

Volume 15 Issue 8

August 2024

ISSN 2156-5570(Online)

ISSN 2158-107X(Print)

Editorial Preface

From the Desk of Managing Editor...

It may be difficult to imagine that almost half a century ago we used computers far less sophisticated than current home desktop computers to put a man on the moon. In that 50 year span, the field of computer science has exploded.

Computer science has opened new avenues for thought and experimentation. What began as a way to simplify the calculation process has given birth to technology once only imagined by the human mind. The ability to communicate and share ideas even though collaborators are half a world away and exploration of not just the stars above but the internal workings of the human genome are some of the ways that this field has moved at an exponential pace.

At the International Journal of Advanced Computer Science and Applications it is our mission to provide an outlet for quality research. We want to promote universal access and opportunities for the international scientific community to share and disseminate scientific and technical information.

We believe in spreading knowledge of computer science and its applications to all classes of audiences. That is why we deliver up-to-date, authoritative coverage and offer open access of all our articles. Our archives have served as a place to provoke philosophical, theoretical, and empirical ideas from some of the finest minds in the field.

We utilize the talents and experience of editor and reviewers working at Universities and Institutions from around the world. We would like to express our gratitude to all authors, whose research results have been published in our journal, as well as our referees for their in-depth evaluations. Our high standards are maintained through a double blind review process.

We hope that this edition of IJACSA inspires and entices you to submit your own contributions in upcoming issues. Thank you for sharing wisdom.

Thank you for Sharing Wisdom!

Kohei Arai
Editor-in-Chief
IJACSA
Volume 15 Issue 8 August 2024
ISSN 2156-5570 (Online)
ISSN 2158-107X (Print)

Editorial Board

Editor-in-Chief

Dr. Kohei Arai - Saga University

Domains of Research: Technology Trends, Computer Vision, Decision Making, Information Retrieval, Networking, Simulation

Associate Editors

Alaa Sheta

Southern Connecticut State University

Domain of Research: Artificial Neural Networks, Computer Vision, Image Processing, Neural Networks, Neuro-Fuzzy Systems

Arun D Kulkarni

University of Texas at Tyler

Domain of Research: Machine Vision, Artificial Intelligence, Computer Vision, Data Mining, Image Processing, Machine Learning, Neural Networks, Neuro-Fuzzy Systems

Domenico Ciunzio

University of Naples, Federico II, Italy

Domain of Research: Artificial Intelligence, Communication, Security, Big Data, Cloud Computing, Computer Networks, Internet of Things

Doroła Kaminska

Lodz University of Technology

Domain of Research: Artificial Intelligence, Virtual Reality

Dr Ronak AL-Haddad

Anglia Ruskin University / Cambridge

Domain of Research : Technology Trends, Communication, Security, Software Engineering and Quality, Computer Networks, Cyber Security, Green Computing, Multimedia Communication, Network Security, Quality of Service

Elena Scutelnicu

"Dunarea de Jos" University of Galati

Domain of Research: e-Learning, e-Learning Tools, Simulation

In Soo Lee

Kyungpook National University

Domain of Research: Intelligent Systems, Artificial Neural Networks, Computational Intelligence, Neural Networks, Perception and Learning

Krassen Stefanov

Professor at Sofia University St. Kliment Ohridski

*Domain of Research: e-Learning, Agents and Multi-agent Systems, Artificial Intelligence, e-Learning Tools,
Educational Systems Design*

Renato De Leone

Università di Camerino

*Domain of Research: Mathematical Programming, Large-Scale Parallel Optimization, Transportation problems,
Classification problems, Linear and Integer Programming*

Xiao-Zhi Gao

University of Eastern Finland

Domain of Research: Artificial Intelligence, Genetic Algorithms

CONTENTS

Paper 1: Ensemble Learning with Sleep Mode Management to Enhance Anomaly Detection in IoT Environment

Authors: Khawlah Harahsheh, Rami Al-Naimat, Malek Alzaqebah, Salam Shreem, Esraa Aldreabi, Chung-Hao

Chen

PAGE 1 – 9

Paper 2: Optimizing Low-Resource Zero-Shot Event Argument Classification with Flash-Attention and Global Constraints Enhanced ALBERT Model

Authors: Tongyue Sun, Jiayi Xiao

PAGE 10 – 17

Paper 3: A Personalized Hybrid Tourist Destination Recommendation System: An Integration of Emotion and Sentiment Approach

Authors: Suphitcha Chanrueang, Sotarat Thammaboosadee, Hongnian Yu

PAGE 18 – 27

Paper 4: Automatic Identification and Evaluation of Rural Landscape Features Based on U-net

Authors: Ling Sun, Jun Liu, Yi Qu, Jiashun Jiang, Bin Huang

PAGE 28 – 38

Paper 5: Analysis of Customer Behavior Characteristics and Optimization of Online Advertising Based on Deep Reinforcement Learning

Authors: Zhenyan Shang, Bi Ge

PAGE 39 – 49

Paper 6: Logistics Transportation Vehicle Monitoring and Scheduling Based on the Internet of Things and Cloud Computing

Authors: Kang Wang, Xin Wang

PAGE 50 – 61

Paper 7: Performance and Accuracy Research of the Large Language Models

Authors: Nicoleta Cristina GAITAN

PAGE 62 – 69

Paper 8: Image Generation Using StyleVGG19-NST Generative Adversarial Networks

Authors: Dorcas Oladayo Esan, Pius Adewale Owolawi, Chunling Tu

PAGE 70 – 80

Paper 9: Applied to Art and Design Scene Visual Comprehension and Recognition Algorithm Research

Authors: Yuxin Shi

PAGE 81 – 90

Paper 10: Quantitative Measurement and Preference Research of Urban Landscape Environmental Image Based on Computer Vision

Authors: Yan Wang

PAGE 91 – 100

Paper 11: Clustering Algorithms to Analyse Smart City Traffic Data

Authors: Praveena Kumari M K, Manjaiah D H, Ashwini K M

PAGE 101 – 107

Paper 12: Prediction of Outpatient No-Show Appointments Using Machine Learning Algorithms for Pediatric Patients in Saudi Arabia

Authors: Abdulwahhab Alshammari, Fahad Aloṭaibi, Sana Alnafrani

PAGE 108 – 116

Paper 13: Performance Optimization of Support Vector Machine with Adversarial Grasshopper Optimization for Heart Disease Diagnosis and Feature Selection

Authors: Nan Tang, Lele Wang, Kangming Li, Zhen Liu, Yanan Dai, Ji Hao, Qingdui Zhang, Huamei Sun, Chunmei Qi

PAGE 117 – 128

Paper 14: Sleep Disorder Diagnosis Through Complex-Morlet-Wavelet Representation Using Bi-GRU and Self-Attention

Authors: Mubarak Albathan

PAGE 129 – 144

Paper 15: Digital Landscape Architecture Design Combining 3D Image Reconstruction Technology

Authors: Chen Chen

PAGE 145 – 154

Paper 16: Software Systems Documentation: A Systematic Review

Authors: Abdullah A H Alzahrani

PAGE 155 – 162

Paper 17: Optimizing Data Security in Computer-Assisted Test Applications Through the Advanced Encryption Standard 256-Bit Cipher Block Chaining

Authors: M. Afridon, Agus Tedyyana, Fajar Ratnawati, Afis Julianto, M. Nur Faizi

PAGE 163 – 170

Paper 18: Diabetes Prediction Using Machine Learning with Feature Engineering and Hyperparameter Tuning

Authors: Hakim El Massari, Noredine Gherabi, Fatima Qanouni, Sajida Mhammedi

PAGE 171 – 179

Paper 19: Computational Modeling of the Thermally Stressed State of a Partially Insulated Variable Cross-Section Rod

Authors: Zhuldyz Tashenova, Elmira Nurlybaeva, Zhanat Abdugulova, Shirin Amanzholova, Nazira Zharaskhan, Aigerim Sambetova, Anarbay Kudaykulov

PAGE 180 – 189

Paper 20: Performance Analysis of a Hyperledger-Based Medical Record Data Management Using Amazon Web Services

Authors: Mohammed K Elghoul, Sayed F. Bahgat, Ashraf S. Hussein, Safwat H. Hamad

PAGE 190 – 196

Paper 21: Enhancing Business Intelligence with Hybrid Transformers and Automated Annotation for Arabic Sentiment Analysis

Authors: Wael M.S. Yafooz

PAGE 197 – 207

Paper 22: A Method by Utilizing Deep Learning to Identify Malware Within Numerous Industrial Sensors on IoTs

Authors: Ronghua MA

PAGE 208 – 217

Paper 23: Quantifying the Effects of Homogeneous Interference on Coverage Quality in Wireless Sensor Networks

Authors: Qingmiao Liu, Qiang Liu, Minhuan Wang

PAGE 218 – 231

Paper 24: Lightweight and Efficient High-Resolution Network for Human Pose Estimation

Authors: Jiarui Liu, Xiugang Gong, Qun Guo

PAGE 232 – 240

Paper 25: Enhanced Resume Screening for Smart Hiring Using Sentence-Bidirectional Encoder Representations from Transformers (S-BERT)

Authors: Asmita Deshmukh, Anjali Raut

PAGE 241 – 249

Paper 26: Machine Learning Techniques for Protecting Intelligent Vehicles in Intelligent Transport Systems

Authors: Yuan Chen

PAGE 250 – 258

Paper 27: Automation of Book Categorisation Based on Network Centric Quality Management System

Authors: Tingting Liu, Qiyuan Liu, Linya Fu

PAGE 259 – 268

Paper 28: Optimization of Distribution Routes in Agricultural Product Supply Chain Decision Management Based on Improved ALNS Algorithm

Authors: Liling Liu, Yang Chen, Ao Li

PAGE 269 – 278

Paper 29: Harnessing Technology to Achieve the Highest Quality in the Academic Program of University Studies

Authors: Rania Aboalela

PAGE 279 – 292

Paper 30: Enhancing Digital Financial Security with LSTM and Blockchain Technology

Authors: Thanyah Aldaham, Hedi HAMDJ

PAGE 293 – 304

Paper 31: Sketch and Size Orient Malicious Activity Monitoring for Efficient Video Surveillance Using CNN

Authors: K. Lokesh, M. Baskar

PAGE 305 – 311

Paper 32: Enhancing Arabic Phishing Email Detection: A Hybrid Machine Learning Based on Genetic Algorithm Feature Selection

Authors: Amjad A. Alsuwaylimi

PAGE 312 – 325

Paper 33: A Feature Interaction Based Neural Network Approach: Predicting Job Turnover in Early Career Graduates in South Korea

Authors: Haewon Byeon

PAGE 326 – 335

Paper 34: A Systematic Review of Virtual Commerce Solutions for the Metaverse

Authors: Ghazala Bilquise, Khaled Shaalan, Manar Alkhatib

PAGE 336 – 346

Paper 35: DIAUTIS III: A Fuzzy and Affective Platform for Obtaining Autism Mental Models and Learning Aids

Authors: Mohamed El Alami, Sara El khabbazi, Fernando de Arriaga

PAGE 347 – 362

Paper 36: Stock Price Forecasting with Optimized Long Short-Term Memory Network with Manta Ray Foraging Optimization

Authors: Zhongpo Gao, Junwen Jing

PAGE 363 – 379

Paper 37: Modified TOPSIS Method for Neutrosophic Cubic Number: Multi-Attribute Decision-Making and Applications to Music Composition Effectiveness Evaluation of Film and Television

Authors: Liang Yang, Jun Zhao

PAGE 380 – 388

Paper 38: Heuristic Intelligent Algorithm-Based Approach for In-Depth Development and Application Analysis of Micro- and Nanoembedded Systems

Authors: Buzhong Liu

PAGE 389 – 398

Paper 39: Optimization of Knitting Path of Flat Knitting Machine Based on Reinforcement Learning

Authors: Tianqi Yang

PAGE 399 – 409

Paper 40: Design and Research of Cross-Border E-Commerce Short Video Recommendation System Based on Multi-Modal Fusion Transformer Model

Authors: Yiran Hu

PAGE 410 – 419

Paper 41: A Hidden Markov Model-Based Performance Recognition System for Marching Wind Bands

Authors: Wei Jiang

PAGE 420 – 431

Paper 42: Fitness Equipment Design Based on Web User Text Mining

Authors: Jinyang Xu, Xuedong Zhang, Xinlian Li, Shun Yu, Yanming Chen

PAGE 432 – 440

Paper 43: Evaluating the Impact of Fuzzy Logic Controllers on the Efficiency of FCCUs: Simulation-Based Analysis

Authors: Harsh Pagare, Kushagra Mishra, Kanhaiya Sharma, Sandeep Singh Rawat, Shailaja Salagrama

PAGE 441 – 449

Paper 44: Hybrid Machine Learning Approach for Real-Time Malicious URL Detection Using SOM-RMO and RBFN with Tabu Search

Authors: Swetha T, Sesaiah M, Hemalatha K L, Murthy S V N, Manjunatha Kumar BH

PAGE 450 – 458

Paper 45: Missing Value Imputation in Data MCAR for Classification of Type 2 Diabetes Mellitus and its Complications

Authors: Anik Andriani, Sri Hartati, Afiahayati, Cornelia Wahyu Danawati

PAGE 459 – 466

Paper 46: Optimizing Dance Training Programs Using Deep Learning: Exploring Motion Feedback Mechanisms Based on Pose Recognition and Prediction

Authors: Yuting Jiao

PAGE 467 – 475

Paper 47: Improved Decision Support System for Alzheimer's Diagnosis Using a Hybrid Machine Learning Approach with Structural MRI Brain Scans

Authors: Niranjan Kumar Parvatham, Lakshmana Phaneendra Maguluri

PAGE 476 – 484

Paper 48: Innovative Melanoma Diagnosis: Harnessing VI Transformer Architecture

Authors: Sreelakshmi Jayasankar, T. Brindha

PAGE 485 – 493

Paper 49: Enhancing Safety for High Ceiling Emergency Light Monitoring

Authors: G. X. Jun, M. Batumalay, C. Batumalai, Prabadevi B

PAGE 494 – 499

Paper 50: Data-Driven Approaches to Energy Utilization Efficiency Enhancement in Intelligent Logistics

Authors: Xuan Long

PAGE 500 – 508

Paper 51: Design and Application of the DPC-K-Means Clustering Algorithm for Evaluation of English Teaching Proficiency

Authors: Mei Niu

PAGE 509 – 518

Paper 52: Enhancing Indonesian Text Summarization with Latent Dirichlet Allocation and Maximum Marginal Relevance

Authors: Muhammad Faisal, Bima Hamdani Mawaridi, Ashri Shabrina Afrah, Supriyono, Yunifa Miftachul Arif, Abdul Aziz, Linda Wijayanti, Melisa Mulyadi

PAGE 519 – 528

Paper 53: Research on Traffic Flow Prediction Using the MSTA-GNet Model Based on the PeMS Dataset

Authors: Deng Cong

PAGE 529 – 539

Paper 54: Laboratory Abnormal Behavior Recognition Method Based on Skeletal Features

Authors: Dawei Zhang

PAGE 540 – 550

Paper 55: Twitter Truth: Advanced Multi-Model Embedding for Fake News Detection

Authors: Yasmine LAHLOU, Sanaa El FKHI, Rdouan FAIZI

PAGE 551 – 560

Paper 56: Protein-Coding sORFs Prediction Based on U-Net and Coordinate Attention with Hybrid Encoding

Authors: Ziling Wang, Wenxi Yang, Zhijian Qu

PAGE 561 – 572

Paper 57: An Improved YOLOv8 Method for Measuring the Body Size of Xinjiang Bactrian Camels

Authors: Yue Peng, Alifu Kurban, Mengmei Sang

PAGE 573 – 580

Paper 58: Towards Secure Internet of Things-Enabled Healthcare: Integrating Elliptic Curve Digital Signatures and Rivest Cipher Encryption

Authors: Longyang Du, Tian Xie

PAGE 581 – 589

Paper 59: Dose Archiving and Communication System in Moroccan Healthcare: A Unified Approach to X-Ray Dose Management and Analysis

Authors: Lhoucine Ben Youssef, Abdelmajid Bybi, Hilal Drissi, El Ayachi Chafer

PAGE 590 – 601

Paper 60: UTAUT Model for Digital Mental Health Interventions: Factors Influencing User Adoption

Authors: Mohammed Alojail

PAGE 602 – 610

Paper 61: ResNet50 and GRU: A Synergistic Model for Accurate Facial Emotion Recognition

Authors: Shanimol. A, J Charles

PAGE 611 – 620

Paper 62: Efficient Parallel Algorithm for Extracting Fuzzy-Crisp Formal Concepts

Authors: Ebtesam Shemis, Arabi Keshk, Ammar Mohammed, Gamal Elhady

PAGE 621 – 630

Paper 63: Automatic Plant Disease Detection System Using Advanced Convolutional Neural Network-Based Algorithm

Authors: Sai Krishna Gudepu, Vijay Kumar Burugari

PAGE 631 – 638

Paper 64: Towards Secure Cloud-Enabled Wireless Ad-Hoc Networks: A Novel Cross-Layer Validation Mechanism

Authors: Zhengu LIU

PAGE 639 – 646

Paper 65: UWB Printed MIMO Antennas for Satellite Sensing System (SRSS) Applications

Authors: Wyssem Fathallah, Chafai Abdelhamid, Chokri Baccouch, Alsharaf Mohammad, Khalil Jouili, Hedi Sakli

PAGE 647 – 656

Paper 66: Novel Data-Driven Machine Learning Models for Heating Load Prediction: Single and Optimized Naive Bayes

Authors: Fangyuan Li

PAGE 657 – 668

Paper 67: Facial Expression Real-Time Animation Simulation Technology for General Mobile Platforms Based on OpenGL

Authors: Mingzhe Cao

PAGE 669 – 678

Paper 68: Noise Reduction Techniques in Adas Sensor Data Management: Methods and Comparative Analysis

Authors: Ahmed Alami, Fouad Belmajdoub

PAGE 679 – 695

Paper 69: DMMFnet: A Dual-Branch Multimodal Medical Image Fusion Network Using Super Token and Channel-Spatial Attention

Authors: Yukun Zhang, Lei Wang, Muhammad Tahir, Zizhen Huang, Yaolong Han, Shanliang Yang, Shilong Liu, Muhammad Imran Saeed

PAGE 696 – 705

Paper 70: Deep Learning and Computer Vision-Based System for Detecting and Separating Abnormal Bags in Automatic Bagging Machines

Authors: Trung Dung Nguyen, Thanh Quyen Ngo, Chi Kien Ha

PAGE 706 – 719

Paper 71: Implementing Optimization Methods into Practice to Enhance the Performance of Solar Power Systems

Authors: Luçiana Toti, Alma Stana, Alma Golgota, Eno Toti

PAGE 720 – 728

Paper 72: Combined Framework for Type-2 Neutrosophic Number Multiple-Attribute Decision-Making and Applications to Quality Evaluation of Digital Agriculture Park Information System

Authors: Wei Ji, Ning Sun, Botao Cao, Xichan Mu

PAGE 729 – 742

Paper 73: Using Pretrained VGG19 Model and Image Segmentation for Rice Leaf Disease Classification

Authors: Gulbakhram Beissenova, Almira Madiyarova, Akbayan Aliyeva, Gulsara Mambetaliyeva, Yerzhan Koshkarov, Nagima Sarsenbiyeva, Marzhan Chazhabayeva, Gulnara Seidaliyeva

PAGE 743 – 752

Paper 74: Blockchain-Based Vaccination Record Tracking System

Authors: Shwetha G K, Jayantkumar A Rathod, Naveen G, Mounesh Arkachari, Pushparani M K

PAGE 753 – 759

Paper 75: Enhance the Security of the Cloud Using a Hybrid Optimization-Based Proxy Re-Encryption Technique Considered Blockchain

Authors: Ahmed I. Alutaibi

PAGE 760 – 771

Paper 76: Malicious Website Detection Using Random Forest and Pearson Correlation for Effective Feature Selection

Authors: Esha Sangra, Renuka Agrawal, Pravin Ramesh Gundalwar, Kanhaiya Sharma, Divyansh Bangri, Debadrita Nandi

PAGE 772 – 780

Paper 77: Enhancing Orchard Cultivation Through Drone Technology and Deep Stream Algorithms in Precision Agriculture

Authors: P. Srinivasa Rao, Anantha Raman G R, Madira Siva Sankara Rao, K. Radha, Rabie Ahmed

PAGE 781 – 795

Paper 78: Comparative Analysis of Small and Medium-Sized Enterprises Cybersecurity Program Assessment Model

Authors: Wan Nur Eliana Wan Mohd Ludin, Masnizah Mohd, Wan Fariza Paizi@Fauzi

PAGE 796 – 804

Paper 79: Real-Time Robotic Force Control for Automation of Ultrasound Scanning

Authors: Ungku Muhammad Zuhairi Ungku Zakaria, Seri Mastura Mustaza, Mohd Hairi Mohd Zaman, Ashrani Aizzuddin Abd Rahni

PAGE 805 – 812

Paper 80: Deep Learning Model for Enhancing Automated Recycling Machine with Incentive Mechanisms

Authors: Razali Tomari, Aeslina Abdul Kadir, Wan Nurshazwani Wan Zakaria, Dipankar Das, Muhamad Bakhtiar Azni

PAGE 813 – 819

Paper 81: A Hybrid of Extreme Learning Machine and Cellular Neural Network Segmentation in Mangrove Fruit Classification

Authors: Romi Fadillah Rahmat, Opim Salim Sitompul, Maya Silvi Lydia, Fahmi, Shifani Adriani Ch, Pauzi Ibrahim Nainggolan, Riza Sulaiman

PAGE 820 – 828

Paper 82: Evaluating the Impact of Yoga Practices to Improve Chronic Venous Insufficiency Symptoms: A Classification by Gaussian Process

Authors: Feng Yun Gou

PAGE 829 – 840

Paper 83: A Semantic Segmentation Method for Road Scene Images Based on Improved DeeplabV3+ Network

Authors: Lihua Bi, Xiangfei Zhang, Shihao Li, Canlin Li

PAGE 841 – 849

Paper 84: Enhancing Tuberculosis Diagnosis and Treatment Outcomes: A Stacked Loopy Decision Tree Approach Empowered by Moth Search Algorithm Optimization

Authors: Huma Khan, Mithun D'Souza, K. Suresh Babu, Janjhyam Venkata Naga Ramesh, K. R. Praneeth, Pinapati Lakshmana Rao

PAGE 850 – 859

Paper 85: Complex Environmental Localization of Scenic Spots by Integrating LANDMARC Localization System and Traditional Location Fingerprint Localization

Authors: Shasha Song, Cong Li

PAGE 860 – 870

Paper 86: Development of a 5G-Optimized MIMO Antenna with Enhanced Isolation Using Neutralization Line and SRRs Metamaterials

Authors: Chaker Essid, Linda Chouikhi, Alsharif Mohammad, Bassem Ben Salah, Hedi Sakli

PAGE 871 – 883

Paper 87: Deep Learning Fusion for Intracranial Hemorrhage Classification in Brain CT Imaging

Authors: Padma Priya S. Babu, T. Brindha

PAGE 884 – 894

Paper 88: Romanian Sign Language and Mime-Gesture Recognition

Authors: Enachi Andrei, Turcu Cornel, George Culea, Sghera Bogdan Constantin, Ungureanu Andrei Gabriel

PAGE 895 – 902

Paper 89: Multiclass Osteoporosis Detection: Enhancing Accuracy with Woodpecker-Optimized CNN-XGBoost

Authors: Mithun D'Souza, Divya Nimma, Kiran Sree Pokkuluri, Janjhyam Venkata Naga Ramesh, Suresh Babu Kondaveeti, Lavanya Kongala

PAGE 903 – 914

Paper 90: Attention-Based Joint Learning for Intent Detection and Slot Filling Using Bidirectional Long Short-Term Memory and Convolutional Neural Networks

Authors: Yusuf Idris Muhammad, Naomie Salim, Sharin Hazlin Huspi, Anazida Zainal

PAGE 915 – 922

Paper 91: Attention-Based Deep Learning Approach for Pedestrian Detection in Self-Driving Cars

Authors: Wael Ahmad AlZoubi, Girish Bhagwant Desale, Sweety Bakyarani E, Uma Kumari C R, Divya Nimma, K Swetha, B Kiran Bala

PAGE 923 – 932

Paper 92: Cryptographic Techniques in Digital Media Security: Current Practices and Future Directions

Authors: Gongling ZHANG

PAGE 933 – 941

Paper 93: Detecting Online Gambling Promotions on Indonesian Twitter Using Text Mining Algorithm

Authors: Reza Bayu Perdana, Ardin, Indra Budi, Aris Budi Santoso, Amanah Ramadiah, Prabu Kresna Putra

PAGE 942 – 949

Paper 94: Securing RPL Networks with Enhanced Routing Efficiency with Congestion Prediction and Load Balancing Strategy

Authors: Saumya Raj, Rajesh R

PAGE 950 – 961

Paper 95: Optimizing Hyperparameters in Machine Learning Models for Accurate Fitness Activity Classification in School-Aged Children

Authors: Britsel Calluchi Arocutipá, Magaly Villegas Cahuana, Vanessa Huanca Hilachoque, Marco Cossio Bolaños

PAGE 962 – 972

Paper 96: Modeling Micro Traffic Flow Phenomena Based on Vehicle Types and Driver Characteristics Using Cellular Automata and Monte Carlo

Authors: Tri Harsono, Kohei Arai

PAGE 973 – 985

Paper 97: Convolutional Neural Network Model for Cacao Phytophthora Palmivora Disease Recognition

Authors: Jude B. Rola, Jomari Joseph A. Barrera, Maricel V. Calhoun, Jonah Flor Oraño – Maaghop, Magdalene C. Unajan, Joshua Mhel Boncalon, Elizabeth T. Sebios, Joy S. Espinosa

PAGE 986 – 990

Paper 98: Leveraging Mechanomyography Signal for Quantitative Muscle Spasticity Assessment of Upper Limb in Neurological Disorders Using Machine Learning

Authors: Muhamad Aliff Imran Daud, Asmarani Ahmad Puzi, Shahrul Na'im Sidek, Ahmad Anwar Zainuddin, Ismail Mohd Khairuddin, Mohd Azri Abdul Mutalib

PAGE 991 – 1002

Paper 99: Interactive Color Design Based on AR Virtual Implantation Technology Between Users and Artificial Intelligence

Authors: Jun Ma, Ying Chen

PAGE 1003 – 1012

Paper 100: A Comprehensive Authentication Taxonomy and Lightweight Considerations in the Internet-of-Medical-Things (IoMT)

Authors: Azlina binti Ahmadi Julaihi, Md Asri Ngadi, Raja Zahilah binti Raja Mohd Radzi

PAGE 1013 – 1025

Paper 101: Dynamic Simulation and Forecasting of Spatial Expansion in Small and Medium-Sized Cities Using ANN-CA-Markov Models

Authors: Chengquan Gao

PAGE 1026 – 1039

Paper 102: Advanced IoT-Enabled Indoor Thermal Comfort Prediction Using SVM and Random Forest Models

Authors: Nurfileu Assymkhan, Amandyk Kartbayev

PAGE 1040 – 1050

Paper 103: Exploration of Deep Semantic Analysis and Application of Video Images in Visual Communication Design Based on Multimodal Feature Fusion Algorithm

Authors: Yanlin Chen, Xiwen Chen

PAGE 1051 – 1061

Paper 104: A Deep Reinforcement Learning (DRL) Based Approach to SFC Request Scheduling in Computer Networks

Authors: Eesha Nagireddy

PAGE 1062 – 1065

Paper 105: Improving Automatic Short Answer Scoring Task Through a Hybrid Deep Learning Framework

Authors: Soumia Ikiss, Najima Daoudi, Manar Abourezq, Mostafa Bellafkih

PAGE 1066 – 1073

Paper 106: BlockChain and Deep Learning with Dynamic Pattern Features for Lung Cancer Diagnosis

Authors: A. Angel Mary, K. K. Thanammal

PAGE 1074 – 1083

Paper 107: Application of Improved CSA Algorithm-Based Fuzzy Logic in Computer Network Control Systems

Authors: Jianxi Yu

PAGE 1084 – 1094

Paper 108: Application of Sanda-Assisted Teaching System Integrating VR Technology from a 5G Perspective

Authors: Zhaoquan Zhang, Yong Ding

PAGE 1095 – 1107

Paper 109: Data Collection Method Based on Data Perception and Positioning Technology in the Context of Artificial Intelligence and the Internet of Things

Authors: Xinbo Zhao, Fei Fei

PAGE 1108 – 1118

Paper 110: Hyperparameter Optimization in Transfer Learning for Improved Pathogen and Abiotic Plant Disease Classification

Authors: Asha Rani K P, Gowrishankar S

PAGE 1119 – 1140

Paper 111: Design and Application of Intelligent Visual Communication System for User Experience

Authors: Chao Peng

PAGE 1141 – 1148

Paper 112: Synchronous Update and Optimization Method for Large-Scale Image 3D Reconstruction Technology Under Cloud-Edge Fusion Architecture

Authors: Jian Zhang, Jingbin Luo, Yilong Chen

PAGE 1149 – 1160

Paper 113: The Application of Anti-Collision Algorithms in University Records Management

Authors: Ying Wang, Ying Mi

PAGE 1161 – 1171

Paper 114: Advancements in Deep Learning Architectures for Image Recognition and Semantic Segmentation

Authors: Divya Nimma, Arjun Uddagiri

PAGE 1172 – 1185

Paper 115: Optimized Retrieval and Secured Cloud Storage for Medical Surgery Videos Using Deep Learning

Authors: Megala G, Swarnalatha P

PAGE 1186 – 1195

Paper 116: Rolling Bearing Reliability Prediction Based on Signal Noise Reduction and RHA-MKRVM

Authors: Yifan Yu

PAGE 1196 – 1205

Paper 117: EIAiMSPS: Edge Inspired Artificial Intelligence-based Multi Stakeholders Personalized Security Mechanism in iCPS for PCS

Authors: Swati Devliyal, Sachin Sharma, Himanshu Rai Goyal

PAGE 1206 – 1217

Paper 118: Integrated IoT-Driven System with Fuzzy Logic and V2X Communication for Real-Time Speed Monitoring and Accident Prevention in Urban Traffic

Authors: Khadiza Tul Kubra, Tajim Md. Niamat Ullah Akhund, Waleed M. Al-Nuwaiser, Md Assaduzzaman, Md. Suhag Ali, M. Mesbahuddin Sarker

PAGE 1218 – 1226

Paper 119: TGMoE: A Text Guided Mixture-of-Experts Model for Multimodal Sentiment Analysis

Authors: Xueliang Zhao, Mingyang Wang, Yingchun Tan, Xianjie Wang

PAGE 1227 – 1234

Paper 120: A Simple and Efficient Approach for Extracting Object Hierarchy in Image Data

Authors: Saravit Soeng, Vungsovanreach Kong, Munirot Thon, Wan-Sup Cho, Tae-Kyung Kim

PAGE 1235 – 1242

Paper 121: Priority-Based Service Provision Using Blockchain, Caching, Reputation and Duplication in Edge-Cloud Environments

Authors: Tarik CHANYOUR, Seddiq EL KASMI ALAOUI, Mohamed EL GHMAYRY

PAGE 1243 – 1257

Paper 122: A Data Augmentation Approach to Sentiment Analysis of MOOC Reviews

Authors: Guangmin Li, Long Zhou, Qiang Tong, Yi Ding, Xiaolin Qi, Hang Liu

PAGE 1258 – 1264

Paper 123: Design and Implementation of Style-Transfer Operations in a Game Engine

Authors: Haechan Park, Nakhoon Baek

PAGE 1265 – 1273

Paper 124: Under Sampling Techniques for Handling Unbalanced Data with Various Imbalance Rates: A Comparative Study

Authors: Esraa Abu Elsouid, Mohamad Hassan, Omar Alidmat, Esraa Al Henawi, Nawaf Alshdaifat, Mosab Igtait, Ayman Ghoben, Anwar Katrawi, Mohmmad Dmour

PAGE 1274 – 1284

Paper 125: Multiclass Chest Disease Classification Using Deep CNNs with Bayesian Optimization

Authors: Maneet Kaur Bohmrah, Harjot Kaur

PAGE 1285 – 1300

Paper 126: Preprocessing Techniques for Clustering Arabic Text: Challenges and Future Directions

Authors: Tahani Almutairi, Shireen Saifuddin, Reem Alotaibi, Shahendah Sarhan, Sarah Nassif

PAGE 1301 – 1314

Paper 127: Impact of Emojis Exclusion on the Performance of Arabic Sarcasm Detection Models

Authors: Ghalyah Aleryani, Wael Deabes, Khaled Albishre, Alaa E. Abdel-Hakim

PAGE 1315 – 1322

Paper 128: A Configurable Framework for High-Performance Graph Storage and Mutation

Authors: Soukaina Firmli, Dalila Chiadmi, Kawtar Younsi Dahbi

PAGE 1323 – 1331

Paper 129: Detecting Malware on Windows OS Using AI Classification of Extracted Behavioral Features from Images

Authors: Nooraldeen Alhamedi, Kang Dongshik

PAGE 1332 – 1339

Paper 130: The Impact of Virtual Collaboration Tools on 21st-Century Skills, Scientific Process Skills and Scientific Creativity in STEM

Authors: Nur Atiqah Jalaludin, Mohamad Hidir Mhd Salim, Mohamad Sattar Rasul, Athirah Farhana Muhammad Amin, Mohd Aizuddin Saari

PAGE 1340 – 1347

Paper 131: The Impact of E-Commerce Drivers on the Innovativeness in Organizational Practices

Authors: Abdulghader Abu Reemah A Abdullah, Ibrahim Mohamed, Nurhizam Safie Mohd Satar

PAGE 1348 – 1355

Ensemble Learning with Sleep Mode Management to Enhance Anomaly Detection in IoT Environment

Abstract—The rapid proliferation of Internet of Things (IoT) devices has underscored the critical need for energy-efficient cybersecurity measures. This presents the dual challenge of maintaining robust security while minimizing power consumption. Thus, this paper proposes enhancing the machine learning performance through Ensemble Techniques with Sleep Mode Management (ELSM) approach for IoT Intrusion Detection Systems (IDS). The main challenge lies in the high-power consumption attributed to continuous monitoring in traditional IDS setups. ELSM addresses this challenge by introducing a sophisticated sleep-awake mechanism, activating the IDS system only during anomaly detection events, effectively minimizing energy expenditure during periods of normal network operation. By strategically managing the sleep modes of IoT devices, ELSM significantly conserves energy without compromising security vigilance. Moreover, achieving high detection accuracy with limited computational resources poses another problem in IoT security. To overcome this challenge, ELSM employs ensemble learning techniques with a novel voting mechanism. This mechanism integrates the outputs of six different anomaly detection algorithms, using their collective intelligence to enhance prediction accuracy and overall system performance. By combining the strengths of multiple algorithms, ELSM adapts dynamically to evolving threat landscapes and diverse IoT environments. The efficacy of the proposed ELSM model is rigorously evaluated using the IoT Botnets Attack Detection Dataset, a benchmark dataset representing real-world IoT security scenarios, where it achieves an impressive 99.97% accuracy in detecting intrusions while efficiently managing power consumption.

Keywords—IoT; IDS; machine learning; ensemble technique; sleep-awake cycle; cybersecurity; anomaly detection

I. INTRODUCTION

The Internet of Things (IoT) encompasses many devices, from small sensors to larger, more complex machines. These devices often have specific characteristics and limitations concerning power capacity and time consumption, which are crucial to consider in their design and deployment. Examples of these limitations include power capacity limitations, time-consuming processes, and capacity constraints [1]. Integrating IoT devices into daily life has raised concerns about power consumption and security. Indeed, many IoT devices run

outdated firmware, rely on old legacy protocols, and have constrained computational resources. These devices are prone to failure and are vulnerable to a wide spectrum of anomalies, such as malicious attacks, traffic congestion, connectivity problems, and flash crowds [2].

Nevertheless, the high resource requirements of complex and heavy-weight conventional security mechanisms cannot be afforded by (a) the resource-constrained IoMT edge devices with limited processing power, storage capacity, and battery life, and/or (b) the constrained environment in which The IoMT devices are deployed and interconnected using lightweight communication protocols [3]. Traditional security measures often require continuous device operation, leading to excessive power usage. A solution that allows IoT devices to remain in sleep mode until necessary can significantly reduce energy consumption while maintaining security.

IoT has revolutionized the way people interact with technology, connecting a myriad of devices to the Internet. However, this interconnectivity poses significant security challenges. IoT devices are often resource-constrained and become easy targets for cyber-attacks, making robust security mechanisms crucial for maintaining system integrity and user privacy. The wide range of different communication technologies (e.g., WLANs, Bluetooth, Zigbee) and types of IoMT devices (e.g., medical sensors, actuators) incorporated in IoMT edge networks are vulnerable to various types of security threats. This raises many security and privacy challenges for such networks, as well as for the healthcare systems relying on these networks [4].

Software-defined networking (SDN) is a modern paradigm that enhances network management through its dynamic and programmable architecture [5]. However, SDN lacks inherent security features, and one significant issue that may impede its widespread adoption is the potential for novel assaults [6]. Characteristics such as network programmability and centralized control introduce new faults and vulnerabilities, opening the door to threats that did not previously exist [7, 8]. The literature identifies seven potential attack vectors against SDNs, with three specific to SDN networks [9]. A key countermeasure to secure SDN is the deployment of Intrusion Detection Systems (IDS), which can identify and mitigate

malicious activities in real-time by monitoring network traffic [10]. IDS plays a pivotal role in identifying and mitigating cyber threats in IoT environments [11]. By monitoring network traffic and analyzing system behavior, IDS can detect potential threats before they cause harm. However, traditional IDS solutions often require significant computational resources, leading to high power consumption and latency, which are impractical for many IoT devices [12].

Traditional IDS solutions are often characterized by their high-power consumption, primarily due to the intensive computational processes involved in monitoring and analyzing network traffic [13]. This poses a significant challenge for IoT environments, where devices are designed to operate with minimal energy use. The deployment of power-intensive IDS can lead to rapid battery depletion, reducing the operational lifespan of IoT devices. This creates a critical trade-off situation: ensuring robust security through comprehensive IDS capabilities versus maintaining the energy efficiency critical to IoT device functionality.

Given the resource constraints of IoT devices, developing Intrusion Detection Systems (IDS) that efficiently manage time and power consumption is critical for practical deployment. This entails ensuring prolonged battery life and quick response times, striking a balance between robust security measures and minimal resource usage. In various domains like risk control, fraud detection, and decision-making, there's a significant focus on identifying unexpected events or patterns from datasets. Both static IoT systems (e.g., smart homes, smart buildings) and dynamic IoT networks (e.g., Vehicular Ad-hoc Networks) incorporate numerous lightweight, resource-constrained devices. Thus, efforts to develop IDS for IoT environments must optimize both intrusion detection effectiveness and resource efficiency to seamlessly integrate and widely adopt IDS within IoT ecosystems [14].

Machine learning (ML) offers promising avenues for enhancing the efficiency of IDS in IoT. By using ML algorithms, IDS can adapt to new threats more efficiently and reduce the time and power required for data processing and threat detection. This paper aims to explore the implementation of machine learning techniques in improving time and power efficiency in IoT intrusion detection systems. Energy efficiency is increased when a device has a sleep-wake mechanism, which enables it to go into sleep mode while not in use. The sleep-wake cycle in IoT devices is a critical feature designed to balance energy consumption with operational functionality. This cycle allows devices to conserve power by entering a low power 'sleep' mode when active operation is not needed and 'waking up' to a fully operational state when required to perform tasks. Additionally, the module integrates an isolation forest with an autoencoder, combining the best features of both techniques to provide enhanced anomaly detection in Internet of Things devices, even in sleep mode.

In this paper, a novel hybrid model designed to conserve power within IoT environments is introduced. This model incorporates a mechanism to keep warning devices inactive until abnormal traffic is detected, thereby reducing unnecessary power consumption. Our proposed module leverages ensemble

learning and a strategic sleep-wake protocol to optimize power usage while maintaining robust anomaly detection capabilities.

