [5, 12].

This study explores a solution that optimizes resource utilization while mitigating cold starts. We leverage AWS Forecast, a machine learning service, to strike a balance between container retention and minimizing resource waste.

While incorporating mathematical expressions for container retention is intriguing, directly modeling this duration can be challenging due to the dynamic nature of workloads. However, we can explore how the workload prediction forecasting approach relates to cold start latency and resource utilization.

Cold start latency (CSL) can be expressed as:

$$CSL = T\_fresh + T\_init + T\_deps \qquad (1)$$

T_fresh is the time to allocate new resources (CPU, memory) for a container. T_init is time to initialize the runtime environment (e.g., Python). T_deps is time to download and load function dependencies.

The implemented forecasting in our study aims to minimize this latency by keeping containers warm during anticipated high-activity periods.

Let P (high_activity) represent the probability of a high workload based on the AWS forecast. We can estimate the average cold start latency (ACSL) with forecasting as

$$ACSL = (1 - P\ (high\_activity)) * CSL + P\ (high\_activity) * T\_warm \qquad (2)$$

T_warm is the minimal overhead associated with a warm container (potentially close to 0).

Here, by maximizing P (high_activity) through accurate forecasting, we aim to minimize ACSL compared to scenarios where containers are not retained strategically.

Resource Utilization (RU) can be a complex metric depending on the specific resource being considered (CPU, memory, etc.). However, we can conceptually represent it as:

$$RU = \frac{\text{total resource consumption}}{\text{total available resources}} \qquad (3)$$

Preloading a fixed number of containers (N) leads to a baseline resource utilization (RU_preloading).

$$RU\_preloading = \frac{N * \text{average container resource consumption}}{\text{total available resource}} \qquad (4)$$

The implemented AWS forecasting approach dynamically adjusts the number of retained containers (N_t) based on the predicted workload. This leads to potentially more efficient resource utilization.

$$R\ U\_forecasting = \frac{\Sigma(N\_t * \text{Average Container}) (\text{Resource Consumption})}{\text{Total Available Resource } (\ \Sigma \text{ across time intervals})} \qquad (5)$$

Here, N_t varies based on the forecast, potentially leading to a lower average value compared to N in preloading, thus improving resource utilization.

Consider an average cold start latency (CSL) of 100 ms and a warm container overhead (T_warm) of 10 ms. If Workload Prediction forecast a 70% chance, (P(high_activity) = 0.7) of high workload, the average cold start latency with forecasting (ACSL) would be:

$$ACSL = (1 - 0.7) * 100\ ms + 0.7 * 10\ ms = 40\ ms \qquad (6)$$

This represents a significant reduction in latency compared to scenarios without container retention.

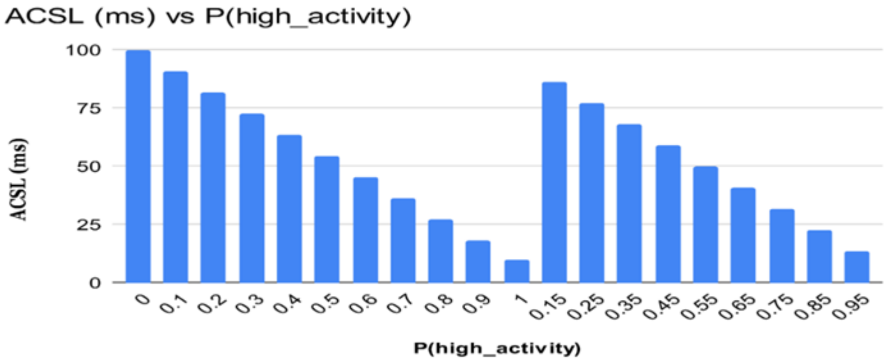

Fig. 1. ACSL vs. P (high_activity).

Considering Fig. 1, for instance, with no prediction (P (high_activity) = 0.0), the cold start latency is at its highest (represented by the point at the far left of the line). This reflects the cold start penalty when containers are not retained proactively. Conversely, as the probability of high activity approaches 1.0 (far right of the line), the ACSL approaches a minimum value (potentially close to 10 ms in your example). This represents the minimal overhead associated with keeping a container warm, significantly reducing cold start latency. The overall trend reinforces the core concept of our research: utilizing workload prediction (P (high_activity)) allows for dynamic container retention, minimizing cold starts, and improving response times in serverless IoT applications.

IV. AWS Forecast

AWS Forecast with machine learning algorithms like DeepAR+ or Prophet offers a more efficient and scalable solution on OpenWhisk by dynamically adjusting container retention durations based on workload predictions.

Workload Prediction: AWS Forecast analyses historical data on IoT function invocation patterns to identify trends and seasonality. This allows for predictions of future invocation frequencies, enabling informed decisions about container retention.

Dynamic Retention: Based on the predicted workload, OpenWhisk can dynamically adjust container retention durations. During periods with high-predicted invocation rates, containers are retained for a longer duration to minimize cold starts. Conversely, during low-predicted activity, containers are allowed to be downscaled.

Algorithm Selection: DeepAR+, with its deep learning architecture, excels at capturing complex patterns or seasonality in IoT function workload data. Prophet is a good choice for simpler trends or seasonality, offering faster training times and interpretable models for easier understanding of the predictions.

AWS Forecast with machine learning offers a dynamic and technically superior solution compared to preloading and chaining on OpenWhisk. It overcomes their limitations by enabling workload predictions and dynamic container retention, leading to optimal resource management for serverless IoT applications.

V. Proposed Workload Prediction Framework

The proposed Cloud Architecture outlines an infrastructure on AWS Cloud Platform for optimizing container retention in a serverless environment shown in Fig. 2.

Here's a breakdown of the components and their interactions:

A. Data Source and Load Generation

- Locust: This is a load testing tool. It uses the provided data set to simulate real-world usage patterns and generate load on your Azure Functions.
- EC2 Deployment: Locust is deployed on an EC2 instance, a virtual server within the AWS cloud. This provides a platform for running the load tests and generating data.
- AWS IoT Core: This acts as the central message hub within AWS. It receives the simulated data stream (function invocation patterns) from the Locust load test running on the EC2 instance.
- S3: Amazon Simple Storage Service. This is a cloud storage solution where the simulated data from IoT Core is likely stored.
- AWS Forecast, a managed service for time-series forecasting, provides pre-built datasets and various algorithms. We implemented DeepAR+, a deep learning algorithm ideal for complex patterns and seasonality in IoT data, and Prophet, suitable for simpler trends with its interpretable models and faster training.

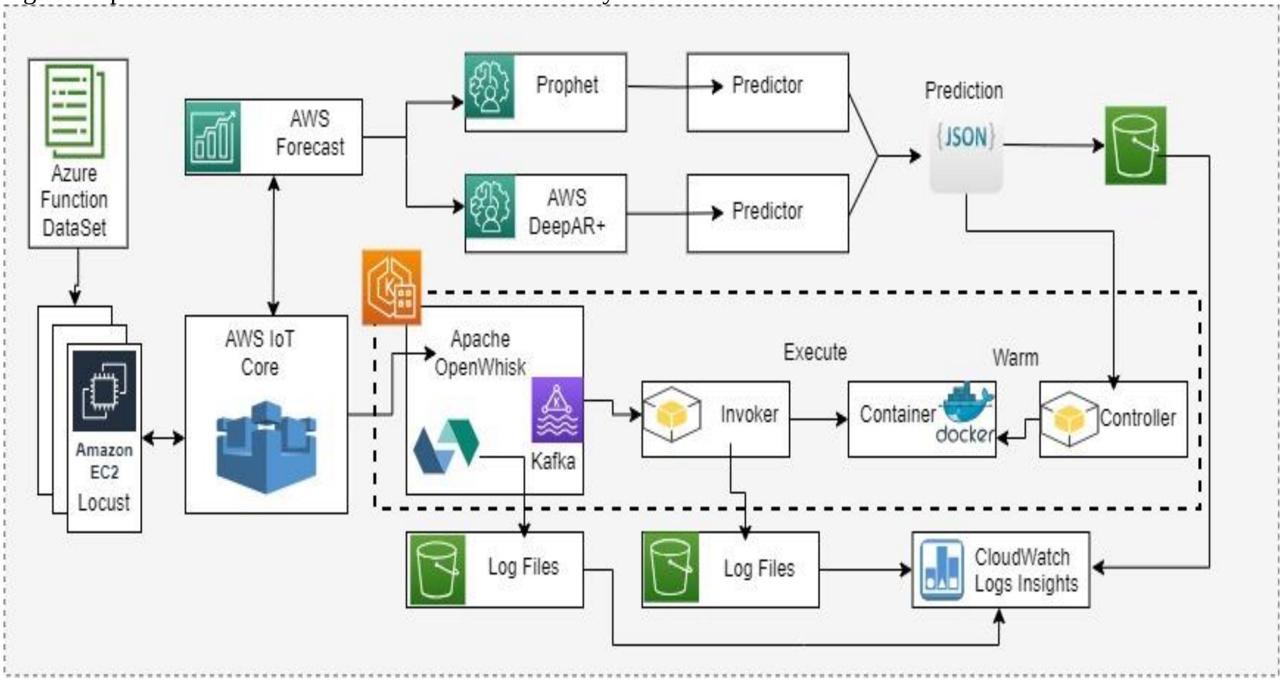

Fig. 2. Proposed cloud architecture.

B. Decision Making and Container Management

DeepAR+ and Prophet will generate separate predictions for future workload patterns based on the ingested IoT function data.

OpenWhisk on EKS: Simultaneously, Apache OpenWhisk, a serverless computing platform deployed on AWS through EKS (Elastic Kubernetes Service) [6], is utilized for executing serverless functions triggered by incoming events or data.

The output generated by AWS Forecast, containing predictions generated by both Prophet and AWS DeepAR+, is directed to storage in Amazon S3. S3 serves as a centralized repository for storing the forecasted data. Based on the predictions, OpenWhisk can dynamically adjust container retention durations for IoT functions.

During periods with a high predicted workload, containers will be retained for longer durations to minimize cold start latency. Conversely, during low-demand periods, containers can be recycled, freeing up resources for other applications.

Dynamic Container Management (Controller, Invoker and Docker): Container Retention Decisions: Based on the chosen or aggregated prediction, the OpenWhisk Controller determines optimal container retention durations.

Docker and Warm Containers: Based on the controller's decisions, the number of warm containers (containing IoT Functions) is dynamically adjusted using Docker within the OpenWhisk framework [6].

During high-demand periods (predicted based on workload forecasts), more containers are kept warm to minimize cold start latency. Conversely, during low-demand periods, containers can be recycled, freeing up resources.

VI. Model Selection Criteria

Prophet: Effective for stable IoT workloads with moderate fluctuations, a single dominant trend (upward/downward), and well-represented by the decomposition [7].

$$y(t) = g(t) + h(t) + s(t) + \varepsilon(t) \qquad (7)$$

where y(t) is the predicted value at time t,

g(t) is the piecewise linear trend function,

h(t) is the seasonality component (can model daily, weekly, and yearly cycles),

s(t) is the effect of holidays (if included) and

ε(t) is the error term.

DeepAR+ captures complex IoT workload patterns with high data variability (sensor readings, user interactions), frequent workload invocations (predicts spikes or troughs), multiple trends and complex seasonality (changing usage, varying amplitude or periodicity) [7].

Analysing the DeepAR+ and Prophet suitability lines across workload complexity reveals trends in Fig. 3. DeepAR+ excels when its line consistently surpasses Prophet's within a specific complexity range (shaded area), making it preferable for workloads in that band. Conversely, Prophet demonstrates superiority when its line consistently remains above DeepAR+'s within another complexity range, indicating its suitability for workloads in that zone. Considering these trends alongside the workload's characteristics enables an informed decision on the most suitable model for study on workload prediction.

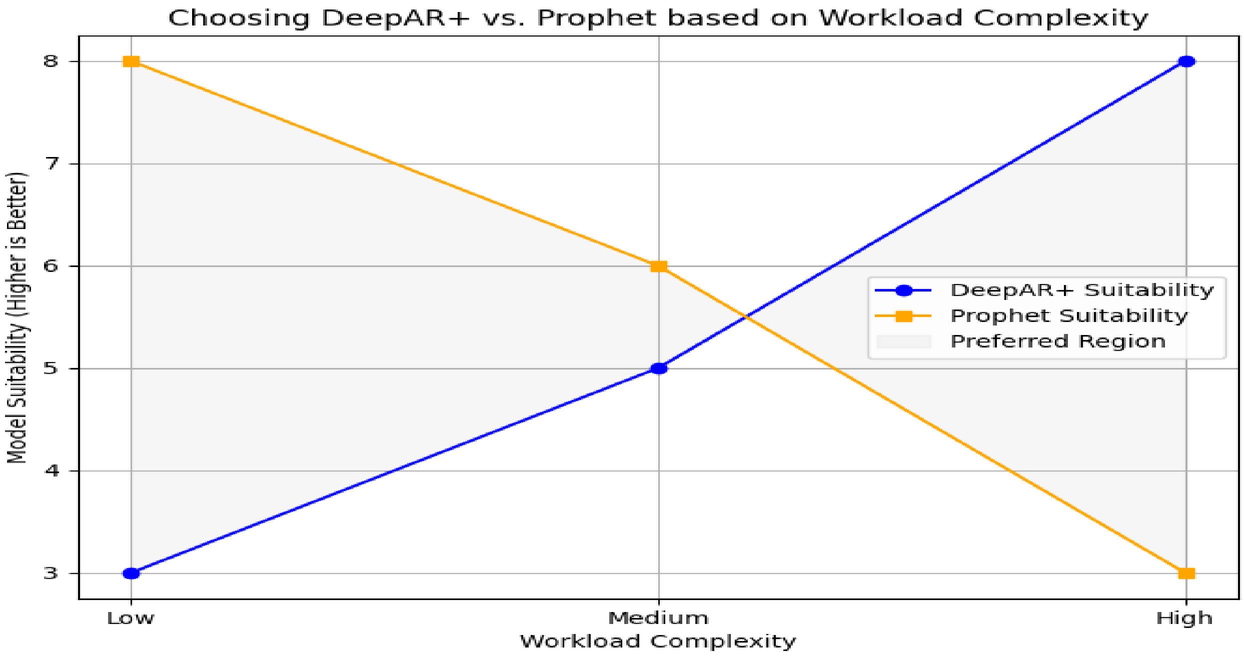

Fig. 3. Model selection based on workload complexity.

A. Workload Prediction with Prophet

Prophet predicts the future workload (function invocation frequency) at time t, denoted as y (t). This prediction is based on the Prophet model's internal workings (including considerations for trend, seasonality, and holidays) and the combined feature set (F_manual and potentially F_built-in) [7].

Container Retention Threshold (T_c): Define a threshold (T_c) representing the minimum number of active containers required to ensure acceptable performance during peak workload periods [8]. This threshold considers factors like average function execution time, which is the desired maximum latency for function invocation.

Scaling Decisions Based on Predictions:

Up-scaling Containers: If Prophet's prediction, y(t_future), for a future time period (t_future) exceeds a pre-defined threshold (T_up),

where T_up > T_c

T_up represents a buffer zone above the minimum threshold to account for potential workload surges beyond the predicted value.

We had initiated scaling up IoT Function application by launching additional containers. This ensures enough containers are available to handle the anticipated workload without excessive cold starts. Down-scaling Containers: If Prophet's prediction, y (t_current), for the current time period (t_current) falls below a pre-defined threshold (T_down), where T_down < T_c:

T_down represents a safety margin below the minimum threshold to avoid under-provisioning during unexpected workload spikes.

We had initiated scaling down IoT application by gracefully terminating unnecessary containers. This reduces resource consumption during low workload periods.

Mathematical Representation:

Up-scaling: if y(t_future) > T_up, then launch additional containers.

Down-scaling: if y(t_current) < T_down, then terminate unnecessary containers.

Setting thresholds (T_up & T_down) Setting these thresholds effectively depends on factors such as predicted workload variations based on output y(t).

AWS Forecast's built-in features (F_built-in) again provide pre-built information about common temporal patterns (e.g., weekly seasonality, holidays).

B. Workload Prediction with DeepAR+

Both F_manual and F_built-in features are fed into the DeepAR+ model during training. The model learns to extract relevant information from these features and utilize it for IoT workload prediction (function invocation frequency).

DeepAR+ builds upon a combination of mathematical concepts to achieve its deep learning capabilities [9, 10].

Loss Function: During training, a loss function (e.g., mean squared error) measures the difference between the model's predictions and the actual workload data. The model iteratively adjusts its internal parameters to minimize this loss, improving its prediction accuracy over time [11].

Mathematical Representation (Simplified):

DeepAR+ employs a complex series of mathematical operations within its RNN architecture [10, 14]. However, a simplified representation could be:

$$y(t) = f\,[W * \{x(t-1), ..., x(t-n)\} + b] \tag{8}$$

where: y(t): predicted workload (function invocation frequency) at time t.

f: activation function (e.g., sigmoid) introducing non-linearity for complex pattern modelling,

W: weight matrix learned during training,

x(t-i): feature vector at time t-i (incorporating F_manual and F_built-in features).

b: bias vector

This simplified equation demonstrates how DeepAR+ uses weights (W) to combine past feature vectors (x) with a bias (b) and applies an activation function (f) to generate a prediction y (t). The weight matrix (W) captures the complex relationships between features and workload that the model learns during training.

VII. Analysis Forecast Workload Prediction

In Fig. 4, spanning weeks 1 to 4, the forecast workload prediction approach showcases notable enhancements in container retention across all four IoT topics. The retention rates soar from 96% to 100%, showcasing a considerable decrease in prematurely discarded containers. This underscores the efficacy of the proposed approach in accurately predicting future workloads, thus maintaining active containers to handle incoming requests. Consequently, this minimizes the necessity for container restarts, thereby augmenting operational efficiency.

Weeks 5-8 (Function Preloading/Function Chaining): The second half of the table shows the performance of the combined Function Preloading and Function Chaining approach for the same IoT topics. Compared to forecast workload prediction, container retention improvement is lower, ranging from 46% to 93%.

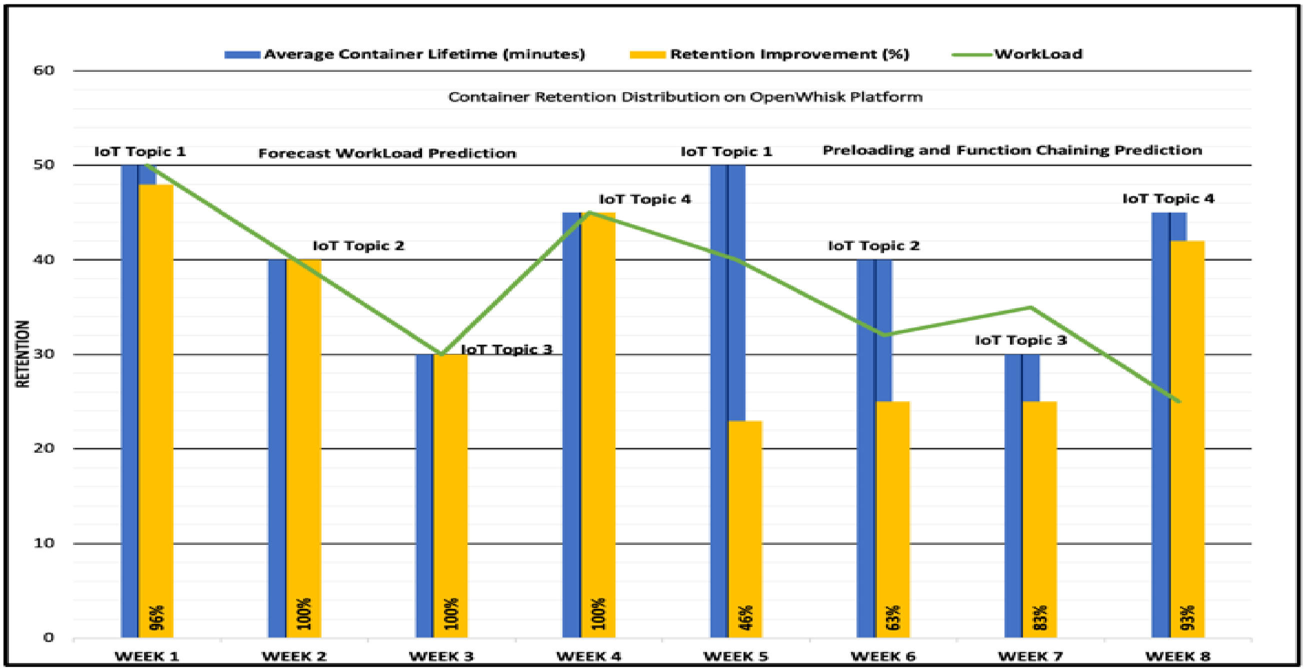

Fig. 4. Workload prediction vs. traditional.

Algorithm 1: Container Retention based on Workload Predictions

```
Inputs: workload predictions (y(t)) for future time intervals (t_i) from DeepAR+ or Prophet and minimum container threshold (T_c) for acceptable performance.
Step 1: For each future time interval (t_i):
    Get predicted workload y(t_i) for time interval t_i

Decision: Does enough warm containers exist?
      (does_container_exist(t_i))
        • Yes: Proceed to down-scaling check
        • No: Launch a new container (create_container)
          (optional: set resource limits based on predicted
          workload)
New (Down-scaling): If containers exist and the predicted
      workload is low (y(t_i) < T_down), gracefully terminate
      unnecessary ones (maintaining at least T_c)
Step 2: Execute the IoT Function: With sufficient warm
      containers, execute the IoT function efficiently (minimal cold
      start latency)
  End
```

Algorithm 2: Custom Invoker

```
Input: function request from Locust via AWS IoT Core Function
Does Container Exist ()
        • Query Docker for warm containers
        • Return True if a warm container exists, False otherwise
Function Create Container ()
        • Create a warm Docker container
 Execute Function ()
        • Run the function request in the container
        • Terminate the container
            Decision: Does Container Exist () == True?
  Yes:
        • Get the name of the existing warm container (container)
        • Execute Function ()
  No:
        • Create Container ()
        • Execute Function ()
      End
      Write Logfile () to S3
```

In Fig. 5, this category showcases the potential impact of a workload prediction approach. With a higher number of invocations in this range compared to Function Preloading and Function Chaining, it suggests a potential in reduction in cold starts.

Combined Stream (Moderate Latency) (501-1000 milliseconds): The number of invocations in this range for the prediction approach might still be higher than the alternatives. This indicates some functions might require slightly more processing time.

Individual Topic Types (Over 1000 + milliseconds): As we move into categories representing specific topic types, the latency distribution might become more balanced. This suggests the processing complexity of these data streams might contribute to slightly higher latencies.

Function Preloading and Function Chaining: These approaches show a presence across all latency ranges. They might still achieve some level of cold start reduction, but their distribution suggests they might have a higher number of cold starts compared to a workload prediction approach, particularly within the low latency range.