By integrating multiple machine learning models, such as Logistic Regression (LR), Random Forest (RF), Decision Tree (DT), Support Vector Machine (SVM), K-Nearest Neighbors (KNN), and XGBoost, and using an ensemble learning and voting mechanism, the module enhances detection accuracy. The sleep-wake mechanism ensures that IoT devices remain in a low-power state until an anomaly is detected, significantly conserving energy. The main contributions of this work can be summarized as follows:

- Enhanced anomaly detection with hybrid ensemble learning: A novel hybrid model integrating multiple machine learning models with a voting mechanism is introduced to improve the accuracy of anomaly detection in IoT systems.
- Optimized power consumption with sleep-wake mechanism integration: This allows devices to conserve energy by entering sleep states when not actively needed, thereby extending battery life and device operation time.
- Improved computational efficiency with caching: A caching mechanism for the fastest-performing model within the ensemble is introduced to reduce processing time for future detections and improve real-time application performance.

The paper is structured as follows: Section II provides an overview of related work and compares the main differences between our work and other existing research. In Section III, the research methodology details the experimental configuration, and the system flowchart is presented. The experimental results and analysis are thoroughly described in Section IV. Future work is articulated in Section V, followed by a conclusion in Section VI.

II. RELATED WORK

In recent years, significant advancements have been made in developing Intrusion Detection Systems (IDS) for secure IoT environments. The integration of machine learning techniques has greatly enhanced the ability to detect and mitigate cyber threats. Various approaches have been proposed to improve the detection accuracy and efficiency of IDS, especially using ensemble learning methods.

An ensemble learning approach that integrates logistic regression, decision trees, and gradient boosting to enhance the performance of IDS was proposed in study [15]. This method addresses challenges in accuracy, speed, false alarms, and unknown attack detection. Using the CSE-CIC-IDS2018 dataset and Spearman's rank correlation, 23 out of 80 features were selected. The proposed model achieved 98.8% accuracy, demonstrating its effectiveness in improving data security.

Another ensemble-based intrusion detection model was proposed in study [16] using multiple machine learning techniques, such as Decision Trees, J48, and SVM. Particle swarm optimization was used to select the nine most relevant

features in the KDD99 dataset, resulting in a model with 90% accuracy.

Additionally, a hybrid IDS model based on Naive Bayes and SVM was presented in study [17]. The study normalized and preprocessed a real-time historical log dataset, enhancing the model to achieve 95% accuracy and precision. The addition of session-based features further increased classifier performance.

Performance analysis of multiple classical machine learning algorithms on several ID-based datasets, including CICIDS2018, UNSW-NB15, ISCX2012, NSLKDD, and CIDD001, was conducted in study [18]. Techniques such as SVM, k-nearest Neighbors, and Decision Trees were deployed, with Decision Trees outperforming other classifiers, achieving detection accuracy rates between 99% and 100% for all datasets.

A lightweight IDS developed using SVM aimed to detect unknown and misuse attempts in IoT networks [19]. Experiments on different functions, such as linear, polynomial, and radial basis, showed reduced processing time and complexity due to selected features. However, the algorithm struggled to detect intrusions without affecting traffic flow rates.

A framework for botnet attack detection using a sequential detection architecture was introduced, reducing processing resource demand through relevant feature selection [20]. The N-BaIoT dataset was used, achieving 99% detection performance with Decision Trees (DT), Naive Bayes (NB), and Artificial Neural Networks (ANN). Hybrid classification was used in each sub-engine to enhance accuracy.

Alzaqebah et al. [21] developed a Network Intrusion Detection System (NIDS) using a modified Grey Wolf Optimization algorithm to enhance the efficiency of IDS. This approach smartly grouped wrapper and filter methods to include informative features in every iteration, combined with an Extreme Learning Machine (ELM) for faster classification.

Additionally, Ugendhar et al. [22] proposed an IDS that uses a deep multilayer classification approach. This system incorporates an autoencoder with a reconstruction feature to perform dimensionality reduction. The developed deep multilayer classification approach uses the autoencoder to reduce the dimensionality of the reconstruction feature, enhancing the efficiency and accuracy of the IDS.

In study [23], Grey Wolf Optimization (GWO) was proposed for feature selection, combined with Particle Swarm Optimization (PSO) to optimize the updating process for each grey wolf position. This hybrid approach harnesses PSO's ability to preserve the individual's best position information, which helps prevent GWO from falling into local optima. The performance of this technique is verified using the NSL-KDD dataset. Classification is conducted using k-means and SVM algorithms, and performance is measured in terms of accuracy, detection rate, false alarm rate, number of features, and execution time.

In another study, Samriya and Kumar [24] used a fuzzy-based Artificial Neural Network (ANN) for developing an IDS.

They employed the Spider Monkey Optimization algorithm for dimensionality reduction and tested the model with the NSL-KDD dataset. Moreover, an ensemble approach combining multiple machine learning models, such as Decision Tree (DT), Naive Bayes (NB), and Support Vector Machine (SVM), has been shown to enhance the detection capabilities of IDS. This method leverages the strengths of individual classifiers to improve overall system performance.

An Ensemble learning-based method was proposed in study [25], combining Isolation Forest and Pearson's Correlation Coefficient to reduce computational cost and prediction time. The Random Forest classifier was used to enhance performance. Evaluations on Bot-IoT and NF-UNSW-NB15-v2 datasets showed RF-PCCIF and RF-IFPCC achieving up to 99.99% accuracy and prediction times as low as 6.18 seconds, demonstrating superior performance.

A study proposed in [26] developed an IDS for CAN bus networks using ensemble techniques and the Kappa Architecture. The IDS combines multiple machine learning classifiers to enhance real-time attack detection. Supervised models were developed and improved with ensemble methods. Evaluation of common CAN bus attacks showed the stacking ensemble technique achieving an accuracy of 98.5%.

A novel approach to enhance intrusion detection was proposed in study [27]. It begins with denoising data to address the imbalance, followed by employing the enhanced Crow search algorithm for feature selection. An ensemble of four classifiers then classifies intrusions. Evaluation of NSL-KDD and UNSW-NB15 datasets shows accuracy rates of 99.4% and 99.2%, respectively, highlighting superior performance compared to existing methods.

Table I provides a detailed analysis of how researchers have used machine learning algorithms for intrusion detection across different datasets. It explores the specific techniques employed in each study, the datasets leveraged for training and evaluation, and any noteworthy remarks about the methodology or findings.

While many studies employ classic machine learning techniques, there is a notable lack of approaches addressing power efficiency in IoT environments, which is critical given the resource constraints of IoT devices. Moreover, these methods often fail to incorporate mechanisms for real-time intrusion detection and efficient computational performance, which is crucial for practical deployment in dynamic IoT networks.

The proposed Ensemble Learning with Sleep Mode Management (ELSM) aims to fill these gaps by using a more recent IoT botnet dataset, offering a contemporary perspective on current security challenges. The proposed method achieves a high detection rate by employing an ensemble learning technique with a novel voting mechanism while enhancing robustness and efficiency. This is particularly important in IoT environments where power conservation is crucial; Hence, integrating sleep-awake management optimizes power usage. Additionally, our approach accelerates the detection process by caching the fastest module for subsequent iterations, thereby improving computational efficiency.

TABLE I. A COMPREHENSIVE REVIEW OF MACHINE LEARNING TECHNIQUES FOR INTRUSION DETECTION IN VARIOUS DATASETS

Reference	Dataset	Techniques Used	Acc	Remarks
[15]	CSE-CIC-IDS2018	Logistic Regression, Decision Trees, Gradient Boosting	98.8%	Uses Spearman's rank correlation.
[16]	KDD99	Decision Trees, J48, SVM	90%	Employs Particle Swarm Optimization for feature selection.
[17]	Real-time historical log	Naive Bayes, SVM	95%	Data normalized and preprocessed before applying machine learning algorithms.
[18]	CICIDS2018, UNSW-NB15, ISCX2012, NSL-KDD, CIDD5001	SVM, k-Nearest Neighbors, Decision Trees	between 99% and 100%	Evaluates multiple classical machine learning algorithms on various datasets.
[19]	CICIDS2017	SVM (linear, polynomial, radial basis functions)	98.03%	Focuses on detecting denial-of-service attacks using simple features (e.g., packet arrival rates).
[20]	N-BaIoT	Artificial Neural Network, J48 Decision Tree, Naive Bayes	99%	Reduces processing demands by selecting relevant features.
[21]	NSL-KDD	Grey Wolf Optimization, ELM (Extreme Learning Machine)	99.12%	Focuses on achieving fast classification using ELM.
[22]	NSL-KDD	A deep multilayer classification approach	96.7%	Autoencoder Employed for dimensionality reduction.
[23]	NSL-KDD	The classification is done using the k-means and SVM algorithms	-	Hybrid Grey Wolf Optimizer with Particle Swarm Optimization for feature selection.
[24]	NSL-KDD	Fuzzy ANN (Artificial Neural Network), Spider Monkey Optimization	98.70%	Utilizes fuzzy logic for potentially enhanced accuracy.
[25]	Bot-IoT, NF-UNSW-NB15-v2	Isolation Forest, Pearson's Correlation Coefficient, Random Forest	99.99%	Utilizes Isolation Forest for anomaly detection and feature selection with Random Forest for classification.
[26]	CAN bus attack datasets	Random Forest, Decision Tree, XGBoost	98.5%	Uses ensemble learning techniques with Kappa Architecture for improved performance.
[27]	NSL-KDD, UNSW-NB15	SVM, k-nearest Neighbors, Random Forest, Long Short-Term Memory (LSTM)	99.4% and 99.2%	Applies data denoising and Crow search algorithm for feature selection and explores LSTM for deep learning.
[28]	CIC-IDS 2017	Improved Golden Jackal Optimizer, ANN	98.60%	Applies deep learning and optimization techniques for intrusion detection in smart city environments.
[29]	NSL-KDD	Random Forest, Naive Bayes, J48	99.10%	Investigates the effectiveness of hybrid classification methods.

III. PROPOSED METHOD

Power management is critical in the world of IoT devices, with a special focus on leveraging sleep mode to enhance energy efficiency. This is particularly crucial for devices operating on limited resources such as batteries. Sleep-wake cycles are essential to prolong operational life and increase longevity by reducing active mode duration, thus lowering maintenance demands and costs. In networked IoT environments, timely activation and communication can mitigate network congestion and minimize communication overhead. Key design considerations include optimizing wake-up frequency to align with specific application needs and power constraints, minimizing wake-up duration to the minimum for task completion before returning to sleep mode, and ensuring device responsiveness and reliability to guarantee timely wakeups.

Anomaly detection in IoT frameworks is crucial for the early identification of issues ranging from minor system faults to major cybersecurity vulnerabilities, thereby enhancing system reliability, security, and operational efficiency. Machine learning is essential in this context, leveraging historical data to detect patterns and anomalies. In IoT, anomalies manifest as deviations from expected behaviors,

signaling potential system failures, security breaches, or environmental changes. Anomalies can be categorized into point anomalies, which are significant deviations in individual data points, context anomalies specific to conditions, and collective anomalies, where seemingly normal data points together indicate suspicious activity. Each type requires distinct detection methodologies, with machine learning playing a pivotal role in their identification and resolution.

The proposed hybrid model aims to reduce power consumption in IoT environments by optimizing usage through a strategic sleep-wake protocol activated exclusively during anomaly detection phases. This methodology employs a composite model merging an autoencoder with an isolation forest, offering dual benefits of increased energy efficiency and enhanced detection precision. The model's construction, illustrated in Fig. 1, includes steps designed to conserve power and enhance IDS compatibility with IoT device limitations. Moreover, deploying this model at the edge is preferable to using cloud resources, as the primary goal is power preservation, while cloud data transmission consumes additional energy. Cloud computing may not be entirely suitable for provisioning IoT applications [29], primarily due to connectivity challenges between cloud resources in the core network and edge devices [30].

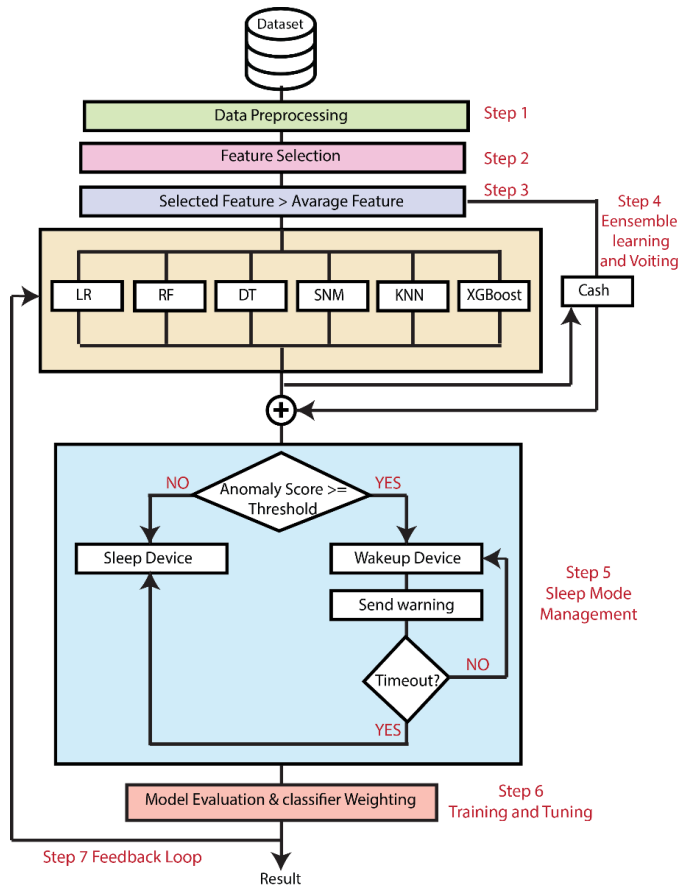

Fig. 1. The flowchart of the ELSM module.

The flowchart in Fig. 1 illustrates a comprehensive methodology for enhancing anomaly detection in IoT environments by leveraging ensemble learning and incorporating a sleep mode management mechanism. The process is divided into several key steps, each contributing to optimizing power efficiency and improving detection accuracy. The steps for Ensemble Learning with Sleep Mode Management (ELSM) are as follows:

1) *Data preprocessing*: Data collection and preprocessing from IoT sensors and devices are critical steps to ensure the suitability of data for machine learning analysis. Initially, data is gathered from sensors embedded in IoT devices, capturing real-time information about the environment or the device itself. This raw data then undergoes preprocessing, which involves cleaning, filtering, and transforming it into a format suitable for analysis. Tasks in preprocessing may include removing noise, missing handling values, normalizing data, and extracting features. Additionally, data may be aggregated or sampled to reduce dimensionality and enhance computational efficiency. By meticulously preparing the data and ensuring its quality and relevance, subsequent machine learning algorithms can effectively derive meaningful insights and support informed decision-making in IoT applications.

2) *Feature selection*: In the proposed methodology, a filter method is employed to enhance the performance of the Intrusion Detection System (IDS). Improving speed is crucial

for minimizing power consumption, reducing the reliance on extensive computational resources, and achieving faster processing times. Filter methods are noted for their swift execution compared to other feature selection techniques [32].

3) *Feature voting*: Selected features that surpass a specified average threshold are advanced to the next phase. This ensures that only the most significant features are used, thereby maintaining system efficiency and ensuring optimal feature selection for further analysis and performance optimization. The Feature Voting process involves ranking features based on their contribution to the classification task. Features with important scores above a predefined average threshold are considered significant and selected for further analysis. This reduction is crucial for maintaining high accuracy while ensuring computational efficiency, particularly in resource-constrained IoT environments.

4) *Ensemble learning and voting*: This step involves training multiple machine-learning models, including Logistic Regression (LR), Random Forest (RF), Decision Tree (DT), Support Vector Machine (SVM), K-Nearest Neighbors (KNN), and XGBoost. These models are combined using ensemble learning techniques to enhance overall prediction accuracy. The ensemble method typically employs a voting mechanism, where each model votes on the presence of an anomaly, and the final decision is based on the majority vote. Each model was evaluated based on two criteria: accuracy and prediction time. For each model, the training time and prediction time per instance are calculated as in Eq. (1), Eq. (2), and Eq. (3) respectively.

$$t_{train,i} = \text{time_end}_{train,i} - \text{time_start}_{train,i} \quad (1)$$

$$t_{pred,i} = \frac{\text{time_end}_{pred,i} - \text{time_start}_{pred,i}}{n_{test}} \quad (2)$$

$$Accuracy_i = \frac{\sum_{j=1}^{n_{tot}} \mathbf{1}(\hat{y}_j = y_j)}{n_{test}} \quad (3)$$

where, $\mathbf{1}$ is the indicator function that returns 1 if the predicted label \hat{y}_j matches the true label y_j , and n_{test} is the number of test instances. The weight and the normalized weight for each module were then calculated separately, as shown in Eq. (4) and Eq. (5), respectively.

$$w_i = \frac{Accuracy_i}{t_{pred,i}} \quad (4)$$

$$w'_i = \frac{w_i}{\sum_{k=1}^6 w_k} \quad (5)$$

Afterwards, the ensemble model which combines the predictions of all individual models using a weighted voting mechanism was calculated. For a given instance x , the ensemble prediction $\hat{y}_{ensemble}$ as in Eq. (6):

$$\hat{y}_{ensemble} = \arg \max_c \sum_{i=1}^6 w'_i \cdot P_i(y = c | x) \quad (6)$$

Where $(y=c|x)$ is the probability predicted by model m_i that the instance x belongs to class c . Finally, the accuracy is calculated for the ensemble techniques as in Eq. (7).

$$Accuracy_{ensemble} = \frac{\sum_{j=1}^{n_{test}} \mathbf{1}(\hat{y}_{ensemble,j} = y_j)}{n_{test}} \quad (7)$$

5) *Sleep mode management*: The sleep-wake cycle plays a crucial role in managing energy consumption in devices, particularly in battery-powered or energy-constrained environments. During sleep mode, the device conserves energy by shutting down non-essential functions, maintaining only vital components in a significantly reduced power state. Triggers such as scheduled timers, external signals such as motion detection, or internal alerts such as critical battery levels prompt the device to transition from sleep to wake mode. In wake mode, the device resumes full functionality, enabling tasks such as sensing, data processing, and communication. Once these tasks are completed, the device can return to sleep mode, ensuring efficient power preservation. This cycle optimizes energy usage, thus enhancing device efficiency and longevity.

6) *Training and tuning*: Testing and validation of the system under real-world conditions are essential to confirm its effectiveness in anomaly detection and power efficiency. During testing, the system's ability to accurately identify anomalies across various scenarios and environmental conditions is evaluated, providing insights into its robustness and reliability. Additionally, efforts are focused on assessing the system's power efficiency to ensure optimal operation within IoT device constraints, while minimizing energy consumption without compromising detection accuracy. By rigorously testing performance metrics and conducting thorough validation procedures, the system's suitability for deployment in practical applications is affirmed, instilling confidence in its ability to enhance security and efficiency in IoT environments.

7) *The feedback loop*: The feedback loop for continuous improvement in the system is pivotal for enhancing its performance over time. This iterative process ensures that the system remains agile and responsive to changes in its environment, thereby improving accuracy in anomaly detection. Additionally, the feedback mechanism facilitates self-optimization based on performance metrics and energy consumption data, allowing for adjustments to algorithms and configurations as needed. This iterative feedback loop enhances the system's overall effectiveness while promoting efficient energy utilization, ensuring sustainable operation in IoT environments.

IV. EXPERIMENTAL RESULTS AND DISCUSSION

This section presents the experimental results and analysis of the proposed model, which aims to enhance anomaly detection in IoT environments through ensemble learning and a strategic sleep-wake mechanism. Additionally, the process crucial for maintaining high accuracy while ensuring efficiency in the resource-constrained nature of IoT environments is demonstrated.

A. Dataset

The dataset utilized in this research is known as the InSDN dataset, published in 2020 by M. Elsayd et al. [31]. The primary objective of creating the InSDN dataset was to reduce its size compared to other IDS datasets while providing a realistic representation of traffic in an SDN environment. Unlike NSL-KDD and KDD99, InSDN includes real-world network traffic collected from an SDN environment and categorizes it based on the presence of DDoS attacks [32].

The dataset comprises a total of 343,889 records with 84 features. Of these, 127,828 records correspond to normal traffic, while 216,061 records represent attack traffic in both OSV and metasploitable files. InSDN encompasses various attack scenarios, including SYN, TCP, UDP, and ICMP floods, as well as Slowloris attacks. The distribution of samples within the InSDN dataset is detailed in Fig. 2.

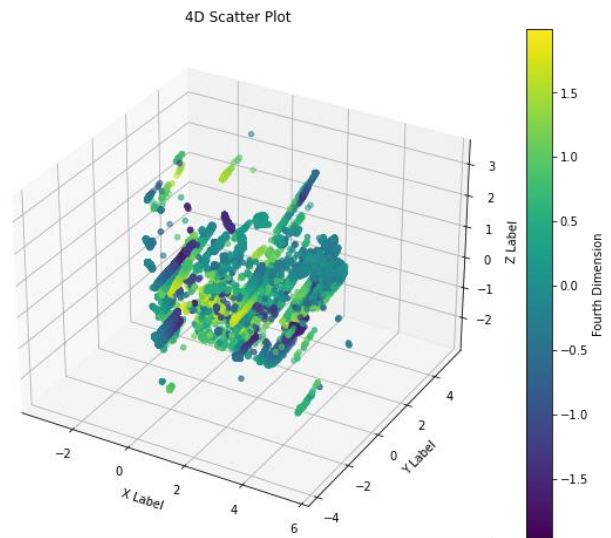

Fig. 2. 4D scatter plot for records on InSDN dataset.

B. Experimental Result and Analysis

The study employed a Random Forest classifier trained on the dataset to evaluate feature importance and classification accuracy. The dataset was split into training and testing sets, achieving an impressive accuracy of 99.97%. Through analysis, the top features contributing to classification were identified, ranked by importance in descending order. Fig. 3 presents a bar chart visualizing the importance of each feature, offering valuable insights into which features are most critical for the model's decisions.

Features with an average importance score above 0.0556 were selected for further analysis, as depicted in Fig. 4, effectively reducing the dataset's dimensionality. This focused approach enabled us to focus on the most relevant features, optimizing the model's performance and computational efficiency. Such selection is crucial for maintaining high accuracy while ensuring the system remains efficient and suitable for the resource-constrained nature of IoT environments.

Fig. 3. The importance of the selected features.

After feature selection, an ensemble model was developed by combining Logistic Regression, Decision Tree, and SVM to leverage the strengths of multiple classifiers, as explained in Section III, Step 4.

As a result, Logistic Regression achieved an accuracy of 99.99% with a prediction time of 1.88e-7 seconds, weighted at 871.5946. The Decision Tree model exhibited 99.96% accuracy with a prediction time of 11.16e-7 seconds, having the highest weight of 5789.0159. SVM achieved an accuracy of 99.98% with a prediction time of 0.00011 seconds, weighted at

167.8950. Details of other classifier results are provided in Table II.

As visualized in Fig. 5, ELSM emerges as a robust performer across multiple key metrics. It achieved an accuracy of 99.97%, closely aligning with top-performing models such as LR, SVM, and XGBoost, which scored 99.99%. ELSM's precision of 94.97% underscores its ability to accurately identify positive instances. Moreover, ELSM achieved a recall of 93.93%, demonstrating its effectiveness in capturing the most actual positive instances. Its F1 score of 94.31% strikes a balance between precision and recall, ensuring robust overall performance.

C. Discussion

ELSM excels with a perfect ROC AUC of 100.00%, indicating its exceptional ability to differentiate between classes with high confidence, which is crucial for minimizing false positives and false negatives in intrusion detection scenarios. This comprehensive evaluation positions ELSM favorably, demonstrating its efficacy in maintaining high accuracy while optimizing precision, recall, F1 score, and ROC AUC. The visual representation in the figure provides a clear comparative analysis, illustrating ELSM's strong performance across these critical metrics and substantiating its suitability for deployment in real-world applications that require reliable and efficient intrusion detection systems.

Fig. 4. The selected features with average importance above 0.0556.

TABLE II. CLASSIFIERS RESULTS AND WEIGHT

Model	Accuracy (%)	Precision (%)	Recall (%)	F1 Score (%)	ROC AUC (%)	Training time (Sec)	Prediction time (Sec)	Weight	Normalized Weight
Logistic Regression	99.99	99.07	94.01	95.59	99.57	18.91	1.88e-7	5295085.502	0.3552
Decision Tree	99.97	95.06	96.78	95.82	98.39	6.77	11.16e-7	8589122.0416	0.5762
SVM	99.98	99.51	93.9	95.77	100	223.49	0.00011	9100.85	0.0006
Random Forest	99.99	99.51	91.24	92.87	99.79	114.69	8.36e-5	119585.259	0.0080

XGBoost	99.99	99.51	94.01	95.83	100	6.54	1.13e-6	887210.96	0.0595
Proposed ELSM	99.97	94.97	93.93	94.31	100				

Fig. 5. Evaluation metrics for different models.

By combining these individual models using a weighted voting mechanism, the ensemble model ELSM achieved an overall accuracy of 99.97%. This high accuracy was attained by leveraging the complementary strengths of different classifiers, thereby enhancing the robustness of predictions and ensuring more reliable anomaly detection. In contrast, other methods achieved lower accuracy for the same dataset, as shown in Table I. This detailed comparison will effectively demonstrate the superiority of our approach in improving anomaly detection performance and reliability.

Subsequently, all previous stage results were integrated into the sleep-wake cycle management. The ensemble model's anomaly score determines whether the device remains in sleep mode or wakes up to handle potential threats. If the anomaly score meets or exceeds a predefined threshold, the device wakes up and sends a warning. If no anomalies are detected, the device remains in sleep mode to conserve energy. This strategic activation ensures that IoT devices are active only when necessary, optimizing power consumption while maintaining high-security standards. This approach effectively addresses the dual challenges of maintaining high-security standards and reducing power consumption, making it ideal for the resource-constrained nature of IoT environments.

V. FUTURE WORK AND CHALLENGES

Our research presents a promising approach to enhancing IoT security through ensemble learning and a strategic sleep-

wake mechanism. However, several areas require further exploration. Future work will focus on scaling the anomaly detection algorithms to handle the increasing volume of IoT data while ensuring real-time processing capabilities. Additionally, the aim is to develop adaptive algorithms capable of dynamically adjusting to diverse IoT environments and data types, explore advanced feature selection techniques, and integrate the model with an edge computing framework to reduce latency.

Despite the improvements demonstrated, several challenges remain. Balancing energy conservation with high performance, addressing data heterogeneity, achieving real-time detection without compromising accuracy, and keeping up with the dynamic threat landscape are significant hurdles.

VI. CONCLUSION

This paper introduces a novel hybrid model designed to enhance anomaly detection in IoT environments by leveraging ensemble learning and a strategic sleep-wake mechanism, significantly improving the efficiency and effectiveness of Intrusion Detection Systems (IDS) in these settings. Our approach addresses the critical challenges of maintaining high-security standards and reducing power consumption, which are essential for the resource-constrained nature of IoT devices. The integration of multiple machine learning models using ensemble learning techniques significantly improved the overall prediction accuracy.

The experimental results demonstrated that our model achieved an impressive accuracy of 99.97% on the IoT Botnets Attack Detection Dataset. The use of feature importance assessment through Random Forest allowed us to reduce the dataset's dimensionality, focusing on the most relevant features and optimizing the model's performance and computational efficiency. By employing a weighted voting mechanism, the strengths of individual classifiers were effectively combined, enhancing the robustness and reliability of anomaly detection. Additionally, the integration of the sleep-wake mechanism ensured that IoT devices remained in a low-power state until an anomaly was detected, thereby conserving energy.

Abstract—Event Argument Classification (EAC) is an essential subtask of event extraction. Most previous supervised models rely on costly annotations, and reducing the demand for computational and data resources in resource-constrained environments is a significant challenge within the field. We propose a Zero-Shot EAC model, ALBERT-F, which leverages the efficiency of the ALBERT architecture combined with the Flash-Attention mechanism. This novel integration aims to address the limitations of traditional EAC methods, which often require extensive manual annotations and significant computational resources. The ALBERT-F model simplifies the design by factorizing embedding parameters, while Flash-Attention enhances computational speed and reduces memory access overhead. With the addition of global constraints and prompting, ALBERT-F improves the generalizability of the model to unseen events. Our experiments on the ACE dataset show that ALBERT-F outperforms the Zero-shot BERT baseline by achieving at least a 3.4% increase in F1 score. Moreover, the model demonstrates a substantial reduction in GPU memory consumption by 75.1% and processing time by 33.3%, underscoring its suitability for environments with constrained resources.

Keywords—Artificial intelligence; natural language processing; event argument classification; zero-shot learning; flash-Attention; global constraints; low-resource

I. INTRODUCTION

Event Argument Classification (EAC) is a crucial part of event understanding and event argument extraction, embodying the complexity and importance of this interdisciplinary field [1, 2]. This domain, which integrates natural language processing (NLP) and knowledge representation, is dedicated to converting narrative event descriptions and their relational dynamics into a structured form of knowledge. As shown in Fig. 1, for a trigger word “paid” in a “Transfer-Money” event, it has several argument spans (e.g., “O’neal”). By determining the roles of these arguments (e.g., identifying “O’neal” as the “Giver”), this structured knowledge enables us to better understand events and use them for knowledge reasoning and automated decision support, benefiting applications such as biomedical research and question answering recommendation systems.

In the domain of event argument classification, a prevalent strategy has been the manual annotation of domains and patterns. Although effective, this approach necessitates significant labeling efforts for model training. This method also presents

Event Type: Transaction:Transfer-Money

Kobe also alleged that O’neal had paid upwards of one million dollars → money in this way as hush money over the years.

Fig. 1. An example of EAC. The arrows indicate the trigger and argument types respectively.

challenges in transferring knowledge across different application domains and scaling to new datasets. The laborious nature of annotation incurs significant costs. To mitigate this, some EAC models have turned to few-shot learning [3–6], which, despite its potential, is sensitive to the selection of examples and requires costly, task-specific training, limiting its practicality. In contrast, zero-shot EAC models have been introduced, leveraging label semantic understanding or prompt learning strategies [7–10]. Although existing methods perform well when dealing with events similar to the training data, they may not achieve the expected results when faced with significantly different new events. Some studies have attempted to improve performance in zero-shot and few-shot learning scenarios by integrating Large Language Models (LLMs) [2, 11], but there is still a considerable gap compared to models that have been specifically fine-tuned. Moreover, the operation of LLMs requires a significant amount of computational resources, which may limit their potential for application in resource-constrained environments. Therefore, tackling the efficiency constraints inherent to Zero-Shot EAC tasks in resource-scarce environments has become a formidable obstacle.

To address the challenges in the field of event argument classification, we propose a Zero-Shot model tailored for low-resource scenarios. This model integrates an ALBERT architecture [12] optimized with Flash-Attention [13] and is enhanced by global constraints with prompting, aiming to improve the performance of zero-shot EAC tasks.

The ALBERT model mitigates the issues of excessive parameters and inefficiency by simplifying its design in the BERT [12, 14]. Furthermore, global constraints provide critical supervisory guidance to our model, as a manifestation of

domain knowledge [2]. This guidance is particularly crucial in zero-shot learning environments with a scarcity of fully annotated data, as it enables the model to better understand and generalize the relations between event arguments. To further accommodate the constrained resources in low-resource scenarios, we propose ALBERT-F, a solution that optimizes the ALBERT model using a Flash Attention module. Flash Attention leverages efficient upper-level storage computational units to reduce access to the slower lower-level storage, thereby maintaining performance while significantly enhancing the model's resource utilization efficiency [13].

Through a series of experiments, we have validated the effectiveness of our proposed method. Specifically, our approach achieved at least a 3.4% increase in F1 score on the ACE dataset compared to the Zero-shot BERT baseline model, with a 75.1% reduction in GPU memory consumption and a 33.3% reduction in processing time. Furthermore, the introduction of Flash Attention resulted in a further 5.1% reduction in GPU memory consumption and an 11.1% decrease in processing time compared to the original ALBERT model. These results not only demonstrate the significant advantage of our method in reducing resource consumption but also confirm its effectiveness in enhancing performance.

Subsequent sections present our experimental setup, results, and a comparative analysis with existing models. We conclude with a discussion on the implications of our findings, limitations and avenues for future research.

II. RELATED WORKS

A. Event Extraction

Event Extraction (EE) is one of the most fundamental tasks in information extraction, which can be further divided into four subtasks: trigger identification, trigger classification, argument identification, and argument classification [1, 15–18].

Traditional event extraction relies heavily on feature engineering, which poses its central challenge [1, 18]. However, these methods often encounter limitations when dealing with deep or complex nonlinear patterns. In recent years, some advanced works based on supervised learning have attracted attention due to their two main advantages: first, the applicability of their embedding representations to large-scale datasets; second, the combination of automated feature extraction with specific deep architectures, which effectively captures more intricate nonlinear patterns [19–23].

In the task of information extraction, models can identify the actions in sentences and their corresponding participants by defining constraints [24]. One of the applications of constraint modeling in NLP is in syntactic analysis, where it is used to represent that an object must satisfy general or very specific properties to exclude those that do not belong to the structure of the language [25]. Particularly in zero-shot scenarios, constraint modeling can provide useful indirect supervision to the model, thereby further improving its performance [26].

Nevertheless, the inherent limitations of supervised learning may impact the model's generalization capabilities across different domains. Moreover, the demand for computational resources and specialized skills (including constraint modeling), along with the reliance on a substantial amount of

manually annotated data, become bottlenecks in their practical application.

B. Few-Shot Learning for EE

Few-shot learning methods have garnered widespread attention in the domain of event extraction, and the majority of current research is concentrated on the task of event identification within the context of Few-shot Event Detection (FSED) [1]. These approaches are dedicated to achieving accurate predictions for specific tasks with minimal training samples, such as one-shot, five-shot, etc. By leveraging prior knowledge, transfer learning, or meta-learning strategies, few-shot learning endeavors to surmount the challenge of data scarcity and enhance the model's generalization capability on novel tasks [3–6].

The DEGREE model [6] excels at synthesizing events from a text segment into coherent, naturally constructed sentences that conform to a pre-established template, aided by manually curated prompts. By integrating the semantic essence of labels with the collective intelligence across sub-tasks, DEGREE discerns interdependencies among entities, thereby reducing the volume of training data required. Many previous works on event extraction (EE) necessitate extensive annotations for model training [6, 8, 23], which incurs high costs due to the labor-intensive nature of annotation and poses challenges in scaling to new domains. While DEGREE refines a pre-existing generative language model [27], the output it generates may reflect the characteristics of the corpus from which it was trained. Although infrequent, there is a possibility that the model might produce sentences that are malevolent, mendacious, or prejudiced, thus raising ethical concerns [28, 29].

For classification tasks, LoLoss [4] is employed for training few-shot learning models based on the matching information of examples within the support set.

$$L(x, S) = L_{\text{query}}(x, S) + \lambda \cdot L_{\text{aux}}(S) \quad (1)$$

The components of this equation are as follows: $L(x, S)$ represents the total loss, which is contingent upon the model parameters x and the training samples S . $L_{\text{query}}(x, S)$ refers to the query loss, which assesses the discrepancy between the model's predictions for the query set and their corresponding true labels. λ is a hyperparameter that modulates the trade-off between the query loss and the auxiliary loss within the total loss calculation. $L_{\text{aux}}(S)$ is the auxiliary loss, which leverages the internal matching information of examples within the support set to provide additional training signals. It not only matches the query examples with those in the support set but also further matches the examples among themselves within the support set, thereby providing additional training signals for the model.

The scarcity of samples in long-tail categories increases the complexity of classification in few-shot learning tasks. To overcome this challenge, the Multi-Level Matching and Aggregation Network (MLMAN) [3] employs a hierarchical matching and aggregation strategy. This strategy comprehensively analyzes the support vectors and query vectors at different levels, capturing local features integrating global contextual information, thereby enhancing the classification accuracy of

long-tail category samples. Adaptive Attentional Network for Few-Shot Knowledge Graph Completion (FAAN) [5] employs a minimal set of reference samples to adeptly predict and discern connections and relations. These reference relation triples are adaptively encoded within a transformer network through the application of embeddings and an attention mechanism, ensuring precise alignment with the query. FAAN's adaptive encoding of entities and reference pairs significantly enhances the performance of traditional knowledge graph embedding methods, particularly for long-tail relations that are characterized by a paucity of samples.

Nonetheless, constrained by a limited sample size, the model is susceptible to overfitting, with an exacerbated risk in scenarios characterized by class imbalance. This propensity may compromise the model's capacity for robust generalization. Furthermore, the necessity for supplementary computational resources or the adoption of intricate model architectures could potentially restrict the practical applicability of these models.

C. Zero-shot Learning for EE

In the context of lacking prior knowledge and labeled data, existing research tends to adopt preset event information frameworks or experience-based strategies to achieve effective classification of unknown event types [7–10]. Similarly, the zero-shot contrastive learning strategy also emphasizes the use of unlabeled data during the training phase to cultivate features that can distinguish between different categories [2]. Although these methods still have a significant gap compared to supervised methods, they offer an insightful perspective and suggest possible directions for improvement in event extraction under resource-constrained environments.

The event extraction task was conceptualized by Huang et al. [7] as a “grounding” problem, wherein it is encapsulated within a structured ontology that delineates event mentions and their respective types. Semantic similarity measures are harnessed for the purpose of prediction. A transferable neural architecture was proposed by Huang et al., one that capitalizes on manually annotated event patterns alongside a modest subset of previously encountered types. This architecture was adept at transferring knowledge from known types to the extraction of novel types, thereby enhancing the scalability of event extraction and conserving human resources. Further exploration into transfer learning methodologies for novel events was undertaken by Lyu et al. [9] They reframed the event extraction challenge within the contexts of textual entailment (TE) and question answering (QA), advocating for the direct application of pre-trained TE/QA models.

Although these models have demonstrated exceptional performance on standard benchmark tests, they have not yet realized the anticipated generalization effect when applied to the event extraction dataset. Nonetheless, they offer an insightful vision and suggest a possible direction for improvement in event extraction within very low-resource environments.

Lin et al. [2] proposed a Global Constraint Regularization Module that standardizes predictions through three types of global constraints: cross-task constraints, cross-parameter constraints, and cross-event constraints. They utilized a method that combines global constraints with prompting, employing

the large language model GPT-J [30], which makes it possible to effectively perform event parameter classification without any annotations or task-specific training. Chen et al. [11], also employing large language models for research, utilized a large language model as an expert annotator for event extraction. Strategically incorporating sample data from the training dataset into the prompts, the researchers ensure that the generated samples from the language model align with the data distribution of the benchmark dataset. This enables the creation of an augmented dataset to supplement the existing benchmarks, alleviating challenges of data imbalance and scarcity, thus enhancing the performance of fine-tuned models. However, existing open-source large language models often require expensive hardware configurations and substantial computational resources [31]. Furthermore, the utility of these models is limited by the fact that most current hardware was developed prior to the emergence of large-scale models, potentially rendering it inadequate for the computational demands of such models during inference. This limitation is particularly pronounced in low-resource settings, where specialized hardware is required to facilitate efficient inference processes for large models [32].

To address low-resource scenarios, we propose a Zero-shot EAC model that incorporates global constraints and prompt, coupled with ALBERT-F. This approach aims to enhance the performance of Zero-shot EAC tasks in resource-constrained environments.

III. METHODOLOGY

Our model comprises two distinct modules. As shown in Fig. 2, the first is the prompting module, which is tasked with the generation of several new passages and the subsequent evaluation of their quality. During this creation process, the model integrates candidate role with prefix prompts that contain information regarding the event type and trigger. These candidates are connected to the target parameter range by embedding them within the passages through a cloze prompt. Subsequently, the model employs an ALBERT model optimized with Flash-Attention (ALBERT-F) to score the newly generated passages. Without the need for manual annotation, the initial prediction is the role with the highest prompting score. The second module is the global constraint regularization module, wherein the model regularizes the predictions through three types of global constraints. These are based on domain knowledge related to inter-task, inter-parameter, and inter-event relationships within the event-related context.