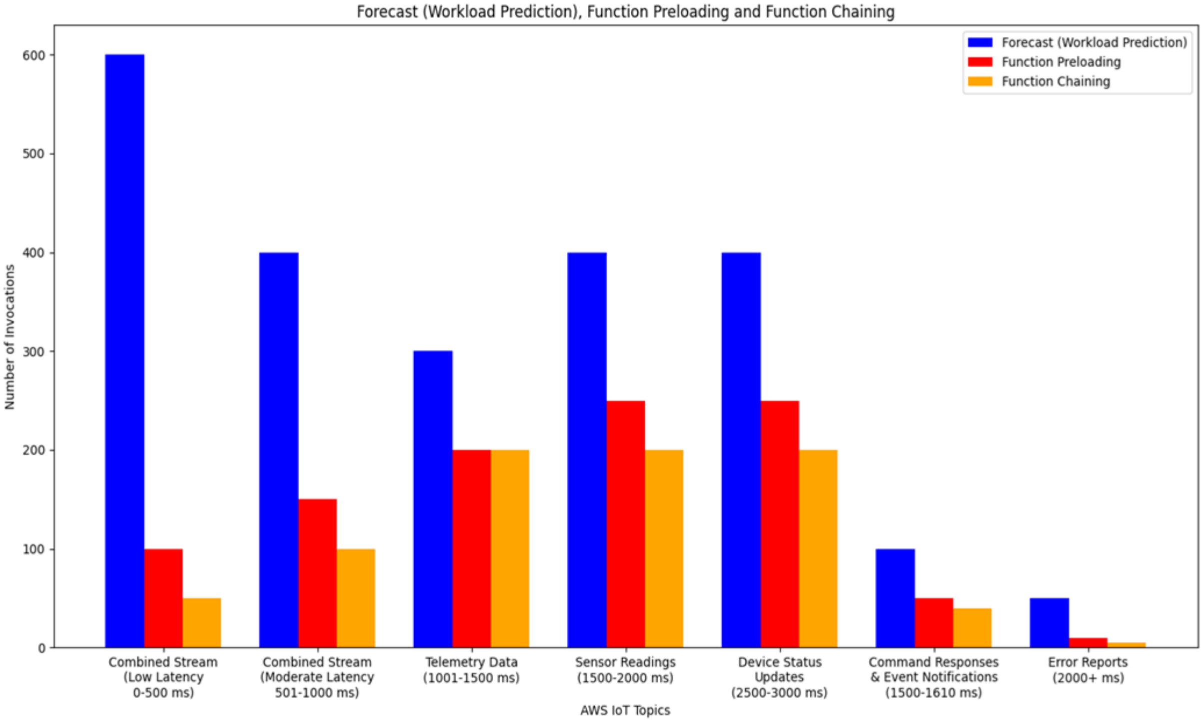

Fig. 5. Workload prediction.

A. Merits of Workload Prediction

- Reduced Cold Starts: A workload prediction approach (like Forecast) has the potential to significantly reduce cold starts by proactively preparing functions for incoming requests, leading to faster response times.
- Improved Efficiency: By minimizing the delays associated with cold starts, a prediction approach can improve the overall performance of serverless functions processing combined IoT topic data.
- Scalability: The ability to handle diverse data streams (various topic types) with reduced cold starts highlights the potential scalability and adaptability of a workload prediction approach.

In Fig. 6, a substantial dataset comprising 1000 data points are utilized to depict the performance metrics for both before and after optimization scenarios.

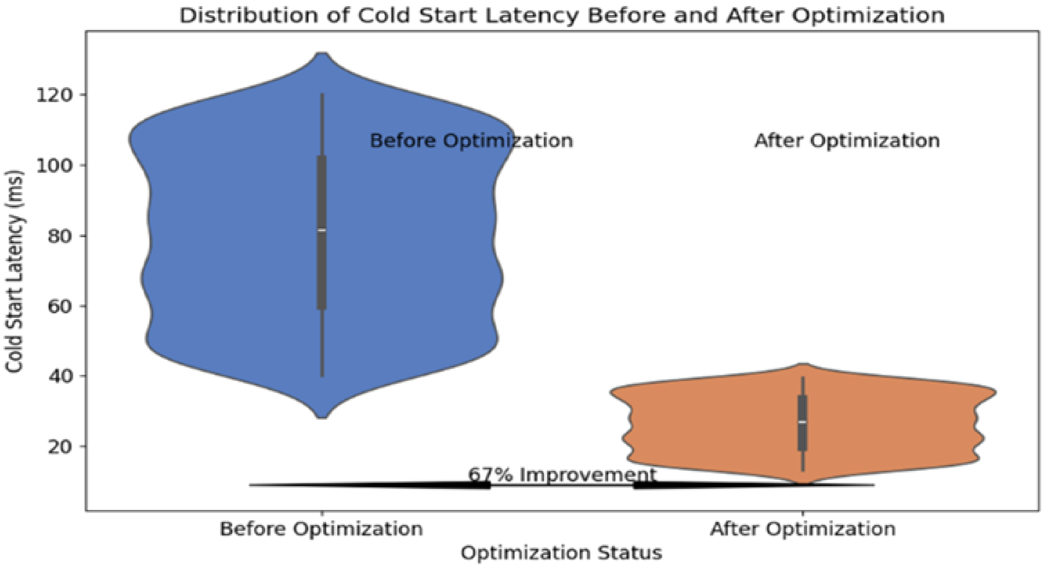

Fig. 6. Optimization impact.

Before Latency: Random values between 40 ms and 120 ms represent the cold start latency experienced before implementing your approach.After Latency: These values are calculated by multiplying the before latency by 0.33, simulating a 67% reduction in cold start latency achieved through your optimization.Workload: Random values between 20 and 100 represent the workload (function invocations) experienced during each cold start.

Median Latency: The thin line within each violin indicates the median cold start latency for that optimization state. A lower median in the "after optimization" violin suggests a general reduction in latency.

VIII. COMPARITIVE STUDIES

This comparative study (Table I) analyzes the efficiency of different methods for reducing cold start latency and improving resource utilization in serverless architectures. The study compares the proposed approach utilizing AWS Forecast with DeepAR+ and Prophet for container retention optimization against four referenced papers [1, 2, 3, 4].

Cold Start Reduction: The proposed work achieves a significant 67% reduction, comparable to or better than other techniques like adaptive pooling and predictive autoscaling.

Resource Utilization: Resource utilization fluctuates across the studies [1, 2, 3, 4], often lower during off-peak times or optimized through various scheduling and scaling techniques. However, the proposed work ensures high resource utilization optimized for current demand. The proposed approach ensures high resource utilization by minimizing unnecessary container activity, similar to workload-aware scheduling and cost-efficient strategies.

Implementation Complexity: Proposed work maintains moderate complexity by leveraging AWS Forecast, which simplifies the implementation compared to ML model-based predictive autoscaling.

Scalability: The proposed method is highly scalable with reduced complexity, making it a robust solution for varying workloads.

Leveraging AWS Forecast for container retention optimization offers a balanced and effective solution for reducing cold start latency, optimizing resource utilization, and maintaining scalability with moderate implementation complexity. The proposed approach stands out as a practical alternative to more complex and traditional serverless computing techniques.

Implementation complexity ranges from high to moderate, with the proposed work leveraging AWS Forecast to maintain moderate complexity. Scalability is generally effective across all references, but the proposed work is highlighted as highly scalable with reduced complexity. Continuous model retraining is necessary for many adaptive and predictive techniques, yet the proposed work reduces this need by relying on AWS Forecast, thus streamlining the process. Lastly, while prewarming resource wastage is a concern during low traffic periods for some techniques, the proposed work effectively prevents wastage through dynamic adjustment.

TABLE I. COMPARATIVE STUDY- 1

Metric	Implementation Complexity	Continuous Model Retraining	Prewarming Resource Wastage
Ref [1]	High for dynamic allocation and request prediction	Required for request prediction models	Yes, during low traffic periods
Ref [2]	Moderate, requires workload analysis	Necessary for adaptive techniques	Reduced through adaptive pooling
Ref [3]	High, involves ML model training and deployment	Necessary for predictive autoscaling	Minimized through accurate auto scaling
Ref [4]	Moderate, balancing cost and performance	Not specified, focus on cost efficiency	Balanced with cost-aware pre-warming
Proposed Work	Moderate, utilizing AWS Forecast	Reduced need, AWS Forecast handles it	No, dynamic adjustment prevents wastage

TABLE II. COMPARATIVE STUDY- 2

Study/ Reference	Techniques	Cold Start Reduction	Resource Utilization	Scalability
Proposed Study	AWS Forecast (DeepAR+, Prophet)	67%	High, dynamic adjustments	High
Ref [5]	Caching Techniques	50-60%	Variable	Good
Ref [6]	SAAF Framework	Not specific	High, predictive modeling	High
Ref [7]	Pool-Based Approach	60-66%	Improved through pre-warming	High
Ref [8]	Function Fusion	55-65%	Enhanced by reducing cold starts	Moderate to High

Table II compares various studies and references on techniques for optimizing serverless computing, focusing on cold start reduction, resource utilization, implementation complexity, and scalability. The proposed study uses AWS Forecast (DeepAR+ and Prophet) to achieve a 67% reduction in cold starts, high resource utilization through dynamic adjustments, and moderate implementation complexity while offering high scalability. The research in [5] employs caching techniques; achieving a 50-60% reduction in cold starts with variable resource utilization, moderate complexity, and good scalability. The study in [6] utilizes the SAAF Framework, which does not specify cold start reduction but ensures high resource utilization through predictive modeling, though it comes with high implementation complexity and scalability. The research in [7] uses a pool-based approach to achieve a 60-66% reduction in cold starts, with improved resource utilization through pre-warming, moderate complexity, and high scalability. Lastly, the study in [8] applies function fusion, reducing cold starts by 55–65% and enhancing resource utilization by minimizing cold starts, with high implementation complexity and moderate to high scalability. Each study offers a unique balance of benefits and challenges, with the proposed study standing out for its effective cold start reduction and scalability.

IX. Conclusion and Future Work

This study focused on Python-based programming workloads and examined the performance of the OpenWhisk Platform in comparison to existing serverless computing platforms in terms of system cost. The findings demonstrated that the OpenWhisk Platform outperformed existing cache cold start tactics, resulting in a reduction of overall system cost. To achieve these improvements, the study proposed the use of the AWS Forecast service with the DeepAR+, Prophet algorithms in combination with containerization. This approach allows for the prediction of demand for a specific function and the pre-warming of a container, thereby reducing cold start-up time in serverless IoT applications. The retention of containers further enhances this technique by keeping the runtime environment warm and ready for subsequent invocations of the function. The application of the Prophet algorithm in container latency prediction offers potential benefits for optimizing resource allocation and workload management in containerized environments. By leveraging its time series forecasting capabilities, it becomes possible to anticipate and mitigate latency issues, thereby enhancing the overall system performance and user experience [12, 13]. Extending the solution to incorporate edge computing can be a promising direction. By deploying the deep learning model on edge devices or edge servers closer to the data source, latency can be reduced, and real-time processing can be achieved [14]. This can be especially beneficial for applications that require low-latency responses or deal with large volumes of data. Facilitating the execution of the solution on other operating systems and supporting serverless functions in multiple programming languages can broaden its applicability and adoption. This can involve developing platform-specific implementations, providing comprehensive documentation and examples, and ensuring compatibility with popular serverless frameworks. However, our limitations are: The study is focused on Python-based workloads, which may not be generalized for use in other programming environments. Moreover, we have used Cloud Service Provider IoT Functions datasets rather than Industrial 4.0 IIoT device data.

Acknowledgment

We thank Dr. Sandeep Shastri for his expertise and assistance throughout all aspects of our study and for the help in writing the manuscript.

***Abstract*—80% of least developed countries populations rely on traditional medicine (TM). West Africa is not left outdone. Multilingualism is very manifest. Additionally, TM practitioners (TMP) commonly desire to keep secret their knowledge. Illiteracy affects the vast majority of TMP in this region. Thus, exchanges between practitioners for knowledge and experience sharing are severely hindered by multilingualism, illiteracy and secretiveness. The reliability and relevance question of the data and knowledge gathered from these practitioners is therefore raised. Conventional data collection methods are not operational in this context. Hence, we designed an original collection data method that we called back-and-forth, to overcome these difficulties. Such method allows us to obtain stable and verbatim collection from the TMP. Both sequential and recursive, it is applied to data collection during visits carried out for 110 practitioners in West Africa, with two to four visits per practitioner. 79 practitioners were finally included in the study project. The others 31 either did not adhere to the project or provided unstable knowledge. 13 diseases and 12 plants were collected, with the "plant cure disease" relations between them, as expressed by these 79 practitioners. Our second objective was to extend the domain ontology of west Africa TM, accurately ontoMEDTRAD, due to the emergence of three new concepts arising from the above. Face to climate change that may lead to some plants extinction, to update some old reference sources contents of TM, it has proved necessary to compare them with the opinions and knowledge collected from TMP.**

***Keywords*—Knowledge elicitation; collection data method; ontology; traditional medicine; West Africa; ontoMEDTRAD**

I. Introduction

For their healthcare, 80% of the least developed countries populations, and particularly those in West Africa, rely on traditional medicine (TM) [1]. TM is complementary to conventional medicine (CM), and is often easier to access, cheaper, and culturally closer to these populations. TM commonly consists in the use of therapeutic plants with few chemical transformations [2], if any. However, most TM practitioners (TMP) have not followed any dedicated training [3]. The TM knowledge transmission mostly relies on oral communication. TMP have mean age, higher than life expectancy. Thus, they usually disappear with their TM knowledge [4]. At the same time, as modernization continues, some local languages are threatened with extinction [5, 6, 7, 8, 9]. Consequently, in order to perpetuate TM knowledge [10, 11, 36, 37, 38, 39], it is mandatory to write and formalize the knowledge from TMP using textbooks, training courses, or even decision support tools based on information and communication technologies (ICT). The first step toward this formalization is knowledge elicitation [34, 35], in verbatim format, i.e. raw written traces.

However, many difficulties arise when collecting knowledge and data in the context of TM. That situation is described in three points: 1) multilingualism: there are more than 1000 spoken languages in West Africa [5, 6, 12]; 2) illiteracy: the vast majority of TMP do not both read and write in any of the three official languages (English, French and Portuguese) [12, 13]; 3) secretiveness: many TMP keep their knowledge secret and are not opened to share it with their colleagues [12, 13, 14].

Given all the above, conventional and regular data collection methods [16, 17] are not operational in such context. In this respect, the reliability of the data and knowledge collected depends highly on the reliability of the method.

In this paper, we propose a specific method to collect knowledge and data in a context of multilingualism, illiteracy and secretiveness. The method is based on more than one interview (also said interview visit) for the same TMP. We thus called it "back and forth".

In the course of our data collection using this method, the *recruited* TMP are gradually divided into *included* TMP and *excluded* TMP. Following the knowledge elicitation, we also enriched and extended our ontology of traditional medicine, ontoMEDTRAD, with three new concepts: Translator, TMP advising on references of TM source, and References of TM sources.

The data collected in this work can also be of great interest from an ecological point of view. For example, one of the recommendations is that the most widely used TM plants should be protected as a priority against extinction and the dangers of climate change.

For the following, we first describe the background context to this work. Then, we detail our method and the results from statistical and ontological angles. Finally, we discuss our work and conclude.

II. Context and Background

Multilingualism constitutes a wealth of habits and customs [18, 19] in several regions of the least developed countries. In West Africa, there are about 1127 local languages, including 527 in Nigeria alone [12, 18, 20]. These languages are rarely written. This constitutes a real language barrier in oral and written exchanges. English, French and Portuguese are the three non-local, so-called official written languages used for intra- and inter-country communication. At the level of education and training, the primary, secondary and higher schools in these countries of the African Sub-region are based essentially on these official languages [24]. Despite advances in the current education level in each of these countries, the majority of expert TMPs are not literate [4, 18, 21, 22] in these official languages. In addition, naturally, we note the tacit character of this African TM [10, 23]. The schools of TM are almost non-existent. Their number is very low [10, 23]. Mutual sharing of knowledge and experience between TMPs is not usual. When some knowledge transfer takes place, it is done orally [10, 23]. Lineage, innateness, recognition and gratitude provide a solid foundation for the reasons for these transmissions [10, 23]. In this part of the world, TMP organizations remain more like social self-help associations and federations. They allow also TMP to dialogue and exchange with public structure (e.g: PNPMT) and non-public one as non-government organization (NGO) (e.g : Prometra) [10]. Their purpose does not include professional exchanges based on knowledge and experience sharing specific to traditional medical art. This situation seems to continue over time. Furthermore, TM is a sensitive issue. The culture of secrecy is strongly shared by TMPs **[**12**]**, both custodians and holders of rooted knowledge in the art of TM.

In all this context, the collection of information, knowledge and data from these mostly illiterate TMP is more than problematic. We are therefore opting for information and communication technologies (ICTs), which are clearly among the most important tools for making the most of information and enriching knowledge. As part of our strategy, we have therefore built innovative technological tools such as the ontoMEDTRAD an ontology and the SysMEDTRAD decision support system [4, 10] to sustain and preserve TM knowledge. The complexity of capturing african TM justifies the progressive, incremental and modular nature of the construction of these tools, a step in a major project to safeguard local, community, cultural and professional knowledge in West Africa [4].

In the light of all the above, the quality of our innovative tools depends to a large extent on the quality of the collected information, data and knowledge. This led us to establish a particular method of this collecting from the TMP. It is a method that allows us to have the verbatim data and knowledge of this TM. This method contrasts sharply with traditional and regular collection ones which cannot be operational, simply because of multilingualism, illiteracy and secretiveness.

III. "Back and forth" Method

The specificity of the back-and-forth method is the replication of similar interviews, in order to achieve stability of the data and knowledge collected from the TMPs. Indeed, several interviews (at least two and at most four) are conducted with a given TMP until the stability of the data and knowledge gathered is assured. Sequential and recursive, the method potentially reduces the semantic bias between on the one hand the knowledge and its interpretation, and on the other those ones of the reality perceived held by the TMP. It is also possible to make implicit knowledge, explicit thanks to the inference system, the reasoner, which is an essential feature in the design and especially in the use of an ontology [32].

The steps of our method are outlined by what follows.

A. *Recruitment of TMP and Translators*

In order to recruit TMPs, we propose the use of facilitating structures such as governmental TM promotion agencies (e.g: PNPMT, a public structure in Abidjan) and NGOs (e.g: PROMETRA in Dakar). These structures are able to provide lists of TMPs, with whom they work regularly and with whom contact is easy. We also suggest contacting TMP associations and federations. They can provide signed letters of introduction and investigation. These letters are an element that can simplify subsequent interviews, even if most TMPs cannot read. We suggest that the presidents of the associations and federations should be approached first, as they can read and know the importance of such letters. These public and private structures are also in contact with translators, who should be recruited to carry out the exchanges with the TMPs. The translators will be part of the interviewers together as the interviewers of the study. TMPs are mostly men. TMP women number is very low.

In our elicitation technique used, the translator takes into account the general features of the TMP's habits and customs.

B. *Awareness-Raising Meeting*

We propose organizing an awareness-raising meeting with all the TMPs recruited for the study. At this meeting, the objectives of the study are presented, as well as the expected results for the TMP. The TMPs are given instructions, in particular to adopt a pedagogical attitude towards the investigators (interviewers). Indeed, TMPs are often afraid that researchers will just come and collect their knowledge without any direct benefit to them. In response term, an advantage for the TMPs selected and included in this research study is to give them access to the software tools for sharing the knowledge which will be produced (acquired). The principle of repeated interviews is also explained, pointing out that feedback on certain knowledge is essential in order to consolidate and stabilize it.

C. *Preparing for the Interviews*

The individual interviews and the paper questionnaire for data and knowledge collection should be prepared (see example of Fig. 5 of questionary forms in annexes). These questionnaires have to be filled in by the interviewers mostly time.

D. *Conducting the Interviews*

The interviews are conducted individually, with one TMP at a time.

For some TMPs, it is useful to provide a modest or bloc, such as a drink, at the beginning or the end of the interview. During the interview, we ask the TMP to list the five of health problems (diseases) that he treats most frequently. He/she must also list the medicinal resources (plant, mineral and animal) that he/she uses to cure each of these problems. In order to be able to identify the plants correctly, we ask them to show us the plants. These plants are compared with the assessments of botanists to verify or determine their scientific name. In this regard, we have recourse to monographs on West African medicinal plants [24, 25, 26, 27, 28, 29, 30]. These cited monographs are not exhaustive.

At the time of the interview, the TMP is asked general questions (e.g. surname, first name and speciality, his education level, number of patients per day, per month, per year, etc.), and questions relating to the health care practices provided and knowledge related to this care. We recommend not making audio or video recordings, as the TMP are reluctant to do so and may get angry if they are recorded.

The same interview is repeated at least twice and at most four times with the same TMP, in order to ensure the stability of the knowledge collected. Repeating the interviews, approximately every three months, makes it possible to clarify the points that remain ambiguous, but also, from the second interview onwards, to compare the knowledge collected with that of the previous interviews to determine the stability of the knowledge expressed. It is then possible to present the TMP with his own contradictions and to evaluate the interviews as a whole (behaviour and explanations). At the end of each interview, the TMP is classified into one of the following three categories:

"excluded TMP", "TMP to be revisited" and "included TMP". TMP cannot be classified as "included TMP" or "TMP to be revisited" at the first or the very last interview, respectively. We give some details on these three categories noted by (1), (2) and (3).

1) Excluded TMP: These are TMPs excluded for one of the following reasons:

a) -TMP's absence from the interview scheduled with his agreement;

b) Lack of willingness to participate in the study, often resulting in digressions or even excessive rambling by the TMP himself (herself);

c) Collected data and knowledge that are contradictory or not stable over the course of the meetings.

Here is an example of an "unwilling" TMP. In a village in Senegal, an appointment was made with a traditional healer. The translator and I arrived in the healer's courtyard, where he usually works. First, we found his wife there. After the usual greetings, she asked us to wait for her husband who was in the house. Ten minutes later, the healer comes out and greets us from a distance. Without any further exchange, he went back to his house. As the wait was getting long, his wife went back to see him. She finally came out to tell us that her husband could no longer honor the appointment. Thus, we had left the place empty-handed.

Here is a second example of the instability of the knowledge expressed by the TMP. At the first appointment, a TMP certified the use of the neem plant (Azadirachta indica) for the treatment of malaria (paludism). At the second meeting, he did not even mention malaria among the five diseases he treats most often.

2) TMP to be revisited: This group of TMPs is committed to the project. The exchanges are going well. This decision is not applicable to the last interview, as the "TMP to be revisited" is an interim decision, and not a final one.

3) Included TMP: The data collected are stable over the meetings. They are consistent with the contents of the books, and of good quality. In these data, knowledge and experience of TMP are often included after a few discussions with him.