A. ALBERT-F

Before delving into the two primary modules, we provide an overview of ALBERT-F. By substituting the attention mechanisms across all modules, the primary structure of our ALBERT network is depicted in Fig. 3.

Flash-attention is designed to expedite the computation of attention mechanisms and curtail memory usage [13]. It leverages the knowledge of the memory hierarchy of underlying hardware, such as the memory architecture of GPUs, to enhance computational speed and reduce the overhead of memory access. By using statistical measures and altering

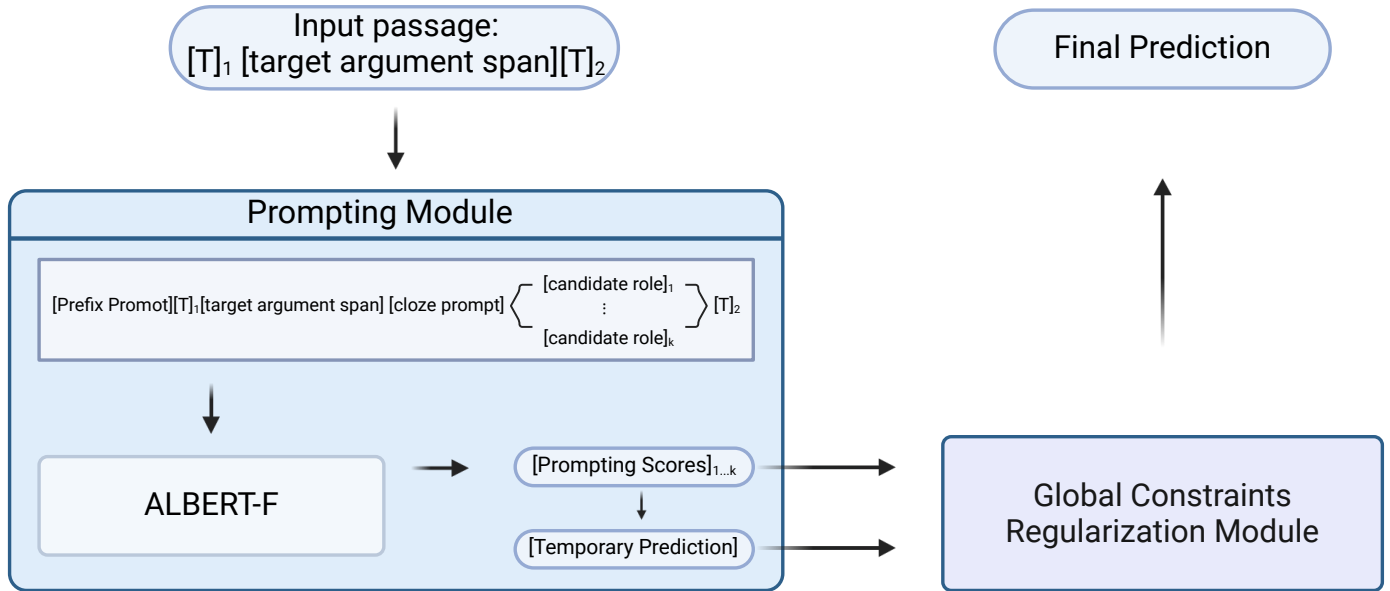

Fig. 2. Model summary, illustrated with the prediction of a single argument span. $[T]_1$ represents the segment of the input text preceding the span, while $[T]_2$ denotes the segment that follows. The variable k signifies the total count of potential roles associated with the event type.

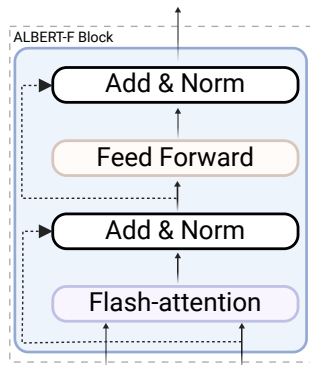

Fig. 3. The main structure of the ALBERT-F module. Enhancing model efficiency by introducing flash-attention to reduce computational resource consumption.

the computation sequence of the attention mechanism, Flash-attention computes in chunks rather than approximates, effectively reducing complexity. The outcomes of Flash-attention are entirely equivalent to those of the native attention mechanism [13, 33].

Increasing the size of a Pre-trained Language Model (PLM) typically enhances its inferential capabilities; however, once the model reaches a certain magnitude, it encounters limitations imposed by the memory capacity of GPUs/TPUs [33]. Consequently, ALBERT implements factorized embedding parameterization, which decomposes the embedding matrix. Instead of directly projecting one-hot encoded vectors into a hidden vector space of dimension H , the vectors are first projected into a lower-dimensional embedding vector space and then into the hidden vector space. This decomposition significantly reduces the number of embedding parameters and results in a more uniform distribution.

In ALBERT, the parameters of the fully connected layers and the attention layers are shared, meaning that ALBERT retains the deep multi-layer connections, but the parameters between layers are identical [12]. Consequently, ALBERT-F optimizes ALBERT using Flash-attention to reduce the model's computational resource consumption, yielding more satisfactory results in low-resource scenarios where computation and memory are constrained.

B. Prompting Module

In this section, we primarily elucidate the prompting module. Given a passage, we initially append a prefix prompt at the onset, which encapsulates information pertaining to the event type and the scope of the trigger. Such a prompt serves to guide ALBERT-F in: (1) accurately capturing the correlation between the input text and the event-related associations; (2) possessing a clear trigger awareness capability. In accordance with the definitions of events and triggers [17], we have formulated the following prefix prompt:

- "This is a $[P_1]$ event whose occurrence is most clearly expressed by $[P_2]$."

Where the first and second pairs of square brackets are placeholders for the event type (P_1) and trigger span (P_2), respectively.

For each candidate role, the module inserts a cloze test prompt subsequent to the target parameter range, with the role filling the slot of the prompt. The cloze prompt employs a hypernym extraction pattern "M and any other $[\]$ ", wherein "M" denotes the parameter range, and the square brackets serve as placeholders for the candidate roles. Such prompts harness the linguistic and common-sense knowledge stored within the ALBERT-F to assist in identifying which candidate role is the most plausible [2, 34].

For each novel passage, we apply ALBERT-F to compute the language modeling loss. The prompting score for the corresponding paragraph is determined by the negative value of the loss, where a more negative loss indicates a higher score, reflecting greater plausibility as assessed by ALBERT-F. Since the scoring process for each candidate role is independent of other candidate roles, we implement the steps for different candidate roles in parallel. This parallel implementation significantly enhances the efficiency of our model.

C. Global Constraints Regularization Module

This module regularizes predictions through global constraints. We refer to and leverage the constraint strategy proposed by Lin et al. [2], employing Event Argument Entity Typing (EAET) as an auxiliary task, which aims to categorize arguments into their contextually relevant entity types. These constraints provide our model with a global understanding of event arguments.

By utilizing the label dependencies between EAC and the auxiliary task, our model can glean global information about event arguments from the auxiliary task. Concurrently, to adapt to applications in low-resource scenarios, our model limits the number of specific arguments for certain or all events.

IV. EXPERIMENTS

We initially present the experimental setup, the baselines for comparison, and certain implementation details. Subsequently, we demonstrate and analyze the results of the experiments. We then conduct an analysis of computational resources and processing duration. Finally, we perform an error analysis.

A. Settings

We utilize the ACE (2005-E +) dataset [23, 35] as the basis for our experiments. The ACE dataset encompasses a total of 33 event types and 22 roles. We preprocess all events, as is done in the work of Lin et al. [23], to retain only the event subtypes when applicable. Since our approach is zero-shot, for each dataset, we consolidate all splits into a single test set, following the preprocessing in the study by Lyu et al. [9].

We evaluate using the F1 score, as proposed by Ji and Grishman [36], employing the ALBERT-F model as the foundational model for our module implementation. We run our experiments on a single NVIDIA RTX 4000 Ada GPU.

B. Main Results

We report results that are compared with several existing zero-shot methods, including those by Huang et al. (2018) [7], Liu et al. (2020) [8], Zhang et al. (2021) [10], and the current state-of-the-art zero-shot approach by Lin et al. (2023) [2]. In our comparisons, we also evaluated the work of Lin et al., where we compared two PLM (Pre-trained Language Model) bases: Bert-large-uncased [12] with a parameter count of 330 million, and GPT-6J [30] with a parameter count of 6 billion.

From Table I, we have the following observations: Compared to all zero-shot baselines, our model has demonstrated superior performance in the Settings category. Specifically, our model has achieved an F1 score on the ACE dataset that

TABLE I. COMPARISON F1 SCORE OF DIFFERENT MODELS ON THE ACE 2005 E+ DATASET, THE BEST PERFORMANCE OF NON-LLM IS MARKED IN BOLD FONT

Model	Year	ACE 2005 E+
Lin et al. [2] (GPT-6J)	2023	66.1
Liu et al. [8]	2020	46.1
Lyu et al. [9]	2021	47.8
Zhang et al. [10]	2021	53.6
Lin et al. [2] (BERT-Large)	2023	58.2
Ours	2024	61.6

surpasses the best non-large model zero-shot baseline by 3.4% (Lin et al., 2023 [2]). This represents a significant gap. Such substantial performance improvement can be attributed to several factors: (1) the prefix and cloze prompts effectively guide the PLM to capture the input's event-related perspectives and triggers; (2) the global constraint regularization incorporates global information and domain knowledge into the inference process; (3) our model has effectively enhanced the inferential capabilities of the EAC (Event Argument Classification) task.

Compared to the state-of-the-art (SOTA) results based on large models, there remains a significant performance gap for our model. Specifically, Lin et al. achieved a 4.5% higher score on the ACE dataset than our model. The advantage of models with ample resources over our zero-shot method is even more pronounced. This may be due to the fact that our model's parameter count (60M) is only 1% of the SOTA model's parameter count (6B). Based on the theoretical knowledge presented in Section III-A, there is still a partial performance gap between our EAC model and those utilizing Large Language Models (LLMs).

C. Comparison Between Different Prefix Prompts

In this section, we conduct experiments on the ACE (2005 E+) dataset to compare the effectiveness of using different prefix prompts within the model. We compare the following prefix prompts with those mentioned in Section III-B:

- 1) "[P1] most accurately represents the occurrence of this [P2]."
- 2) "The event type is [P1] and the trigger is [P2]."

TABLE II. PERFORMANCE OF DIFFERENT PREFIX PROMPTS

Prefix Prompt	F1 Score
Prefix(0)	61.6
Prefix(1)	61.3
Prefix(2)	60.8

From Table II, it can be observed that the prompts described in Section III-B are the most effective, which may be attributed to the fact that the prefix prompts are not only based on the definitions of events and triggers [17], but also possess a naturally fluent expression [2].

D. Computational Resource Analysis

The state-of-the-art (SOTA) model based on GPT-J, with its substantial parameter count of 6 billion, excels in resource-intensive tasks but also implies a significant demand for computational resources, making it generally unsuitable for low-resource scenarios. Therefore, in this section, we primarily compare the version implemented within the framework of Lin et al. [2] using BERT-Large with our model.

In contrast, the BERT-Large model used by Lin et al. has a parameter count of 334 million, whereas our model has a parameter count of only 60 million, significantly reducing the model's storage and computational requirements. Runtime and GPU memory usage are key indicators for gauging the feasibility of models in practical applications. We independently ran each model five times to calculate their average resource consumption.

TABLE III. THE RESOURCE CONSUMPTION OF EACH MODEL, WITH NUMERICAL VALUES REPRESENTING THE AVERAGE DURATION AND GPU MEMORY USAGE OVER FIVE INDEPENDENT RUNS

Model	Parameters	Run Time	GPU Memory
Lin et al. (BERT-Large)	334M	1.2h	2151MiB
Ours. (w/o Flash-att)	60M	0.9h	563MiB
Ours. (Flash-att)	60M	0.8h	534MiB

As shown in Table III, the model of Lin et al. requires 1.2 hours to complete training or inference, while our model (without Flash-Attention) and (with Flash-Attention) only requires 0.9 hours and 0.8 hours, respectively. Compared to the BERT-Large-based model and the model without Flash-Attention, the time consumption is reduced by 33.3% and 11.1%, respectively, indicating that our model can provide faster processing speeds while maintaining a smaller parameter size.

The model of Lin et al. (BERT-Large) [2] requires 2151 MiB of GPU memory, whereas our model significantly reduces this demand, with the version without Flash-Attention requiring 563 MiB and the Flash-Attention version further reducing to 534 MiB. This indicates that our model, while maintaining a smaller parameter size, has reduced GPU memory usage by 75.1% and 5.1%, respectively, making it more suitable for operation in resource-constrained environments.

The results indicate a substantial improvement in F1 score and a significant reduction in resource consumption. We attribute these improvements to the synergistic effect of Flash-Attention and global constraints within our model. However, we also acknowledge potential limitations, such as the model's generalizability to other domains and the need for further adaptation to enhance its robustness.

E. Discussion

The ALBERT-F model, without the implementation of Flash-Attention, exhibits an average runtime of 0.9 hours, which is further reduced to 0.8 hours with the integration of Flash-Attention. This is a significant reduction compared to the 1.2 hours required by the BERT-Large model. Concurrently, the GPU memory consumption is markedly decreased

from 2151 MiB for the BERT-Large to 563 MiB for the ALBERT-F model without Flash-Attention, and an additional reduction to 534 MiB is achieved with the utilization of Flash-Attention. These results indicate that the ALBERT-F model substantially diminishes resource consumption while maintaining performance, making it particularly suitable for scenarios with limited computational resources.

The fusion of global constraints and prompting strategies enhances the model's generalizability to unknown events, rendering it more competitive in zero-shot learning tasks. This characteristic implies that in practice, the model can make reasonable predictions for new event types even without specific training data, which is invaluable in situations where data is scarce or difficult to annotate. However, despite the ALBERT-F model demonstrating advantages in multiple aspects, its limitations in handling complex event structures and long-distance dependencies remain a subject worthy of investigation. Complex events often involve multi-layered nested semantic relationships, and long-distance dependencies require the model to capture associations between words that are distant in the text. The model's performance may be compromised in such cases, as traditional attention mechanisms may not effectively span long sequences to capture crucial information. Therefore, future research could focus on developing more advanced attention mechanisms or model architectures to strengthen the model's comprehension of complex events.

V. CONCLUSION

In conclusion, we propose a ALBERT-F model for zero-shot EAC that employs global constraints and prompting. Compared to previous works, our model has a significantly lower parameter count, which not only reduces storage requirements but also potentially mitigates the risk of model overfitting. Additionally, it offers advantages in terms of run time, implying faster iterations and adaptation to new data. In terms of GPU memory usage, our model is substantially suitable for operation on devices with limited memory. These advantages make our model particularly appealing in resource-constrained environments.

VI. LIMITATIONS

In this section, we summarize the limitations of our work as follows:

1) *Expressiveness*: Although the ALBERT-F model demonstrates exceptional resource efficiency, it may not match the robust expressiveness of large language models in certain complex natural language understanding tasks. Large language models typically excel in handling intricate linguistic structures and long-distance dependencies due to their substantial parameter count and deeper network architectures.

2) *Domain-specific performance*: In certain domains or tasks, large language models may exhibit superior performance due to exposure to a more diverse range of texts during their pre-training phase. While the ALBERT-F model possesses strong zero-shot learning capabilities, it may require additional domain adaptation to achieve optimal results with specialized terminology and concepts in specific fields.

3) *Scalability*: Although the ALBERT-F model shows significant optimization in resource consumption, whether it can maintain these advantages when dealing with larger datasets or more complex tasks, or if further adjustments to the model structure and parameters are needed, remains a subject that necessitates further research and validation.

ACKNOWLEDGMENT

We sincerely appreciate the collaboration and insightful discussions with all authors, which greatly contributed to this work. Our thanks also extend to the anonymous reviewers for their thorough and thoughtful evaluations, which have helped us refine our approach and presentation of the findings.

School of Computing Engineering and the Built Environment, Edinburgh Napier University, Edinburgh, United Kingdom³

Abstract—This research introduces a personalized hybrid tourist destination recommendation system tailored for the growing trend of independent travel, which leverages social media data for trip planning. The system sets itself apart from traditional models by incorporating both emotional and sentiment data from social platforms to create customized travel experiences. The proposed approach utilizes Machine Learning techniques to improve recommendation accuracy, employing Collaborative Filtering for emotional pattern recognition and Content-based Filtering for sentiment-driven destination analysis. This integration results in a sophisticated weighted hybrid model that effectively balances the strengths of both filtering techniques. Empirical evaluations produced RMSE, MAE, and MSE scores of 0.301, 0.317, and 0.311, respectively, indicating the system's superior performance in predicting user preferences and interpreting emotional data. These findings highlight a significant advancement over previous recommendation systems, demonstrating how the integration of emotional and sentiment analysis can not only improve accuracy but also enhance user satisfaction by providing more personalized and contextually relevant travel suggestions. Furthermore, this study underscores the broader implications of such analysis in various industries, opening new avenues for future research and practical implementation in fields where personalized recommendations are crucial for enhancing user experience and engagement.

Keywords—Recommendations; hybrid recommendation system; Collaborative Filtering; Content-based Filtering; social media data; travel planning

I. INTRODUCTION

Tourism significantly boosts the economy, creates jobs, and reduces poverty through spending, investments, and government backing [1]. Effective government policies are crucial for maximizing tourism's benefits and fostering overall economic growth. Social media, especially Facebook, plays a pivotal role in influencing travel choices and providing essential information to travelers [2]. Many travelers primarily rely on blogs and vlogs [3] for travel inspiration.

Emotions expressed on Facebook, such as anger, sadness, fear, joy, and love, can be identified through advanced textual analysis techniques [4]. Among these, anger, sadness, and fear are the most common, while love and amazement top the reactions [5]. Sentiment analysis, powered by sophisticated machine learning algorithms, evaluates sentiments on Facebook by analyzing data from the Top Page [6]. Understanding user perceptions and engagement is crucial for informed decision-

making on social media platforms. This technique can also be applied to other digital platforms to assess customer feedback sentiment. Automating this process facilitates the examination of large datasets, effectively addressing the inherent challenges in sentiment analysis [7].

Recommender systems are instrumental in helping tourists discover attractions that match their personal preferences and needs. These systems utilize various techniques, including social and Bayesian networks, Collaborative Filtering (CF) algorithms, and deep learning models, to analyze user behavior, textual sentiment, and similarities among options. By considering user characteristics, behaviors, social network connections, and search contexts, these systems can make precise recommendations for tourist destinations that align with individual interests [8].

In this study, we introduce a personalized hybrid tourist destination recommendation system that leverages emotional and sentiment data from social media platforms. Unlike conventional models, our system integrates these emotional cues to provide more nuanced and accurate travel suggestions. Our system combines CF and Content-based Filtering (CB) with sentiment analysis techniques. CF is used to recognize emotional patterns, while CB analyzes sentiment-driven data, resulting [9] in a sophisticated weighted hybrid model [10]. This approach ensures recommendations are finely tuned to capture the nuanced emotional responses of users.

By integrating emotional and sentiment analysis, our system enhances user satisfaction by adapting to changes in user preferences over time, providing dynamic and contextually aware recommendations. This leads to a more engaging and satisfying user experience. The key advancements of our model include dynamic weighting of user data, enhanced emotional resonance, and adaptability. These improvements make our model more accurate and personalized compared to traditional methods.

Overall, the sentiment and emotion-based Weighted Hybrid technique not only improves the technical robustness of recommender systems but also significantly elevates their practical application by delivering a more personalized, accurate, and emotionally resonant travel experience. This advancement represents a substantial leap forward in the field of tourism recommendation systems, setting a new standard for personalized travel planning.

In terms of technical aspects, the proposed model combines CF and CB with sentiment analysis techniques. CF is used to recognize emotional patterns, while CB analyzes sentiment-driven data, resulting in a sophisticated weighted hybrid model. This approach ensures recommendations are finely tuned to capture the nuanced emotional responses of users. To the best of our knowledge, no previous research has utilized emotions derived from social media reactions in their recommendation systems.

Regarding practical applications, by integrating emotional and sentiment analysis, the developed approach enhances user satisfaction by adapting to changes in user preferences over time, providing dynamic and contextually aware recommendations. This leads to a more engaging and satisfying user experience. The key advancements of this model include dynamic weighting of user data, enhanced emotional resonance, and adaptability. These improvements make the proposed model more accurate and personalized compared to traditional methods.

Therefore, the objectives of the presented paper are to:

1) Extract and analyze data focusing on the emotions and sentiments in posts, comments, and reactions about tourist spots to discern their influence on travel decisions.

2) Develop a state-of-the-art hybrid recommender system that combines CB and CF with sentiment analysis from Facebook data, offering personalized suggestions for tourist destinations.

The paper is structured into six sections, including a comprehensive review of related works in Section II, system design and methods in Section III, experimental results in Section IV, a discussion of these findings in Section V, and conclusions and future directions in Section VI.

II. RELATED WORKS

A. Recommender Systems

Recommendation systems have become indispensable across numerous sectors, including e-commerce, entertainment, news, and social networking, by facilitating access to tailored information and resources. These systems streamline the search process, allowing users to find resources suitable to their needs by providing individualized suggestions or guiding them to relevant resources within a large data space. They simplify the process of finding information and solutions, making it easier for customers and project providers to identify and receive projects and other services [11]. In the tourism sector, these systems assist users in locating resources that match their specific requirements by offering personalized recommendations or directing them towards pertinent resources within a vast data environment [12]. By analyzing user preferences and behavior, they filter and present tailored options, significantly reducing the time and effort needed to find relevant information or items in an otherwise overwhelming data landscape [13]. They also play a crucial role in guiding customers throughout their shopping journey, presenting the most relevant products without the need for explicit searches [14]. By incorporating ontologies and machine-learning algorithms, recommender systems enhance accuracy and

efficiency [15], addressing challenges and improving business productivity.

Recommendation systems can be categorized into several types, each with a unique approach to providing personalized recommendations. CF is one of the most common methods [16] and can be divided into user-based and item-based approaches. User-based Collaborative Filtering recommends items based on the preferences of users who have similar tastes, while Item-based Collaborative Filtering suggests items that are similar to those the user has previously liked or interacted with. CB focuses on recommending items that share similar attributes or features with those the user has shown interest in. Hybrid Systems (HS) combine multiple recommendation techniques, such as CB and CF, to enhance the overall accuracy and relevance of the recommendations. Context-aware Recommender Systems consider contextual factors such as time, location, or current activity to tailor recommendations more closely to the user's present situation. Demographic Recommender Systems provide suggestions based on demographic data, such as age, gender, or education level.

The research methodologies employed in tourism recommendation systems exhibit considerable diversity. Some studies focus on analyzing and quantifying user sentiment toward tourism destinations based on text reviews [17], integrating these sentiments [18] into the recommendation model. Others employ hybrid methods that combine CB and CF, utilizing preprocessed data from websites for recommendation. Additional approaches include probabilistic topic modeling and custom day itinerary models to analyze tourist travel patterns and preferences. While some studies emphasize recommending points of interest within a tourist attraction based on visitor interests, others offer broader recommendations spanning entire countries.

In summary, personalized hybrid recommendation systems across various domains leverage individualized suggestions and advanced techniques like opinion mining and hybrid filtering (HF) to enhance accuracy [19] and user experience. Despite their effectiveness in simplifying information discovery and improving the customer journey, these systems encounter challenges related to relevance computation, personalization, and the integration of specific user interests within large data spaces.

B. Factors Influencing Personal Travel Destination Choices

The decision-making process regarding travel destinations is influenced by a complex interplay of factors that vary significantly among individuals based on their preferences and circumstances, timing of the travel, and the quality of infrastructure and traffic conditions, which collectively shape the feasibility [20] and appeal of a destination [21]. The broad availability of information from different channels like online platforms, print media, and travel agencies plays a crucial role in informing potential travelers about their options, thereby significantly influencing their destination choices [22]. Moreover, the operational efficiency and overall attractiveness of a tourism destination, determined by factors like labor quality, capital investment, technological advancement, environmental sustainability, financial expenditure, generated revenue, and the potential length of stay, are critical in swaying personal travel

destination choices [23]. These considerations encompass a range of practical, economic, and subjective factors that contribute to the appeal and competitiveness of a destination, highlighting the multifaceted nature of travel decision-making. In essence, the choice of a travel destination emerges from a dynamic balance of these practical considerations, individual preferences, and the intrinsic attributes of the destination itself, underscoring the complexity of travel planning and the importance of understanding these factors for stakeholders in the tourism industry.

C. Sentiment and Emotion as New Factors for Recommendation Systems in the Tourism Domain

Sentiment and emotion play a crucial role in enhancing recommendation systems [24], [25] in the tourism domain. Incorporating sentiment analysis from user-generated content like reviews can significantly improve the accuracy [26] and quality of recommendations. By utilizing sentiment and emotion scores derived from user reviews, tourism recommendation systems can better capture user preferences and generate personalized recommendation lists based on semantic similarity [27]. Additionally, aspect-based sentiment analysis models can extract sentiment polarity from reviews, providing insights into tourists' evaluations and enhancing service and product upgrades [28].

These sentiment-driven approaches not only help in understanding tourists' emotions but also assist tourism organizations in their decision-making processes, ultimately leading to more effective recommendations [29] and greater customer satisfaction.

D. Weight Hybrid Recommendation System

A weighted hybrid model in recommendation systems combines multiple techniques, such as CF and CB, by assigning different weights to each technique based on their effectiveness in predicting user preferences. This approach leverages the strengths of each method to enhance recommendation accuracy and relevance [30]. The model integrates CF, which identifies patterns based on user interactions, and CB, which recommends items with similar attributes to those the user likes. Each method generates a recommendation score, and their contributions are weighted differently, with the weights determined [31] through experiments or data characteristics. One of the key advantages of a weighted hybrid model is its flexibility. The weights can be adjusted dynamically based on the recommendation context, user behavior, or data changes. This adaptability helps improve recommendation relevance over time, addressing limitations like the cold start problem and data sparsity [32], and providing more accurate and diverse suggestions.

In summary, a weighted hybrid model strategically combines multiple recommendation techniques with assigned weights to enhance accuracy and personalization. This method leverages the strengths of different techniques, adapts to changing data and user behaviors, and provides a robust and personalized recommendation experience.

III. SYSTEM DESIGN AND METHODS

The model aims to develop an innovative personalized tourist attraction recommendation system, showcasing a novel

architecture that incorporates advanced HF techniques, as illustrated in Fig. 1. This system leverages three distinct types of information, marking a significant advancement in tourist recommendation technologies.

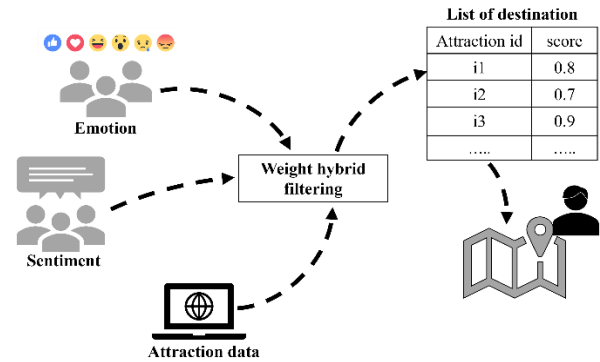

Fig. 1. Proposed architecture for a tourism recommender system.

A. Data Collection and Authorization

In collaboration with five Thai Facebook fan pages, we secured authorization to extract a wealth of data, including comments from followers, their emotional reactions via the 'reaction' button, and detailed information on various tourist attractions. This comprehensive dataset, accumulated two years, offering deep insights into tourist preferences and behaviors.

The architecture of a Personalized Hybrid Tourist Destination Recommendation System, as depicted in Fig. 1, employs a hybrid approach that integrates both CB and CF models. An in-depth explanation of the main segments and their respective processes is provided in multiple sections, as shown in Fig. 2.

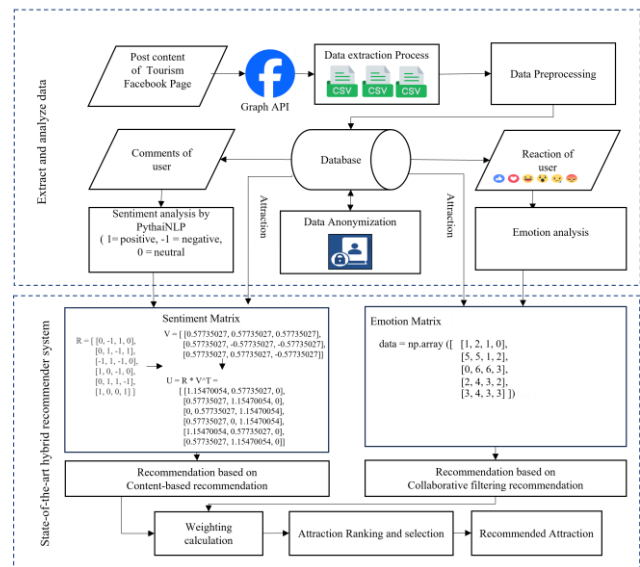

Fig. 2. Architecture of a weighted hybrid recommendation system.

B. Data Collection Process

As illustrated in Fig. 2, the architecture of a WHF begins with the data collection process, which gathers information from various sources. One such source is Facebook, where data is collected using the Graph API. This data, which ranges from

user demographics to their interactions with content, is typically stored in a CSV format to facilitate handling and analysis.

The initial stage of data preprocessing involves extracting and refining the gathered information through a series of steps. This phase focuses on ensuring data quality by cleaning inaccuracies, making necessary corrections, and identifying essential information to enable accurate recommendations. In respect of user privacy, data anonymization is implemented. During this process, data is stripped of personal identifiers, ensuring user privacy protection while still allowing for personalized content suggestions.

The system performs sentiment analysis by categorizing user comments as positive, neutral, or negative. Additionally, it evaluates user reactions, such as likes or emojis, by assigning numerical values from one to six to quantify user engagement. The processed data is organized into a matrix format, where users are listed alongside the items they interact with, creating a comprehensive map of interactions.

C. Data Selection Criteria

Selecting data for a tourism recommendation system is a complex endeavor due to the sheer number of tourism attractions and the overwhelming volume of information available online and across social media platforms. Existing recommender systems encounter challenges in delivering precise recommendations, as they must contend with variations in users' interests, the ever-changing contexts, and the sequential patterns of travel [33]. The lack of sufficient historical user data in the tourism sector further complicates matters, leading to difficulties such as cold starts and data sparsity, which hinder the delivery of accurate and reliable recommendations [34]. Furthermore, the infrequent browsing and purchasing of travel products, along with the influence of factors such as departure, destination, and price, adds another layer of complexity to recommending travel products [35].

Our method for selecting sentiment and emotion data follows strict criteria to ensure its relevance, accuracy, and diversity, while maintaining privacy and ethical standards. We identify key emotional data like user comments and reactions, verify their accuracy, and source them from various platforms, including social media. This data must be scalable and comprehensive to support reliable analysis and improve the system's ability to offer accurate and trustworthy recommendations, thereby enhancing its effectiveness.

D. Data Extraction Process

In social media data extraction, using Facebook's Graph API is crucial for researchers and technologists retrieving data from fan pages. Facebook Graph API allows developers to access and interact with Facebook data, such as user profiles, posts, and photos, using HTTP requests. It requires authentication via access tokens for secure data access and supports CRUD operations. This API enables the integration of Facebook data into applications for social media management, analytics, and personalized content delivery. Our study utilizes Facebook's Graph API [36] as a key tool, following a systematic method that values user privacy and adheres to privacy regulations, as shown in Fig. 3.

Fig. 3. Data preparation process.

The process starts by configuring an application on Facebook Developer Console to obtain an App ID and App Secret, enabling user consent through OAuth 2.0 for an access token. The access token allows fetching data from fan pages using Graph API, which is crucial for analysis.

Data retrieval involves accessing posts, reactions, and comments from fan pages through Graph API to gather raw data for analysis and recommendations. Anonymization techniques are applied to protect user data, including removing identifiers, randomizing sensitive data, and auditing the process regularly. The system securely stores anonymized reactions and comments in a privacy-compliant database and manages them through an ETL pipeline to maintain anonymization. Utilizing Facebook's Graph API involves access setup, data retrieval, and strict anonymization, laying the groundwork for further data processing in the Data Preparation phase.

E. Data Preparation

The data preparation phase involves handling three types of raw data crucial for constructing the dataset.

1) *Social network data*: Provides attraction names from social networks to identify and categorize tourist destinations.

2) *Sentiment data transformation*: Categorizes opinions from user reviews into three sentiment categories using the PyThaiNLP library [38] for sentiment analysis tailored to the Thai language. This library is vital for tasks specific to Thai, such as word tokenization for interpreting user sentiments accurately.

3) *Model for identifying and scoring user emotions*: This model identifies core emotions such as anger, disgust, fear, happiness, sadness, and surprise. The proposed model is consistent with Ekman's framework and is widely acknowledged in the field of emotion recognition. Emotions are scored to reflect user engagement [39]: Love = 6, Like = 5, Haha = 3, Wow = 4, Sad = 2, and Angry = 1, providing insights into the subtleties of user emotional feedback. The process is illustrated in Fig. 4.

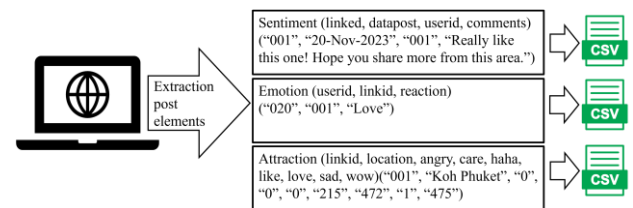

Fig. 4. Data preparation process.

Social network and user review data hold implicit details, requiring specific feature extraction techniques. Social computing retrieves social information from social network data, whereas sentiment analysis uncovers emotional cues from user feedback. Data collection and integration procedures prioritize safeguarding user privacy by anonymizing sensitive

information. These privacy steps are vital for upholding trust and efficiency in our recommendation system, offering personalized suggestions while protecting user privacy.

F. Creation of Recommendation System

The creation of the recommendation system involves the integration of CF and CB models. Below, we detail the methodologies used for each model:

1) *Collaborative Filtering model*: The development of a tourist attraction recommendation system using CF with the Singular Value Decomposition (SVD) algorithm is achieved through the following steps, with conceptual underpinnings and practical implementation in Python. Installation and Setup: Begin by installing the Surprise package using a package manager like pip, and import necessary classes such as Dataset, Reader, SVD, and accuracy functions from the library.

Conceptual Framework of SVD: For a matrix A with dimensions $m \times n$, SVD decomposes A into three matrices (1):

$$R = U \cdot \Sigma \cdot V^T \quad (1)$$

U : User ser features matrix, where rows represent users and columns represent hidden characteristics.

Σ : Diagonal matrix of singular values indicating the importance of the latent features.

V^T : Item-feature matrix, with row for items (attractions) and columns for latent features.

The procedure includes constructing matrices for User factors and Item factors, as illustrated in Fig. 5. Based on the example data provided, this step entails training a model using SVD.

Fig. 5. Matrices are generated for user factors and item factors.

Data Preparation: Prepare the data, including 'User_id', 'Attraction_id', and 'emotion' scores ranging from 1 to 6. An example data structure is provided.

Model Training: Define the range of 'emotion' scores using the Reader class, setting the minimum and maximum values. Load the data using the Dataset module, formatted according to the Reader specifications. Split the data into a training set for training the model and a test set for evaluating its performance. Instantiate the SVD algorithm and fit it to the training dataset.

Prediction and Evaluation: The system makes predictions for unseen user-attraction combinations in the test set. For example, it predicts the 'emotion' score for a given user-attraction pair, such as 'User123' (user_ID) and 'Attraction456' (attraction_ID). If the actual emotion score given by the user is 4 and the score estimated by the SVD model is 3.8, this indicates the model's performance. The details section, which shows 'was impossible': False, confirms that the prediction was successfully computed. To evaluate the model's accuracy, metrics such as Root Mean Square Error (RMSE) and Mean Absolute Error (MAE) are used [40]. These metrics compare the predicted scores against the actual scores in the test set. RMSE measures the square root of the average squared differences between the predicted and actual values, while MAE measures the average of the absolute differences between the predicted and actual values.

Practical Considerations: To protect user privacy, data anonymization is crucial. This involves removing or obscuring personal identifiers from the data to prevent individual users from being easily identified. Regular audits of the anonymization process are essential to ensure the data remains secure and to minimize the risk of re-identification, maintaining user trust and compliance with privacy regulations.

2) *Content-based filtering model*: Implementing a CB model for travel recommendations with Support Vector Machine (SVM) involves a structured approach, focusing on harnessing powerful capabilities in handling complex data patterns. The key steps in this process include data preparation, model selection and tuning, training, and evaluation.

Data Preparation: Transform sentiment data into numerical scores of (-1, 0, 1) to align with the SVM models' requirements. This step converts subjective sentiments into objective data points. Convert characteristics of tourist attractions, such as type and location, into numerical forms labeled as 'Attraction_type'. This numerical transformation is crucial for machine learning algorithms to process and learn from the data.

Model Selection and Tuning: Choosing and tuning the model is crucial as we opt for SVM due to its proficiency in classification tasks, especially its effectiveness in high-dimensional spaces and its ability to handle non-linear data separation through kernel methods. Fine-tune parameters like C (regularization), 'kernel type', and 'gamma' (kernel coefficient) to optimize the model for the dataset. In classification tasks, the primary objective is to find an optimal hyperplane that best separates the classes in the given dataset.

The SVM algorithm seeks to find an optimal hyperplane that best separates different classes in the dataset, as expressed by the hyperplane Eq. (2):

$$w^T x + b = 0 \quad (2)$$

where w represents the weight vector, x is the vector of data points, and b signifies the bias. Alongside the hyperplane equation, SVM involves an optimization problem, which is geared towards maximizing the margin between the data classes, as shown in Eq. (3):

$$\min(w, b) \left(\frac{1}{2} \|w\|^2 \right) \quad (3)$$

Subject to the constraints for each data point i :

$$y_i(w^T x_i + b) \geq 1, \forall i \quad (4)$$

In this context: $\|w\|/2$ is the norm of the weight vector, and minimizing it is key to maximizing the margin. The labels of the data points are denoted by y_i and x_i represents each data point.

Training and Evaluation: During model training, we divide our dataset into training and test sets to both train the model and evaluate its predictive performance accurately. After training, we assess the model's performance using metrics such as accuracy, precision, recall, and F1-score. These metrics provide a comprehensive understanding of the model's effectiveness in classification tasks.

Implementation: Once the model proves its effectiveness, it can be utilized to forecast user preferences for different tourist attractions and provide suitable recommendations. Utilizing SVM enables us to adjust and explore the model for optimal performance on our dataset. This methodology is especially beneficial for tasks demanding nuanced data analysis.

Visualize the sentiment feature matrix in SVM as shown in Table I to understand the data's distribution and how the model determines decision boundaries. Once the model is optimized and validated, it can accurately predict user preferences for various tourist attractions, providing personalized recommendations based on these analyzed features.

1) *Weight hybrid recommendation:* Integrating CB with CF in a WHS involves a structured approach to leverage the advantages of both methods. The workflow is as follows:

TABLE I. SENTIMENT FEATURE MATRIX OF SVM

Seq	Attraction_id	User_id	Sentiment
0	101	201	-1
1	102	202	0
3	104	204	-1
4	105	201	-1
5	105	202	0

a) *Data processing and score calculation:* Initially, both CB and CF systems process their respective datasets to compute scores for tourist destinations. These scores are based on each system's unique algorithms and the data provided.

b) *Blending scores:* The critical step of blending involves merging the scores from both systems using a predefined formula. This formula assigns specific weights to the scores from each system, balancing their contributions. For instance, the hybrid score can be calculated as:

$$\Sigma \chi \rho \epsilon_{\text{H}\psi\beta\rho\iota\delta} = \alpha \times \Sigma \chi \rho \epsilon_{\text{X}\text{B}} + (1 - \alpha) \times \Sigma \chi \rho \epsilon_{\text{X}\text{o}\lambda\lambda\alpha\beta\text{o}\rho\alpha\tau\iota\text{w}\epsilon} \quad (5)$$

Here, α represents the weight assigned to the score from the CB Filtering system.