However, after the first interview, it is not possible to make a comparison due to the lack of previous collections. Therefore, the stability of knowledge cannot be assessed at all. The TMP cannot be included after only one interview. Therefore, there are at least two interviews for each TMP in order to make the decision on which TMP to include. Similarly, after the fourth and final interview, the TMP must necessarily be either included or excluded. If the knowledge is still not stabilized at this stage, we recommend excluding the TMP. Table I illustrates the different successive interviews (RDVi , for i from 1 to 4) and the possible decisions following an interview. The Included TMP (IT) are fully committed to the project.

TABLE I. TYPE OF DECISION TAKEN FOR A TMP BY STAGE OF THE INTERVIEWS CYCLE (FROM BEGINNING TO END) SPECIFIC TO THAT TMP

N° of interview appointment with the same TMP	**Possible decisions at the interview issue**
RDV1	ET, TBR
RDV2	IT, ET, TBR
RDV3	IT, ET, TBR
RDV4	IT, ET

Legend: ET: Excluded TMP; IT: Included TMP; TBR: TMP to be revisited. Notice: three months is the estimated period between two interviews with the same TMP.

It is not necessary for all TMPs to be at the same stage of interview. As far as the four appointments are concerned, there is a period of at least three months between two interview visits to the same TMP.

It is only at the end of the campaign of data collection that we can draw accounting conclusions about the final number of included or excluded TMPs. The duration of our campaign of TMP data collection and knowledge acquisition was one year and a half.

E. Techniques for Refining this Method Multiple Confrontations

Our collections focus mainly on plants which constitute the largest proportion of all medicinal resources in TM of in west Africa. The plants collected are identified with the public structures and NGOs help. Local botanist teachers can also intervene for certain confirmations in addition to the confrontations with Internet sources and other sources such as books. They have a reference list of plants with their corresponding vernacular names in local languages and scientific names.

We also pursue these comparisons through the use of monographs on West African medicinal plants [14, 24, 25, 26, 27, 28, 29, 30]. When scientific name of a plant used by a TMP is unknown, we approach a university botanist. For the same reason, we can solicit botanists from botanical gardens in conjunction with universities. We also use monographs [24, 26] supported by the advice of facilitating state structures (e.g: PNPMT).

For this purpose, during our collection visits to the TMP, photographs of plant parts such as leaves are used to contribute to identify the plant scientific name.

Some stabilized data and knowledge collected from included TMP are synthesized and compared with that found in recent books and other miscellaneous sources. For certain intermediate validations, this collection is essential for all the modeling stages (conceptualization, formalization, operationalization) involved in any ontology construction methodology (Neon, Diligent, OntoForInfoScience, …) [10, 37, 40]. However, the knowledge of the TM recorded in older reference sources (e.g. before 2000) may differ with the practices of current TMP. This can be explained by the extinction of certain plants or medicinal resources as a result of climate change, e.g. due to reduced rainfall, or by anthropic actions in relation to the overuse of traditional and medicinal resources (plant, mineral and animal).

IV. RESULTS

We recruited a total of 110 TMPs. 50 were Ivorian and 60 were Senegalese. In Côte d'Ivoire, we relied on the National Program for the Promotion of Traditional Medicine (PNPMT). In Senegal, we received support from the University of Gaston Berger (UGB) in Saint-Louis and the NGO Prometra.

In addition, some of the TMPs we visited led us to contact additional TMP. For example, after our interview with one TMP, this one led us to a more reputed other. The list of TMP, thus, grew over the course of the study to reach 110.

We also recruited two translators, one in Côte d'Ivoire and one in Senegal, each translating several local languages.

The awareness meetings in Côte d'Ivoire and Senegal were similar. The Ivorian TMP received a short training in anatomy, the content of which was provided by a medical doctor (physician).

The duration of the interviews varied from one TMP to another. For the first meeting, it ranged from one to three hours, depending on the TMP's interest in the study. After this first appointment, subsequent interviews are of shorter duration, ranging from 25 minutes to 1 hour. On the other hand, for some TMPs, the final interviews tend to be of slightly longer duration as their interest grows over the course of these interviews. During these interviews, we were surprised by the wealth of knowledge collected. Some of the speeches distanced us from a cartesian and scientific approach. They deal with concepts relating to metaphysics or the supernatural (djinn or djinan means genius in form of water, fire, stone, mountain, wind, etc.).

For example, one TMP told us that he could find any plant in the West African sub-region, no matter where it was growing. However, he didn't explain to us the technique he uses to quickly obtain a plant that only grows very far away. We put aside these speeches without really taking them into account. Many TMPs find it difficult to separate the physical and bodily dimension from the psychological and societal dimension of the disease. We have tried as much as possible to focus on the somatic (physical and bodily) dimension of human health and not on the holistic approach [10] that TM claims. This somatic dimension is currently more measured. The repeated interviews were not conducted in waves, but as the TMPs were recruited. The TMPs were therefore not all at the same stage at any given time. The Fig. 1 shows the inclusion and exclusion decisions made at the end of each of all forth interviews. Inclusion decisions are made at the end of each of the last three interviews. This means that such a decision can only be taken at the end of second interview, and immediately after the first interview phase (RDV1), no TMP was included. This is justified by the back-and-forth nature of our collection method. We need at least two interviews with the same TMP to make a comparison and assess the stability of the knowledge collected in order to decide.

The very first "excluded TMP" were excluded because they did not keep their appointments or showed signs of total absence of adherence to the research project. On the margins of our interviews with the TMP, our curiosity led us to ask and have aside the opinion of patients who came to consult the TMP. They told us that they were satisfied with the TMP's health care. Some of the most open-minded TMPs have asked us for advice on how to help them certify the active ingredients in their products, or even on how to register patent.

A. Statistics on Information and Knowledge Gained from Interviews

Figures numbered from 1 to 3, illustrate this back-and-forth method. In Fig. 1, each bar of the diagram represents one of the four interview visits, denoted RDVn (n being an index going from 1 to 4). Interview RDVn is achieved after interview RDVn-1, with n greater than 1. The height of the bars in Fig. 1 represents the number of TMPs. At the end of the four interview phases, 31 TMPs (28%) were excluded and 79 TMPs (72%) were included. Table II shows these totals for TMPs admitted as ITs or as ETs, as well as the progressive trends from which they are calculated.

The TMPs were asked to identify the five most frequent plants they use, and the five most frequent diseases they treat. After eliminating duplicates, 12 medicinal plant species in TM were observed in TMP prescriptions for health care treatment. From the same interviews, 13 diseases were identified as being cited by the TMPs. We found a high degree of overlap: the same plants are used or prescribed by most TMP, and most TMPs treat the same diseases. We noted that malaria is the most common disease treated by the TMPs. Tables III and IV list respectively the diseases and plants with the number of times they were mentioned by distinct TMP.

As TM is not an exact science, there is not a 1-1 mapping between plants and diseases. Various TMPs may cite the same plants, but to treat different diseases, or may cite the same disease, but treat it with different plants. It is therefore important to quantify the number of TMP that cited each plant-disease association. For this purpose, Fig. 2 and Fig. 3 show diagrams of the number of citations obtained from TMP resulting from Tables III and IV, respectively.

Whether, it is a plant or a disease, the number of times it is cited is that of the TMPs having cited it.

The Table V shows the exhaustive citations numbers between plants and diseases. For instance, one can see that Azadirachta indica A. Juss. (Neem) was cited 14 times for treating paludism, which suggests a high confidence. On the contrary, the same plant was cited only once for treating diarrhea and edema, which is associated with a much lower confidence. In all cases, we have the stability of the information obtained. From the data and knowledge collected, other outcomes as the emergence of three concepts to integrate in ontoMEDTRAD, arise. ontoMEDTRAD's construction method [10] based on the other three, namely Neon, Diligent and OntoforIinfoscience, justifies the point of transition between this first part and the second which follows.

TABLE II. NUMBER OF DECISION TYPES TAKEN ON TMP BY THE STAGE OF THE INTERVIEWS CYCLE (FROM BEGINNING TO END)

		N° of interviews visit to TMP				**Totals**
		RDV1	RDV2	RDV3	RDV4	
Number of decision types taken on TMP	TMP to be revisited : **TBR**	**94**	**68**	**52**	**0**	
	Included TMP : **IT**	**0**	**19**	**11**	**49**	**79**
	Excluded TMP : **ET**	**16**	**7**	**5**	**3**	**31**

B. Addition of New Concepts to the Ontology of Traditional Medicine, OntoMEDTRAD

This second part, far from being opposed to the previous one, is a consequence of it. None of the ontology development methods has been adopted to date [10, 36, 38, 39, 40], but for now the emphasis is on the main objectives of sharing semantic of concepts and common standards (for axiomatization of concepts), co-construction and mutual understanding for a given community of actors (humans and computer machines). It should also be noted that the phases of requirements specification, conceptualization, formalization, implementation, maintenance and evolution are present in most of these methods.

Of course, other consequences of our back-and-forth method concern three new concepts to integrate into our TM ontology, ontoMEDTRAD. These three new concepts are: "Translator", TMPAdvisingReferencesSMT and "ReferencesTMsource". Clearly, two of the terms in these concepts are mnemonics. In the following section, we describe the three concepts to show what they can be more semantically identified with.

- Translator

The importance of the role of the translator-interpreter is well established. When we have to conduct an interview with the TMP, the translator is indispensable. This translator is also essential when it comes to checking the content of books or the web or brochures..., whose publications are too old or undated. However, the translator may impact the knowledge collected and, in particular, a poor translator might ruin the entire process. Therefore, it is important to track the translator associated with the various pieces of knowledge collected. It would therefore be appropriate to specify the concept "Translator" in our ontology, ontoMEDTRAD. Translator will inherit from the Person class.

- TMP advising on references of TM sources : TMPAdvisingReferencesSMT

Many sources are old, dating back 20 or even 30 years. However, knowledge may have evolved and the plants available may no longer be the same, particularly as global warming may alter their geographic area range. It is therefore important to compare these sources with the opinions of current TMPs, in order to validate, correct or reject them. Some plants, notably the neem tree (Azadirachta indica), are harvested intensively. TMPAdvisingReferencesSMT is therefore the concept term chosen to canonize the TMPs that have carried a validation and confrontation opinion. This concept is subsumed by TMP, itself subsumed by Person.

- References of TM sources : ReferencesTMsource

Given their importance, the sources of knowledge and data derived from TM must be canonized. These sources include references from the web, books and scientific publications (thesis in botany, ethnobotany and bioscience) related to TM. It is precisely the contents of these sources that are concerned with the remedies and recipes used to treat a patient with a given disease. In the above, we have given some reasons for collecting TMP opinions on this TM knowledge obtained from these sources. This should be able to further reassure us about the medical virtues of these resources in human health. All these TM sources found on the web or contained in books or in documents (brochures, bioscience documents, thesis and scientific publications) and having object as TM recipes, remedies and medicinal resources are to be retained in our ontology. ReferencesTMsource is the concept term canonizing all these TM sources. It is subsumed by Thing, the universal class, as it does not yet have an explicit ontological existence class subsuming it in ontoMEDTRAD.

C. Onto MEDTRAD : Integration of Three Concepts: Translator, TMPAdvising References SMT and ReferencesTMsource

Three concepts (classes), Translator, TMPAdvisingReferencesSMT and ReferencesTMsource have been integrated into ontoMEDTRAD, specifically in its ontoCONCEPT-Term module, which is entirely terminological, whereas its ontoICONE module is both terminological and iconic. For that, we have used Protégé tool in which ontoGraf is a plugin for visualizing ontologies (owl, owl/xml, rdf/xml, turtle, …). In Fig. 4, the use of Ci symbologies (with i from 1 to 3) is only intended to highlight these three newly integrated concepts.

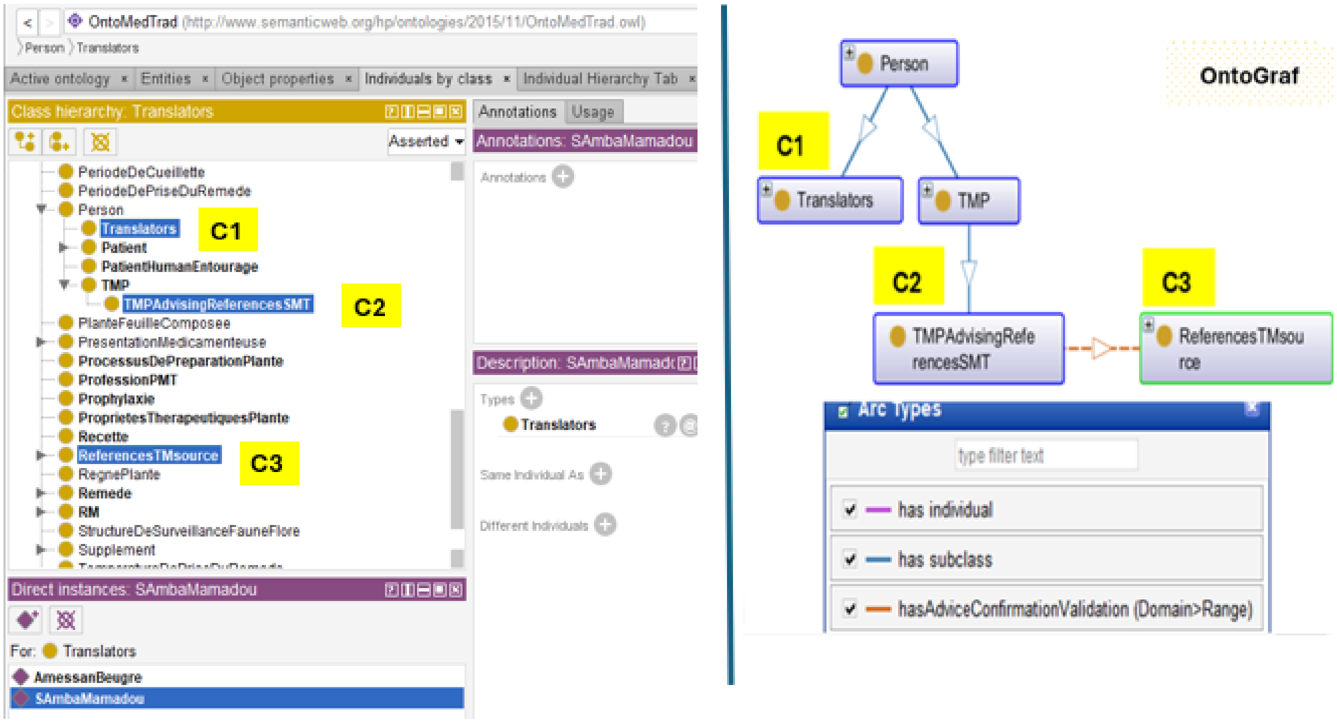

Fig. 4. Three integrated concepts in ontoMEDTRAD : Translator (**C1**), TMPAdvisingReferencesSMT (**C2**) and ReferencesTMsource (**C3**).

V. Discussion

In this paper, we proposed an original method for knowledge elicitation in a context of multilingualism, illiteracy and secretiveness. We applied this method to the elicitation of knowledge relative to TM in West Africa.

The method used allows secrecy to be partially reduced. To do this, the knowledge, information and data gathered from the TMP during at least two successive visits are compared to establish their stability. In this way, information and knowledge that are not stable and consistent with the same questioning concerns are either questioned and rediscussed with the TMP, or rejected with the exclusion of that TMP. With the help of the translators who follow our method, multilingualism, illiteracy and secrecy are largely overcome. Our ultimate goal is to reduce the semantic gap between knowledge and information acquired through TMPs and reality. The second level of response for a sustainable solution to the three challenges is found in the ontology, ontoMEDTRAD, through its two aspects, one terminological and the other visual-iconic. At this level, the consensus inherent to ontolgy such ontoMEDTRAD, is necessary between experts PMT in the face of secrecy. Iconic language frees these PMTs from the linguistic barriers associated with proven multilingualism and illiteracy.

In our defined collection approach, the translator may speak more than two local languages in addition to the official language. At the very least, the translator understands both the official language of the country where the TMP is working and this TMP's local language. He is an important pillar of trust. However, he can also be the source of important semantic bias when translating the TMP knowledge. We note that the translator's selection is facilitated by recognized structures (e.g. Prometra, a TM NGO in Senegal and PNPMT, a public TM program structure in Côte d'Ivoire).

To avoid the TMP becoming aware of the repetitive nature of the interviews, two key elements can be taken into account the number of translators and the number of interview visits to the TMP. We recommend two translators who alternate between two visits with the same TMP. Indeed, after one interpreter's intervention, another follows for the next visit of interviews session for the same TMP. However, an additional burden of collection resources can be a drawback. Nor should the number of interpreters be inflated, to avoid semantic bias. It is therefore preferable to recruit people who are sufficiently multilingual to already achieve a certain degree of semantic uniformity in the collection. From this point of view, the duration parameter could be suitably adapted. It is also necessary to create a changing environment during the different visits for the TMP interviews and for the confrontation of TMP opinions with specific physical or digital contents of TM already collected from books, documents, publications, thesis and websites. These contents are all aimed at the relevance of TM primary care offerings. They are therefore specific not only to diseases, recipes and remedies, but also to medicinal resources seen as the raw materials for these recipes and remedies. These resources include minerals, animals and plants, certain natural instruments such as the pestle and mortar, and other traditional means and protocol used by TMP. The order of the questions should not be static from one interview to the next, even if the targeted content stays the same. Groups of questions can be maintained so as not to distort the semantics targeted above all. It is also advisable to broaden the range of elicitation techniques. It is therefore of great interest to ensure the regularity, stability or convergence of the content of the TM knowledge and data collected or acquired despite the heterogeneity of the sources [14, 24, 25, 26, 27, 28, 29, 30], with considering the TMP as a pivot expert. The knowledge base obtained will have to undergo a continuous enrichment of consensual and stable knowledge around the expert TMPs. We have opted to leave the TMPs in their natural working states without any overwhelming influence. That's why we don't make them come to us, but we have decided to go to them through these collection visits. They have been trained to be attentive with a pedagogical attitude.

For TMPs (ITs) who are more open to the research study, we could increase the number of collection channels in the sense of back-and-forth method, which is such an important part of our strategy.

Furthermore, valuing TM also means engaging and convincing all levels of society, and populations in general to accept TM primary health care offerings without inferiority or superiority complexes, stigmatization or discrimination. Mutual acceptance between the world of TM and the one of conventional medicine (CM) [15] needs to be strengthened through their gradual integration of the former into the second [33].

It should be noted that it is not easy to define the critical threshold of the ontology's population to enter its effective exploitation phase. This work has also made it possible to obtain figures on the frequency of use of medicinal plants, and thus to determine which plants are most frequently used (frequently prescription plant). These results could also be invaluable in making the protection of these plants a priority in the current context of climate change and deforestation.

The results obtained as shown in Table V, suggest a high heterogeneity in the use of plants by TMPs : Six plants were used, each, for treating 10 or more diseases, and no plant-disease association was cited by more than 15 TMPs (out of 79). This heterogeneity may be related to the lack of oral and secretive dimensions of TM. Future works may be needed in order to determine which plant-disease associations are significant, e.g. by fixing a minimum number of citations.

This raises the question of strengthening the cultivable reproduction capacity of prescribed TM plants threatened with extinction for a variety of reasons (global warming, pests and parasites capable of attacking certain medicinal resources (plants and animals) [31]. It should also be noted that Table V is rich in significant interpretations, not all of which have been annotated.

VI. Conclusion

In TM of west Africa, multilingualism, illiteracy and secrecy are the basic obstacles to sharing and exchange collaboratively in this field of health. The traditional methods for gathering data and knowledge from TMP experts, mostly illiterate, are no longer appropriate. We have therefore proposed a specific and original method, "back and forth", for verbatim collecting knowledge and data. The backbone of the "back and forth" is based on the content stability of the interviews carried out during the TMP visits. It therefore involves the repetition of interviews. Increasing the semantics of data and knowledge in the technological tools under construction requires such a meticulous and careful collection method. It is a rigorous , sequenced and recursive method that makes it possible, at the end of stage 2, known as interview 2 or RDV 2, to take decision : continue with a third interview, exclude the TMP, or include the TMP. It is easy to see whether the data, knowledge and experience collected or acquired from a given TMP, become stable from this stage onwards. Enhancing the value of TM is about improving the environment of all the links in the chain around the TMP as a pivot from the detection of symptoms and diseases to the administration of primary health care on the patient. TMP is also at the heart of the collections source [14, 24, 25, 26, 27, 28, 29, 30] on this TM until we can have ontoMEDTRAD operationally.

With this method, the comparison of old reference TM sources (before 2000) with the opinions of the TMP has proved to be more than necessary in view of climate change, in order to update the data concerned (resources plant, animal, mineral, remedy, recipe, …).

At the end of the application of this back-and-forth method, we have reliable data and knowledge that can constitute a stable core that will guarantee the future exploitation and evolution of the technological tools (ontoMEDTRAD, SysMEDTRAD). In addition, there is the emergence of three new concepts to be integrated into ontoMEDTRAD. As this detailed method has highlighted their crucial role, these concepts are: "translator", TMPAdvisingReferencesSMT and ReferencesTMsource.

This work also made it possible to obtain, by means of figures and graphs, the frequency of use of medicinal plants (medicinal resources) in terms of prescription by TMP. So, it's clear which plants are the most widely used and the most virtuous. These results could be invaluable in ensuring the physical preservation of these plants as a priority, in the current context of climate change or disruption [31], deforestation or abuse of all kinds of uses of these plants. In the same vein, we need to raise awareness among the general public, including TMPs, of the importance of building and preserving botanical and wildlife gardens.

This back-and-forth method is special because it goes out of conventional and classic methods of gathering data and knowledge. It makes our strategy, of which it is a part, inductively original.

This work augurs well for the architectural reinforcement not only of ontoMEDTRAD, but also of the intelligent applications (as SysMEDTRAD) that will use it.

In perspective, all these awareness-raising activities carried out, which are costly and on our own funds, are still necessary on a larger scale. Thus, we recommend strengthening this strategy in Côte d'Ivoire and Senegal on the one hand, and then extending it to other countries in the sub-region for the final and definitive validation of our tools (ontoMEDTRAD and sysMEDTRAD) at the national and sub-regional levels in West Africa.

Hôpital militaire principal d'instruction de Tunis, Tunisia[3, 4]

***Abstract*—Globally, lung cancer remains the leading cause of cancer-related deaths, with early detection significantly improving survival rates. Developing robust machine learning models for early detection necessitates access to high-quality, localized datasets. This project establishes the first lung cancer dataset in Tunisia, utilizing DICOM CT scans from 123 Tunisian patients. The dataset, annotated by experienced radiologists, includes diverse forms of lung cancer at various stages. Using transfer learning with pre-trained 3D ResNet models from Tencent's MedicalNet, our tests showed the dataset outperformed previous models in specificity and sensitivity. This demonstrates its effectiveness in capturing the unique clinical characteristics of the Tunisian population and its potential to significantly enhance lung cancer diagnosis and detection.**

Keywords—Lung cancer; Tunisia; dataset; transfer learning; medical imaging; annotations

I. INTRODUCTION

The lungs are the main organs of respiration. They regulate breathing, ensuring that each and every cell in the body receives oxygen [1]. The human body's specifically designed defense mechanisms shield the organs. However, they are unable to completely eliminate the risk of contracting specific lung diseases. Infections, inflammation, or even more serious conditions like the emergence of a malignant tumor can affect the lungs. One of the main causes of death in industrialized countries is lung cancer. Toxic surroundings, long-term inflammation, and smoking are only a few of the variables that frequently cause long-term harm. Phlegm is one of many strategies that the lungs use to clean their airways on their own. However, this is not enough for a smoker [2].