1) *Optimizing the weight parameter (α):* Fine-tuning α is crucial for balancing CB and CF systems. Experimenting with various α values, calculating blended scores, and analyzing outcomes enhances recommendation accuracy and diversity. K-

grid tuning optimizes model parameters by adjusting the K value for cross-validation groups. Selecting an optimal K value, evaluating model performance, and refining based on results analysis ensures models align with data characteristics and task requirements.

2) *Performance evaluation:* After the hybrid recommendation system is in place, its performance should be evaluated to ensure it provides relevant and accurate suggestions. Utilizing feedback from users and analyzing performance metrics such as Accuracy, Precision, Recall, and F1-Score are integral to this phase. These evaluations facilitate ongoing refinement, improving the system's capability to effectively cater to user preferences.

This methodology underscores the importance of a balanced integration of CB and CF techniques, ensuring that the recommendations are not only accurate but also varied, catering to the diverse interests of users.

IV. EXPERIMENTAL RESULTS

The analysis of recommendation results derived from a comprehensive dataset provides valuable insights for the development and evaluation of a tourist attraction recommendation system. The following discussion presents a structured analysis based on the dataset results.

A. Dataset Results

The data extraction process leveraged a fan page dedicated to tourist attraction reviews, a valuable resource for assessing recommendation models. The dataset's composition and its implications for the recommendation system are as follows:

1) *Dataset overview:* The dataset contains 252,568 records split into two segments: 151,541 records for training and 101,027 for testing. This division ensures a robust framework for both developing and validating the recommendation model.

2) *User participation and attraction diversity:* A total of 38,739 users have contributed to the dataset, reviewing 508 different attractions. Examples of the data can be found in Tables II to IV. This level of participation and variety underscores the dataset's richness and diversity, providing a solid foundation for generating nuanced and wide-ranging recommendations.

3) *Sentiment classification:* Sentiments extracted from the dataset are categorized into three categories: positive, negative, and neutral, as indicated in Table II. This classification facilitates a detailed understanding of user preferences and emotions regarding various attractions.

TABLE II. EXAMPLE OF SENTIMENT DATA

User Id	Attraction		Sentiment	
	Id	Type	Type	Score
1	157	1	Neutral	0.5
1	122	5	Positive	0.8
2	28	1	Positive	0.7
3	89	6	Positive	0.6
3	210	2	Neutral	0.5

4) *Emotion ratings*: User ratings are based on an emotional scale from 1 to 6, where each number corresponds to a specific emotion (e.g., love = 6, like = 5, wow = 4, haha = 3, sad = 2 and angry = 1), as illustrated in Table III.

TABLE III. EXAMPLE OF USER EMOTION DATA

User ID	Attraction		Emotion	
	Id	Type	Word	Value
1	627	2	wow	4
1	781	5	like	5
3	783	6	wow	4
3	210	2	like	5
7	157	1	love	6

The dataset shown in Table IV includes a variety of attraction types, illustrating the diverse interests of the users. Understanding the range of attractions is crucial for tailoring recommendations to suit individual user preferences effectively.

The following table, Table V, lists different types of attractions along with their corresponding type names.

TABLE IV. EXAMPLE OF ATTRACTION DATA

Attraction ID	Name	Location	Type
1	Khun Dan Prakam Chon Dam	14.7994° N, 98.5969° E	4
2	Sai Yok National Park	14.417778° N, 98.747222° E	4
3	Singha Historical Park	14.03583° N, 99.23972° E	3
4	Phra Pathom Chedi	13° 49' 6.59" N, 100° 03' 22.20" E	6

TABLE V. EXAMPLE OF ATTRACTION TYPE DATA

Attraction Type	Type Name
1	Eco tourism
2	Arts and sciences educational attraction
3	Historical attraction
4	Natural attraction
5	Recreational attraction
6	Cultural attraction

B. Recommendation Results

The recommendation results in Table VI provide a comparative analysis of the performance of three models: CF, CB, and HF using Precision, Recall, and F1-score metrics. The HF model outperforms both CF and CB in all three metrics. This superior performance can be attributed to its ability to combine the strengths of both CF and CB techniques, along with additional enhancements such as sentiment and emotion analysis. This integration allows the HF model to provide more

accurate and reliable recommendations, better predicting user preferences and enhancing the overall user experience in tourism settings. In conclusion, the HF model is the most effective approach for recommending tourist attractions, as it achieves the highest precision, recall, and F1-score, significantly improving recommendation accuracy compared to the CF and CB models.

TABLE VI. RESULT OF PRECISION, RECALL AND F1- SCORE

Model	Precision	Recall	F1-score
CF	0.780	0.740	0.760
CB	0.660	0.690	0.670
HF	0.850	0.830	0.840

This analysis compares the efficacy of three recommendation models: CF, CB Filtering, and HF, using Precision, Recall, and F1-score as performance metrics. Fig. 6 displays the trends of these metrics as the value of K changes, illustrating how different parameter settings affect model performance.

Fig. 6. Model discrimination score by K-value.

Content-Based Filtering vs. Collaborative Filtering: CF demonstrates robust performance with a well-balanced trade-off between Precision (0.78) and Recall (0.74), resulting in an F1-score of 0.76. In contrast, CB Filtering, while slightly less effective, demonstrated modest performance with Precision (0.66) and Recall (0.69), and an F1-score of 0.67. This suggests a modest decline in performance compared to CF. The HF model, which combines CB and CF, demonstrated superior performance across all metrics. It achieved the highest Precision (0.85), Recall (0.83), and F1-score (0.84), signifying its effectiveness in providing accurate and comprehensive recommendations.

The accuracy of a recommendation system, which measures how precisely it predicts user preferences, can be assessed using metrics like the RMSE or MAE [37]. These metrics, along with the MSE, provide insight into the system's performance and can be calculated using the functionalities available in Scikit-learn [41]. The results of these calculations are presented in Fig. 7.

Fig. 7. Model performance comparison.

Error Rate Analysis: The analysis of RMSE, MAE, and MSE metrics presented in Fig. 7 revealed that the CB model exhibited the highest error rates, suggesting limitations in its predictive accuracy. The CF model showed moderate error values, indicating a balanced yet not optimal level of accuracy. The Hybrid model outperformed both with the lowest error values in all metrics, indicating its superior accuracy in predicting user preferences. This summary indicates that the HF model, which combines elements of both Collaborative and CB methodologies, offers the most effective approach for accurate user preference prediction.

C. Comparison of Methods, Items, and Values Results

The proposed method demonstrates the highest efficiency in recommendation systems, exhibiting the lowest error rates across all evaluated metrics, including RMSE, MAE, and MSE. This method integrates sentiment and emotion analysis with CF and CB techniques, leading to a significant improvement in recommendation accuracy. The integration of these emotional and sentimental data allows the system to better understand and predict user preferences, resulting in more personalized and precise recommendations.

In comparison, other methods such as those referenced in [21], [30], and [42], utilize various combinations of CF and CB techniques, sometimes incorporating additional methods like SVD and SVM. Despite these efforts, they still exhibit higher error rates. For instance, the method in [21], which uses a hybrid approach with SVD and weighted techniques, shows better performance than some but still falls short compared to the proposed method. The methods in [33] and [42], although incorporating diverse techniques, demonstrate even higher error rates, indicating less accuracy in their recommendations. All the data is detailed in Table VII.

Overall, the proposed method's ability to integrate emotional and sentiment analysis with traditional filtering techniques sets it apart, achieving superior performance and underscoring the importance of these factors in enhancing recommendation systems.

TABLE VII. COMPARISONS WITH RECENT METHODS

Ref	Method	Technique	Result		
			RMSE	MAE	MSE
[21]	Hybrid	SVD Weighted	0.500	0.414	0.254
[30]	CB+CF	Weighted	0.880	0.670	-
[42]	Hybrid	Cosine, SVD, SVM	0.864	0.666	-
<i>Proposed Method</i>	Baseline+ CB+CF	SVD, SVM, Sentiment, Emotion	0.301	0.317	0.311

V. DISCUSSION

This study demonstrates the potential of a Hybrid Filtering method for enhancing efficiency and accuracy in tourist attraction recommendations. By intelligently combining CB and CF techniques with adjustable method weights, the proposed approach delivers highly personalized recommendations that align closely with individual user preferences. Previous research has highlighted the strengths of CB and CF methods individually, but the integration of these techniques with customizable weights offers a novel approach that addresses limitations in prior studies [8], [10]. Despite these advancements, the methodology encounters significant challenges in sentiment analysis and data extraction from social media platforms, particularly Facebook.

A. Sentiment Analysis Challenges

The study acknowledges the inherent complexities in interpreting emotions expressed on social media, consistent with findings from existing literature [4], [6]. Social media users often present idealized versions of their emotions, which may not accurately reflect their true sentiments [20]. Additionally, the diversity of content types (text, images, videos) and nuanced language used on these platforms further complicate sentiment interpretation [27]. These challenges underscore the need for advanced sentiment analysis tools capable of understanding diverse expressions and cultural contexts [26]. Future research could build on recent advancements in sentiment analysis techniques to improve interpretation accuracy [18].

B. Data Extraction Complexities

Relying on Facebook's Graph API for data retrieval introduces significant challenges, a problem well-documented in the literature [4]. Researchers must navigate strict personal data access restrictions, frequent API changes, data request limits, and complex verification processes, all while managing privacy risks. The complexity of ensuring compliance with Facebook's policies adds another layer of difficulty, requiring careful data transformation to protect personal information—a process that is often time-consuming. While the WHF method demonstrates superior performance by effectively leveraging data from multiple sources, it still faces substantial hurdles in sentiment analysis and social media data extraction. These findings are consistent with earlier studies that have identified similar challenges in working with social media data. These challenges highlight critical areas for future research, emphasizing the need for:

1) *Advanced sentiment analysis tools*: The development of tools capable of accurately interpreting complex emotions expressed through various content types and linguistic nuances on social media.

2) *Improved data extraction techniques*: The exploration of efficient methods adaptable to the dynamic nature of social media platforms and APIs, while ensuring user privacy and data compliance [16], [23].

The discussion section highlights the efficacy of the WHS method in providing accurate and personalized tourist attraction recommendations. However, it also underscores the challenges in sentiment analysis and data extraction. Future research should focus on developing advanced sentiment analysis tools and improving data extraction techniques to further enhance the performance and reliability of hybrid recommendation systems.

VI. CONCLUSIONS AND FUTURE DIRECTIONS

This section provides a summary of the research conclusions and suggests future directions, highlighting key findings, limitations, implications, and areas for further investigation.

A. Conclusions

The WHF model demonstrates significant potential for personalized recommendations in tourism, outperforming CF and CB models in Precision, Recall, and F1-score. Its ability to align recommendations with users' emotions and preferences highlights the model's superiority. This success has broader implications for recommendation systems across various sectors, where aligning with user emotions and preferences can enhance satisfaction and engagement through personalized experiences.

B. Limitations

The extraction of large volumes of data from social media is time-consuming and requires careful handling, slowing the process. Additionally, sentiment analysis faces challenges when dealing with abbreviations and slang, complicating accurate interpretation.

C. Future Directions

To further enhance the model's capabilities and expand its applications, the following strategies are proposed:

1) *Advanced hybrid data preprocessing techniques*: Implementing sophisticated hybrid data preprocessing methods to improve model efficiency and performance across various databases. This will facilitate more accurate comparisons and refinements, leading to superior recommendation accuracy.

2) *Image-based preference analysis*: Utilizing image-based approaches to analyze user preferences more accurately for travel products. Integrating visual data will enable the recommendation system to better understand and predict user interests.

By adopting these strategies, the WHF model can address current challenges in sentiment analysis and data extraction, thereby advancing its personalization and accuracy. These enhancements have the potential to transform recommendation systems not only in tourism but also across other sectors.

Ongoing development and the integration of advanced techniques will ensure that recommendation systems continue to evolve, providing increasingly personalized and effective solutions to meet diverse user needs.

ACKNOWLEDGMENT

I sincerely thank the Ministry's studentship division for their generous scholarship, which has been vital to my doctoral research.

Abstract—The study delves into the landscape feature identification method and its application in Xijingyu Village, investigating landscape composition elements. Analyzing rural landscape structure holistically aids in dividing landscape characteristic zoning maps, essential for guiding rural landscape and territorial spatial planning. By utilizing GIS software for superposition analysis based on topography, geology, vegetation cover, and land use, the village range of west well valley undergoes further refinement. To address the inefficiencies of common foreground extraction algorithms relying heavily on rural landscape images, a novel approach is introduced. This new algorithm focuses on directly extracting foreground areas from rural landscape interference images by leveraging stripe sinusoidal characteristics. An adaptive gray scale mask is established to capture the sinusoidal changes in interference stripes, facilitating the direct extraction of foreground areas through a calculated blend of masks. In evaluating the results, the newly proposed algorithm demonstrates significant improvements in operation efficiency while maintaining accuracy. Specific enhancements include classifying pixel gray values into intervals and recalibrating them to enhance analysis metrics. Compared to traditional methods, the algorithm showcases advantageous enhancements across various parameters, such as PRI, GCE, and VOI. Moreover, to address challenges in unwrapping low-quality rural landscape phase areas, a ResU-net convolutional neural network is employed for phase unwrapping. By constructing image datasets of interference stripe wrapping and unwrapping alongside noise simulations for model training, the network structure's feasibility is verified. The study's innovative methodologies aim to optimize rural landscape analysis and planning processes by enhancing accuracy and efficiency in landscape feature identification, foreground area extraction, and phase unwrapping of rural landscapes. These advancements offer substantial improvements in quality and precision for territorial spatial planning and rural landscape management practices.

Keywords—Rural landscape; foreground area extraction; deep learning; phase unwrapping; ResU-net

I. INTRODUCTION

In recent years, it has been faced with many ecological problems in its development. First, a large number of spontaneous rural construction and rural reconstruction under the lack of overall planning, many of the arable land has been converted into construction land, Forest land is changed to cultivated land [1, 2]. China's original harmonious rural ecological environment has been destroyed; Second, excessive

exploitation and deforestation, Causing large-scale soil erosion and desertification phenomenon, Such as rural farmland sand and stone accumulation, The decrease in soil fertility, water loss and soil erosion [3, 4]. This also further affects the development of the rural economy and aggravates the deterioration of the ecological environment, Reduce the villagers' production income, Reducing the quality of rural life; Third, the discharge of harmful waste and waste liquid into the nature in the production process, Seriously polluting the environment, Industrial production for the discharge of solid waste containing sulfur dioxide and fuel dust, Disrupted the ecological balance of the countryside, These algorithms use variability between different image features to set thresholds and detect different image features by classification to identify foreground and background regions [5, 6]. The image extraction algorithm based on gray threshold is mainly used for images with target and background occupying different ranges of gray level. Among them, the maximum inter-class variance method proposed by Otsu is a common threshold calculation method. In addition, the best entropy threshold method proposed by Kaptur et al. The main work of image extraction by the threshold method is to select the appropriate threshold value [7]. The cluster-based extraction method enables the extraction of various pixels by classifying pixels with the same or similar features, which can be divided into classification clusters and block clustering methods [8]. The pixel-based extraction algorithm has the advantages of high efficiency, stable algorithm and simple operation, but the extraction effect largely depends on the selection of threshold and the prior knowledge of the operator. In addition, the pixel-based algorithm only analyzes a single pixel attribute, and does not consider the internal characteristics of the image frequency domain [9]. The algorithm is relatively shallow, which makes the image extraction result very sensitive to noise.

In the image foreground extraction algorithm based on the model features, the deformation model has two categories: geometric deformation model and parameter deformation model. The deformation model is robust the definition of the energy function, and the setting of the termination conditions [10]. Therefore, the selection and setting of these factors need to be carefully considered carefully when using the algorithm to improve the stability of the algorithm and the accuracy of segmentation results. With the development of algorithms, model-based extraction methods change to feature extraction methods, which include unsupervised feature extraction algorithms, such as principal component analysis [11, 12]. By

finding a set of orthogonal transformations, and minimizes the sample reconstruction errors generated during the process. Also include supervised learning algorithms, such as linear discriminant analysis, typically used to divide data into two or more categories to find a low-dimensional linear space to maximize variability between categories and minimize variability within the same category [13, 14]. However, these algorithms prefer to target the images with obvious features, while the rural landscape interference stripe belongs to a kind of image without regular change, so it is difficult to effectively extract the foreground area through such methods. The extraction method based on the image edge feature is to find the boundary of the target area in the image according to the assumption of the boundary, and then segment the image along the boundary [15, 16]. Most of the algorithm to image gray gradient change direction and in x direction and y direction partial derivative trend data analysis, through the change rule set threshold of the image pixels, finally to different area pixel properties and feature recognition to complete the effective area edge segmentation, the algorithm field appeared many famous operators, based on edge extraction methods such as Canny operator, Sobel operator and Laplacian operator in extracting the overall target area in the image. But in the study of the interference stripe image stripe light and dark distribution, there are very obvious connected domains between the stripes, so through this kind of image edge algorithm will foreground area into many strips area, cannot realize the correlation between the connected domain, it is difficult to accurately obtain the edge of the foreground area. Therefore, such methods are not applicable in the foreground area of rural landscape interference images in this study [17].

The region growth-based image extraction method divides the image into multiple small regions and gradually merges pixels with similarity into a single region through a series of iterative processes. Each iteration will form a new area until the entire image is completely covered [18]. On the regional growth rules and order, and on setting the regional growth termination conditions. To solve the problem of initial seed point selection, developed an algorithm without seed point can realize automatic image extraction, fuzzy theory and optimization algorithm applied to regional growth algorithm, regional growth method combined with anisotropic filtering technology and algorithm, and add adaptive parameters in the regional growth algorithm, realize the automatic extraction of medical images [19, 20].

II. DATA PROCESSING METHODS FOR LASER INTERFEROMETRY IN RURAL LANDSCAPE

A. Typical Method for Identifying the Foreground Regions of the Interferograms

Large-angle oblique incidence of irradiation. Two identical optical wedges are placed symmetrically on both sides. The front wedge deflects the light at a small Angle, and the light incident to the measured at a large Angle. As shown in Eq. (1) and Eq. (2), I_m is the measured light wave intensity, I_r is the reference light wave intensity, the reflected light is deflected by the small angle of the back light wedge, and the main direction of the deflection light is the same direction as the light before the front light wedge.

$$I_i(i, j) = I_m(x, y) + I_r(x, y) + 2\sqrt{I_m(x, y)I_r(x, y)} \cos[\Delta\phi(x, y) + \delta_i] \quad (1)$$

$$I_i(x, y) = a_0 + a_1 \cos \delta_i + a_2 \sin \delta_i \quad (2)$$

Using the above large Angle oblique incidence scheme, and for the convenience of experimental operation, such as Eq. (3), Eq. (4), I is the sequence number for introducing phase modulation, E is the grayscale distribution value, the interferometer designed the interferometric measurement system for the model. The light in the measured light path and phase shift in the reference light path.

$$\Delta\phi(x, y) = -\arctan \frac{a_2}{a_1} \quad (3)$$

$$E = \sum_{i=1}^N [a_0 + a_1 \cos \delta_i + a_2 \sin \delta_i - I_i(x, y)]^2 \quad (4)$$

The point light emitted by the laser becomes a flat wave beam with uniform light intensity distribution. The beam meets the polarization spectroscopic prism, and the s-polarized path, and the p-polarized light transmitted perpendicular to the long axis of the incident surface enters the reference light path. As shown in Eq. (5), and Eq. (6), P_{RI} is the refractive fiber value, $I()$ is the measured optical path function, in the measured optical path, s polarized light uses the double optical wedge combination to complete the measured large angle oblique incidence, and then enters the imaging co-optical path through the semi-reverse and semi-lens.

$$P_{RI}(S, \{G_N\}) = \frac{1}{C_n^2} \sum_{i < j} [c_{ij} P_{ij} + (1 - c_{ij})(1 - p_{ij})] \quad (5)$$

$$I(S, S_{\text{test}}) = \sum_{k=1}^N \sum_{k'=1}^N P(k, k') \log [P(k, k') / P(k) / P(k')] \quad (6)$$

The semi-reverse lens to make it into the imaging common path. As shown in Eq. (7), Eq. (8), $VI()$ is the imaging common path function, $L_{RE}()$ is the interference optical path function, the measurement light and the reference light meet here and produce interference on the photosensitive surface of the CCD camera after the imaging lens. The computer controls the camera to collect and control the PZT in the reference light path to realize phase shift.

$$VI(S, S_{\text{test}}) = H(S) + H(S_{\text{test}}) - 2I(S, S_{\text{test}}) \quad (7)$$

$$L_{RE}(S, S_{\text{test}}, X_i) = \frac{|P(S, X_i) / P(S', X_i)|}{|P(S, X_i)|} \quad (8)$$

Relying on rural landscape non-interferometric image mask indirectly extract rural landscape interference image foreground information, cannot achieve directly for rural landscape interference image extraction method and change of measurement conditions will lead to great difference in threshold value, even if the same group phase interference stripe threshold extraction is not interlinked, such as Eq. (9), Eq. (10), $G_{CE}()$ is the threshold calculation function, and m is the modulation ratio calculation formula, and the increase of

the measurement link will not guarantee the consistency of the extraction results, at the same time, the measurement light path has certain limitations, can only be used for non-common light measurement system.

$$G_{CE}(S, S') = \frac{1}{n} \min \left\{ \sum L_{RE}(S, S', X_i), \sum L_{RE}(S', S, X_i) \right\} \quad (9)$$

$$m = \frac{m_1 + m_2}{2} + m_1 \quad (10)$$

B. Rapid Identification Method for the Foreground Area of the Rural Landscape Interference Image

After the helium-neon laser, there is the polarization direction and the optical axis of the polarization spectroscopic prism, as shown in Eq. (11) and Eq. (12), n is the angle optical axis selection ratio, and $E()$ is the grayscale calculation function, thus changing the light intensity ratio between the p light entering the measured light path and the s light entering the reference light path.

$$n = \frac{n_{min} + n_{max}}{2} + n_{min} \quad (11)$$

$$E(X) = \frac{Gray_L + Gray_R}{2} \quad (12)$$

Even if the light intensity loss in the measured light path is different from the reference light in the reference light path, the measured light intensity can still be adjusted by the rotating half-wave sheet to ensure that the resulting interference stripes have the best contrast. As shown in Eq. (13) and Eq. (14), m and n is the size of the interference image, x and y are the coordinates of the interference point, the interference fringe image contains the phase difference caused by the surface topography of the tested rural landscape and is an important way of presenting the measurement information. Through a series of calculations, we can recover the physical properties contained in the measured object, using the characteristics of the light and shade changes in the interference stripe image.

$$\sigma^2 = \frac{(\varphi_i(x, y) - E(X))^2 + \sum_{i=1}^{m \times n - 1} (\varphi_i(x, y) - E(X))^2}{m \times n} \quad (13)$$

$$\phi(x, y) = \varphi(x, y) + 2n\pi \quad (14)$$

The interference phenomenon of light is an important feature of light volatility. It is a phenomenon that meets the interference conditions overlap each other when they meet in space, which always strengthen or weaken in some areas, forming a stable strong and weak distribution. As shown in Eq. (15) and Eq. (16), J is the momentum of the light wave, U and V are the directions of the light wave vector, respectively, only the vibration direction of the coherent light source is the same, the frequency of the two light waves is the same and the phase difference is constant.

$$J = \varepsilon^p = \sum_{i=0}^{M-2N-1} \sum_{j=0}^{M-1N-2} |\phi_{i+1,j} - \phi_{i,j} - \Delta_{i,j}^x|^p + \sum_{i=0}^{M-1N-2} \sum_{j=0}^{M-2N-1} |\phi_{i,j+1} - \phi_{i,j} - \Delta_{i,j}^y|^p \quad (15)$$

$$(\phi_{i,j} - \phi_{i-1,j} - \Delta_{i-1,j}^x)U(i-1,j) - (\phi_{i,j} - \phi_{i,j-1} - \Delta_{i,j-1}^y)V(i,j-1) = 0 \quad (16)$$

The overall process of the foreground area recognition and extraction algorithm is to obtain the processed mask the measured image, as shown in Eq. (17), Eq. (18), M and N represents the number of refractions, $U(i,j)$ represents the mask image threshold, and then the smooth mask image is obtained by smoothly adjusting the image-by-image morphology processing or linear fitting. Finally, the mask image treats the measured image to obtain the image containing only the effective information in the foreground area.

$$J = \varepsilon^2 = \sum_{i=0}^{M-2N-1} \sum_{j=0}^{M-1N-2} |\phi_{i+1,j} - \phi_{i,j} - \Delta_{i,j}^x|^0 + \sum_{i=0}^{M-1N-2} \sum_{j=0}^{M-2N-1} |\phi_{i,j+1} - \phi_{i,j} - \Delta_{i,j}^y|^0 \quad (17)$$

$$U(i, j) = |\phi_{i+1,j} - \phi_{i,j} - \Delta_{i,j}^x|^{-2} \quad (18)$$

At present, there are many prospect area recognition algorithms in the field of image algorithm, but in the highly targeted research field, the processing results and performance of the algorithm are not satisfactory. Due to the large number of connected areas in the foreground area of the rural landscape interference image and the irregular noise shadow of the gradient in the background area. As shown in Eq. (19) and Eq. (20), $V(i,j)$ is the edge algorithm value, i and j are the cyclic factors, and the results of Canny algorithm cannot connect a large number of connected domains in the rural landscape interference image.

$$V(i, j) = |\phi_{i,j+1} - \phi_{i,j} - \Delta_{i,j}^y|^{-2} \quad (19)$$

$$\rho_{i,j} = (\Delta_{i,j}^x - \Delta_{i-1,j}^x) + (\Delta_{i,j}^y - \Delta_{i,j-1}^y) \quad (20)$$

III. DESIGN ALGORITHM FOR AUTOMATIC RECOGNITION OF FORE LANDSCAPE IMAGE OF LANDSCAPE IMAGE

A. Adaptive Threshold Foreground Region Extraction Algorithm Based on Object Image Grayscale

In a set of phase-shift interference maps, the relative modulation regime of pixels refers to the ratio of the amplitude of the AC component to the amplitude of the DC component. When high-precision data or data processing tasks are required, the image quality can be evaluated directly through quantitative analysis, and the relative modulation system can be used to identify the foreground region and the background region in the distinguishing interferogram [21, 22]. The basic basis of the judgment method is: the proportional operation of the AC component amplitude and DC component amplitude can be realized by adjusting the system algorithm. The gray value information of each pixel can be mapped within the range of [0, 1] by the two amplitude proportions [23, 24]. The larger the amplitude of the AC component, the more effective information contained in the pixel, and the higher the regulation value obtained by this algorithm. Therefore, the foreground area can be distinguished from the background area, which can be distinguished from the background area by threshold setting [25, 26]. Fig. 1 is the detailed diagram of the U-net model architecture, and the relative modulation system value can be filtered. Because the path tracking method can be separated from the phase discontinuous integral, the local phase deviation can be prevented from spanning the whole integral

region. The operation speed is fast, and more accurate results can be obtained in the region under the influence of low noise [27, 28]. Therefore, the foreground area of rural landscape interference image can be extracted by evaluating the phase

gradient continuity of rural landscape interference image. In the interference field, the interference intensity changes sinusoidal with space, forming an interference stripe between light and dark.

Fig. 1. Detailed diagram of the U-net model architecture.

Therefore, if a single interference stripe image is filtered by gray-scale thresholding, the dark stripes in the foreground region will also be filtered, although the background region can be removed. According to the optical wave shift phase interference formula, the interference intensity of the fixed position in the interference field will change according to the sinusoidal law as the phase shift goes on. This shows that the brightness of any pixel in the interference region changes alternately in a set of phase-shifting interference images. This means that, in a set of phase-shifting interference images taken, the pixel has at least one chance to be captured in its higher brightness state. Considering the above two aspects, a method based on the common filtering of similar interferograms is proposed to distinguish between regions and non-regions in the measured interferograms. Fig. 2 is the graph of feature extraction and fusion strategy. In the common filtering method of the same group of interference graphs, because it is necessary to control the two variables to extract the foreground region simultaneously, so the algorithm extraction results with thresholds of 30,50 and 70 when the flicker times are 1, 2 and 3 are selected. When the flicker number is more than 1 and the threshold is set to 50, the extraction results of the algorithm are still relatively normal, but the right part of the gray value and the background region are not well extracted, the extraction effect of the right part is getting worse and worse, so the algorithm also needs to adjust the parameters for the target image for a long time.

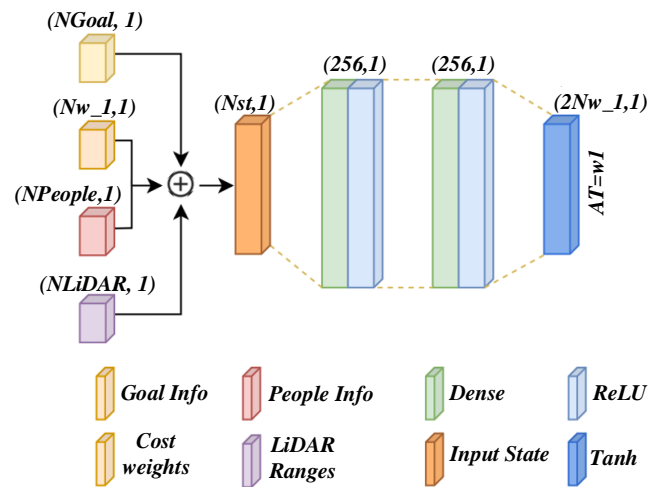

Fig. 2. Feature extraction and fusion strategy plots.

B. Direct Extraction Algorithm for the Foreground Area of Rural Landscape Interference Image Based on Stripe Sinusoidal Characteristics

Unlike the idea of guiding the unwrapping path through the branch cut line, the mass graph guidance method. The algorithm utilizes a tool called a "mass graph" to guide the choice of the mass graph guidance method is the need to define the neighboring solutions. The mass map is a two-dimensional image, where each pixel represents a combination of the search direction and the step size, while the color and direction can be selectively adjusted to achieve a more efficient search process. The idea of path tracking of mass graph guidance method is

similar to that of diffuse water filling method, Starting point selection first performed by phase quality evaluation parameters, The starting point is the point with the highest pixel quality in the parcel phase map, then establish the neighborhood window and its growth ring, Where the neighborhood window can be a cross or a field shape, Common neighborhood window size is 33, Unpackage the adjacent pixels in each direction, Fig. 3 shows the evaluation diagram of the training set and test set, And the phase mass of each point in the neighborhood window is stored in the growth ring from high to low, The highest mass point in the adjacent to each

pixel. Cycle this operation until the image completes phase unwrapping. Application of this method need to pay attention to growth ring memory, if the package image size is larger, in the process of cycle package growth ring internal pixel number will increase rapidly, this will lead to the algorithm of package efficiency decreased significantly, the need to pass the algorithm of growth ring processing, on the one hand, to ensure that the pixels solution package order does not change, on the other hand to control the size of the growth ring, said this process for growth ring dressing program.

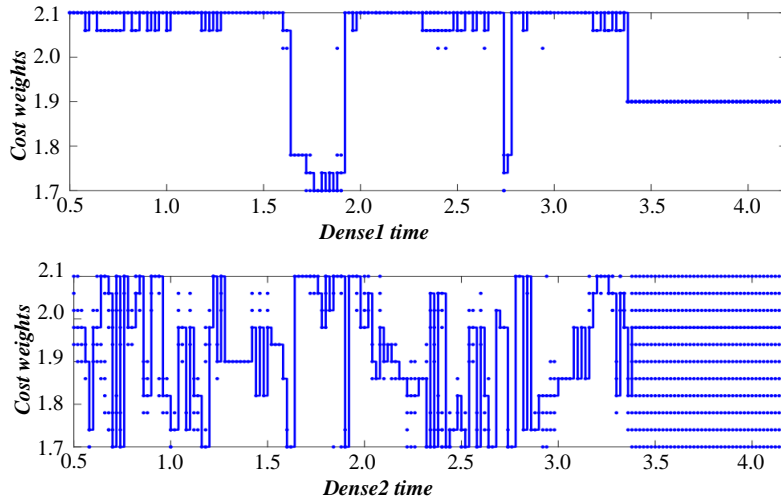

Fig. 3. Evaluation plot of the training set and the test set division.

In order to control the size of the growth ring, the value size needs to be pre-set. For MN size images, the growth ring size can be controlled by the size of MN. Next, the growth ring dressing procedure will work with the number of the pixels in the growth ring. When the number of points exceeds the preset value, the point with the mass value in the growth ring will be removed, and the lowest quality value in the remaining points will be set as the new mass threshold of the growth ring. The removed points were marked with special signs indicating that they were delayed points and would back into the growth ring in the subsequent process. In the next step, only those points with mass values above the threshold are deposited into the growth ring, while those below the threshold are labeled as deferred points. Points in the growth ring are constantly extracted for unwrapping until the growth ring is empty, when the growth ring threshold needs to be lowered (take 0) and the delayed points are put back into the growth ring for unwrapping. Table I shows the GSA pixel matching accuracy evaluation, and the above process is repeated until all points are unwrapped. There are three main parameters reflecting the phase quality: pseudo-coherence coefficient (PSD), phase derivative deviation (PDV) and maximum phase gradient (MPG). At present, the most widely used and most effective is the phase derivative deviation. The main influencing factor of the quality guide method for solving the package result is the image quality of the package image (including the accuracy of the foreground extraction technology and the stability of the shooting equipment), and the image quality will directly affect the accuracy of the final quality map guide. With good image

quality, the phase solution of the mass graph guidance method will be better than the other traditional path tracking algorithms. In the mass graph guidance method, there is also a technique called "taboo search", by recording and avoiding the previously searched solutions.

TABLE I. EVALUATION OF PIXEL MATCHING ACCURACY IN GSA

Appraise	Consult	The GSA algorithm results	Results of the method in this paper
Picture	Bear fruit	Pixel number	Accuracy
A group	408000	387681	73.67%
B group	408000	384975	72.98%
C group	745608	724625	75.81%

The mask cutting method, also known as the mask-based cutting algorithm, is a segmentation method based on image edges. The core idea is to divide the image into different regions according to the edge information in the image. The method can be seen as a combination of the pruning method and the mass graph guidance algorithm. It requires searching for residual debris and placing the branch cut line, but the difference from the branch cut method is that the branch cut line placement is guided by the mass map. The brief step is as follows: Select a mask to traverse the entire image, usually select a square or circular mask; move the mask along the edge of the image and calculate the difference of pixel value in the mask; divide the image according to the obtained boundary position, such as algorithms based on the threshold value and

area growth. The process of creating the mask cut line is similar to the pixel diffusion in the higher mass area, but the difference is that the process starts with a residual miss without equilibrium and then gradually spreads into the surrounding low mass area. Fig. 4 evaluates the graph as the loss function changes with the number of iterations. This process continues until the connected residue almost reaches equilibrium or reaches the image boundary. In fact, the process of generating the mask cutting line is a process of regional growth, so the

generated mask cut line is rough and needs further refinement. Whether the point on the mask cut line needs to be removed depends on two points: whether the point is close to the handicap; whether the point removal affects the connectivity of the mask cut line. The detection of near disability is simple, while the detection of connectivity needs to be conducted in the 33-neighborhood centered on this point. If the coordinates of this point are (i, j) , the point can be removed from the mask cut line if any of the following cases exist.

Fig. 4. The loss function changes with the number of iterations.

IV. AUTOMATIC IDENTIFICATION AND EVALUATION OF RURAL LANDSCAPE FEATURES BASED ON U-NET

Phase solution package is optical interferometry structure light projection measurement is a common problem in the field of contactless measurement, phase solution package algorithm in the 80s to 90s in the rapid development stage, this stage appeared a lot of for all kinds of phase solution algorithm, for the subsequent further development provides an effective theoretical basis, phase solution package algorithm basically can be attributed to algorithm reduces the unwrapping problem to the problem of optimal path selection, which uses the correlation of adjacent pixels in space. The classical algorithms based on path tracking mainly include: branch cutting method, mass graph guidance algorithm, mask cutting method and minimum discontinuity algorithm. Fig. 5 is the confusion matrix evaluation graph, which connects the detected positive

and negative residues into branch tangents and then bypasses them to unwrapping. The difficulty lies in the setting of the branch, doing a lot of work on the connection strategy of the branch, and proposing many improvement methods, and the effect is obvious. The quality map guide algorithm does not identify the residual or set the branch, but guides the solution path through the phase mass map. The mask cutting method combines the first two methods to guide the setting of branches by mass diagram, without rigorous process and detailed algorithm, which is the first feasible algorithm: minimum discontinuity algorithm. This method draws on the relevant theories of computer graphics, clever conception, solution accuracy and algorithm stability; moreover, proposes the regional growth algorithm, using the phase information of the surrounding pixels to predict the solution results and make consistency test, thus selecting the optimal solution path, achieving success in processing complex SAR phase data.

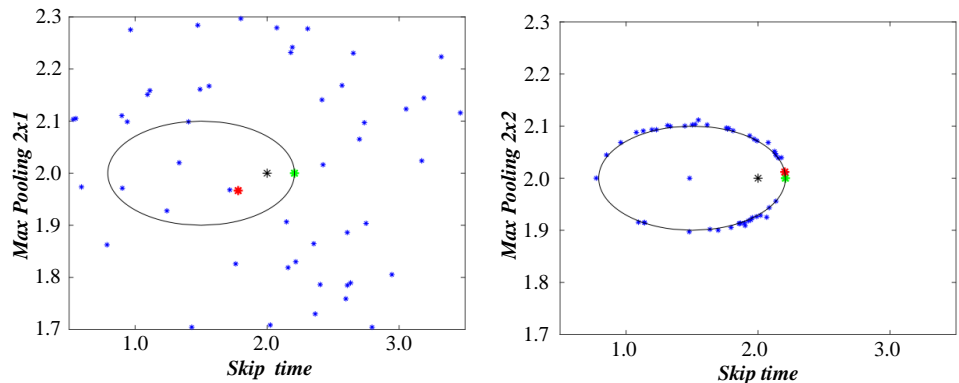

Fig. 5. Confusion matrix evaluation.

The problem of finding the minimum by calculating the minimum of the p power of the difference between the

synthetic phase gradient and the wrapping phase gradient. Initially, this method was limited to the least squares method,

divided into weighted least squares and no right least squares method. The concept of minimum norm is proposed, the least squares method is incorporated into this concept, and the significance of different norm values is clarified from the mathematical perspective, and the specific algorithm steps are given, which greatly enriches the understanding of parcel theory. After entering the new century, phase disassembly has entered the stage of diversified development. On the one hand, AI algorithms such as deep learning, genetic algorithms and ant colony algorithms were introduced into the branch method. Table II shows the RMA pixel matching accuracy evaluation to optimize the placement of branches. Compared with previous methods, the artificial intelligence algorithm can better place the branch line, but the characteristics of the branch method are difficult to work in the residual close density area. On the other hand, the network planning algorithm is introduced into the minimum norm method to try to solve this optimization problem through this optimization algorithm. The network planning method has better stability in the accuracy of these algorithms is still not high, and the efficiency is also general. In addition, filtering the parcel phase diagram is also a new development direction. Before unsolving the parcel, the parcel phase diagram is filtered first. While fully retaining the useful information, the noise is filtered out as much as possible to obtain the nearly perfect parcel phase diagram, so as to reduce the difficulty of unwrapping. The effect of this method is very significant on the images with severe noise interference. Different application fields have different requirements for unwrapping results. General algorithms have not appeared in the field of rural landscape interference image phase unwrapping. However, with the gradual iterative progress of neural network structure.