The latest advancements in imaging and sequencing technology have resulted in tremendous progress in the clinical investigation of lung cancer. However, the human mind's ability to comprehend and utilize the collection of such enormous amounts of data is limited. Machine learning-based techniques enable the integration and analysis of these large and complex datasets, which have extensively described lung cancer through the application of diverse viewpoints from these acquired data [3].

Developing precise and trustworthy diagnostic tools, especially in the areas of cancer detection and medical imaging, requires a rich dataset. Researchers can train sophisticated machine and deep learning models that can effectively generalize to a wide range of populations by using comprehensive datasets that include a wide array of patient demographics, imaging modalities, and annotated examples. These datasets are essential for enhancing individualized treatment strategies, early diagnosis, and early detection of diseases like lung cancer [4].

Nevertheless, there is a dearth of such extensive medical records in Tunisia. The creation of specialized diagnostic instruments that can cater to the unique requirements and traits of the community is hampered by this scarcity. Due to variations in genetics, environment, and demography, diagnostic models trained on data from other locations could not perform as well in the absence of localized datasets. To close this gap and improve the precision and efficacy of lung cancer diagnosis and treatment in the area, high-quality, annotated medical datasets must be created and shared immediately in Tunisia.

This study intends to overcome these shortcomings and offer a useful resource that can aid in the development of AI-driven diagnostic tools customized for the Tunisian population by producing the first dataset from Tunisia for intelligent lung cancer detection. Such initiatives are necessary to ensure that medical technology improvements benefit all regions equally and to improve healthcare outcomes.

We start this article with a definition of lung cancer where we present the lung anatomy and explain the origin of the disease, its types, and stages. Next, Section III describes lung cancer detection and diagnoses using imaging techniques. Moving on to Section IV, highlights the importance and impact of data in cancer detection, introducing the challenges we face in finding Tunisian datasets for regional analysis. Section V describes related work, positioning our research in the context of other studies and highlighting how our approach differs and contributes to the field. Then, the process of building our Tunisian lung cancer dataset is described. We go over how we found and collected the data, how the images were prepared and annotated, and the stringent quality control procedures put in place to guarantee data integrity. In Section VII, we present the model used to validate our created dataset, the results are then compared with literature models and discussed in Section VIII. Finally, the paper is concluded in Section IX.

II. LUNG CANCER DEFINITION

The lungs are two sponge-like organs inside the chest. Three lobes, or parts, make up the right lung. Two lobes make up the left lung. It is smaller on that body side because the heart occupies more space there. When we inhale, air enters our nose or mouth and goes to our lungs via the trachea (windpipe). The trachea divides into bronchi, which enter the lungs and divide further into smaller bronchi. Bronchioles are tiny branches that divide from them. There at the tip of the bronchioles are small sacs of air known as alveoli. When we breathe air, the alveoli transport oxygen in the blood and expel carbon dioxide. Our lungs' primary functions are to take in oxygen and expel carbon dioxide. Lung cancers typically develop in the cells that make up the bronchi and other parts of the lung, like the alveoli or the bronchioles. The pleura is a thin layer of membrane that surrounds the lungs. As the lungs expand and contract during breathing, the pleura shields them and aids in their sliding back and forth against the chest wall. A narrow, dome-shaped muscle known as the diaphragm, separates the chest from the belly beneath the lungs. As we breathe, the organ contracts and expands, propelling air into and out of the lungs [5]. Cancer arises when the body's cells begin to proliferate uncontrolled. When it's in the lungs, we talk about Lung Cancer. For both sexes, lung cancer is one of the most common cancer-related causes of death [6].

The most common indicator of this type of cancer is coughing, which needs to be treated carefully because most lung cancer patients also have chronic obstructive pulmonary disease, which can cause coughing on its own. More importantly, the cough's characteristics change—becoming more intense, persistent, and possibly accompanied by expectoration or bloody sputum. Lung cancer also manifests as expectoration, chest pain, shortness of breath, anorexia, fever, hemoptysis, and weight loss [7].

A pulmonary nodule, often known as an abnormal growth, forms in the lung. Respiratory problems and infections can lead to the development of nodules in the lungs. Most lung nodules are not indicative of lung cancer and do not require medical attention. On X-rays or scans, these growths could show up as a shadow or spot on the lung. One or more nodules may form in one lung or more in both [2].

A. Lung Cancer Types

Two primary forms of lung cancer exist [10]:

Non-small cell lung cancer (NSCLC): The most common type, approximately 80–85% of instances of lung cancer are caused by non-small cell lung cancer (NSCLC). Adenocarcinoma, Squamous cell carcinoma and Giant cell carcinoma are the three main types of non-small cell lung cancer.

- The most prevalent subtype of NSCLC, Adenocarcinoma is typically present in the lung's outer regions. It affects women and non-smokers more frequently.

- Squamous Cell Carcinoma is frequently associated with smoking, typically begins in the middle of the lungs, close to a bronchus.

- Large Cell Carcinoma is a rarer variety that can develop anywhere in the lung and has a rapid growth and dissemination rate.

Small cell lung cancer (SCLC): It is less common and more aggressive than NSCLC, this type of lung cancer accounts for 10% to 15% of all cases of lung cancer. It's also known as oat cell cancer at times. Compared to NSCLC, this type of lung cancer develops and spreads faster. In most patients, the cancer has already exited the lungs when they are diagnosed with SCLC. Because it spreads quickly, this cancer usually responds well to chemotherapy and radiation treatments. Unfortunately, most patients will experience recurrent cancer. SCLC is heavily associated with smoking and it has two main subtypes which are:

- Small Cell Carcinoma: Sometimes referred to as Oat cell cancer, is the most aggressive type and frequently spreads to other body areas.

- Combined Small Cell Carcinoma: It consists of both non-small cell and small cell cancer.

B. Lung Cancer Stages

Comprehending the distinct forms of lung cancer is imperative in order to comprehend the progression of each type through its varied phases. Depending on the severity of the disease, each kind of lung cancer—small cell lung cancer (SCLC) or non-small cell lung cancer (NSCLC)—follows a different course of development and dissemination and is divided into phases.

1) NSCLC stages: NSCLC develops in a number of stages, each of which indicates how far the disease has spread. The tumors' stage is determined by their size and whether or not they have spread to adjacent lymph nodes or other organs [9]:

a) First stage: A 5 mm diameter tumor was discovered; it has not spread to any organs or lymph nodes. Usually, these tumors can be removed surgically.

b) Second stage: The tumor has grown to neighboring lymph nodes and is no more than 7 mm across. As an alternative, there can be more than one distinct tumor nodule visible. These tumors can usually be surgically removed.

c) Third stage: Any size tumor is possible, and it has spread to the lymph nodes. It might have also extended to nearby regions. It is possible for a single lung to have two or more tumors in separate lobes. At this point, it is not possible to remove the tumors.

d) Fourth stage: Characterized by pleural effusion or metastasis (spread) to other body parts. Any size lung tumor has progressed to the fluid surrounding the lungs, lymph nodes, and other distant organs.

Fig. 1 shows the different NSCLC stages explained.

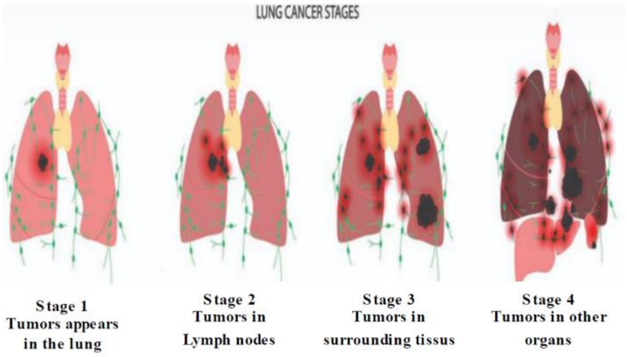

Fig. 1. NSCLC stages [8].

Fig. 2 presents the two SCLC stages.

2) SCLC stages: Because SCLC is aggressive in character, it splits into two primary stages [8]:

a) Limited stage: One radiation field can be used to treat cancer that is limited to one side of the chest, including just one lung and adjacent lymph nodes.

b) Extensive stage: The cancer has progressed to distant organs or other areas of the chest. Because SCLC progresses quickly, the majority of cases are diagnosed at this point.

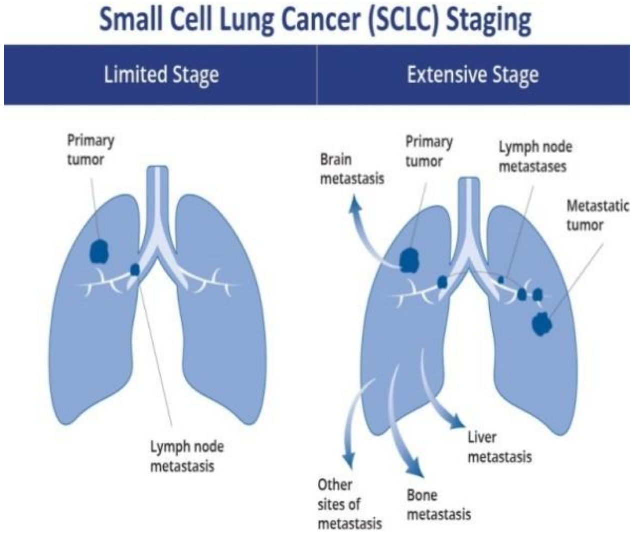

Fig. 2. SCLC stages [11].

Understanding the stage of your lung cancer is essential to determining course of therapy. Even though advanced-stage cancer might potentially prolong a person's life, earlier-stage tumors are usually easier to treat.

III. Lung Cancer Diagnosis and Imaging

A general practitioner (GP) will talk about the patient's overall health and symptoms in order to identify lung cancer. If the patient's physical examination and history suggest that they may have lung cancer, more testing will be done. Imaging studies may be one of them. Imaging tests produce pictures of the internal organs. There are several reasons to undergo imaging tests, both before and after being diagnosed with lung cancer [12], such as: investigating suspicious or possibly malignant areas; estimating the extent to which cancer may have spread; evaluating the efficacy of the treatment; and looking for any signs that the disease might recur following treatment.

When it comes to lung cancer detection, staging, and treatment, imaging is essential. Comprehensive information regarding lung tumors' existence, size, location, and extent—as well as their potential to spread to other body parts—can be obtained using a variety of imaging methods. Chest X-rays, computed tomography (CT), positron emission tomography (PET), and magnetic resonance imaging (MRI) are the main imaging modalities used in lung cancer[13]:

When lung cancer is suspected, X-rays of the chest are frequently the first imaging tests carried out. Large tumors and notable anomalies may be seen, but smaller or less noticeable lesions may go unnoticed. The majority of lung cancers appear as a white-gray mass on X-rays like shown in Fig. 3.