Traditional interferometry obtains useful information by directly analyzing interference stripes, but due by noise interference, stripe density and manual operation error. Phase shift technology is applied to optical interferometry. This new technique analyzes the phase difference to obtain the

information of the measured surface. The measurement accuracy is higher. In phase shift interferometry, the inverse triangle function is used to obtain the phase. Due to the nature of the inverse triangle function, the recovered phase information is limited to a fixed interval, so the phase data discontinuity caused by the restriction problem should be eliminated to obtain the real data. Therefore, it is necessary to find the discontinuous cutoff point in the parcel image through the algorithm and restore it to continuous phase information. This process is called phase unwrapping. After decades of optimization, the basic phase unwrapping algorithm is specifically divided into two categories: path tracking method and minimum norm method. Fig. 6 is the ROC assessment diagram, where the path tracking method is a local algorithm. The core idea of this algorithm is to search for another target pixel by evaluating the polarity of the pixel data and determining the polarity, and establish a connection during the search process. If the two pixels have opposite polarity, stop the search; if the polarity is the same, expand the search range and build connections based on their data quality and polarity until the two pixels have the same polarity or the search range reaches the maximum. Then, repeat to override all unconnected pixels throughout the image until the target pixels are searched. The path tracking method mainly includes branch cutting method, mass map guide method, mask cutting method and minimum discontinuity method.

TABLE II. EVALUATION OF PIXEL MATCHING ACCURACY OF RMA

Appraise	Consult	The RMA algorithm results		Results of the method in this paper	
		Pixel number	Accuracy	Pixel number	Accuracy
A group	475000	392478	92.21%	348272	98.14%
B group	464000	382577	97.53%	347864	97.25%
C group	737808	747816	96.42%	747884	98.31%

Fig. 6. ROC assessment.

Boundary function to cut down the subspace that is impossible to reach the optimal solution, so as to improve the search efficiency. First, determine the specific functions and constraints of the branch processing target, and then initialize the search queue and the current optimal branch point. The search queue contains the branch point to be expanded, and the

current optimal branch point can be set to positive infinity. Secondly, for each unexpanded node, the upper and lower bounds corresponding to the node are calculated and sorted according to this bound value, and then each node is expanded in the sorted order. Again, when extending a node, first check if a better solution appears, if so, update the current optimal

solution and compute the bound value of all possible extended nodes of that node and insert it into the search queue. Finally, the above steps are repeated until the wrapping image completes the branch tangent arrangement and the phase unwrapping. After sorting all the residues, the first round of search was started from the first residue in the sequence. Set a search window of size 3 around the remnant close, and traverse the pixel information at the edge of the window. The position of the edge was determined by searching for the residual handicap. First, two adjacent residues are found and connected to form an approximate branch tangent. Fig. 7 evaluates the

graph of the feature importance ranking, and then, determines. If so, the branch is considered to be equilibrium, you can stop the search; if not, find a new stump in the adjacent area and connect it to the existing branch and continue the search. When the whole search window is traversed, if still did not reach balance, expand the size of the search window, and on the edge of the search, until find the line balance conditions, size every 2 until to set the maximum size value, after completing the maximum size of the search, whether to achieve balance, will end the round of search. Furthermore, if the edge of the image is reached during the search, the search round also ends.

Fig. 7. Feature importance ranking evaluation.

In the phase unwrapping algorithm, starting from a point on the non-branched, unwrapping to the periphery. Before performing unwrapping, a series of judgments are required, including checking whether the point is at the edge of the image or the mask point and whether it has been unwrapped by another path. If none of the above conditions hold and the point is not branch, the solution can be performed. From the point where the package is completed as the starting point, judge again, and choose the appropriate path step method. Tra-walk through the entire image iteratively and untangle its normal parcel phase. An "island" is generated when the branch tangent forms a closed loop. These points are distributed on the branches and need to check if there is phase information that has been successfully unwrapped. If so, use this information to disentangle; otherwise, these points are "exceptions". By this way, we get the real phase distribution map, which effectively solves the error transfer problem caused by noise. The biggest advantage of branch cutting is it's very computationally efficient. In the case of less disability loss, the solution results are relatively credible. However, when the residue is dense, the algorithm will produce a large number of unreasonable branches and lines, which is easy to produce closed areas that

cannot unwrap, and can easily lead to errors in the unwrapping results. In addition, this method only uses residual missing information and ignores other information, so the placement of branch tangents lacks convincing criteria.

V. EXPERIMENTAL ANALYSIS

In the rural landscape interferometry, the phase is moved with a fixed step size, so the gray scale of the phase shift interference stripe shows a certain periodic change. Under ideal conditions, to simulate the phase-shift interference stripe image, it can be seen that when the phase shift is different, the difference of the pixel gray value at the same position reaches the maximum. Fig. 8 evaluates the model performance comparison, which has very obvious sinusoidal change characteristics. Simulated phase-shift interference stripe image after adding noise. It can be seen that under the influence of Gaussian noise such as noise, salt and salt noise (PSNR=13.3035) and the phase error of the interference stripe caused by the common light path, the interference stripe still has obvious sinusoidal change characteristics, which ensures that the algorithm logic can be stable in real situations.

Fig. 8. Model performance comparison evaluation.

Rural landscape interference stripe image groups of rows 150 of all pixels and observe the change in gray scale. In the measured rural landscape interference image, the sinusoidal variation of the interference fringe. The gray value of false foreground pixels in the background area does not change much by phase shift. Fig. 9 shows the overfitting detection evaluation diagram, so the characteristics of the pixels at different phases can be used to eliminate the wrong foreground information, while connecting the connected domain and improving the. The treatment is divided into grayscale mask M1 and repair mask M2 stages. The target image needs to undergo preprocessing, difference operation, gray scale set allocation, threshold extraction, neighborhood local variance analysis and other steps, to realize the direct extraction of the

foreground area of the final rural landscape interference image, to avoid the blur of image details.

To obtain the gray value of the processed image to extract the foreground area and take the image segmentation task. For example, the threshold needs to be set to extract the foreground area information of the rural landscape interference image. Mask cutting method is suitable for various types such as target detection, face recognition, medical image analysis, etc. Fig. 10 is the evaluation diagram of IoU index. Although the algorithm is simple and easy to understand, its dependence on edge information, the segmentation effect may be disturbed for some complex images, which needs to be optimized in combination with other image processing methods.

Fig. 9. Overfitting detection assessment.

Fig. 10. IoU index evaluation.

VI. CONCLUSION

In the process of feature identification, we should not only pay attention to the decomposition of landscape feature elements, but also the grasp of the overall landscape structure. Using landscape perception, field research detailed records of local survey information, combined with residents' interviews, increase a lot of subjective observation, this method can more accurately identify and understand the landscape features, help people understand the landscape characteristics of different landscape area, to manage the change of landscape characteristics, help local policy for its landscape change. In the path tracking method, the phase reciprocal deviation is used between the mass map and the weight parameters. The black pixel area appearing in each image represents the absolute value of its phase difference, which belongs to the discontinuous breakpoint appearing when the algorithm phase unwrapped the rural landscape interference image. Such points will have some impact on the restoration accuracy when the final rural landscape morphology error is restored. Longlong branch lines appeared in some areas, The reason for this kind of branch line is the failure to form a good closed ring or some area noise when calculating the phase difference value of adjacent points, The branch tangent has not formed the closure of the wrong package; The mass map guidance method is the good algorithm of phase unwrapping in the path tracking method, Unsuccessful discontinuous points in the unpacking results, However, since the phase quality evaluation parameters can be adjusted appropriately, Make the solution quality of the algorithm in the rural landscape interference image is better than the branch method; The image unwrapping quality of mask cut line method and mass map guidance method is similar, Although part of the branch fails to undergo good phase unwrapping, However, you can see the integral traces of the algorithm; The unwrapping mass of the minimum weighted discontinuity method is similar to the above method, Failure to solve the discontinuity problem in the unpacking process.

In order to further analyze the prospect extraction results, the segmentation results of all the pixels in each group of images are extracted, and the reference segmentation results of the three groups, the comparison algorithm segmentation results and the proposed algorithm segmentation results. The number of pixels in groups A and B was 408000 and 745608. Image similarity reached 97.84% in group A, 96.21% in group B, and 99.33% in group C. The accuracy of GSA algorithm is improved by 2.82%, 5.18% over ICF algorithm, 1.54% over RMA algorithm; GSA algorithm by 1.86%, 4.92% over ICF algorithm, 2.76% from RMA algorithm; GSA algorithm by 2.14%, 2.77% compared with ICF algorithm, and 1.27% over RMA algorithm. By comparison, the maximum accuracy of the algorithm is 2.82% and the minimum increase is 1.86%. Compared with the ICF algorithm, the maximum accuracy increased by 5.18% and 2.77%, the maximum accuracy increased by 2.76% and the minimum improvement by 1.27%.

Analysis of Customer Behavior Characteristics and Optimization of Online Advertising Based on Deep Reinforcement Learning

Zhenyan Shang, Bi Ge

Chongqing College of International Business and Economics, Chongqing 401520, China

Abstract—With the shift from traditional media to online advertising, real-time strategies have become crucial, evolving to meet contemporary demands. Advertisers strive to succeed in online advertising evaluations by demand-side platforms to secure display opportunities. Discrepancies in information evaluation can impact click-through rates, emphasizing the need for precise prediction models in asymmetric contexts. Time dynamics significantly influence online ad click-through rates, with rest hours outperforming working hours. This study introduces the ARMA model to refine click predictions by preprocessing hits and employing a single XGBoost model. Furthermore, a reinforcement learning model is developed to explore online advertising strategies amidst information imbalances. Data is segmented into training (70%), validation (15%), and test sets (15%), with model parameters optimized using the DQN algorithm over 48 hours. Validation and testing on separate datasets comprising 15,000 entries each yield model accuracies of 0.85 and recall rates of 0.82. The incorporation of regret minimization algorithms enhances reward functions in deep reinforcement learning. Leveraging Tencent data, a comparative analysis evaluates advertisers' click rates as overrated, underrated, or accurately predicted by DSPs. Findings indicate that smart customer behavior characteristics outperform DQN, converging swiftly to optimal solutions under complete information. Smart characteristics exhibit stability and flexibility, with human-machine collaboration circumventing the drawbacks of random exploration. Transfer Learning amalgamates experimentation with real-world insights, bolstering algorithm adaptability for intelligent decision-making tools in enterprises.

Keywords—Real-time online advertising; ARMA-XGBoost model; information asymmetry; deep reinforcement learning decision-making behavior; Transfer Learning

I. INTRODUCTION

The publishing platforms and advertising types of online advertising showed a positive trend of development. Online advertising with the Internet as the media, provides advertisers with a high-yield and low-cost way of delivery [1, 2]. Compared with expensive display signs and paper advertisements, online advertising, through big data matching technology based on the characteristics of the audience, can deliver the most accurate revenue for advertisers. At the same time, through the identification of user intention, online advertising can provide users with more interesting advertisements, achieving a win-win situation for users and advertisers [3, 4]. At present, online advertising is generally divided into three categories: sponsored search advertising, general display advertising and real-time

online advertising. In general, sponsored search ads are ads displayed in search results after users query their keywords on search engines such as browsers [5]. The general display advertisement will pop up when the user browses the website information, or when the user uses the mobile App, in the open screen animation of the software or the rotation map at the top of the home page [6]. The principle of RTB advertising is that advertisers design online advertising strategies, and through the demand side platform, online advertising on the web or the mobile App, to realize the advertisers to choose the corresponding advertising audience [7, 8].

RTB advertising has experienced explosive growth since its birth. In 2011 internationally, 88% of North American advertisers switched to RTB ads when they bought online ads. The RTB market is expected to grow to \$9 billion in 2023, or 40% of the total advertising budget. In China, the RTB market first started with the TANX system launched by Taobao in 2011. By 2013, the number of RTB AD requests in China had reached five billion, and the RTB investment budget for advertisers had increased by 300% to \$83 million [9]. RTB advertising is widely used in the era of mobile Internet. Compared with sponsored search advertising and general display advertising in the PC era, RTB advertising has changed the pattern of online advertising to a large extent. Every time in online advertising, you can accurately target the potential user audience, and select the most appropriate ads from the advertising library [10]. RTB iterates on data that is more relevant to user habits than focusing only on context keywords. Advertisers urgently need to make a more accurate prediction and evaluation of the display effect of advertising and design an appropriate online advertising model according to the estimated display effect. The display effect of advertisements can be evaluated by the conversion rate. The better the estimated display effect, the higher the cost of online advertising [11, 12]. Whether we can accurately predict the click rate is the key to the accuracy and effectiveness of the online advertising model. At the same time, in the actual online advertising process, multiple advertisers may participate in the online advertising auction. DSP ranks shot ads based on the effective click cost, and the highest ranked advertisers pay according to the broad second online advertising mechanism [13, 14].

In real, online advertising auctions, the price of online advertising needs to meet the cost constraints of the budget. How to accurately estimate the AD click-through rate, combined with the estimated click-through rate, participate in online advertising within the limited budget, win the DSP online advertising

evaluation has great research significance. In the background, the prediction and bidding model of real-time online advertising advertisements under asymmetric information [15]. After users see the ads they are interested in, they may click, download, register, buy and a series of behaviors, that is, the advertising effect has been transformed. Whether users respond to ads is one of the most concerned issues on the demand side. Users' download, registration and purchase behavior may cause longer delays, so scholars pay more attention to click-through prediction models, both in industrial applications and in academia [16]. In general, the click-through rate prediction model not only predicts the probability of users clicking after seeing an AD, but also describes how much the user is interested in the AD. Early AD click-through rate prediction models can be roughly divided into two categories: feature-based click-through rate prediction models and maximum-likelihood-based click-through rate prediction models. In feature-based methods, the prediction models are constructed based on page display features [17]. These features may include the text of the AD, the picture content, the location on the page, etc. Feature-based methods usually utilize logistic regression models. It describes the click and non-click behavior of ads as a dichotomy problem and is solved with a logistic regression model. Through the experiment, the model has a good prediction effect on the repeatedly displayed advertisements, and the accuracy of the prediction has increased steadily with the increase of the number of repeated displays [18, 19]. However, LR model is only effective for first-order features, and the ability to learn sparse features is poor. It relies on manual preprocessing of combined features, which should meet the shortage of complex data in practical applications.

II. INFORMATION ASYMMETRY IN REAL-TIME ONLINE ADVERTISING

A. Information Asymmetry Analysis in Real-Time Online Advertising

Maximum-likelihood-based methods attempt to smooth the response estimates using the advertised exposure and hits, such as the Gamma-Poisson model. As shown in Eq. (1) and Eq. (2), these methods are all based only on simple linear models and cannot capture the associations between the data. In this case, a hybrid method is proposed by combining the hierarchical information of advertisements and the display information through matrix decomposition using the display features of advertisements.

$$x_t = \phi_1 x_{t-1} + \phi_2 x_{t-2} + \dots + \phi_p x_{t-p} + \xi_t \quad (1)$$

$$z^p - \phi_1 z^{p-1} - \phi_2 z^{p-2} - \dots - \phi_p = 0 \quad (2)$$

This method uses MF to learn a set of latent features from the data while correcting the prediction results with a feature-based approach. However, the MF used in this method is limited to binary relationships and does not satisfy higher-order relationships. As shown in Eq. (3) and Eq. (4), in the factorization machine model, the implicit vector of the first-order combined features is calculated to obtain the weight of the second-order combined features.

$$\text{Cov}(\varepsilon_t, \varepsilon_s) = \sigma^2 \delta_{t-s} = \begin{cases} \sigma^2, & t = s, \\ 0, & t \neq s, \end{cases} \quad (3)$$

$$\hat{\rho}_k = \frac{\sum_{t=1}^{N-k} (x_t - \bar{x}_N)(x_{t+k} - \bar{x}_N)}{\sum_{t=1}^N (x_t - \bar{x}_N)^2} \quad (4)$$

The combination problem under sparse features is further solved. The concept of "field" is proposed on the FM model, classifying the features of the same properties into the same field and learning the hidden vector for each field. When learning different combinations of features, the internal product, as shown in Eq. (5) and Eq. (6), as the weight of the combined features. The experiment proves that FMM model can more accurately estimate the click rate of online ads compared with FM model.

$$LB = n(n+2) \sum_{k=1}^m \left(\frac{\hat{\rho}_k^2}{n-k} \right) \quad (5)$$

$$X_t = \phi_0 + \phi_1 X_{t-1} + \dots + \phi_p X_{t-p} + \varepsilon_t + \theta_1 \varepsilon_{t-1} + \dots + \theta_q \varepsilon_{t-q} \quad (6)$$

Although FM and FMM models can solve the combined characteristics well, their theoretical essence is still the second-order combined characteristics stage, so they are not much used in the industry. As shown in Eq. (7) and Eq. (8), when the application of the click-through rate prediction algorithm in the industry occurs, the following problems are encountered: First, the user's response to advertising is a dynamic process, which will change over time. The prediction algorithm of click-through rate needs to take into account the time factor when applying it to landing.

$$\hat{\rho}_k = \frac{\sum_{t=1}^{n-k} (x_t - \bar{x})(x_{t+k} - \bar{x})}{\sum_{t=1}^n (x_t - \bar{x})^2}, \forall 0 \leq k \leq n \quad (7)$$

$$\hat{\phi}_{kk} = \frac{\hat{D}_k}{D}, \forall 0 < k < n \quad (8)$$

Because mobile applications usually use cold start as a startup in order to save memory, most ads have little history in pages, or limited history. In order to solve the historical exposure rate of advertising or new advertising estimates, a hierarchical importance perception factor machine was developed, HIFM provides an effective general framework, as Eq. (9), Eq. (10), the framework combines importance weight and hierarchical learning, after experimental data validation, HIFM better than the existing FMM model in terms of time sensitivity, and the importance of HIFM perception and hierarchical learning plays a significant role in improving the cold start scenario.

$$\min AIC = n \ln \hat{\sigma}_\varepsilon^2 + 2(p+q+1) \quad (9)$$

$$x_t = \sum_{i=1}^p \phi_i x_{t-p} + \mu_t + \sum_{j=1}^q \theta_j \mu_{t-q} \quad (10)$$

B. The Impact of Information Asymmetry on Real-Time Online Advertising

In order to solve the problem of click rate prediction in industrial applications, a method of screening and combining features with gradient promotion decision tree is proposed by generating a discrete feature vector and taking it as the input parameter of the LR model. GBDT is essentially an integrated learner, as shown in Eq. (11) and Eq. (12), the combination of multiple decision trees can describe the differentiated feature combinations more accurately; compared with the single decision tree, the combination method of GBDT and time series is often applied in the recommendation system.

$$\text{Gini}(D) = \sum_{k=1}^K p_k(1-p_k) = 1 - \sum_{k=1}^K p_k^2 \quad (11)$$

$$\text{Gini}(D, A) = \frac{|D_1|}{|D|} \text{Gini}(D_1) + \frac{|D_2|}{|D|} \text{Gini}(D_2) \quad (12)$$

Also in the industrial applications, the improvement model is put forward. The model adopts the idea of partition and treatment, group and slice the samples, and LR model is used to predict the partition samples, as shown in Eq. (13) and Eq. (14). Finally, weighted regression is used to combine the results of the partition. The model is proven to fit complex nonlinear functions, and the LS-PLM model using L1 and L2 regulars has good sparsity, which improves the online prediction ability.

$$\Delta D_A = \text{Gini}(D) - \text{Gini}_A(D) \quad (13)$$

$$y = \sum_{k=1}^K f_k(x), f_k \subset \Gamma \quad (14)$$

With the in-depth research of deep learning technology in the advertising industry and the breakthrough results, deep neural networks have been realized to fit high-order combination characteristics through nonlinear functions, as shown in Eq. (15) and Eq. (16), so DNN technology is gradually used in the click-through rate prediction model. Based on the DNN model, the deep neural network model of the factorization machine is proposed. This model uses the hidden vector and its weight obtained by FM pre-training as the initial value of the neural network, and then provides the weight of DNN to learn higher-order features, and predicts the click rate of online ads.

$$\text{Obj} = \sum_{i=1}^n l(y_i, \bar{y}_i) + \sum_{k=1}^K \Omega(h_k) \quad (15)$$

$$\Omega(h_k) = \gamma J + \frac{\lambda}{2} \sum_{j=1}^J \omega_{kj}^2 \quad (16)$$

However, because the DNN model relies on the pre-training of the FM model, it affects the model performance. An improvement is proposed on the DNN model. As shown in Eq. (17) and Eq. (18), the improved PNN model can significantly improve the expression ability of the combined features. The DNN-based model predicts the click rate of online ads by solving the weights of higher-order combined features. We find the importance of low-order features for the prediction of online AD hits and propose Wide and Deep models for the combination of low-order and high-order features.

$$L_t = \sum_{i=1}^m L(y_i, f_{t-1}(x_i) + h_t(x_i)) + \gamma J + \frac{\lambda}{2} \sum_{j=1}^J w_{ij}^2 \quad (17)$$

$$g_{it} = \frac{\partial L(y_i, f_{t-1}(x_i))}{\partial f_{t-1}(x_i)}, h_{it} = \frac{\partial^2 L(y_i, f_{t-1}(x_i))}{\partial f_{t-1}^2(x_i)} \quad (18)$$

The model is divided into two parts, where the Wide part consists of a generalized linear model, and the Deep part is composed of a DNN model with three hidden layers. In past studies, as shown in Eq. (19) and Eq. (20), click rate prediction and bid optimization are usually carried out in order, firstly minimizing the error between the prediction result and the user response in the real situation by establishing the model. After obtaining the user response prediction result, it is used as input to optimize bids based on other factors such as activity budget, market price, etc.

$$L_t = \sum_{j=1}^J [G_j w_{ij} + \frac{1}{2} (H_j + \lambda) w_{ij}^2] + \gamma J \quad (19)$$

$$\text{score} = \max(\text{score}, \frac{1}{2} \frac{G_L^2}{H_L + \lambda} + \frac{1}{2} \frac{G_R^2}{H_R + \lambda} - \frac{1}{2} \frac{(G_L + G_R)^2}{H_L + H_R + \lambda} - \lambda) \quad (20)$$

III. ONLINE ADVERTISING MODEL BASED ON REINFORCEMENT LEARNING

A. CNN Incomplete Information Game and Regret Minimization Algorithm

When a user views the web page or opens a new page in the mobile App, one or more RTB AD spots will appear on the page. The reserved AD space on the page will launch an online AD display request to the supplier platform that provides the advertising agent for the website through the pre-written script code [20, 21]. After receiving the online AD request by clicking the AD display on the user page, the supplier platform SSP will send the AD space information and the web context information to ADX, the AD trading platform that performs the online advertising RTB [22, 23]. AD trading platform ADX receives online AD requests and publishes them to the DSP. In this process, the same online AD request may be sent to multiple different DSPs simultaneously. Fig. 1 shows an overview of the deep reinforcement learning framework. Each demand-side platform publishes details of online advertising requests to advertisers and carries out the first round of online advertising within the demand-side platform. Advertisers can query users' basic personal information, such as education, occupation, gender, etc. After query information, make a decision whether to participate in online advertising auction according to the established online advertising strategy [24, 25]. If you participate in online advertising, you will return your bid to the DSP. After the demand-side platform DSP receives the bid request of each advertiser, it will first rank the bid of each advertiser from the highest to the lowest level.

The advertisers with the highest bids will win the first round of online advertising. The DSP returns the graphic or video information of the top-ranked advertisers together with the bidding price determined by the broad second-highest price mechanism. Each demand side carries the highest-ranked advertising information and bidding price to participate in the second round of online advertising in ADX [26, 27]. ADX ranks

the bids of each demand side, and the highest-ranked demand side wins the second auction. Table I shows the values of AIC, BIC and HQIC, which won the first round of auction by the demand side. The advertising trading platform sends the information of the advertisement to the supplier platform. The supplier platform SSP transmits the advertising text, advertising links or advertising video information of the online advertising winner among the advertisers to the page viewed by the user, and the data will be displayed to the user after rendering through the page [28, 29]. After seeing the advertisement, users may click on the advertisement because of their own interests or be attracted by low discounts, or log in to register the website in the advertisement to complete the transformation, or they may feel that the content of the advertisement is novel and interesting, so they share the advertisement [30]. The complete RTB process describes a two-stage auction. That is, in each DSP internal, the advertisers carry out online advertising auctions. The green box mark part is the second stage of the auction, where each DSP with the highest ads in the first round of online advertising ranking, the second round of online advertising in ADX, competing for the display opportunity of advertising.

Online advertising with accurate positioning of users, and efficient online advertising mechanism, significantly improve users' use experience and delivery efficiency. A top DSP company such as Byte Dance can handle Cookie data from more than 570 million Internet users and use 3,155 attribute tags to represent each Cookie. The DSP sells more than three billion AD displays a day, with each AD display being auctioned off within 50ms. With this Cookies-based audience targeting technology, the market efficiency and effectiveness of RTB advertising have been increased by 50%. It is the Internet big data analysis technology that makes RTB advertising more accurate, controllable and efficient, and also makes RTB become the standard business model of the future online advertising market. The link of RTB is very complex and has a lot of uncertain factors. Fig. 2 shows the updated flow chart of the state-action value function. Therefore, it has certain practical significance to design an applicable online advertising model. When the settlement is CPM, the risk of advertising is estimated and controlled by the demand side. At the same time, because there is no quantification of the user's subsequent behavior, it is difficult to calculate and analyze the advertising effect. When

the settlement is made by CPC, the supplier platform SSP can obtain a relatively accurate click rate estimate through the historical user data, and since the subsequent conversion is conducted in the AD demand side site, the AD demand side can make more accurate click value estimation. When the settlement is made by CPA, there is no risk of loss to the demand side, and the supply side is more difficult to operate. So now, in the form of CPA the settlement of online advertising, is gradually decreasing. Through comparison and synthesis, the settlement method of settlement by the click of advertising is the most beneficial to give full play to the advantages of the advertising supply side and the advertising demand side, so the CPC settlement method is widely recognized and accepted in the advertising market. From the perspective of CPC settlement, the online advertising model is discussed.

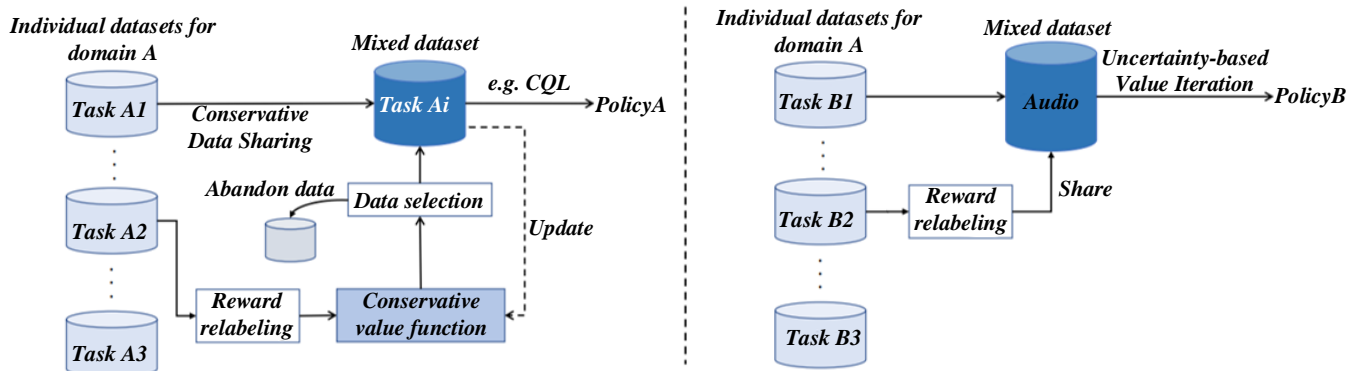

Fig. 2. State-update flow chart of the action value function.

B. Improve the DQN Customer Behavior Characteristic Analysis Model

After receiving the online advertising notification, advertisers use the known information to predict the click-through rate. After the advertiser gets the forecast result, the bid decision is made based on the value that the user's click brings to the brand, the advertising budget, the importance of the advertising space and other information. In most cases, the advertisers' bids are independent of each other. After receiving the quotation returned by each advertiser, DSP will also use known information to predict shot advertisements, calculate eCPC and rank online ads. In this calculation, advertisers with

low click-through rate predictions cannot get advertising opportunities with high offers alone. To verify the proposed model, this paper introduces the famous advertising company, the published data training set for the global RTB algorithm competition. After pre-processing the data, it was found that the exposure of the advertisement changed periodically, and the exposure during the weekend period was significantly higher than the weekday's period. Fig. 3 is a graph of feature selection and network structure optimization algorithm. At the same time, the exposure at 12 and 22 points during the rest time is significantly higher than the working and sleep time. Before modeling the time series, the original sequence is required to verify the stationarity requirements.

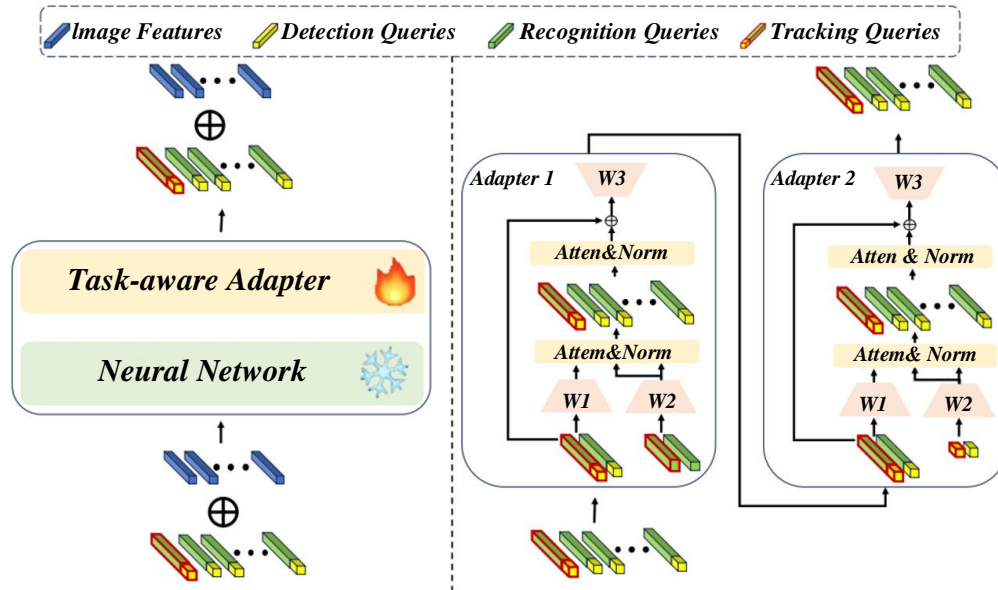

Fig. 3. Feature selection and network structure optimization algorithm.

The pattern of the characteristics of non-stationary sequences at various time points change randomly, which needs to be transformed by differential or logarithmic processing, and then modeling analysis. The randomness test is also known as a white noise test. In general, a white noise test of the stationary sequence is required before modeling to determine whether it has an analytical value. Table II shows the cross-entropy of different algorithms. In the time series model, the more unknown parameters contained, the more the independent variables are included, and the more flexible the corresponding model changes, the higher the accuracy of fitting the model and the greater the likelihood function value; however, when the number of unknown parameters in the model increases, the instability of the model becomes more difficult to fit the model. In general, a time series model is a good model when it considers the fitting accuracy and the number of unknown parameters.

TABLE II. CROSS-ENTROPY OF THE DIFFERENT ALGORITHMS

Algorithm Name	Logloss Cross Entropy
LR	0.423
XGBoost	0.414
ARMA-XGBoost	0.391

In the AD click rate prediction, the classification regression tree is generally chosen as the weak learners. The nature of the classification tree: First, make the basic assumptions, assume that the model is a basic binary tree, and then divide the nodes in the tree by constantly learning the features in the data set, and finally generate the classification tree that meets the expectations. In this article, By dividing it from the top down, The CART classification tree construction using a greedy strategy, Each child node in the tree is split according to the impurity of the subset elements, The urity of the set D that requires training using the Gini Expo measure, For the dataset D included in each node, XGBoost The model training goal is to computational solve the model to find the most appropriate division criterion and the final division value, Making the absolute value of the Gini index difference before and after the split, Fig. 4 shows a comparative evaluation chart of the effect of advertising channels, DA represents the size of the information gain: XGBoost has made great improvements in the algorithm and engineering application of GBDT. GBDT iterates on a set of weak learners, such as a decision tree, and outputs the final prediction results. Specific can be described as the error rate of the iterative decision tree to update the weight of the training set, and through the result of multiple decision tree accumulation as the prediction results output, through the

precise algorithm for all the information gain calculation value, select the maximum feature again using accurate algorithm for segmentation, get the corresponding training feature barrel. However, this order is not the optimal solution. According to Bayesian decision theory, the learning goal of the user response model should be determined by the final bid utility. In the paper, it is proposed that the accuracy of click rate required to predict and the computing resources are not the same within the range of all advertisements to be predicted. The prediction methods and the allocation of computing power should focus on cases

with higher return on investment and learn how to predict more accurately. Therefore, the market price and competitive performance are included in the model, and if the investment return of an advertising space is relatively high, the confidence of whether the advertiser can take the advertisement will be predicted. When the confidence is low, the optimization method of click-through rate prediction and the allocated computing resources should be more concentrated than the advertising space with low investment return on ratio.

Fig. 4. Comparison and evaluation diagram of the effect of advertising channels.

IV. RESEARCH ON CUSTOMER BEHAVIOR CHARACTERISTICS ANALYSIS AND ONLINE ADVERTISING OPTIMIZATION BASED ON DEEP REINFORCEMENT LEARNING

Grid search is a model hyperparameter optimization technique, which is essentially an exhaustive method. For each hyperparameter to be determined, a smaller finite set is chosen to explore. Then, we find the Cartesian products of the selected parameters to obtain several combinations of the hyperparameters. The grid search method trains the model using a combination of hyperparameters and selects the combination of hyperparameters that minimize the validation set error as the final parameter of the model. In the process of practical model training, the cross-validation method and the grid search method are usually combined, as the method of parameter evaluation, and this comprehensive method is recorded as the cross-

validation grid search method. Fig. 5 shows the time evaluation chart of customer click behavior, and divides the labeled training data in the data set into n-folds for cross-validation. First in the super parameter grid search parameter calculation, and then each set of super parameters into the model for n fold training, select the score of the highest super parameter combination into model, using the model to train the training set data, while using the validation set data validation model training results, get the final results. In this paper, the area enclosed between the receiver working characteristic curve and the coordinate axis and the cross-entropy Logistic Loss is used to evaluate the prediction results of the click rate prediction model. AUC value evaluation index. In the online advertising auction, in order to ensure the maximum benefit and disturb users as little as possible, the accuracy index of the model is very important.

Fig. 5. Time assessment chart of customer click behavior.

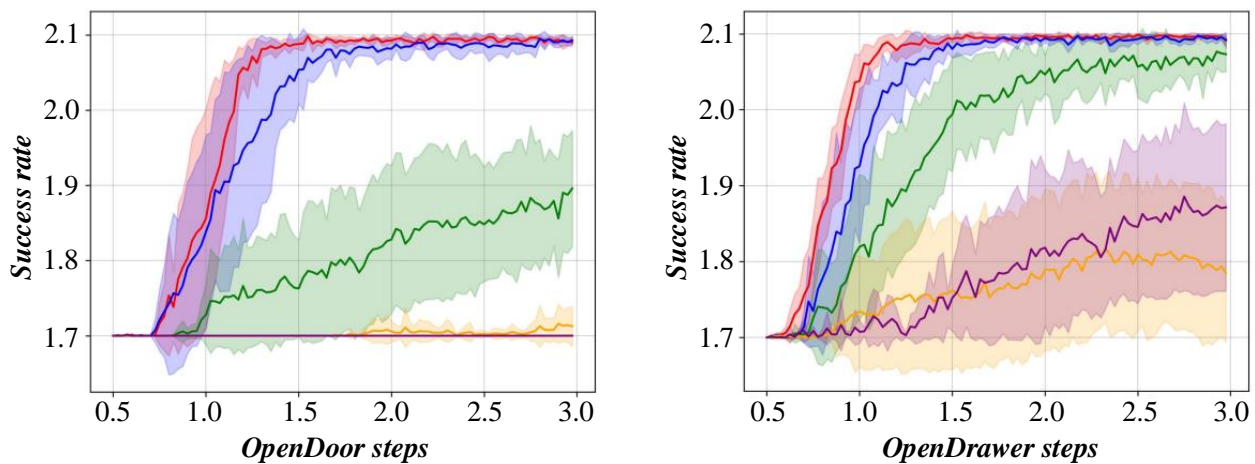

Fig. 6. Assessment chart of AD exposure and conversion rate.

The AUC value is the area obtained by calculus calculation of the ROC curve and the coordinate axis. It indicates the probability that the two samples are randomly selected and predicts the probability that the click rate. Where R_{ins} , i represents the serial number of the sample, M represents the number of positive cases, and N represents the number of counterexamples. AUC value range between $[0, 1]$, when the model AUC value of 0.5 represents a random classifier, the selection of threshold. The higher the AUC score indicates that the better the classifier predicts in the AD click rate prediction problem, the more meaningful the online advertisement. Game theory is based on rigorous mathematical models and introduces the limits of confrontational conflict in the real world. Fig. 6 shows the evaluation chart of advertising exposure and conversion rate, which defines the dominant strategy as follows: assuming that during the game process, the participants will adopt a certain strategy for any strategy choice of the other party. On this basis, if the strategy combination of all the players in the game is the dominant strategy for the other side, then the strategy combination of the two players is called the Nash equilibrium. The RTB online advertising problem discussed in this paper constitutes information asymmetry because the two parties do not know the other party's prediction of the click-through rate. But traditional game theory requires a complete set of situation information and strategies, such as in Texas Hold 'em, the opponent's cards must be a subset of the complete cards; in Go, the opponent's next strategy must be one of the feasible positions on the board. Therefore, the RTB online advertising problem discussed in this paper does not satisfy the incomplete information game; but it can make references for the incomplete information and its solving methods.

In actual online advertising, the demand parties need to compete with each other in order to win the first auction round. In addition, in the process of continuous auction, both parties can push back the asymmetric information about the click rate by observing the auction results and testing the bid many times.

Thus, it develops in the direction of an evolutionary game and achieves the equilibrium of the game through trial and error. In the first round of an auction, different demand parties may offer different bids, but they all face the DSP when predicting the click rate to calculate the eCPC ranking. Therefore, the scenario of the first round of auction is simplified, considering only the interaction between a single AD demand side and the DSP, and not the competition between the demand sides. In the process of continuous auction, the AD demand side and DSP may speculate positively or reverse the information about each other to achieve the dynamic equilibrium of evolution. However, in the early stage of the auction, designing the bid model for the unequal information between the parties is still beneficial to gain more benefits, and helps to seize the first advantage in evolution. In recent years, the ability to process large-scale data, discover the underlying features and extract the underlying features, so as to achieve specific goals more accurately. Fig. 7 shows the evaluation diagram of customer interest preferences at different ages. As a learning method with interactive ability, the online advertising decision model based on reinforcement learning is essentially a Markov decision process. Markov decision process has the characteristics of interacting with the environment, so this kind of model has the natural characteristics of modeling online advertising decision behavior, and the application of exploration mechanism can make the agent more fully explore the state and action space, and improve the accuracy and diversity of decision results to a certain extent. Among them, the online advertising decision system based on reinforcement learning consists of the current environment of the agent, the budget, the remaining advertising space and the information mastered by the DSP. In the process of the interaction between the agent and the environment, the decision agent constantly explores the decision scheme for the agent to obtain the maximum revenue according to the given budget, obtained traffic and other information, decide the bid at each auction time, and finally spends the budget to presents a decision scheme.

Fig. 7. Assessment chart of customer interest preferences at different ages.

Action space A: Action A represents the current moment, when the decision agent decides for the probability that the decision agent takes action a under state s , updates the budget and click rate, and moves to the next state S' . If the AD is won; if the AD is not won, one online advertising opportunity is lost. The decision agent can be converted to an immediate reward $R(s, a)$ based on the feedback results. Discount factory: the factor that determines the value of long-term rewards at the current moment, the decision agent uses the greedy method, which is only considered for the immediate rewards; when $\gamma=1$, the subsequent rewards have the same value at the current moment. Strategy π represents the basis for an individual taking an action, with its data described as a conditional probability distribution, namely the probability of taking an action a at state s . Action value function: the decision agent takes action A according to the strategy. The value function is an expectation function. Although $R_t + 1$, if only referring to the delay reward, it is easy to ignore the global situation and fall into the local optimal solution. Therefore, it is necessary to consider the delay reward of the current action and the potential delayed reward of the subsequent action. This section refers to the CFR algorithm for solving incomplete information games and improves the setting of the reward function in DQN. The regret value calculation method in CFR is introduced to set the reward function by taking the bid action and getting the environmental feedback regret value. The traditional Q-Learning reinforcement learning algorithm uses Q table to store data when making online advertising decisions. However, when the bidding environment is complex and the advertising space becomes more, Q table becomes huge and causes storage problems, and the search problem caused by the increase of data volume is easy to lead to the explosion of algorithm dimension. At present, in order to solve this problem, the industry generally uses other solutions to replace the Q value table, the most widely used is to use function approximation to replace. However, because the function approximation is calculated by calculating the value function, this alternative method is prone to the instability of the algorithm model and the failure to converge. The DQN algorithm combines the advantages of the traditional reinforcement learning algorithm Q-Learning and the deep neural network, which significantly improves the instability problem when the algorithm approximates the value function, which solves the problem of model instability and convergence to a certain extent.

V. EXPERIMENTAL ANALYSIS

The core idea of the DQN algorithm is experience playback. During the training process, the reward results and model state update of each environment interaction are saved to the specified position, so that they can be used for the subsequent update operation of the target Q value. Fig. 8 for customer purchase path evaluation diagram, generally speaking, through the Q network calculated Q value and through experience playback target Q value will have some error, when the need to reduce the error can through the Q value gradient backpropagation to update the deep neural network parameter w , when the parameter w convergence, can get less error of approximate Q value.

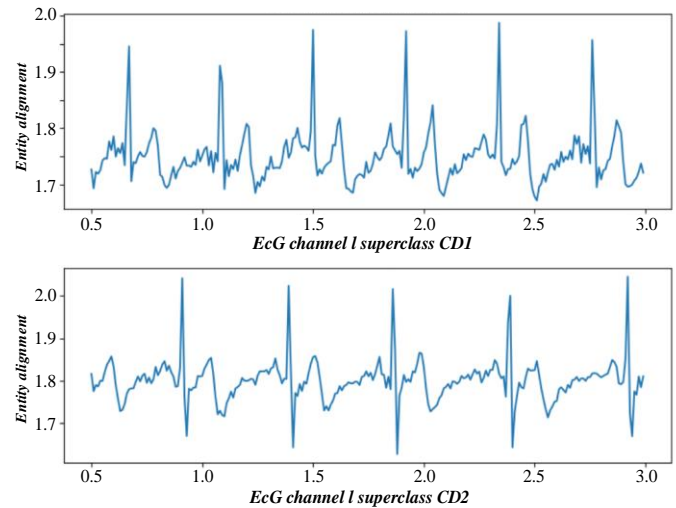

Fig. 8. Customer purchase path evaluation chart.

In reinforcement learning, the agent needs to explore in the current state to make better decisions, so as to obtain better returns, and choose the corresponding strategy to make the expected decision accordingly. The commonly used action selection strategies are the e-greedy algorithm. This paper selects the e-greedy algorithm. E-Greedy algorithm is a multi-arm gambling algorithm improved based on the greedy algorithm. Fig. 9 shows the evaluation diagram of the correlation of advertising creative type and click-through rate. In order to

avoid the agent always choosing the action with the current highest return to make the calculation probability of action execution. To obtain a better selection strategy, the strategy is randomly selected at probability E in the initial state.

In order to verify and analyze the prediction model and the subsequent online advertising model, the data set published by Tencent's 2019 advertising algorithm competition was selected. Fig. 10 is the evaluation chart of advertisement exposure during active time, which will hereinafter referred to as Tencent Data Set. In RTB transactions, Tencent can act as an advertiser to promote their games, or as an advertiser to publish ads for other brands on social platforms.

Therefore, Tencent's data set includes the whole process data and log of online advertising from online advertising to display

and complete transformation: including historical exposure log, user characteristic and attribute data, advertising static data and advertising operation data. According to the assumptions of the model, the information inequality between the DSP and the demand side is discussed separately. Fig. 11 shows the cost-benefit analysis and evaluation chart of advertising, considering the following three experimental designs: the click rate predicted by the preset DSP is higher than the demand side, the click rate predicted by the preset DSP is lower than the forecast result of the demand side; and the real prediction results of the participants after dividing the data set. In the ideal stage of the initial transaction, by analyzing the winning results feedback by DSP, the estimated range of the DSP click rate is obtained.

Fig. 11. Cost-benefit analysis and evaluation chart of advertising delivery.

VI. CONCLUSION

This paper introduces the common settlement method of online advertising, and introduces the eCPC formula of calculating online advertising ranking in the real production environment. Public information and private information in RTB transactions are defined and divided. This paper analyzes the problems caused by information asymmetry in the process of online advertising. Considering the difference in DSP and advertisers in the first auction, there is information asymmetry in online advertising. In this paper, the reinforcement learning model is designed, and the AD click rate is underestimated or overestimated by DSP, and the real prediction situation is designed respectively. The experiment shows that in the three scenarios, the click rate of improved DQN is higher than the traditional online advertising model. In the case where the click-through rate of advertising is overestimated by DSP, the high-frequency bid low-price advertising can maximize the interests of advertisers; in the situation where the click-through rate is underestimated by DSP, the low frequency for high-value advertising space is conducive to the exposure of the advertisement; in real scenes, using 10% of the budget to explore the environment, the price distribution of the final bid of the decision agent is the same as the distribution of click-through rate prediction results.

DSP and advertisers' click-through rate estimates follow a random distribution, and the prediction results are different in different ads. The prediction model of the final DSP has 23 inputs for training features and advertisers have 21 inputs for training features. According to the prediction results, the gap of DSP and advertisers within 0.02 was 15.7%, DSP higher than advertisers 41.7%, and DSP lower than advertisers 42.6%. LinBid Online advertising of Experiment 1 and 2, the LinBid winning rate always increases linearly with the budget. In contrast, the winning rate of the proposed improved DQN algorithm fluctuates greatly with the budget, and the improved DQN algorithm increases significantly when the budget increases. If the DSP predicted click-through rate is higher than the advertisers, the advertisers adopt the "positive" bidding

strategy, high frequency bid low price ads, and achieve the click target; if the DSP predicted click-through rate is lower than the advertisers, the advertisers adopt the "cautious" bidding strategy, low frequency bid high price advertising, high price advertising, can significantly improve the return-on-investment ratio. When DSP has accumulated the user information of the brand and the transaction environment is gradually complex, DSP may overestimate or underestimate the click-through rate prediction results of advertisers: when the budget is low, advertisers can consider using the relatively stable LinBid online advertising model to bid based on the historical transaction price and the clicks predicted by advertisers. When the budget is high, and the pursuit of high profit, 10% of the budget to explore the proportion of the number of low-priced and high-priced ads in the final bid follows the proportion of the number of ads whose click rate is overestimated and undervalued by DSP.

Logistics Transportation Vehicle Monitoring and Scheduling Based on the Internet of Things and Cloud Computing

Kang Wang*, Xin Wang

School of Economics and Management, Jiaozuo University, Jiaozuo, China

Abstract—This paper addresses challenges in the logistics industry, particularly information lag, inefficient resource allocation, and poor management, exacerbated by global economic integration and e-commerce growth. An advanced logistics and transportation vehicle monitoring and scheduling system is designed using IoT and cloud computing technologies. This system integrates Yolov5 for real-time vehicle location, DeepSort for continuous tracking, and a space-time convolutional network for vehicle status analysis, forming a comprehensive monitoring model. An improved multi-objective particle swarm optimization algorithm optimizes vehicle scheduling, balancing objectives like minimizing travel distance, time, and carbon emissions. Experimental results demonstrate superior performance in real-time monitoring accuracy, scheduling efficiency, arrival time prediction, road condition forecasting, and failure risk prediction. Notable achievements include 95% vehicle utilization, a 0.25 RMSE for predicted arrival times, and a 0.20 MAE for failure risk prediction. While the system significantly enhances operational efficiency and supports resource optimization, future work will focus on data security, system stability, and practical deployment challenges. This research contributes to transforming the logistics industry into a smarter, greener, and more efficient sector.

Keywords—Internet of Things; cloud computing; logistics and transportation; vehicle monitoring; vehicle scheduling

I. INTRODUCTION

In the context of accelerated global economic integration and the rise of e-commerce, logistics plays a critical role as the bridge between production and consumption. However, the traditional logistics model faces significant challenges, including information lags, inefficient resource allocation, and low management effectiveness, which hinder the industry's potential and efficiency [1]. On one hand, the slow pace of information updates does not match the rapidly evolving business environment. In traditional systems, the lack of a real-time, transparent information flow mechanism leads to asymmetric information across the supply chain, impacting decision-making and causing issues like cargo delays and retention. On the other hand, inefficient resource utilization is another pressing issue [2]. Common problems include empty vehicles, idle warehouses, and redundant manpower, indicating significant room for optimization in capacity planning, warehouse layout, and human resource management. These inefficiencies increase logistics costs and undermine sustainability. Furthermore, limitations in management efficiency are evident, with traditional models and techniques

making it difficult to achieve refined and intelligent management in areas such as order processing, distribution scheduling, and customer service [3].

To address these challenges, the logistics industry must embrace new technologies like IoT, cloud computing, big data, and AI to develop smart and efficient logistics and transportation vehicle monitoring and scheduling systems. This will enable the industry to innovate and upgrade, transitioning from information technology to intelligence, and ensuring competitiveness in the global logistics landscape. A technology share diagram for vehicle monitoring and scheduling is shown in Fig. 1.

Fig. 1. Technology shares in-vehicle monitoring and scheduling (Source: UCI machine learning repository).

In the context of global economic integration and the rapid evolution of e-commerce, the logistics industry, as a core link connecting production and consumption, is becoming a key driver of global trade and economic growth. However, the traditional logistics model faces significant challenges, including information lags, unbalanced resource allocation, and low management efficiency, which hinder the industry's potential and efficiency [3].

*Corresponding Author.

Information transmission lags and the absence of real-time, transparent information sharing mechanisms lead to asymmetric information across the supply chain, affecting decision-making and causing issues like cargo delays and delivery holdups [4]. Unreasonable resource allocation, such as empty vehicles and wasted storage space, highlights significant optimization opportunities. These inefficiencies increase costs and undermine sustainability goals. Extensive management practices further limit service quality and customer satisfaction [5].

While there have been discussions about using new technologies to improve logistics efficiency, key issues remain unresolved, such as how to integrate IoT and cloud computing technologies to achieve intelligent upgrades, and how to address real-time data processing, resource optimization, security, and cost control [6].

To address these challenges, this study proposes an innovative logistics transportation vehicle monitoring and scheduling system based on IoT and cloud computing technologies. The system aims to promote the intelligent transformation of the logistics industry by focusing on (1) Building a comprehensive logistics vehicle monitoring network using IoT technology for transparent supply chain management. (2) Leveraging cloud computing for efficient data processing and storage, enabling deep analysis of logistics data to improve scheduling accuracy and efficiency. (3) Optimizing vehicle scheduling through intelligent algorithms to reduce idle time, optimize routes, and minimize energy consumption. Additionally, enhancing safety management during logistics transportation. (4) Optimizing logistics resource allocation through data analysis to improve the efficiency and service quality of the entire logistics chain.

The research innovations include: (1) Combining advanced computer vision technology (Yolov5 for vehicle positioning) with DeepSort tracking and spatio-temporal convolutional networks to create a comprehensive vehicle condition monitoring system. (2) Introducing and optimizing a particle swarm optimization algorithm, particularly focusing on multi-objective optimization strategies to resolve common conflicts in logistics transportation, such as balancing cost, time, and environmental impact. (3) Designing an end-to-end technical framework from data acquisition to intelligent decision-making, ensuring the solution's comprehensiveness and operability.

This paper addresses the challenges faced by the logistics industry, proposing an advanced logistics and transportation vehicle monitoring and scheduling system using IoT and cloud computing technologies. The system integrates Yolov5 for real-time vehicle location, DeepSort for continuous tracking, and a space-time convolutional network for vehicle status analysis. An improved multi-objective particle swarm optimization algorithm optimizes vehicle scheduling, balancing objectives like minimizing travel distance, time, and carbon emissions. Experimental results demonstrate superior performance in real-time monitoring accuracy, scheduling efficiency, arrival time prediction, road condition forecasting, and failure risk prediction. Notable achievements include 95% vehicle utilization, a 0.25 RMSE for predicted arrival times,

and a 0.20 MAE for failure risk prediction. The paper is structured as follows: Section II provides a literature review and related work; Section III describes the methodology and technical framework; Particle Swarm Algorithm is given in Section IV; Section V presents the technical framework; Section VI presents the experimental setup and results; finally, Section VII concludes the paper and outlines future research directions.

II. LITERATURE REVIEW

A. Vehicle Monitoring Methods

In today's logistics and transportation industry, IoT technology has become an important tool for realizing efficient vehicle monitoring, which significantly enhances the transparency and controllability of the logistics and transportation process by integrating a variety of sensing devices to collect real-time and accurate information about the status of vehicles and their cargo.

1) *Application of IoT technology in vehicle monitoring and control:* The use of Internet of Things (IoT) technology in logistics vehicle monitoring has gained widespread scientific attention and practical application. Technologies such as GPS global positioning systems [8] are commonly embedded inside vehicles and can continuously provide real-time geographic location of vehicles, which not only supports precise geographic navigation, but also can be used to track the trajectory of logistics vehicles to ensure compliance and efficiency of transportation routes [9]. In addition, on-board rfid (radio-frequency identification) tags and reader systems [10] can monitor the identity and status changes of goods in real time, effectively preventing misallocation or loss of goods. Environmental monitoring equipment such as temperature and humidity sensors [11] can monitor the temperature and humidity conditions of the goods in real time to ensure the safe preservation of perishable or special goods during transportation.

2) *Data transmission and processing:* The massive amount of data generated by IoT devices must be efficiently transmitted and processed before it can be transformed into valuable information. Advances in wireless communication technologies, such as 4g/5g wide-area networks [12] and narrow-band IoT (nb-IoT) technology [13], provide high-speed, stable channels for data transmission from IoT devices, ensuring real-time transmission of vehicle monitoring data to cloud servers. The cloud computing platform plays a crucial role in this process. Through the infrastructure provided by cloud service providers such as alicloud, aws, azure, etc., the data collected by IoT can realize large-scale and highly concurrent data storage [14]. In addition, cloud computing platforms use their powerful data processing capabilities to clean, integrate, and analyze the collected data in real time, and even perform deep mining through machine learning algorithms [15] to report on operating conditions, predict failures, and optimize scheduling strategies. For example, a study [16] successfully realized remote monitoring and intelligent warning of logistics vehicles by building a cloud

computing-based IoT platform, improving the safety and efficiency of the transportation process. The study shows that by combining IoT data with cloud computing, it can not only effectively solve the problem of information silos in logistics and transportation, but also greatly improve the management effectiveness and customer service satisfaction of logistics enterprises.

Despite the advancements in IoT technology for vehicle monitoring, several limitations persist. One critical challenge lies in the interoperability and standardization of IoT devices across different manufacturers and platforms, which can result in data inconsistencies and compatibility issues. Moreover, the sheer volume of data generated often surpasses the analytical capabilities of some organizations, leading to a gap between data collection and actionable insights. There is also a need for more robust cybersecurity measures, as the increased connectivity exposes logistics systems to higher cyberattack risks [26]. Addressing these limitations requires the development of universal standards, enhancing data analytics capabilities, and implementing advanced security protocols.

B. Vehicle Scheduling Model

1) *Traditional vehicle scheduling models*: Traditional vehicle scheduling models have always been the core theoretical basis for logistics and transportation optimization, and the most representative ones include the capacitated vehicle routing problem (cvrp) and vehicle routing problem with time windows (vrptw). The cvrp model focuses on solving the problem of how to plan the shortest total distance traveled path to serve all customers while ensuring that each vehicle does not exceed its cargo capacity [17]. The vrptw model, on the other hand, adds complexity to this by not only considering vehicle capacity constraints but also ensuring that each customer is served within a preset time window. Although these models play an important role in rational allocation of resources and cost reduction, they mainly rely on pre-set static information and cannot adapt to changes in the external environment in real-time. For example, in real logistics scenarios, the uncertainty caused by traffic congestion, sudden demand changes, vehicle failures, etc., makes the traditional scheduling model show obvious limitations in solving the real-time scheduling problem.

2) *Intelligent scheduling model Based on IoT and cloud computing*: With the rapid development of the Internet of Things (IoT) technology and cloud computing technology, a new type of vehicle scheduling model with highly flexible and intelligent features has emerged. This model makes full use of the real-time sensing capability provided by the Internet of Things and the advantages of large-scale data processing and high-speed computing of the cloud computing platform and greatly improves the shortcomings of the traditional scheduling model in dealing with dynamic and complex environments. Various sensors, GPS positioning systems, and in-vehicle communication devices deployed by IoT technology in the logistics and transportation chain are able to collect and update multifaceted information such as vehicle

location, status, and road conditions in real time [18]. After these real-time data are uploaded to the cloud computing platform, they are rapidly integrated and mined through big data analytics technology [19] to form a panoramic view reflecting the current overall operational situation. On this basis, advanced machine learning algorithms such as reinforcement learning (rl) [20] and deep learning (dl) [21] are applied to dynamic route planning and real-time scheduling optimization, enabling the system to respond optimally and quickly in the face of various uncertainties. Intelligent scheduling systems are able to adjust travel routes, reassign tasks, and predict potential delay risks in real time, thus effectively reducing the idle rate and waiting time, and greatly improving the efficiency of logistics and transportation and the quality of service [22].

Comprehensively speaking, the intelligent scheduling model based on IoT and cloud computing has realized the transformation from static to dynamic and from lagging to instantaneous compared with the traditional model, which can better adapt to the ever-changing market demand and operating conditions, and bring unprecedented level of refined management and efficient operation for the logistics and transportation industry.

Traditional vehicle scheduling models, despite their contributions, often struggle with real-time adaptability due to their reliance on predetermined parameters. These models may not effectively handle unexpected events such as sudden weather changes, traffic incidents, or urgent customer requests, which can lead to suboptimal route planning and inefficient resource allocation. Additionally, the computational complexity of these models escalates rapidly with the increase in the number of vehicles and delivery points, which can strain computational resources. To overcome these limitations, there is a pressing need for models that incorporate real-time data processing and predictive analytics to enhance decision-making flexibility and accuracy under dynamic conditions.

C. Application of Monitoring and Scheduling of Logistics and Transportation Vehicles Based on Internet of Things and Cloud Computing

1) *Practical application cases*: Nowadays, many leading domestic and international logistics companies have begun to adopt vehicle monitoring and dispatching systems based on IoT and cloud computing technologies, which have achieved significant practical benefits. For example, sf express has introduced IoT equipment and cloud computing platform in its logistics network, effectively realizing remote monitoring and intelligent dispatching of its huge fleet of vehicles through real-time monitoring of vehicle location and status information [23]. Through IoT technology, real-time transmission of vehicle gps data, driving status data, etc. To the cloud platform, combined with big data analysis technology, the system is able to accurately predict and plan the optimal driving routes, reduce unnecessary empty mileage, and improve the loading rate, thereby saving fuel costs and improving logistics efficiency [24]. In practice, Cainiao

network has also created an intelligent logistics system using IoT and cloud computing to realize dynamic vehicle scheduling and real-time monitoring [25]. Through the sensors installed on the vehicle and mobile communication technology, the system can provide real-time feedback on the vehicle's operating status, cargo status and driver behavior, etc. The cloud computing platform carries out rapid processing and analysis of these data to optimize the vehicle scheduling program in real time, reduce operating costs, and improve service quality.

2) *Application challenges and countermeasures:* Although the logistics vehicle monitoring and dispatching system based on IoT and cloud computing has made remarkable achievements, it still faces a series of challenges in the process of practical application. First, data security and privacy protection is a major challenge. The large amount of data generated by IoT devices may be subject to malicious attacks or illegal theft during transmission and storage. In order to ensure information security, researchers are actively exploring and applying advanced encryption technologies, such as lightweight encryption algorithms and blockchain technology, to ensure the integrity and confidentiality of data during transmission and storage. Secondly, the stability and real-time responsiveness of the system is also an issue that should not be ignored. Large-scale IoT device access may lead to data flooding, affecting the processing efficiency and response speed of the cloud computing platform [28]. In order to solve this problem, researchers propose to adopt an edge computing strategy, i.e., offloading part of the data processing and analysis tasks to edge nodes close to the data source, reducing the pressure on the central cloud platform and improving the real-time response performance of the system. Optimizing communication protocols to ensure efficient and stable data transmission is also a research hotspot. By optimizing wireless communication technologies such as 4G and 5G, the network coverage and data transmission rate are improved, and the delay is reduced to ensure the real-time transmission of monitoring data.

While the integration of IoT and cloud computing in logistics has demonstrated substantial benefits, practical implementation faces several hurdles. Integration complexity, especially in legacy systems, poses a significant challenge as it requires seamless interfacing between various hardware components and software platforms. Additionally, the cost associated with the initial setup and ongoing maintenance of IoT infrastructure and cloud services can be prohibitive for smaller logistics companies. Ensuring continuous power supply for IoT devices in remote locations and managing the overwhelming amount of data generated without compromising data quality remains another challenge. To mitigate these issues, strategies such as phased implementation, leveraging cloud-based pay-as-you-go models, and investing in advanced data filtering and cleaning techniques are imperative.

Furthermore, fostering collaboration among stakeholders to establish common standards and best practices can facilitate smoother integration and wider adoption of these advanced technologies in the logistics sector.

In preparation for this study, this paper conducted extensive literature research to fully understand the current state of the field of vehicle monitoring and scheduling in logistics transportation. This paper searched academic databases (e.g. Web of Science, Scopus, IEEE Xplore, SpringerLink, and Google Scholar) for relevant literature from the past decade, using keywords such as "IoT Logistics", "Cloud Computing Dispatch", "Vehicle Monitoring System", "Intelligent Logistics", etc. for precise searches. Through careful screening, this paper focusses on those representative and innovative research papers in technology implementation, algorithm optimization, system design and practical application effect evaluation. In particular, documents [1] to [5] provide us with a macro perspective of the challenges and opportunities facing the logistics industry, pointing out the key role of information technology, especially the Internet of Things and cloud computing technologies, in logistics modernization. Documents in study [6] and [7] discuss in depth the latest advances in vehicle monitoring technology and how they improve logistics management through real-time data transmission and intelligent analysis. The study [8] to [10] focuses on the development of vehicle scheduling models, from traditional optimization methods to dynamic scheduling strategies based on intelligent algorithms, which provide the theoretical basis for model design. In addition, this paper also refers to a number of case studies [23], [25] that demonstrate the successful application of IoT and cloud computing technologies in real-world logistics operations, providing valuable lessons learned and implementation strategies. Although there have been studies on the application of the Internet of Things and cloud computing in logistics, there is still a lack of in-depth and systematic research on how to deeply integrate these technologies, realize seamless connection from real-time vehicle monitoring to intelligent scheduling strategy, and how to effectively deal with the resulting data security and system stability problems. In addition, the application effect evaluation and parameter optimization method of multi-objective optimization scheduling model in actual logistics scenarios are also weak.

Based on the findings of the above literature review, this paper defines research orientation: to build an integrated logistics vehicle monitoring and scheduling system integrating advanced Internet of Things monitoring technology, cloud computing processing capabilities and multi-objective particle swarm optimization scheduling algorithm. The system was designed to address several challenges identified in the literature, including improving information transparency and decision efficiency, optimizing resource allocation, ensuring data security, and increasing scheduling flexibility. Through this innovative research, this paper not only deepens and expands the application of existing logistics technology but also provides a new theoretical basis and practical guidance for the intelligent transformation of the logistics industry.

III. VEHICLE MONITORING MODEL

A. Constructing a Vehicle Localization Module Based on Yolov5

Yolov5 is a real-time target detection model that outputs all target classes and their locations in an image in a single prediction. In a vehicle monitoring system, yolov5 is responsible for the initial localization of vehicles. Its network structure employs techniques such as cross-stage partial connectivity (csp) and cross-scale feature pyramid networks (fpn) to achieve fast and accurate vehicle detection. The output of the yolov5 model is a two-dimensional tensor containing the predicted values of multiple bounding boxes for each grid cell, including the confidence, class probability) and the center coordinates, width and height of the bounding box. The location loss function l (location loss) can be expressed as:

$$L_{loc} = \sum_{i=0}^{S^2} \sum_{j=0}^B x_{ij}^{obj} \left[\lambda_{coord} \sum_{xywh} L_1(pred_{ij}^{xywh}, truth_{ij}^{xywh}) + L_1(pred_{ij}^{obj}, truth_{ij}^{obj}) \right]$$

Where S^2 is the number of grids, B is the number of bounding boxes predicted for each grid, B is an indicator variable indicating the presence or absence of an object, $pred_{ij}^{xywh}$ and $truth_{ij}^{xywh}$ are the bounding box coordinates for the predicted and true values, respectively, $pred_{ij}^{obj}$ and $truth_{ij}^{obj}$ are the confidence level predicted and true values, λ_{coord} is a balancing coefficient, and L_1 is the mean squared error (MSE) or the huber loss function.

B. Deepsort-Based Vehicle Tracking Module

On the basis of vehicle localization, deepsort algorithm is used for continuous vehicle tracking. deepsort combines kalman filter for state prediction and deep learning methods (e.g., reid model) to extract vehicle features, and trajectory matching is performed by calculating similarity and iou values between detection frames.

The core of the correlation algorithm is to calculate the correlation score between the detection frame and the previous trajectory, which can be expressed as eq:

$$AssociationScore_{ij} = \exp\left(-\frac{\|f(Detection_i) - f(Track_j)\|_2^2}{2\sigma^2}\right) \times IOU(Detection_i, Track_j)$$

C. Vehicle Condition Monitoring Module Combining Spatio-Temporal Convolutional Networks

Temporal convolutional networks (tcns) are used to analyze vehicle state time-series data, such as speed, acceleration and other dynamic features. Accurate monitoring of vehicle states is realized by capturing short-term and long-term dependencies of time series through deep convolutional layers [20].

In the tcn model, the convolution operation at each layer can be represented as:

$$H_t^n = f\left(\sum_{k=\max(0,t-K)}^{\min(T-1,t+K)} W_k^n * X_{t-k}^{n-1} + b^n\right)$$

Where, H_t^n is the output feature of the n th layer at time step t , X_{t-k}^{n-1} is the input feature of the previous layer at time step $t-k$, W_k^n is the weight of the temporal convolution kernel, b^n is the bias term, f is the nonlinear activation function, K is the time span of the convolution kernel, and T is the total length of the time series [26].

D. Integrated Monitoring Modeling Framework

The above three modules are organically combined to build a comprehensive vehicle monitoring system, as shown in Fig. 2. First, yolov5 performs real-time vehicle detection on the video stream to generate vehicle location information; next, deepsort receives this location information and combines it with historical data for vehicle tracking to maintain the tracking of the vehicle's continuous motion state; finally, the spatio-temporal convolutional network analyzes the vehicle's time-series state data in order to provide more comprehensive monitoring of the vehicle's state [21].

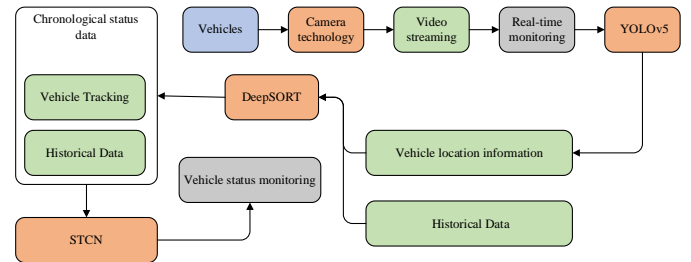

Fig. 2. Framework model.

The proposed integrated vehicle monitoring system (see Fig. 2) integrates the above three modules to form a highly coordinated and comprehensive solution. Starting with YOLOv5's real-time positioning, to DeepSORT's continuous, accurate tracking, to TCNs' deep analysis of vehicle dynamics, this framework enables closed-loop monitoring from initial vehicle detection to detailed behavior analysis. This system not only optimizes the real-time monitoring efficiency, reduces the false detection rate and missed detection rate, but also significantly enhances the adaptability and robustness to complex environments through the application of deep learning technology. Its innovation lies in:

Efficient Integration: Seamless integration of cutting-edge computer vision and deep learning technologies to build an end-to-end solution from object detection to behavioral analysis.

Accurate tracking: Through the optimization of DeepSORT algorithm, continuous and accurate tracking of vehicles in dynamic and complex scenes is realized, and the stability of the overall system is improved.

In-depth analysis: The application of TCNs breaks through the limitations of traditional monitoring systems, realizes a deep understanding of vehicle dynamic states, and provides possibilities for advanced applications such as intelligent scheduling and safety warning.

Real-time response: The entire framework design focuses on real-time, ensuring that the monitoring system can respond quickly, process and feedback vehicle status information in a timely manner, and improve logistics transportation efficiency and safety.

To sum up, the proposed system not only has clear structure and strict logic, but also significantly improves the intelligent and refined level of vehicle monitoring through technological innovation, which brings innovation to the logistics industry and other fields related to large-scale vehicle management.

IV. PARTICLE SWARM ALGORITHM-BASED VEHICLE SCHEDULING MODEL IN LOGISTICS TRANSPORTATION

A. Modeling of Logistics Transportation Vehicle Scheduling

In logistics transportation, vehicle scheduling problems are usually manifested in the form of capacitated vehicle routing problem (cvrp) or vehicle routing problem with time windows (vrptw). Factors considered include vehicle cargo capacity, customer delivery demand, traveling distance, service time window, driver working time constraints, and other dimensions. When modeling, the problem can be transformed into an optimization problem where the objective is to find one or more vehicle travel paths that satisfy all customer demands while minimizing the total travel distance, total travel time, or total cost. In logistics and transportation, the mathematical model of a vehicle scheduling problem usually involves the

following key elements: x_{ij} Represents 1 if the vehicle travels directly from customer i to customer j , and 0 otherwise. Q represents the maximum cargo capacity of the vehicle. q_i Represents the demand of customer i . d_{ij} Represents the distance from customer i to customer j . T represents the maximum working time of the driver. s_i Represents the service time at customer i . e_i, l_i represent the service time windows of logistics task i with start and end times, respectively [34].

The objective function is to minimize the total distance

traveled:
$$\min \sum_{i=1}^n \sum_{j=1, j \neq i}^n d_{ij} x_{ij}$$
. The constraints mainly include that each customer can only be visited once:

$$\sum_{i=1, i \neq j}^n x_{ij} = 1 \quad \forall j \in 1, \dots, n$$
, the vehicle load does not exceed

the maximum load q :
$$\sum_{i=1}^n q_i x_{ij} \leq Q \quad \forall j \in 1, \dots, n$$
, the driver's working time does not exceed t :

$$\sum_{i=1}^n \sum_{j=1, j \neq i}^n (d_{ij} + s_i) x_{ij} \leq T$$
, and the service time window constraints: $e_i \leq t_i \leq l_i \quad \forall i \in 1, \dots, n$ Where, t_i denotes the time when the vehicle arrives at the customer i [22].

B. Traditional Particle Swarm Algorithm for Scheduling of Logistics and Transportation Vehicles

Particle swarm algorithm in solving logistics transportation vehicle scheduling problem, each feasible vehicle scheduling program as a "Particle", its position vector indicates the driving route of each vehicle, the speed vector indicates the possibility of changing the driving route. The main process of particle swarm algorithm is as follows:

1) *Initialization*: Setting the swarm size, maximum number of iterations, initial velocity and position, as well as inertia weights W and acceleration constants c_1, c_2 .

2) *Evaluate the fitness*: Calculate the fitness value (e.g., total distance traveled, total cost) corresponding to each particle's position (i.e., vehicle scheduling scheme).

3) *Update personal optimal solution (pbest)*: If the fitness value corresponding to the position of the current particle is better than its historical optimal solution, then update the personal optimal solution of this particle.

4) *Update the globally optimal solution (gbest)*: Find the particle with the best fitness value in the whole particle swarm and take its position as the global optimal solution [23].

5) *Update speed and location*:

$$v_{i,d}(t+1) = w \cdot v_{i,d}(t) + c_1 \cdot r_1 \cdot (pbest_{i,d} - x_{i,d}(t)) + c_2 \cdot r_2 \cdot (gbest_d - x_{i,d}(t))$$

The value of particle i personal optimal solution and global optimal solution in the d_{th} dimension is given by $x_{i,d}(t+1) = x_{i,d}(t) + v_{i,d}(t+1)$ and. Where $(v_{i,d}(t))$ and $x_{i,d}(t)$ denote the velocity and position of particle i in the d_{th} dimension, respectively, and $pbest_{i,d}$ and $gbest_d$ denote the values of the personal and globally optimal solutions of particle i in the d_{th} dimension, respectively.

6) *Judge the stop condition*: Check whether the maximum number of iterations is reached, if not, then return to step 2 to continue iteration.

C. Improved Multi-Objective Particle Swarm Algorithm Applied to Logistics Transportation Vehicle Scheduling

In practical logistics and transportation, the vehicle scheduling problem often involves multiple conflicting objectives, such as minimizing the driving distance, minimizing the total transportation time, and reducing carbon emissions. At this time, multi-objective particle swarm algorithm (mopso) can be used. In mopso, each particle has multiple objective function values, forming a pareto front

solution set. The algorithm process is basically the same as the traditional pso, but the adaptation evaluation and the selection of the optimal solution need to take into account multiple objectives. The fitness function can adopt multi-objective optimization strategies such as hierarchical weighting method or objective space decomposition method.

For multiple objective values of a particular particle i $f_1(x_i), f_2(x_i), \dots, f_m(x_i)$, its position in the pareto front can be computed using the non-dominated ordering and the crowding distance. When updating the velocity and position, not only the optimal solution of a single objective is considered, but also the distribution of the whole pareto front is taken into account. In the improved multi-objective particle swarm algorithm, the velocity update formula becomes:

$$v_{i,d}(t+1) = w \cdot v_{i,d}(t) + \sum_{k=1}^m c_k \cdot r_k \cdot (\text{dominant_solution}_{i,k,d} - x_{i,d}(t))$$

Where $\text{dominant_solution}_{i,k,d}$ is the position of particle i in the objective k dimension that dominates its solution in the d th dimension. The improved multi-objective particle swarm algorithm is able to find the pareto optimal solution set for the logistics and transportation vehicle scheduling problem, thus providing the decision maker with multiple choices of optimal scheduling solutions that consider multiple objectives in a balanced manner [24].

V. TECHNICAL FRAMEWORK

The overall architecture of the system is designed around building an advanced and efficient solution for monitoring and scheduling of logistics transportation vehicles, taking full advantage of Internet of Things (IoT) technology and cloud computing, aiming to comprehensively improve the overall intelligence level of the logistics industry chain. The following is a description of the overall framework of the system after refinement:

In the data collection layer, this paper deploys a complete set of on-board IoT devices and sensor components. The core role of this layer is to capture rich operational data in real-time, covering various status information of the vehicle itself, such as vehicle position, speed, running status, etc.; in addition, it also includes cargo status data, such as temperature, humidity and other environmental parameters, as well as identification and tracking of cargo with the help of rfid tags. Various types of vehicle terminals, such as high-precision GPS locators, temperature and humidity sensors, vehicle cameras (which can realize safety monitoring or driver behavior analysis) and load sensors and other multifaceted equipment work together to weave a tight and detailed data collection network [25].

As data is continuously generated from the first layer, the second network communication layer acts as a bridge to efficiently and reliably transmit this real-time data to the data center. This process relies on the power of modern communication technologies, including but not limited to 4g/5g mobile networks, satellite communications, Wi-Fi, and even lpwan technology for long-distance, low-power scenarios, to ensure seamless data transmission, whether it's on city streets or in remote areas [26].

After data transmission to the data center, this paper step into the third layer of the system - data storage and processing layer. This layer mainly relies on a powerful and stable cloud computing platform, through the server cluster to build a "Data warehouse". That can accommodate massive real-time monitoring data. Advanced cloud storage technology is utilized to ensure secure data storage and on-demand expansion, while significantly improving data access efficiency. In addition, a specialized big data processing module is set up to perform a series of cleaning, integration and pre-processing operations on the raw data received, and tools such as hadoop and spark are used to realize rapid analysis and mining of large-scale data using distributed computing frameworks [27].

After the data has been effectively processed, it comes to the fourth layer of the system - the intelligent analysis and decision-making layer. This layer includes a number of key modules, in which the real-time monitoring module, with accurate real-time data, can not only track the location of the vehicle in real time, but also reproduce the vehicle's driving trajectory, as well as timely identification of irregular or abnormal driving behavior. The intelligent prediction module utilizes the powerful prediction capability of machine learning algorithms to make precise and forward-looking assessments of vehicle arrival time, dynamic changes in road conditions, and even potential risks of mechanical failure. Intelligent scheduling module is the intelligent core of the whole system, which makes use of optimization methods such as particle swarm algorithm to make fine and flexible intelligent scheduling decisions based on real-time data and prediction results, taking into account the reasonable allocation of capacity resources, the degree of matching of order demand and the constraints of route planning, so as to realize the maximum efficiency of the capacity [28, 29].

Fig. 3. Logistics transportation vehicle monitoring and scheduling solution.

The last layer, the user interface and interaction layer, is the key interface between the system and people. This layer contains two key parts: Visualization management system and mobile application. The visualization management system provides logistics managers with rich and vivid vehicle dynamic information display, dispatch result query and all kinds of business statistics report through the intuitive interface of web terminal or mobile terminal, and also supports remote control and real-time issuance of dispatching instructions [30].

In summary, the system builds a complete information link from bottom to top, from data acquisition, transmission, storage and processing, to intelligent analysis and decision-making, until the final human-computer interaction, forming a set of highly integrated and fully functional solutions for monitoring and scheduling of logistics and transportation vehicles, whose process is specifically shown in Fig. 3. This set of solutions effectively combines the Internet of things technology and cloud computing closely, and strongly promotes the intelligent process of the logistics industry.

VI. EXPERIMENTAL RESEARCH ON MONITORING AND SCHEDULING SYSTEMS FOR LOGISTICS TRANSPORTATION VEHICLES BASED ON INTERNET OF THINGS AND CLOUD COMPUTING

A. Experimental Design and Baseline Modeling

In this chapter, this paper provides an in-depth exploration of the Internet of Things (IoT) and cloud computing based monitoring and scheduling system for logistics and transportation vehicles and provides an exhaustive comparative analysis of its performance with eight different baseline models, which include a fixed route model, a priority assignment model, a proximity principle scheduling model, a capacity matching model, a total trip minimization model, a fuel consumption minimization model, reactive scheduling model based on GPS real-time location monitoring and statistical analysis model. Among them, is the fixed route model: This model performs tasks according to a preset route without considering changes in real-time road conditions? Priority assignment model: The transportation tasks are assigned according to the urgency or importance of the goods. Proximity principle scheduling model: The nearest vehicle is selected to perform the task in order to reduce the waiting time. Capacity matching model: Matching based on cargo size and vehicle capacity to improve loading efficiency. Total trip minimization model: It aims to reduce the total distance traveled by vehicles. Fuel consumption minimization model: Optimizes routes to reduce fuel consumption and costs.

B. Experimental Environment and Assessment Indicators

Conducted in an environment equipped with cutting-edge IoT facilities and an efficient cloud computing platform, the experiment utilizes real-world logistics and transportation datasets to comprehensively evaluate the models against six key evaluation metrics - real-time monitoring accuracy, dispatch efficiency (including vehicle utilization, on-time rate, and empty rate), arrival time prediction accuracy (measured by RMSE and MAE), road condition change prediction accuracy (evaluated by RMSE), breakdown risk prediction accuracy (judged using MAE), and monitoring response latency.

(Measured by RMSE and MAE), road condition change prediction accuracy (evaluated by RMSE), failure risk prediction accuracy (judged by MAE), and monitoring response latency - are comprehensively evaluated for each model. Among them, real-time monitoring accuracy: Assesses the accuracy and reliability of system monitoring data. Dispatch efficiency: Includes vehicle utilization rate, on-time rate, and empty rate to measure the overall efficiency of the dispatch system. Arrival time prediction accuracy: Assesses the accuracy of prediction using root mean square error (RMSE) and mean absolute error (MAE).