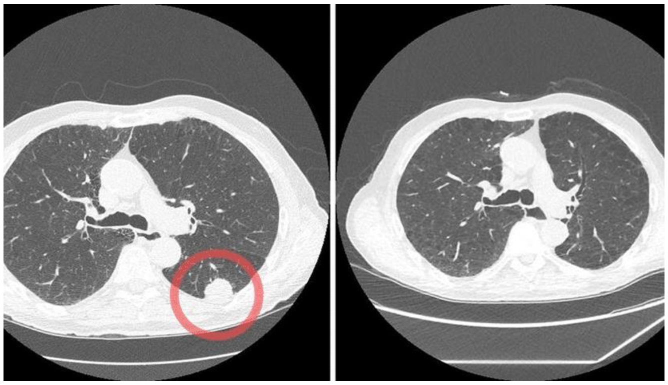

Fig. 3. Lung X-ray image [15].

More precise cross-sectional images of the lungs and other chest tissues are provided by CT scans, which aid in the detection of smaller tumors as well as the localization and size of malignancy. It is common practice to perform a CT scan after a chest X-ray. A CT scan uses X-rays and a computer to create detailed images of the inside of the body. It creates complex images of the body in cross-section. A CT scan gathers many images, as opposed to a typical X-ray, which only captures one or two. These images are then combined by a computer to create a slice of the body portion under study [14]. The Fig. 4 shows an example of a lung cancer CT scan.

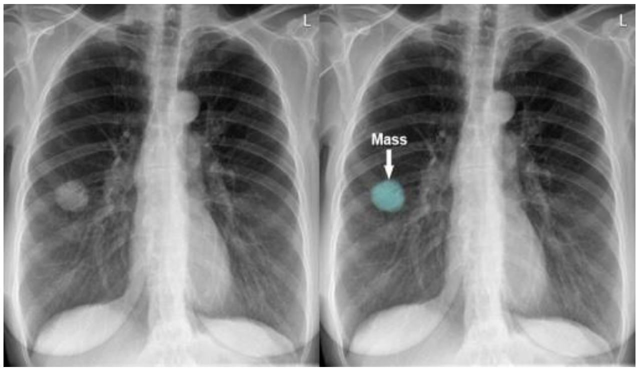

Fig. 4. Lung CT scan image [16].

Usually, PET scans are performed to find metastases and evaluate the metabolic activity of lung cancer cells. A tiny quantity of radioactive glucose is injected using this approach, and because cancer cells have a greater metabolic rate than other cells, they absorb the glucose. In order to improve diagnostic precision, PET scans are frequently coupled with CT scans (PET/CT). The Fig. 5 shows an example of a lung cancer PET scan.

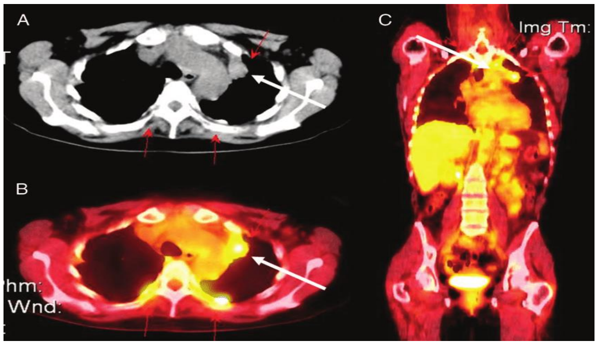

Fig. 5. Lung PET image [17].

While less frequently used for lung cancer, MRI is especially helpful for analyzing tumors close to important blood vessels and determining whether cancer has progressed to the brain or spinal cord. Similar to CT scans, MRIs produce finely detailed images of the body's soft tissues. However, MRI scans employ strong magnets and radio waves in place of X-rays. The most prevalent use for MRI scans includes the detection of possible brain or spinal cord metastases from lung cancer.

Out of all the approaches outlined, the CT image technique is the most widely used since it may give a view without showing structures that overlap. It might be difficult for physicians to diagnose and interpret cancer. The use of CT imaging allows for the accurate diagnosis of lung cancer [14].

On imaging studies, lung cancer can appear as a single microscopically small nodule, ground-glass opacity, lung collapse, pleural effusion, numerous nodules, or multiple opacities. Simple and tiny lesions are extremely hard to locate. Due to their late diagnosis, lung cancer patients usually have a poor prognosis. Due to the unpredictability of imaging results, and histology, it is challenging for doctors to choose the best course of treatment for lung cancer [1]. Because so many images need to be analyzed, radiologists must rely largely on their years of expertise to spot anomalies. Even highly qualified individuals may overlook tiny indications of cancer. The process is made more difficult by the variety in tumor appearance, which includes variations in size, shape, and density. Tumors can be hidden by overlapping bodily structures, making it challenging to identify them. Furthermore, determining the difference between benign and malignant lesions necessitates meticulous examination, which is laborious and prone to human mistakes. Patient outcomes may be impacted by missed diagnoses or false positives due to human error and fatigue.

These constraints can be overcome by machine learning models, especially deep learning algorithms. These algorithms are able to understand and identify complicated patterns linked to different types of malignancies because they have been trained on large databases of annotated medical images.

Using these models contributes to early tumor diagnosis, which is essential for bettering patient outcomes. Large volumes of imaging data can be processed and analyzed swiftly by automated methods, which can deliver reliable results quickly. This improves overall diagnostic efficiency by relieving radiologists of some of their duty and freeing them up to concentrate on more complex patients. Additionally, as these models are exposed to additional data, they can get better over time, increasing their capacity to identify even the smallest and most subtle problems. Thus, the application of AI to medical imaging marks a substantial breakthrough in the early diagnosis and treatment of cancer, resulting in a quicker, more precise, and more easily accessible diagnostic procedure.

IV. Data Importance

The development and success of machine learning models, particularly in medical imaging and cancer diagnostics, depend heavily on rich and comprehensive datasets. The quality and comprehensiveness of the data directly affect the models' performance, accuracy, and reliability. Extensive datasets with a wide range of patient demographics, imaging modalities, and detailed annotations are crucial for capturing the entire spectrum of disease presentations and variations.

Machine learning models need to be trained on datasets that accurately represent the variety of real-world medical cases in order for them to identify and categorize cancers. This covers differences in imaging methods and instruments in addition to variances in tumor sizes, forms, locations, and stages. Rich datasets let the model understand intricate patterns and characteristics linked to various tumor forms, improving generalization and improving prediction accuracy across a range of patient populations.

A large dataset helps reduce the possibility of overfitting, in which a model performs well on training data but poorly on new, unseen data; by exposing the model to an extensive variety of examples, it learns to generalize well, improving its robustness and accuracy. This is especially important in medical imaging, where variation in patient anatomy and imaging conditions can be significant. A high-performing model requires a large amount of data to be trained on.

Reducing biases resulting from training models on small or homogeneous datasets is another benefit of having an extensive data set. The model's capacity to discriminate between benign and malignant lesions is enhanced when it is trained on a dataset that encompasses a wide variety of cases. This is especially crucial for early detection, as tiny irregularities could be readily missed in the absence of an extensive collection of training data.

Furthermore, thorough annotations from knowledgeable radiologists and oncologists improve learning by giving exact labels and classifications. The model uses these annotations as a vital source of information when it is being trained, which enables it to link particular imaging characteristics to related diagnostic categories. Extensive data means that the model is exposed to a broad range of scenarios, increasing its robustness and ability to manage challenging cases in actual practice.

A. Localized Data Importance

Not only data is necessary for training machine learning models, but having a unique dataset for every location is also essential. Local data document the population’s distinct demographic, genetic, and environmental features, all of which have a substantial impact on how diseases like lung cancer manifest, develop, and react to therapy. Diagnostic techniques and treatment plans might not work as well without localized data because they are frequently created using data from other areas with distinct demographic characteristics.

The access of such extensive medical databases is restricted in Tunisia for a number of reasons:

- First, many healthcare organizations lack the infrastructure and resources necessary for the systematic gathering and processing of data. This includes a lack of financing for the staff and equipment required to compile and manage huge datasets.
- Second, issues with privacy and regulations may make it difficult to integrate and share data throughout various medical facilities. The capacity to gather and exploit big, centralized datasets is frequently hampered by stringent data protection regulations and worries about patient confidentiality.
- Third, incomplete or inconsistent datasets are frequently the result of a lack of qualified individuals who can appropriately annotate and curate medical images.
- Fourth, different healthcare facilities lack uniform standards for data collection and interpretation. This discrepancy can result in inconsistent and fragmented data, which makes it challenging to assemble a coherent and extensive dataset.
- Sixth, the low acceptance and knowledge of electronic health records (EHRs) in many healthcare settings is another difficulty. A considerable portion of patient data is still in unstructured or paper formats in the absence of widespread use of EHRs, making it difficult to access for in-depth analysis and model training.
- Seventh, healthcare facilities sometimes face financial barriers that keep them from making the investments in the equipment and training needed for efficient data handling.
- Eighth, a large number of healthcare practitioners may also give priority to short-term clinical demands over long- term data gathering initiatives, which adds to the dearth of thorough datasets.
- On top of that, competitive tactics or a lack of incentives to exchange data might hinder collaboration between institutions, resulting in underutilized information silos.

B. The Impact of Limited Data

The creation and application of sophisticated diagnostic techniques in Tunisia are severely hampered by the absence of good datasets. Due to variations in demographics, genetics, and environmental factors, machine learning models trained on datasets from other regions would not function as well in the Tunisian setting without extensive local data. Poorer patient outcomes and less accurate diagnosis may result from this. Personalized medicine, which depends on comprehensive patient data to customize therapies to specific needs, is also constrained by the incapacity to use large amounts of data.

Improving Tunisia’s healthcare will require addressing these data constraints. The creation and dissemination of superior annotated medical datasets would improve the precision and dependability of diagnostic models, resulting in improved identification and management of conditions like lung cancer. Tunisia can make sure that its healthcare system takes advantage of the advances in medical technology and offers its people equitable care by making investments in data infrastructure, hiring qualified staff, and creating frameworks for data sharing.

V. Related Work

Localizing populations in medical datasets is crucial for ensuring that diagnostic models are accurate and applicable to specific demographic groups. Many existing machine learning models for medical diagnosis are trained on datasets with a broad demographic range, which may not capture the unique characteristics of specific populations, such as those in Tunisia. This lack of localization can limit the effectiveness of these models in particular clinical settings. For instance, while the Lung-PET-CT-Dx dataset is extensive, it predominantly includes data from diverse regions and may not reflect the specific clinical characteristics seen in the Tunisian population.

Generalizing machine learning models across diverse populations is essential for robust performance. However, this generalization must be balanced with localization to ensure that models remain effective for specific demographic groups [33]. Localized datasets are tailored to capture the nuances of a particular population, leading to improved diagnostic accuracy within that group. Researchers stress the importance of creating more localized and representative datasets to address gaps in current research and ensure that models can accurately diagnose within specific populations [34].

A study titled "Optimizing double-layered convolutional neural networks for efficient lung cancer classification," published by BioMed Central, underscores the importance of localized datasets in training robust models. This research demonstrates that incorporating data from specific regions enhances a model’s ability to accurately diagnose within those populations, thereby improving diagnostic accuracy and reliability. The authors found that models trained on localized datasets perform better in real-world scenarios, emphasizing the need for datasets like ours that focus on the Tunisian population [34].

Regarding Tunisian data, significant advancements have been made in understanding the epidemiological profile and risk factors specific to Tunisia. The study “Lung Cancer in Central Tunisia: Epidemiology and Clinicopathological Features” details the clinical and pathological characteristics of lung cancer cases in Central Tunisia over a 15-year period. It reveals that lung cancer is the most common cancer among Tunisian men, typically presenting at advanced stages, with squamous cell carcinoma being the most prevalent histological type in men and adenocarcinoma in women. These findings highlight the need for effective lung cancer control and prevention programs tailored to the Tunisian context [35].