The real logistics and transportation dataset used in this paper is "Logistics Operation Insights Dataset", which is publicly published on Kaggle platform (kaggle.com/datasets/logisticsoperation/real-world-logistics-data) and covers multiple dimensions such as cargo information (such as name, quantity, weight, volume), transportation information (including transportation mode, freight, transportation time), delivery details (delivery address, consignee information), storage status and inventory changes. These data directly come from real logistics business operations, aiming to improve transportation efficiency, optimize cost control, intelligently plan transportation routes and refine inventory management through detailed analysis, providing powerful support for logistics enterprises to realize management optimization and intelligent decision-making with data insight.

During the experimental design and baseline modeling phase, this paper not only selected eight models covering a wide range of strategies for comparison, but also paid special attention to the closeness of the experimental setup to ensure the validity and universality of the results. To ensure the authenticity and comprehensiveness of the data, the logistics and transportation datasets used cover multiple dimensions, including but not limited to historical transportation routes, vehicle performance data, real-time traffic information, weather condition records and incident logs. Data preprocessing steps include data cleansing, outlier removal, missing value imputation, and data normalization to ensure that all models are evaluated based on consistent and high quality data.

When building the Internet of Things scheduling system, this paper make full use of the real-time sensing capability of Internet of Things devices and the massive data processing capability of cloud computing platforms. IoT devices installed on vehicles continuously collect vehicle status, cargo information and environmental data, and upload the data to the cloud through a stable wireless communication link. The cloud server integrates multi-source data using advanced data fusion algorithms and performs in-depth analysis through machine learning models to support vehicle scheduling decisions. The system designs a dynamic adjustment mechanism that can quickly re-plan the optimal path according to real-time road conditions, vehicle conditions and customer demand changes, thereby maximizing transportation efficiency and reducing costs while ensuring timeliness.

During the experiment, this paper pay special attention to the real-time response ability of the system. In the simulation

scheduling test, the IoT scheduling system demonstrated excellent performance, and its monitoring response latency was much lower than other models, ensuring that scheduling instructions could be quickly communicated to vehicle drivers to effectively respond to emergencies. In addition, the built-in fault prediction module of the system can warn potential faults in advance by analyzing abnormal patterns in vehicle operation data, which is verified by the mae index of fault risk prediction accuracy in Table V. The low score of 0.15 of Internet of Things dispatching system highlights its advantages in preventive maintenance.

It is worth noting that in the experiment, this paper also implemented a series of stress tests, simulating complex scenarios such as peak logistics demand surge, route change caused by extreme weather, and temporary emergency task insertion to verify the stability and flexibility of the IoT scheduling system. The results show that the system can maintain a high level of scheduling efficiency and accuracy, vehicle utilization and punctuality remain high, and empty rate remains low, even in a highly stressed logistics environment, which proves the effectiveness and robustness of the system design.

To sum up, through comprehensive experimental design and detailed performance evaluation, this study not only verifies the superiority of logistics transportation vehicle monitoring and scheduling system based on Internet of Things and cloud computing, but also reveals its specific performance in different application scenarios, providing powerful technical support and practical reference for intelligent upgrading of logistics industry. Future work will further explore how intelligent the system can be, such as by integrating more advanced prediction algorithms and optimization strategies, as well as enhancing the system's ability to adapt to uncertainties and external disturbances, to continuously improve the efficiency and reliability of logistics operations.

C. Experimental Results

The experimental process follows rigorous steps: First, this paper collects and preprocess a large amount of logistics transportation data to ensure data quality and consistency; second, this paper simulates the scheduling of the data by using the above baseline model and recording the performance of each evaluation index; then, this paper simulate the scheduling by using the self-developed IoT scheduling system and record the relevant indexes; then, this paper analyze the differences between the models in different evaluation indexes by comparing and analyzing their advantages and disadvantages. Assessment indicators to reveal their advantages and disadvantages.

Table I lists the performance of different models in terms of real-time monitoring accuracy in terms of percentage. The IoT scheduling system demonstrates excellent performance in terms of accuracy and reliability of real-time monitoring data, reaching 98%.

Table II shows the performance of different models in terms of dispatching efficiency in terms of vehicle utilization, on-time performance, and idle rate. The IoT dispatch system achieves optimal results in all three key metrics, with vehicle

utilization as high as 95%, on-time performance at 98%, and idling rate reduced to a minimum level of 5%.

TABLE I. COMPARISON OF REAL-TIME MONITORING ACCURACY

Model name	Real-time monitoring accuracy
Fixed route model	85%
Prioritization model	90%
Proximity principle dispatch model	88%
Capacity matching model	87%
Total travel minimization model	89%
Fuel consumption minimization model	92%
GPS real-time location monitoring	95%
Statistical analysis model	90%
Model name	Real-time monitoring accuracy

TABLE II. COMPARISON OF SCHEDULING EFFICIENCY

Model name	Vehicle utilization rate
Fixed route model	70%
Prioritization model	75%
Proximity principle dispatch model	78%
Capacity matching model	80%
Total travel minimization model	83%
Fuel consumption minimization model	85%
GPS real-time location monitoring	88%
Statistical analysis model	82%
IoT dispatch system	95%

Tables III and IV evaluate the accuracy of the arrival time prediction by each model through two statistical metrics, RMSE (root mean square error) and MAE (mean absolute error), respectively. The IoT scheduling system again outperforms the other baseline models in terms of prediction accuracy, with significantly lower values for both RMSE and MAE, indicating that it is more accurate in predicting arrival times.

TABLE III. COMPARISON OF ARRIVAL TIME PREDICTION ACCURACY (RMSE)

Model name	Time of arrival forecasting (RMSE)
Fixed route model	0.50
Prioritization model	0.45
Proximity principle dispatch model	0.40
Capacity matching model	0.42
Total travel minimization model	0.38
Fuel consumption minimization model	0.35
Gps real-time location monitoring	0.30
Statistical analysis model	0.40
IoT dispatch system	0.25

TABLE IV. COMPARISON OF ARRIVAL TIME PREDICTION ACCURACY (MAE)

Model name	Time of arrival forecast (mae)
Fixed route model	0.40
Prioritization model	0.35
Proximity principle dispatch model	0.30
Capacity matching model	0.32
Total travel minimization model	0.28
Fuel consumption minimization model	0.25
Gps real-time location monitoring	0.20
Statistical analysis model	0.30
IoT dispatch system	0.15

Table V reflects the accuracy of the models in predicting changes in road conditions, again evaluated in terms of RMSE. The IoT dispatch system still maintains its lead in predicting changes in road conditions, with a RMSE value of 0.30, which is lower than the other baseline models, reflecting its strong ability to analyze and respond to real-time data.

Fig. 4 compares the accuracy of the models in predicting the risk of failure through the MAE metric. The MAE value of the IoT dispatching system is 0.20, which is much lower than the other baseline models, indicating that the system is able to

more accurately predict and prevent the risk of possible failures, thus reducing the possibility of operational disruptions. Through a series of exhaustive data analyses and table comparisons, the IoT and cloud computing-based logistics and transportation vehicle monitoring and scheduling system achieves excellent results in a number of core metrics, such as real-time monitoring accuracy, scheduling efficiency, and prediction accuracy, which highlights its great advantage over traditional baseline models.

TABLE V. COMPARISON OF ROAD CONDITION CHANGE PREDICTION ACCURACY (RMSE)

Model name	Road condition change prediction (RMSE)
Fixed route model	0.60
Prioritization model	0.55
Proximity principle dispatch model	0.50
Capacity matching model	0.52
Total travel minimization model	0.48
Fuel consumption minimization model	0.45
GPS real-time location monitoring	0.40
Statistical analysis model	0.50
IoT dispatch system	0.30

Fig. 4. Comparison of failure risk prediction accuracy (mae).

Table VI reveals the performance differences between 10 different logistics models under their respective optimization scenarios by comparing and analyzing their performance on different data sets. In urban logistics scenarios, GPS real-time location monitoring systems can increase vehicle utilization to 85%, demonstrating their ability to efficiently utilize resources. In the field of rural logistics, the Internet of Things scheduling system stands out with 97% real-time monitoring accuracy, showing extremely high monitoring accuracy. For the arrival

time prediction of long-distance freight, the RMSE of GPS system is only 0.34, indicating that its prediction accuracy is high. For seasonally varying failure risk predictions, IoT scheduling systems showed high accuracy of their predictions with an MAE of 0.23. Overall, IoT scheduling systems perform best across all datasets, with clear advantages in real-time monitoring and failure risk prediction. In contrast, the fixed-route model performs relatively poorly on each dataset, suggesting that we should choose the most appropriate model for a particular scenario in practice.

TABLE VI. COMPARATIVE ANALYSIS OF PERFORMANCE ON DIFFERENT DATA SETS

Model Name	Dataset A: Urban Logistics (Vehicle Utilization Rate)	Dataset B: Rural Logistics (Real-Time Monitoring Accuracy)	Dataset C: Long-Distance Freight (Arrival Time Prediction RMSE)	Dataset D: Seasonal Variability (Failure Risk Prediction MAE)
Fixed Route Model	68%	83%	0.52	0.35
Prioritization Model	72%	87%	0.48	0.33
Proximity Principle Dispatch Model	75%	86%	0.45	0.32
Capacity Matching Model	77%	85%	0.43	0.31
Total Travel Minimization Model	80%	88%	0.40	0.30
Fuel Consumption Minimization Model	82%	90%	0.37	0.28
GPS Real-Time Location Monitoring	85%	93%	0.34	0.26
Statistical Analysis Model	83%	91%	0.36	0.27
IoT Dispatch System	92%	97%	0.29	0.23

Through the above experimental process, this paper can comprehensively assess the advantages of the IoT and cloud computing-based scheduling system compared to the traditional model in terms of real-time monitoring, scheduling efficiency, prediction accuracy, and response speed. These advantages not only improve the efficiency and reliability of logistics transportation but also provide new ideas and solutions for future logistics transportation.

VII. CONCLUSION

Based on the urgent needs of modern intelligent traffic management and logistics and transportation industries, this study designs and implements an efficient vehicle monitoring and scheduling framework with the support of the Internet of Things (IoT) and cloud computing technologies. The research process covers the whole process from real-time vehicle detection to intelligent scheduling decision-making: Firstly, the advanced yolov5 model is used to implement real-time vehicle recognition on the video stream and generate high-precision position information in real-time; secondly, the deepsort algorithm is introduced to integrate real-time position data and historical trajectory information to ensure the accurate tracking of the vehicle's continuous motion state; finally, spatio-temporal convolutional network is applied to finally, the use of spatio-temporal convolutional network to deeply excavate the time series characteristics of the vehicle state greatly enhances the integrity of the state monitoring.

A. Innovation Points

1) A set of comprehensive vehicle monitoring models integrating yolov5, deepsort and spatio-temporal convolutional networks is constructed to realize the whole chain processing from position detection to state analysis.

2) An improved multi-objective particle swarm algorithm is proposed and successfully applied to the logistics

transportation vehicle scheduling model, which improves the scientificity and effectiveness of scheduling decisions.

3) The scheduling system built using the Internet of Things and cloud computing technology has effectively improved real-time monitoring capability, scheduling efficiency and forecast accuracy, shortened response time and made significant progress compared with traditional models.

B. Deficiencies

1) The adaptability of the current system still needs to be further enhanced, especially the accuracy of vehicle detection and tracking in complex environments still needs to be improved.

2) Although spatio-temporal convolutional networks can better handle time-series data, when dealing with large-scale vehicle state data, the consumption of computational resources is large and the optimization space still exists.

3) Improved multi-objective particle swarm algorithms may require more diversified optimization strategies to cope with various uncertainties when facing extremely complex logistics scenarios.

In future work, this paper will focus on the following aspects: First, although this study successfully demonstrated the efficiency and accuracy of the logistics transportation vehicle monitoring and scheduling system based on IoT and cloud computing, as the technology continues to evolve, this paper will continue to explore and integrate the latest advances in emerging technologies such as 5G communication, edge computing and artificial intelligence algorithms to further optimize data transmission speed, improve system responsiveness and intelligent decision-making. Second, given the growing importance of environmental sustainability and green logistics, future research will aim to incorporate carbon

footprint calculations and environmental path optimization capabilities to ensure that systems not only improve logistics efficiency, but also support corporate sustainability goals and reduce the environmental impact of logistics activities. Finally, in order to promote and validate the system's broad applicability, this paper plan to conduct field pilots in logistics enterprises of different sizes and types, collect more diverse data, and conduct long-term follow-up studies to assess the long-term benefits and potential improvements of the system. Through interdisciplinary collaborations, bringing together operations management, information technology and social science perspectives, this paper will also delve into the socioeconomic impacts of technology implementation to ensure that technological advances benefit the entire logistics ecosystem.

Abstract—Starting with the end of 2022, there has been a massive global interest in Artificial Intelligence and, in particular, in the technology of large language models. These reduced the resolution of many problems dailies of varying degrees of complexity at a level accessible to every individual, whether it was an academic, business or social environment. A multitude of digital products have begun to use large language models to offer new functionalities such as intelligent messaging applications trained to respond efficiently depending on the specific parameters of a company, virtual assistants for programmers (GitHub Copilot), video call summarization functionality (Zoom), interpretation and extraction rapid drawing of conclusions from massive data (Big Data). These are just a few of the many uses of these technologies. Therefore, the general objective of this paper is the comparative analysis between three large language models such as ChatGPT, Gemini, and Llama3. Each model's strengths and constraints are analyzed, offering insights into their optimal use cases. This analysis provides a comprehensive understanding of the current state of large language models powered by deep learning, capable of executing various natural language processing (NLP) tasks, guiding future developments and applications in the field of artificial intelligence (AI).

Keywords—Large language models; artificial intelligence; ChatGPT; natural language processing

I. INTRODUCTION

Large language models (LLMs) are artificial intelligence (AI) systems capable of understanding and generating human language by processing vast amounts of text data [1] [2]. A large language model is a deep learning algorithm that can perform a variety of natural language processing (NLP) tasks.

Since the release of the first public version of ChatGPT in 2022 by the company OpenAI [3], there have been a lot of other versions of ChatGPT, but also other completely distinct models, as a result of a very close competition between the giants of the international technology industry (Big Tech): Meta (Facebook), Alphabet (Google), and Amazon, in an attempt to hold the key to winning and innovative technology.

A multitude of digital products have begun to use large language models to offer new functionalities such as intelligent messaging applications trained to respond efficiently according to the specific parameters of a company, virtual assistants for programmers (GitHub Copilot), summarization functionality of a video call (Zoom), interpreting and quickly drawing conclusions from massive data (Big Data). These are just a few of the many uses of this technology. Currently, most digital

products offer at least some functionality based on artificial intelligence, which in reality is based on large language models.

If traditionally machines and computers were programmed by humans using different programming languages, in the context of this new technology, this can be done using natural language. Specialists named all these techniques "Prompt Engineering".

The general objective of this paper is the comparative analysis between three large language models: ChatGPT, Gemini and Llama 3. Initially, I set out to carry out this research on the accuracy and performance of large language models using the newest model released in April of this year: MetaAI. Unfortunately, this model is only available for use in the United States of America, plus a few countries in Asia and Africa. So, we replaced the newest MetaAI model with Llama 3, which is also part of the same company.

The specific objectives of the paper are the evaluations of large linguistic models according to certain selected criteria. Each criterion will be applied to each of the models separately, following their evaluation following the answers provided. In this paper, text responses representing the outputs of large language models will be evaluated. The image generation is not covered in this benchmark.

This paper presents a comparative analysis of three leading large language models: ChatGPT (GPT-4), Gemini, and Llama3. These models represent the forefront of natural language processing (NLP) advancements, each showcasing unique architectural designs, training paradigms, and application capabilities. ChatGPT, developed by OpenAI, utilizes an extensive Transformer-based architecture optimized for conversational tasks and general-purpose language understanding. Gemini, from Google DeepMind, integrates sophisticated contextual understanding with Google's vast data resources, excelling in multilingual and domain-specific applications. Llama3, created by Meta, prioritizes computational efficiency while maintaining high performance in text generation and real-time interaction tasks. ChatGPT is noted for its versatility in various NLP tasks and robust conversational abilities. Gemini leverages proprietary data for enhanced contextual reasoning and problem-solving. Llama3 stands out for its resource-efficient design, making it suitable for lightweight applications.

This paper presents a study about performance and accuracy research of the most used large language models. Section II

reviews state of the art of these models, while Section III describes the large language models, and evaluation criteria is given in Section IV. Finally, discussion and conclusion is given in Section V and Section VI respectively.

II. RELATED WORKS

In 1950, the first experiments with neural networks and neural information processing systems were carried out to allow computers to process natural language. Researchers at the Georgetown University and IBM have created a system that

would be able to automatically translate phrases from Russian to English. Being a real demonstration of machine translation, it can be said that research in this field started from there.

The notion of a large language model was first introduced with the creation of Eliza in the 1960s (see Fig. 1), which was the world's first chatbot [2]. Designed by MIT researcher Joseph Weizenbaum, the Eliza chatbot marked the beginning of research into natural language processing (NLP), providing the basis for future more complex language models.

Fig. 1. The history of large language models.

In the year 1997, deeper and more complex neural networks appeared that managed larger amounts of data, based on Long Short-Term Memory (LSTM) networks.

Three years later, in 2010, Stanford's CoreNLP suite was introduced, allowing developers to perform sentiment analysis and named entity recognition.

Later, in 2011, a smaller version of Google Brain appeared with advanced features such as word embedding, which allowed NLP systems to gain a clearer sense of context.

Google researchers introduced a 340 million parameter bidirectional model, BERT (Bidirectional Encoder Representations from Transformers), in 2019, the third largest model of its kind. This model was able to understand the relationships between words by being pre-trained by self-supervised learning on a very large data set. Thus, BERT became the basic tool for natural language processing tasks, and more than that, it was behind every English query made through Google Search.

OpenAI brought to the scene the GPT-2 (Generative Pre-trained Transformer) transformer model with 1.5 billion parameters, and in 2020 release the GPT-3 with 175 billion parameters.

Fig. 1 shows those models that dictated the standard for large language models and formed the basis of ChatGPT that was released in November 2022 [3] [5]. Most recently, OpenAI introduced GPT-4, which is estimated to have one trillion parameters - of five times larger than GPT-3 and approximately 3,000 times larger than BERT when it first appeared.

III. LARGE LANGUAGE MODELS

A. Selection of Large Language Models

1) *Chat GPT4*: What most captured the public's imagination was OpenAI's launch of ChatGPT, which reached 100 million users in just two months, making it the fastest-growing consumer app in history. This was the main reason why we chose this model for the comparative analysis.

The largest model in OpenAI's GPT series, Generative Pre-trained Transformer 4 was released in 2023 [3] [5]. Like other large language models, it is a transformer-based model. The main differentiating factor between the versions is that the number of parameters is more than 170 trillion. It can easily process and generate both language and images, and it can analyze data and produce graphs and charts. It features a system message that allows users to specify the tone of voice and task. It also powers Microsoft's Bing AI chatbot.

2) *Gemini*: Gemini [6] entered the generative artificial intelligence market in late 2023 after the rebranding of BARD, being the improved version of which initially faced several problems. Trained by Google, one of the world's largest technology companies and a giant in the field of artificial intelligence, Gemini wants to be positioned as a competitor to ChatGPT. This is the main motivation for choosing Gemini for comparison and evaluation. Is Gemini a competitor to ChatGPT? We will find out in what follows.

3) *Llama 3*: The reason why I chose the Llama 3 model is the fact that it was launched in April 2024 [7]. An important

leap compared to the Llama 2 is the fact that the Llama 3 comes with two variants of parameters, 8B and 70B.

One way that Llama 3 differs from other big language models such as Gemini and GPT is that Meta has released the model as open source - meaning that it is available for research

as well as commercial purposes. However, the license is customized and requires users to follow specific regulations to avoid misuse. The Llama 3 models are available on AWS, Databricks, Google Cloud, Hugging Face, Kaggle, IBM Watson X, Microsoft Azure, NVIDIA NIM, and Snowflake.

Fig. 2. Large language model training.

Llama 3 achieved compliance with major data protection standards, reducing data breaches in tested environments by over 40%. Understanding the critical importance of data security, Llama 3 incorporates enhanced privacy features that ensure the safe management of user data. Training Large Language Models.

An example of training large language models [9] is presented in Fig. 2.

B. How Large Language Models Work?

The large language models work by continuously predicting the next token, (about three-quarters of a word), starting from what was in the request.

Tokens are the basic elements of text in natural language processing. Each new token is selected according to the probability of appearing next, with a random element, controlled by the temperature parameter. The temperature parameter of large language models influences the output of the language model. Thus, it is determined if the result is more random and creative or more predictable. A higher temperature will result in a lower probability, i.e., more creative results. A lower

temperature will output a higher probability, meaning more predictable results. This means that, through adjustment, the fine modelling of the model's performance will be obtained.

The large language models are based on a class of deep learning architectures called transform networks. A transformer model is a neural network that learns context and meaning by looking for relationships in sequential data.

The architecture of a transformer was introduced in a paper in the field of natural language processing (NLP). This work is called "Attention is All You Need" [4]. Because of their unique design and efficiency, transformers have become the foundation of natural language processing tasks. A transformer has an encoder-decoder type structure. The best performing models connect the encoder and decoder through an attention mechanism.

C. What is Normalization in the Context of Large Language Models?

The normalization [8] is a crucial step in the operation of large language models. Normalization helps ensure that the model will efficiently process and understand the data, being

used in both preprocessing and training and inference. In the context of large language models, inference refers to the process of obtaining an answer from the trained model by querying or asking the user.

In the preprocessing step, normalization is used to standardize and scale the input data. This helps reduce redundancy and ensure that the data is in a format that the model can easily understand. In the training step, normalization is used to ensure that the model is not biased towards any particular feature or data point. In the inference step, normalization is used to ensure that the output of the model is in a standard format.

D. What are Activation Functions?

Activation functions play a critical role in determining the complexity and capacity of neural networks [10]. The activation function in a neural network is a mathematical function that determines a neuron's output. The neuron takes as an argument the weighted sum of the inputs and the bias and produces an output that is used as input for the next layer in the network. The activation function is responsible for transforming the input signal into an output signal, and this output is what decides whether a particular neuron will be activated or not.

The training of large linguistic models involves going through the eight stages shown in Fig. 2, such as:

1) *Data gathering*: Training a large language model starts with collecting a huge amount of unstructured text data, data that comes from various sources such as books, web pages, articles or social networking platforms.

2) *Data cleaning*: This process is called preprocessing. The collected data must be cleaned and prepared for training. This involves removing unwanted characters, breaking the text into smaller parts called tokens, and putting it into a format that the model can work with.

3) *Data splitting*: The previously cleaned data is split into two sets. One set, the training data, will be used to train the model. The other set, the validation data, will be used later to test the performance of the model.

4) *Model set-up*: In this step, the structure of the large language model, known as the architecture, is defined. This involves selecting the type of neural network and deciding on various parameters such as the number of layers and hidden units in the network.

5) *Model training*: Now the actual training begins. The large language model learns by analyzing training data, making predictions based on what it has learned so far, and then adjusting internal parameters to reduce the gap between its predictions and the actual data.

6) *Model checking*: The learning of the large language model is verified using the validation data. This allows viewing the model's operation and modifying its settings for better performance.

7) *Model usability*: After training and evaluation, the large language model is ready for use and can be integrated into applications.

8) *Model enhancement*: By using updated data or adjusting settings based on real-world feedback and usage, the large language model can be further refined over time.

This training process requires massive computing resources such as powerful processing units and large storage as well as specialized machine learning knowledge. The amount of unstructured data that the model will learn through self-supervised learning starts at a size of at least 1000 GB, having billions of parameters. A parameter in the context of large linguistic models defines the behaviour of the artificial intelligence model, being used in predictions. An infrastructure with multiple GPUs is essential to be able to train such large models. Purchasing such a large number of GPUs is not feasible for most organizations. Even OpenAI, the creator of the ChatGPT model, did not train its models on its own infrastructure, but relied on Microsoft's Azure cloud platform. In 2019, Microsoft invested \$1 billion in OpenAI, and it is estimated that much of the money was spent on training large language models on Azure cloud resources.

Although incredible advances have been made with the introduction of large language models, it is important to understand the limits of these models to avoid potential pitfalls and ensure responsible use. Misinformation, malware, discriminatory content, plagiarism and information that is untrue can lead to unwanted or dangerous results.

E. What is a Hallucination in the Context of Large Language Models?

Hallucinations are the occurrences where large linguistic patterns produce coherent and grammatically correct but incorrect or nonsensical results. In this context, the term "hallucination" means the generation of false or misleading information. The main factors causing hallucinations are training data limitations, model biases, inherent complexity of language, vague questions, and semantic gaps.

IV. EVALUATION CRITERIA

Before evaluating the models and giving them instructions, an important aspect in the field of large language models should be mentioned, namely prompting. Prompt engineering is the process of discovering cues that reliably provide useful or desired results. A request is a natural language text that describes the task that an artificial intelligence model should perform. The prompt serves as a set of instructions that the model uses to predict the desired response.

These criteria come in the form of questions, prompts, or sets of instructions that I provide as input to large language models. There are many ways to ask an AI model to do a task, and even slight changes can make a big difference. The large language models work by continuously predicting the next token (about three-quarters of a word) from what was in the request provided as input. Each new token is selected based on the probability of appearing next, with a random element.

The large language models are trained on essentially the entire text of the Internet and then later tuned to provide useful answers. Average requests will return average responses, causing some people to be disappointed when their results don't live up to expectations. What is entered in the request changes

the probability of each generated word, which matters a lot for the results that will be obtained. These models have seen the best and worst of what humans have produced and are capable of emulating almost anything if you know how to ask.

A. Criterion 1: Mathematics Problem, Topic Taken from the National Mathematics Olympiad

Request 1: "Imagine you are a math teacher and you have the following 5th grade math problem to solve: A store sold 235 robots in the 12 months of a year. Every month either 16, 20 or 25 robots were sold. Determine the number of months in which exactly 20 robots were sold. Provide a detailed explanation of the solution and the correct solution to the problem."

ChatGPT Response, like in Fig. 3.

Rating from ChatGPT – ChatGPT chose a solution method by which it tested every possible variant for the value of x. It's not wrong, but if we have a higher number of attempts, how will it perform? However, it provided the correct solution. He also explained in detail how to solve the problem, so he complied with the requirements in the request.

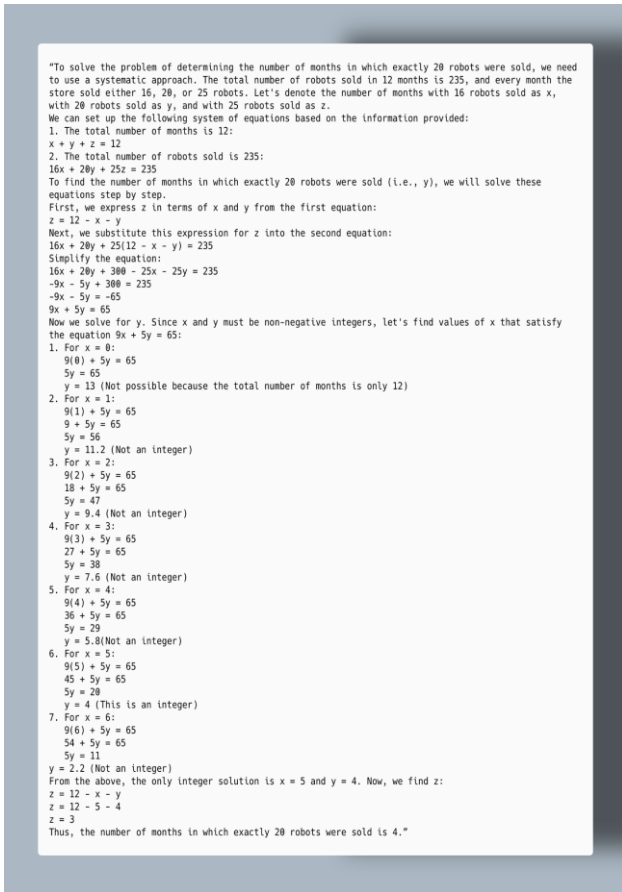

Fig. 3. ChatGPT response.

Gemini Response, like in Fig. 4.

Rating from Gemini – Gemini has a particular style of detailing and structuring problem-solving methods, offering a very explicit and logical description of the solution steps. It seems that he is not able to solve equations, the solution offered by Gemini not being correct.

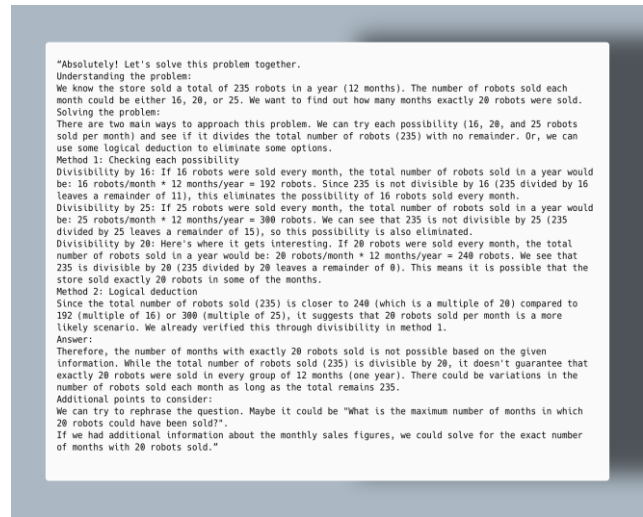

Fig. 4. Gemini response.

Llama3 Response, like in Fig. 5.

Rating from Llama3 – It seems that Llama 3 offered detailed explanations, logically structured the solution to the problem, however, the solution is not correct. The bottom line is that Llama 3 needs precise directions, but even so, it's sometimes unstable. The less positive part in the case of Llama 3 is that you cannot provide feedback, it does not have this feature implemented. So far, Llama3 has provided correct answers, even if in a different language than the received request. This response is evidence of the model's first hallucination.

Fig. 5. Llama3 response.

B. Creating a Culinary Recipe, Having a List of Ingredients Available

Request 2: "I have the following ingredients: 500 milliliters of milk, six eggs, 750 grams of flour, 250 grams of chorizo and a coupon for two additional ingredients (it can be whatever I decide in whatever quantity). I want to make a focaccia but I

don't know which are the exact ingredients and the quantities for that. Please tell me a good recipe of focaccia to make in house."

ChatGPT Response, like in Fig. 6.

Fig. 6. ChatGPT response to request2.

Rating from ChatGPT – This is by far the best, most comprehensive and detailed answer ChatGPT has provided yet. Not only did he describe in detail every step for preparing and cooking the product, but he also made a number of correct suggestions regarding the coupon mentioned in the request: how I can use it and what missing ingredients from the list I can purchase with it.

Then, he mentioned that only 500g of the 750g of flour should be used for the proposed recipe, and he also realized that from the list of ingredients provided, two of them are not used for the focaccia recipe. Awesome, ChatGPT!

Gemini Response, like in Fig. 7.

Rating from Gemini – Gemini, this time had a good performance. The answer provided is correct, well structured, explained in detail. The ingredients used are the correct ones for a focaccia, as well as the method of preparation and cooking of the product. He also gave some tips at the end on how to improve the recipe, not bad at all, but not up to ChatGPT's level. Also, he didn't exactly understand the use of the coupon, the idea of the request was to purchase ingredients missing from the list with its help. However, on the whole it performed well the Gemini

model, which until now has accustomed us to not very accurate answers.

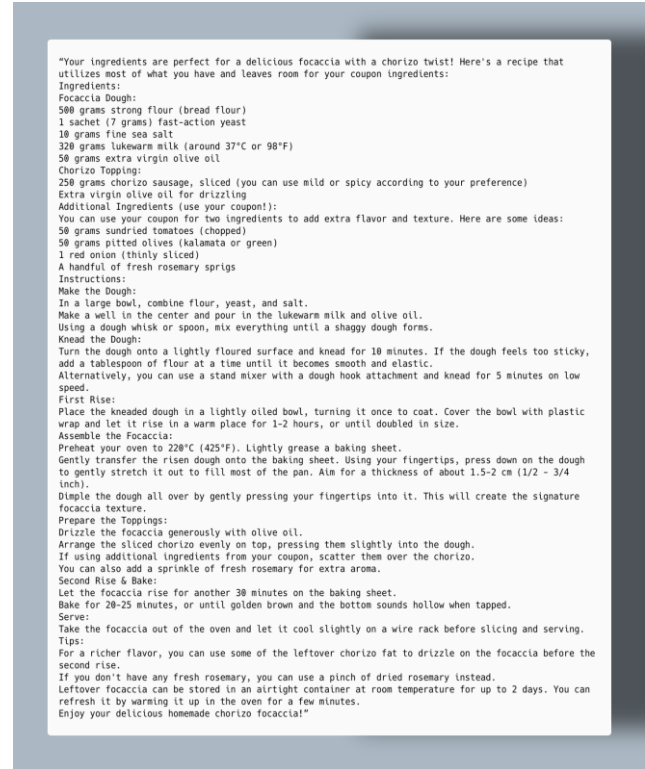

Fig. 7. Gemini response to request2.

Llama3 Response, like in Fig. 8.

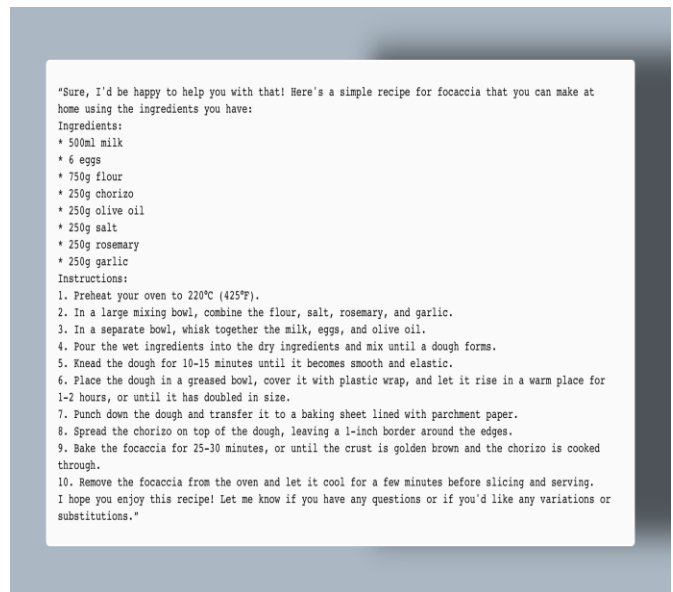

Fig. 8. Llama3 response to request2.

Rating from Llama3 – The Llama3 model used all the ingredients on the list plus some added, and invented a recipe. We could say that he was creative, but comparing the answer with that of the ChatGPT model or even Gemini, I think more that he did not understand exactly the requirement. He did not

mention anything about the coupon, and he also used two ingredients that are not part of the focaccia recipe, ingredients that, at least ChatGPT specified, should not be used. It cannot be compared on this criterion with the first two models, once again remaining in last place. From what I have analyzed so far, it seems that the Llama 3 is not a stable model.

V. DISCUSSIONS

Following the comparative analysis carried out in this paper, we have learned some important aspects about these large linguistic patterns. First, these models are not stable. Although it is true that they were trained on massive data sets, these models have difficulties in solving more complex problems, logic, etc. Also, another argument to support this conclusion is the fact that their answers differ from one request to another, so much so that the final result can be completely different, and here I refer in particular to the Llama3 model. Of the 3 models chosen for comparative analysis, Gemini and Llama 3 are the most unstable.

An important aspect that deserves to be mentioned and put into practice is the observance of the principles of prompt engineering. An essential principle is to assess the quality of models when they do not provide a correct or true answer. Thus, these large language models can improve their performance and accuracy in future responses. This is confirmed by the analysis where ChatGPT's response improved after giving feedback that it did not respect the text size range specified in the request, ultimately providing the correct and complete response. The same can be said about the Gemini model, which improved its response after receiving feedback and respected the text size range specified in the request. Another principle of agile engineering that is very important to follow is providing direction. When interacting with a large language model, it is crucial to provide as much context as possible and to be as specific as possible about what we want to get from that model.

Regarding the performance and accuracy of the three models, observing the table. We can immediately conclude that ChatGPT is the language model that performed best in most of the criteria if we take into account the fact that after evaluating the quality of the answer and giving the feedback, it gave the correct final answer in case of the first evaluation criterion. Also, the ChatGPT language model provided accuracy and precision in most responses.

The Gemini model performed poorly overall, hallucinating several times and not giving accurate answers. These things are supported by several examples, namely: failure to respect the specified size range although we evaluated the quality and provided feedback on this aspect, it is not able to solve a math problem that also involves logic, as well as it is not even able to generate a code in the Python language that does not return an error and works correctly, and in the case of the interview simulator it performed very poorly, compared to the other two big language models, ChatGPT and Llama 3. A positive aspect in the Gemini model is the fact that it does not have an extremely important limitation, namely harmful or toxic results. Gemini, led by Llama 3, demonstrated that they are not limited from this point of view. We can't say the same about ChatGPT, unfortunately.

In terms of performance and accuracy of the answers provided, Llama 3 model is in the 2nd place, so it is located in the middle of the ranking. The worst hallucination from my point of view of this model was in the case of criterion 1 given by the wrong answer to the math problem and the incorrect focaccia recipe.

In conclusion, these large language models are far from stable, far from hallucinating, and even far from having a human understanding of a task. Although a lot is invested in this field, and many articles describe these models as being very capable, in essence, there is still a lot of work to be done before creating a machine with "human" characteristics. It is possible that in 10 years these models will have excellent performance and accuracy to match, but at the moment, although such a model can give you a very elaborate answer, most of the time, it is not useful in everyday reality, as we saw in the interview simulator. It is true, however, that such a model is really helpful, it can give you answers to guide you in your tasks if you know how to ask for these answers.

VI. CONCLUSIONS

Each model has its strengths and is designed to excel in different areas. ChatGPT (GPT-4) is versatile and strong in general-purpose conversational AI. Gemini leverages Google's extensive data and infrastructure for advanced contextual understanding and multilingual capabilities. Llama3 focuses on efficiency and performance, making it suitable for applications requiring lightweight and resource-efficient solutions. The choice between them would depend on the specific requirements of the application, such as accuracy, computational resources, and the need for real-time data integration.

Nowadays, these large language models are massively used in big companies and corporations. By incorporating these models in various fields, companies have witnessed improved customer interactions, improved content generation and efficient data analysis. The large language models have emerged as a transformative force in natural language processing, reshaping the way industries interact with and use text data.

As future directions, we can affirm that the insights gained from this comparative analysis highlight the importance of selecting the appropriate language model based on specific application needs and resource constraints. Future developments in large language models should focus first on improving accuracy and reducing bias where efforts should be made to enhance the accuracy of responses and minimize biases, particularly for models trained on diverse datasets; second on enhancing resource efficiency, continued innovation in model architecture improvement to optimize performance while reducing computational requirements that will be crucial, and third expanding accessibility and use cases that can increase the accessibility of these models and broadening their applicability across different domains and industries that will drive further advancements in artificial intelligence.

In conclusion, ChatGPT, Gemini, and Llama3 each offer unique benefits tailored to different applications, and their continued evolution will play a significant role in the advancement of natural language processing technologies.

Image Generation Using StyleVGG19-NST Generative Adversarial Networks

Dorcas Oladayo Esan, Pius Adewale Owolawi, Chunling Tu

Department of Computer Systems Engineering, Tshwane University of Technology, Pretoria, South Africa

Abstract—Creating new image styles from the content of existing images is challenging to conventional Generative Adversarial Networks (GANs), due to their inability to generate high-quality image resolutions. The study aims to create top-notch images that seamlessly blend the style of one image with another without losing its style to artefacts. This research integrates Style Generative Adversarial Networks with Visual Geometry Group 19 (VGG19) and Neural Style Transfer (NST) to address this challenging issue. The styleGAN is employed to generate high-quality images, the VGG19 model is used to extract features from the image and NST is used for style transfer. Experiments were conducted on curated COCO masks and publicly available CelebFace art image datasets. The outcomes of the proposed approach when contrasted with alternative simulation techniques, indicated that the CelebFace dataset results produced an Inception Score (IS) of 16.57, Frecher Inception Distance (FID) of 18.33, Peak Signal-to-Noise Ratio (PSNR) of 28.33, Structural Similarity Index Measure (SSIM) of 0.93. While the curated dataset yields high IS scores of 11.67, low FID scores of 21.49, PSNR of 29.98, and SSIM of 0.98. This result indicates that artists can generate a variety of artistic styles with less effort without losing the key features of artefacts with the proposed method.

Keywords—Artworks; VGG19; Neural Style Transfer; Generative Adversarial Network; inception score; StyleGAN

I. INTRODUCTION

Drawings, paintings, and carvings with pencils, brushes, and cardboard were traditional tools used by artists to express their unique creativity and ideas [1]. This infers that the production of artwork requires the craftsman who expects to integrate unique and special imaginative artistic styles to invest much time and energy to show their innovative skills, which can be tiring and overwhelming.

The introduction of Artificial Intelligence (AI) into computer technology applications in recent years has made it possible for artists to enhance their original and creative artwork styles incrementally and effortlessly [2]. GANs have received impressive consideration in artistic image generation due to their ability to learn deep representations without extensive training data. GANs utilize their generator engine to reconstruct the input image and discriminator engine to differentiate between the generated images and input images [3].

Traditional GANs are facing challenges of model inability to generate high-resolution images, poor choice of parameter optimisation methods, and difficulty in the generation of another image style from the content of existing images [4].

The lack of in-depth capability to capture intricate image features makes effective transferring of complex artistic styles

to images, resulting in unappealing visual image-generated outputs [5]. Also, most of the existing techniques lack a robust starting point for training, which significantly affects the efficiency and stability of the GANs during the training process [6]. Furthermore, the inability of conventional image generation techniques to separate content and style representations effectively is challenging, thereby affecting the content structure of the original image and the desired style [7]. These issues have significantly affected many artists in the generation of closely related artworks from existing works, thereby creating hindrances for the artist to mitigate their innovative and creative styles in their artworks.

Several studies have made efforts to tackle these issues by using GAN models for artistic image style generation and manipulation [8, 9]. These models include Convolutional Neural Networks (CNNs) [10], Cycle GAN [11], Conditional GAN [12], Genetic Algorithm (GA) [13], etc., which have performed to varying degrees of success, but none have given conclusive solutions to address the challenging gap of creating perfect and realistic artwork due to difficulty in many of the methods to adjust the content structure in images which consequently results in the missing of some important features, distortion, and ambiguity creating local features. Hence, it is important to address the issue of style loss and the generation of imperfect and unrealistic images that most existing GAN models exhibit to assist artists in the improvement and enhancement of their artwork creativity.

To better generate perfect and realistic styled artwork based on existing artwork, this study introduces an innovative method to enhance the creation of artistic images without losing the art image contents. Leveraging StyleGAN, VGG19Net and Neural Style Transfer, StyleGAN generates top-notch images, while the VGG19Net model extracts features and NST is utilized to retain artistic image characteristics for the generation of artistic artefacts having high perceptual and realistic art images [14]. Utilizing this approach can serve as a mechanism for artists to manipulate and generate different artistic styles from existing artworks with minimal effort.

The following are the primary contributions of this study:

1) *Fusion of models*: The development of a new architecture that integrates multiple inputs and outputs, employing a StyleGAN with the application of VGG19Net for feature extraction, and NST for the preservation of image features, and generation of artistic artefacts having high perceptual and realistic art images. This offers an innovative approach to enhance the performance of art image generation.

2) *Parameter optimization*: Tweaking different parameters to enhance the aesthetic images generated for visual quantitative visual evaluation.

3) *Evaluation metrics*: Utilization of different performance evaluation metrics to determine the quantitative enhancement and generation of the newly generated images on the proposed model and other state-of-the-art models.

4) *Computational time*: Evaluation of the proposed model and other selected recent GAN models on the datasets used to determine their execution time on both CPU and GPU systems.

5) *Comparative analysis*: Benchmarking and comparing the proposed model performance on curated Coco Mask African and publicly available CelebFace datasets against other Art GAN models.

The remainder of this article follows this structure: Section II outlines related works and the theories of the proposed method. Section III provides an in-depth explanation of the proposed method. Section IV deliberates on the experimental outcomes and assesses the proposed model. Concluding remarks are presented in Section V.

II. RELATED WORKS

An extension to GANs, called ARTGAN, is proposed in a study in [15] to artificially generate more difficult and complex images, like abstract art. The suggested model can create artwork that looks natural because it learns more quickly and produces high-quality, realistic images based on the CIFAR-10 dataset, as demonstrated by the results the authors obtained. The authors measure the log-likelihood of the generated artwork using the trained GAN models. One of the limitations of this approach is that the generator works with a limited number of image samples and with hyper-parameter choices and generates imperfect images.

The instability of GAN training was addressed with the proposal of StackGAN [16]. By stacking several generators that can produce images with varying resolutions, the authors used a hierarchical structure. The outcomes showed that 256 by 256 resolution images produced by StackGAN can be visually appealing. In contrast to the more advanced technologies used for statistical data conception, visualizing textual data, particularly for creative text is still in its early stages of development. The limitation of this method is that it cannot handle more extreme and varied image transformations.

In study [17], the concept of image super-resolution using Super Resolved Generative Adversarial Networks (SRGAN) was introduced. To produce photo-realistic natural images, the authors incorporated a perceptual loss function that combines both adversarial and content losses. The adversarial loss incentivizes the solution to conform to natural image attributes by employing a discriminator network that has been trained to differentiate between super-resolved images and authentic photo-realistic images. The model was tested on the BSD100 dataset, where the deep residual network successfully reconstructed photo-realistic textures from significantly down-sampled images within the public benchmarks' dataset. Extensive Mean Opinion Score (MOS) testing highlighted substantial enhancements in perceptual quality with SRGAN.

The MOS scores obtained from SRGAN were notably closer to those of the original high-resolution images compared to other prominent methods.

The recovering and restoring of artwork that has been damaged over time due to several factors was introduced in study [18]. The authors utilized a conditional Generative Adversarial Network that involves the generator combining adversarial loss and a discriminator that uses binary cross-entropy loss for optimization. The result of the experiment conducted shows that the method completely removes damage in most of the image and perfectly estimates the damage region. Although the method might be unstable causing the generator to output only a certain type of image and the discriminator to be unable to distinguish between the input image and generated image.

One can see that the existing literature regarding artistic image generation and style techniques has become apparent from the limitations. Previous research has contributed immensely but often lacked comprehensive and advanced approaches to deal with the intricacies of creating perfect and realistic artwork, style loss representation and in-depth capability in capturing intricate image features make effective transferring of complex artistic styles to images. Also, a robust starting point for training optimization of the GANs during the training process is hampered by the computing efficiency of real-time artistic image generation systems. Through a variety of noteworthy contributions like those listed above, this research greatly strengthens solutions to these weaknesses. It develops a novel approach integration of the GAN model which integrates principles of Style Transfer to generate high-quality image styles without losing any art image features.

III. PROPOSED METHOD

This section discusses the suggested approach. There are four steps in the suggested method: (a) image acquisition (b) the image preprocessing stage (c) the image feature extraction stage (d) the image generation stage. A detailed explanation is given in the following subsections.

A. Image Acquisition Stage

The experiments in this study used COCO African Mask art images [19]. The dataset is images of African masks that will help readers experience the pinnacle of African art. This dataset consists of 9,300 images of African art as in Fig. 1.

Fig. 1. Samples of the Coco African mask dataset [19].

The detailed proposed framework is shown below in Fig. 2.

Fig. 2. Proposed styleVGG19-NST framework for artistic image generation.

B. Image Pre-Processing Stage

The input data is pre-processed to improve feature transfer. The pre-processing includes image noise removal and image segmentation. The image pre-processing is done to remove unnecessary and unwanted artefacts that can affect the performance of the GAN models used in this research. Fig. 3 illustrates all the steps in the pre-processing stage used for the implementation of this research.

Fig. 3. Flowchart of pre-processing stage.

1) *Image segmentation (background removal)*: In this study, an Otsu segmentation technique is used to model the image from a series of image frames to perform image segmentation. The foreground image's pixels are separated from the background using this technique. To accomplish this, subtract one image at a time ($t-1$) from the image generated at the time (t). Then the background subtraction is calculated as in Eq. (1).

$$B(x, y, t) = (I_{(t-1)}(x_{t-1}, y_{t-1}) - I_t(x_t, y_t)) > Thr \quad (1)$$

The selected threshold denoted by Thr is dynamically determined to adjust to the changes in frame surroundings. The background image is updated as in Eq. (2).

$$I_{t+1} = \begin{cases} I_t(x_t, y_t) > B(x, y, t), & \text{foreground} \\ \text{otherwise} & \\ I_t(x_t, y_t) < B(x, y, t), & \text{background} \end{cases} \quad (2)$$

2) *Image noise removal*: After extracting the image foreground, some environmental noises are still present in the foreground image, such as illumination, shadow, light intensity etc. This research adopted the median filtering technique where the noisy image pixels are replaced by the average value of their neighbouring pixels (mask) as in Eq. (3).

$$I'(x', y') = \text{median}\{g'(x' + i), (y' + j), i, j \in w'\} \quad (3)$$

Where, $I'(x', y')$ is the image median $g'(x', y')$ is the input image, and $j \in w'$ denotes a 2-D image mask. The output of the enhanced image is passed to the feature extraction stage for further processing.

3) *Feature extraction stage*: At this stage, the objects are recognized based on certain characteristics they possess and the HSV colour feature extraction is utilized as in Eq. (4).

$$\mu_{HSV} = \frac{1}{N} \sum_{i,j}^N = 1 P_{HSV}(i, j) \quad (4)$$

Where μ_{HSV} is the image HSV colour mean value, N is the pixel number, and $P_{HSV}(i, j)$ the colour component in image shape. The output of colour extraction is fed to feature selection to remove any redundant features.

4) *Feature selection*: Feature selection is the selection of a subset of relevant features with short dimensionality, short training time, and low overfitting. The extracted features are then spatially related to each other, but there are some semantic inconsistencies between them which can lead to overfitting. In this study, feature selection is performed using the correlation-based features as in Eq. (5).

$$correlation = \frac{\sum(F_{1i}-\bar{F}_1)\sum(F_{2i}-\bar{F}_2)}{\sqrt{\sum(F_{1i}-\bar{F}_1)^2 \sum(F_{2i}-\bar{F}_2)^2}} \quad (5)$$

Where, (F_1, F_2) represents the cross-correlation between space F_1 and F_2 . The correlations (F_1, F_2) of the two features are in the range of -1 to 1. If two features F_1 and F_2 are independent of each other, then the correlation is $(F_1, F_2) = 0$. The image generation stage receives the feature extraction output after it has been processed.

C. Image Generation Stage

Here, the output of the image extracted is fed to the image generation stage, where the generator (G) is used to generate a 512-dimensional latent vector Z , which is fed into 8 convolutional layers of the Mapping Network (MP). The latent vector Z is converted to a space w that defines the style of the resulting image. The latent code of the input image is continuously optimized for the parameters to achieve the differences between the input image and the generated. The latent code Z , often referred to as the latent spatial mapping of the image, is applied to reduce the painterly style. The vector Z is sampled from a predefined distribution (uniform Gaussian distribution) in the latent space Z which is mapped to the latent space N to produce w which is passed to the AdaIN module. After the model has been trained, the generator is applied to gradually increase the resolution of generated images with 8 convolutional layers from 512x512 to 1024x1024, and AdaIN to add noise to each layer. AdaIN (Adaptive Instance Normalization) converts the latent vector into two scalars (scaling and bias) to control the style of the image generated at each resolution level. In this module, the encoded information w obtained from the mapping network to the generated image. The latent code 'w' generated by the mapping network is passed to the affine transform and AdaIN layer for training. Affine transformations are implemented using two linear planes to create a style using the AdaIN in Eq. (6).

$$AdaIN(x, y) = y_{s,i} \frac{x_i - \mu(x_i)}{\sigma(x_i)} + y_{b,i} \quad (6)$$

Where x is the output feature map to the previous level. AdaIN first normalizes the "zero mean" and "uniform variance" of each channel x_i and then applies the scales y, s and y, b . This means that style y controls the stats of the next convolutional layer's feature map. Where y, s is the standard deviation and y, b denotes the mean.

The discriminator (D) receives the generated image afterwards. A backpropagation algorithm is used to modify the weights of the three networks to enhance the quality of the final image. Furthermore, the generated image from the StyleGAN model was fed into the VGG-19 model alongside the content image. StyleGAN uses a combination of Progressive Generative Adversarial Networks (PGGAN) and neurotransmission

techniques [20]. StyleGAN has gained prominence due to its ability to transform low-resolution images into enhanced images [21]. The mean and variance of the feature map x_i generated by the layers in the synthetic network are altered by StyleGAN using reference style bias $y_{b,i}$ and scale $y_{s,i}$ in equation (6). As shown in Fig. 4, the generator grows incrementally, adding new constants, scaling the image, and applying style and noise to each block as illustrated in Fig. 4.

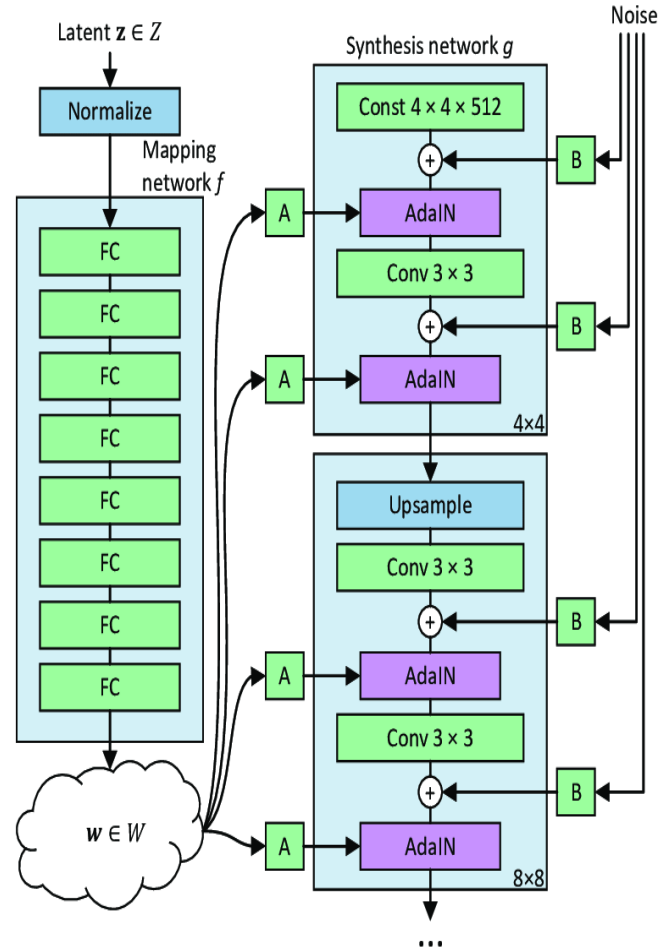

Fig. 4. Architecture of StyleGAN adopted from study [22].

D. Stochastic Variation with Noise Injection

Stochastic variations in an image are small details that do not change the context of the image. There are generators embedded in StyleGAN that try to learn how to generate image styles and content. Noise injection into the StyleGAN created before the AdaIN layer helps create such variations. The noise added to the feature map has zero mean and low variance compared to the feature map. Therefore, the overall context of the image is preserved as the feature map statistics remain the same. From the network, the latent W vector is employed to control the image style of the generated images.

E. VGG19-Network

The VGG-19 is a fully connected model with nineteen deep trainable convolutional layers that include dropout and max pooling layers. The convolutional layer is trained to extract features produced by the StyleGAN in this paper. model output

with a regularized dropout layer and a densely connected classifier [23]. To extend the depth, VGG-19 employs a 3×3 convNet configuration. To reduce dimensionality, max-pooling layers are utilized as handlers. The two FCN layers contain 4096 neurons each. To minimize the false positives, while testing, all lesions are considered, as VGG is trained on individual lesions. Convolution layers execute convolution operations across pixel by pixel, enabling the output to progress through the next layers. Filters within the convolution layer are typically 3×3 in size and are trained to extract features. After every series of convolutional layers, a Rectified Linear Unit (ReLU) layer and a max-pooling layer are included. ReLU is recognized as an effective non-linear activation function, permitting only the positive values from the input. The architecture of VGG-19 is illustrated in Fig. 5.

Fig. 5. VGG-19Net adopted from study [23].

F. Neural Style Transfer Model

Blending two images, one with content and the other with style can result in new artwork through Neural Style Transfer. The process of transferring an image's style while preserving its content is known as Neural Style Transfer. To add an artistic touch to your image, all that needs to be changed are the style configurations. The two sets of images that Neural Style Transfer works with are the content image and the Style image.

The content image can be replicated using this technique in the reference image's style. The creative style is applied from one image to another using Neural Networks. To synthesize features and transfer style from one image to another, NST uses a pre-trained Convolutional Neural Network with additional loss functions. NST specifies the following inputs:

- an input (generated) image (g) that contains the final result.
- a content image (c) that is the image to which a style is to be transferred.
- an input style image (s) that is the image from which the style is to be transferred.

The Neural Style Transfer architecture is depicted in Fig. 6.

Fig. 6. Neural Style Transfer architecture adopted from study [24].

1) *Content loss*: Comparisons between the content image and the generated image are made easier by the content loss. The model's upper layers, intuitively, concentrate more on the characteristics seen in the image (the picture's general content). The equation for content loss computes the Euclidean distance between the input image (x) and the content image (p) at layer l , which correspond to the respective intermediate higher-level feature representations. The content loss is shown in Eq. (7).

$$L_{content}(\vec{p}, \vec{x}, l) = \frac{1}{2} \sum_{i,j} (F_{ij}^l - C_{ij}^l)^2 \quad (7)$$

In this context, with the content image denoted as "C," the target image as "x," and the processed layer as "l," "F" and "P" represent the feature representations of the content image and the target image, respectively, on layer "l."

2) *Style loss*: Style loss, similar to content loss, uses the squared loss function to measure the difference in style between the synthesized image and the style image. The style loss involves calculating the Maximum Mean Discrepancy between two images, and it is determined using Eq. (8).

$$\mathcal{L}_{style}(\vec{p}, \vec{x}) = \sum_{l=0}^L w_l E_l \quad (8)$$

Where, w_l is a weight given to each layer during loss computation, the content image is p , and x is the target image.

Three key components are essential for generating a style transfer image: content image, style image and generated image. The content image and the style image are modified together to generate new artistic images. The style is the variation added to the content image that produces an entirely new image. The NST model produced stylized images resembling a blend of the content and style images.

Maintaining the generated image's proximity to the local textures of the style reference image was achieved by utilizing the style loss function. However, the generated image's high-level representation is maintained close to the base image by the content loss function. To ensure that the generated locally coherent, the total loss function is used.

G. Evaluation Mechanism

Quantitative and qualitative evaluation metrics are used in this research to analyse the performance of a proposed model. For the quantitative evaluation, the FID, PSNR, SSIM, and IS. For the qualitative evaluation, the enhancement of the image is visually inspected to show the performance of the models used in terms of image clarity. The quantitative metrics are further explained in the following sub-section.

1) *Frecher Inception Distance (FID)*: This metric is used to quantitatively evaluate the quality of created images using the proposed model [25] as in Eq. (9).

$$FID(r, g) = \|\mu_r - \mu_g\|_2^2 + Tr(\Sigma_r + \Sigma_g + 2(\Sigma_r \Sigma_g)^{1/2}) \quad (9)$$

Where the mean and covariance of the real and generated data are represented as $(\mu_g, \Sigma g)$ and $(\mu_r, \Sigma r)$.

2) *Inception Score (IS)*: The quality of images generated by GANs is measured by the inception score [25], as in Eq. (10).

$$\exp(E_x[KL(p(m|n) || p(m))]) = \exp(H_y - E_x[H(m|n)])(10)$$

Where, $p(m|n)$ is the probability of marginal image distribution.

3) *Peak Signal-to-Noise Ratio (PSNR)*: This compares the peak signal-to-noise ratio of two monochrome images, I and k, to determine how good a generating image is compared to a set of real images. As the PSNR (measured in dB) rises, the generated image's quality increases. It is computed as in Eq. (11).

$$PSNR(I; K) = 10 \log_{10} \left(\frac{\max_i^2}{MSE} \right) = 20 \log_{10}(\max^2 I) - 20 \log_{10}(MSE_{I,K}) \quad (11)$$

$MSE_{I,K} = \frac{1}{m} \sum_{i=0}^{m-1} \sum_{i=0}^{n-1} (I(m, n) - K(m, n))^2$ and Max_i is the minimum possible pixel value.

4) *Structural Similarity Index Measure (SSIM)*: This is an indicator of how similar two images are to one another. The SSIM is expressed as in Eq. (12).

$$SSIM_{(x,y)} = [l(x, y)]^\alpha \cdot [c(x, y)]^\beta \cdot [s(x, y)]^\gamma \quad (12)$$

Where, α , β , and γ are the positive constants, and l , s , and c are the luminance, brightness, and contrast ranges, respectively, that are used to compare two images. On the other hand, the structure s is utilized to analyze the local luminance pattern of two images to determine their level of similarity or dissimilarity.

IV. RESULT AND DISCUSSION

This section presents different experiments carried out to achieve the generation of historical artistic images using the proposed method. The configuration and parameter settings and the experimental simulation are discussed in the subsequent section.

A. Configuration Experimentation and Parameter Setting

The experiment was done on a Central Processing Unit (CPU) and Graphic Processing Unit (GPU) computer using the Google Collaboratory with the Tensor Flow library installed independently. Experiments were quantitatively and qualitatively conducted on both the COCO Mask African dataset and publicly available CelebFace datasets which were validated on selected techniques in sections B - D. A total of 1,500 frames were selected during the simulation. This test data can assist in effective observations of the test performance of the pre-trained proposed model on the trained model. The image resolution is 512*512 and the training has been iterated 1500 times with

0.0001 learning rates and 250 batch numbers. The values chosen for learning rate and batch iterations improve stability and speed during training. Detailed experiments are described in the next section.

B. Hyperparameter Selection for the Proposed Model

During the implementation, the proposed SyleGANVGG19-NST model parameter values were set to the following as shown in Table I.

TABLE I. HYPERPARAMETERS USED IN THE IMPLEMENTATION OF TRAINING STYLEGAN MODELS

Parameters	Values
Learning rate	0.0001
Batch size	250
Epochs	1500
Beta	0.5
Adversarial loss mode	lsgan
loss weight	10
Identity loss weight	0
Pool size to store fake samples	60

C. Experiment 1.1: A Qualitative Evaluation of the Proposed Model and the Existing Recent Used GANS on the COCO African Mask Dataset

The objective of this study is to address the issue of image style transfer and also generate images with high resolution using the style transfer. Different image pre-processing methods were used, such as image enhancement and feature extraction.

Fig. 7. Qualitative evaluation of SyleGANVGG19-NST model on COCO African mask dataset.

Fig. 7(a), 6(f), 7(k), and 7(p) consist of the original/content image, Fig. 7(b), 7(g), 7(l), and 7(q) is the style image to be matched with the content image, Fig. 7(c), 7(h), 7(m), and 7(r) are the generated image and Fig. 7(d), 7(j), 7(n), and 7(s) is the second style image to be matched with the content image, Fig. 7(e), 7(j), 7(o), and 7(t) are the second generated images. This result shows that the proposed model was able to generate an artistic image that is different from the content image. Furthermore, the proposed method is compared with other recently used baseline methods as shown in Fig. 8.

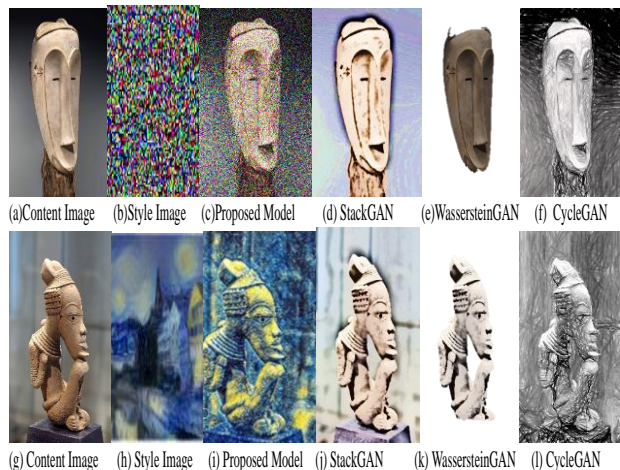

Fig. 8. Qualitative evaluation of the proposed model with other recent baseline art GAN models.

Fig. 8(a) and 8(g) show the content of the original image, Fig. 8(b) and 6(h) shows the style, Fig. 8(c) and (i) are the

images generated by the proposed StyleVGG19-NST, Fig. 8(d) and (j) represent the image generated by the Stack GAN model, Fig. 8(e) and (k) and Fig. 8(f) and (l) are the images generated by the Wasserstein GAN and CycleGAN models respectively. One can see that the images generated by the Style method do not transfer the style image into the generated images, the Wasserstein GAN-generated images in Fig. 8(e) have a style transfer issue as some parts of the image generated have already been cut off. The image obtained in Fig. 8(c) and 8(i) a clearer image generated by the proposed StyleVGG19-NST method which contains the style image compared with other methods. Loss values of the corresponding training of the selected models with the proposed model as in Table II.

Table III shows the iteration of training loss for all the models, one can observe that the proposed model has lower content loss values compared to other models, and this shows the consistency of the model in terms of generated image content with the original image. The findings from this experiment show that the optimization used in this experiment was able to generate a perfect image with epoch 1500 which is better in comparison to the image generated with optimization parameters in study [15].

D. Experiment 1.2: Quantitative Evaluation of the Proposed Model and the Existing Recent Used GANS on Curated Dataset

This section aims to quantitatively compute the generated images because of the difficulty in evaluating the model objectively using only subjective visual assessment of the synthetic image. The summary of the result generated in terms of FID, IS, PSNR and SSIM score is used in Table III.

TABLE II. GENERATOR AND DISCRIMINATOR LOSS VALUES WITH DIFFERENT EPOCHS FOR COCO AFRICAN MASK DATASET

Epoch	StackGAN		Wasserstein GAN		CycleGAN		Proposed model	
	Discriminator loss	Generator loss	Discriminator loss	Generator loss	Discriminator loss	Generator loss	Discriminator loss	Generator loss
200	0.3095	0.8521	0.3721	0.4176	0.3216	0.3987	0.2112	0.2021
500	0.3728	0.5711	0.3364	0.3792	0.3411	0.3769	0.3462	0.3291
800	0.3111	0.4277	0.3516	0.3618	0.3423	0.3591	0.3063	0.2537
1000	0.3693	0.3631	0.3433	0.3536	0.3482	0.3419	0.3146	0.3093
1500	0.4331	0.2911	0.4036	0.3240	0.3855	0.3892	0.3021	0.2187

TABLE III. METRICS RESULT OF THE PROPOSED MODEL WITH OTHER RECENTLY USED ART GAN MODELS

Models	FID	IS	PSNR	SSIM
StackGAN	24.83	6.13	21.85	0.61
Wasserstein GAN	25.56	7.76	24.19	0.68
CycleGAN	29.32	5.72	25.59	0.78
Proposed Model	21.49	11.67	29.98	0.98

From Table III, the art image generated using the proposed StyleVGG19-NST model has improvements in FID, IS, PSNR, and SSIM compared with the Stack GAN, Wasserstein GAN, and CycleGAN models. The proposed model has a higher IS of 11.67, a lower FID of 21.49, an SSIM of 0.98 and a higher PSNR of 29.98 The higher IS, SSIM, and PSNR signifies that the better

image quality produced by the proposed StyleVGG19-NST model, and the lower FID indicates that the proposed model generated images that have more structural features than the original image. The findings here show that the proposed method has a better image generation in terms of FID in comparison to the method used in study [16].

E. Experiment 2: Benchmarking the Proposed Methodology on Publicly Available Celebface Dataset

Since there is no common set of image data of similar artistic for the different existing techniques, the validation performance of the proposed technique is tested on a publicly available CelebFace dataset. The face image is randomly selected. The result obtained from the proposed model is compared with some existing recent state-of-the-art Art GAN techniques in terms of image style generation and the use of qualitative evaluation

metrics such as FID, IS, PSNR, and SSIM. The details of the experiments are presented in the following sections.

F. Experiment 2.1: A Qualitative Assessment of the Proposed Model and the Existing Recent Art Gans on the Celebface Dataset

The objective is to assess the dependability and strength of the proposed model using the CelebFace dataset, which is openly accessible. The performance of the image pre-processing stages in image enhancement and feature extraction on curated datasets is qualitatively evaluated as shown in Fig. 9(a)-(o).

Fig. 9. Qualitative evaluation of the proposed model on the CelebFace dataset.

Fig. 9(a), 9(f), and 9(k) consists of the original/content image, Fig. 9(b), 9(g), 9(l) is the style image to be matched with the content image, Fig. 9(c), 9(h), and 9(m) are the generated image and Fig. 9(d), 9(i), and 9(n) are second style images to be matched with the content image, Fig. 9(e), 9(j), and 9(o) are the second generated images. This result shows that the proposed model was able to generate a stylistic artistic image that is different from the content image. Furthermore, the proposed model and the other existing recent Art GAN models as shown in Fig. 10(a) - (l).

Fig. 10(a) and 10(g) show the images Content image, Fig. 10(b) and 10(h) shows the style, Fig. 10(c) and 10(i) are the images generated by the proposed model, Fig. 10(d) and 10(j) represent the image generated by the Stack GAN model, Fig. 10(e) and 10(k) and Fig. 10(f) and 10(l) are the images generated by the Wasserstein GAN and CycleGAN models respectively. The image obtained image in Fig. 10(c) and 10(i) a clearer image generated by the proposed image which contains the style image compared with other methods.

Fig. 10. Qualitative evaluation of the proposed model with other recent baseline art GAN models.

The generator and discriminator loss values of the corresponding pre-trained selected models with the proposed model are shown in Table IV.

TABLE IV. GENERATOR AND DISCRIMINATOR LOSS VALUES WITH DIFFERENT EPOCHS

Epoch	StackGAN		Wasserstein GAN		CycleGAN		Proposed model	
	Discriminator loss	Generator loss	Discriminator loss	Generator loss	Discriminator loss	Generator loss	Discriminator loss	Generator loss
200	0.381	0.4473	0.3931	0.5211	0.2652	0.2827	0.3667	0.3117
500	0.3693	0.3652	0.3672	0.3633	0.2977	0.3081	0.3406	0.3513
800	0.3511	0.3630	0.4021	0.4213	0.3211	0.2953	0.3542	0.3911
1000	0.3271	0.4019	0.3163	0.3177	0.3123	0.3078	0.3183	0.3485
1500	0.3522	0.3586	0.3011	0.3033	0.3433	0.3988	0.3496	0.3698

Table IV shows the iteration of training loss for all the art GAN models, it is observed that the proposed model has lesser content loss values compared to other existing recent Art GAN models, and this shows the consistency of the model in terms of generated image content with the original image.

G. Experiment 2.2: Quantitative Evaluation of the Proposed Technique and the Existing Recent Art Gans on the Celebface Dataset

This section aims to quantitatively evaluate the generated images because of the difficulty in evaluating the model objectively using only subjective visual assessment of the synthetic image. The summary of the result generated in terms of FID, IS, PSNR and SSIM score is used as shown in Table V.

TABLE V. METRIC RESULT OF THE PROPOSED TECHNIQUE WITH OTHER EXISTING RECENT ART GAN MODELS

Models	FID	IS	PSNR	SSIM
StackGAN	45.32	9.31	21..32	0.78
Wasserstein GAN	31.45	10.29	24.25	0.83
CycleGAN	35.92	8.11	22.73	0.89
Proposed StyleVGG19-NST method	18.33	16.54	28.33	0.93

From Table VI, one can observe that the proposed StyleVGG19-NST method used in this research on the input image has improvements in terms of FID, IS, PSNR and SSIM compared with the Cycle GAN, DC GAN, and C-GAN models. The proposed model has a higher IS of 16.54, a lower FID of 18.33, an SSIM of 0.93 and a higher PSNR of 28.33. The higher IS, SSIM, and PSNR indicate that the proposed model generates better image quality, and the low FID score signifies that the proposed StyleVGG19-NST model produced images that have more structural features than the original image. Furthermore, the FID of the proposed method is better than the author in study [18].

H. Computational Time

Since most of the image-generated models evaluate the computational time of the model, the computational time of the selected recent Art GAN models is also measured in this

research using the same image resolution, the epoch of 1500, and GPU processor on both curated Coco African Mask and publicly available CelebFace datasets. The computational time for each model is shown in Fig. 10(a) and (b) respectively.

From Fig. 11(a), the proposed model has a lower computational time on the same dataset with the same GPU when compared to other techniques. Also, Fig. 11(b) exhibits that the proposed model has a reduced computational time of 45 hours in comparison to other models.

I. Benchmarking Proposed Model with Other Existing Recent Art GAN Techniques in Literature

Validating the performance of the proposed model on CelebFace datasets by comparing it to widely used GAN techniques for artistic image generation is one of the study's goals. The comparison of the proposed StyleVGG19-NST model with recent Art GAN approaches in terms of the dataset, IS score, FID, PSNR, and SSIM score is shown in Table VI.

From Table VI, the proposed model shows significantly better performance on the celeb datasets with FID of 21.49, IS of 11.69, PSNR of 29.98 and SSIM of 0.98 compared to other models. It's worth noting that the higher the IS, PSNR and SSIM of the model the better image quality generated, and the lower the FID the better the structural features that the proposed methodology exhibits when compared with selected baseline recent Art GAN techniques.

Fig. 11. Computational time of the proposed model with other recent art GAN models; (a) Coco african mask dataset and (b) publicly available CelebFace dataset.

TABLE VI. COMPARATIVE OF PROPOSED MODEL WITH OTHER EXISTING RECENT ART GAN MODELS

Ref	Model	Dataset	FID	IS	PSNR	SSIM
[26]	Boundedness and Continuity GAN (BC-GAN).	Celeb Face	22.8	8.40	19.76	0.76
[27]	Layered Recursive GAN (LR-GAN)	Celeb Face	-	7.17	-	0.89
[28]	Orthonormal	Celeb Face	27.40	2.9	13.56	-
[29]	Denosing Feature	Celeb Face	37.72	-	-	-
[30]	MSGAN	Celeb Face	28.44	-	17.78	-
Proposed Model	StyleVGG19-NST	Celeb Face	21.49	11.67	29.98	0.98

V. CONCLUSION

In this study, the proposed StyleVGG19-NST model was applied to the Coco African Mask artistic dataset and the publicly available CelebFace dataset to generate realistic artistic. The trained model network generated convincing artistic images compared to other baseline model images due to the ability of the proposed model to learn the rich and varied distribution of images. The use of a generator and discriminator network allows the proposed method to capture the spatial structure of an image, which is essential for many artistic image generation tasks. The application of this proposed model on curated artistic dataset images can transform works of art into different styles. Also, both generative loss and adversarial loss values are presented to apply constraints on brightness, colour contrast, and structure of the generated image. This allows the network to converge faster and retain more image detail as a result.

Qualitative and quantitative simulations were performed on the publicly available CelebFace dataset and the curated artistic dataset using the proposed method and other selected baseline methods. The qualitative comparison results show that the proposed model produces better and higher image quality in terms of structural and texture features compared with the baseline models. From the quantitative analysis perspective, the results of the proposed technique on the curated dataset have a high IS score of 11.67, a low FID score of 21.49, PSNR of 29.98 and SSIM of 0.98 while on the CelebFace dataset, the IS of 16.57, FID of 18.33, PSNR of 28.33 and SSIM of 0.93 which is superior compared to other methods used in the simulation. Furthermore, the computational period of the proposed method and baseline models on both curated and publicly available CelebFace datasets with the same training iterations processes show that the proposed technique has a lower computational time than to other models used in the simulation with 48 hours. The overall results of this research exhibit the potential of the proposed methodology for artistic image generation and suggest that the proposed model can be used for extensive image-generation tasks.

Further research is needed to explore how the proposed model performs. Also, future work can be investigated on how inherent biases in the training data of the proposed model can translate to the generated images. Nevertheless, the findings presented in this study can help artists in the generation of different artistic styles with less effort.

ACKNOWLEDGMENT

The authors would like to thank the Department of Computer Systems Engineering for their financial support.

Xiangyang 441025, Hubei, China

Abstract—Combining advanced intelligent algorithms to improve the scene visual understanding and recognition method for art design can not only provide more inspirations and creative materials for artists, but also improve the efficiency and quality of art creation, and provide scientific and accurate references of artworks. Focusing on the art design scene visual understanding and recognition problem, a scene visual understanding and recognition method based on the intelligent optimization algorithm to optimize the structural parameters of the multilayer perception machine is proposed. Firstly, the scene visual recognition method is outlined and analyzed, and the application scheme of multilayer perceptron in the understanding and recognition problem is designed; then, for the problems of the multilayer perceptron model, such as the training does not generalize, combined with the Pond's optimization algorithm, the training parameters of the multilayer perceptron model are optimized, and the visual understanding and recognition scheme of the art design scene is designed; finally, the proposed model is verified with the image dataset, and the scene visual understanding and recognition accuracy reaches 0.98, compared with other models, the proposed method has higher recognition accuracy. This research solves the problem of scene visual understanding and recognition, and applies it to the field of art design to improve the efficiency of art design assistance.

Keywords—Art design; scene visual understanding and recognition; multilayer perceptron; pond goose algorithm; image dataset

I. INTRODUCTION

Traditional art design methods are carried out using software or hand-drawing and so on [1]. With the rapid development of multimedia technology, the art design method based on computer technology has gradually been highly valued by experts and scholars in the field of art design [2]. At present, art design software presents diversified types and functions, which enriches the creativity of visual effects, improves the working method of art design, and becomes one of the future trends of art design research [3]. Scene visual understanding and recognition, as one of the key technologies most widely used in the field of art, uses computer vision and image processing technology to deeply understand and analyse the scenes in images and videos [4]. Art design that combines scene visual understanding and recognition algorithms can provide artists with more inspiration and creative materials, and can also improve the efficiency and quality of art creation and provide scientific and accurate references for artwork [5]. Therefore, the study of art design methods combining scene visual understanding and recognition algorithms is an

important theoretical research significance for art design to assist decision-making and creation. According to the principle of design process, the research on scene visual understanding and recognition for art design generally includes the research contents of scene image segmentation, extraction of target features, and understanding and recognition model construction [6]. Scene image segmentation processes the image from colour segmentation, morphological processing, etc.; extracting target features captures the key information of the image, i.e., shape, colour, texture, edges, etc.; as a key part of the scene visual understanding and recognition problem [7], deep learning or machine learning algorithms are trained and constructed based on the annotated feature sample set. According to the principle of the core approach, scene visual understanding and recognition methods can be classified into search-based scene visual understanding and recognition methods [8], template matching-based scene visual understanding and recognition methods [9], and language model-based scene visual understanding and recognition methods [10]. Sandrine et al [11] obtained image descriptions by constructing the mapping relationship between images and texts using similarity to obtain the compliant utterances; Mustafa et al [12] proposed a visual scene description scene based on coordinate position by analysing a large number of images and annotation information; Daniel et al [13] improved convolutional neural network using encoding-decoding network to further improve the accuracy of the scene visual understanding recognition model; Chen et al [14] combined the current state of the art of domestic and international research and used encoding-decoding network and attention mechanism model to construct and analyse the visual scene understanding model. Although the current scene visual understanding and recognition algorithms for art design have achieved a lot of results and application progress, there are still some challenges, such as the generalisation ability needs to be improved, more sensitive to the smile change of the data, the real-time needs to be further improved, and the consumption of computational resources is more [15].

This paper focuses on the scene visual understanding and recognition problem for art design, combines the intelligent optimization algorithm to optimize the network structure parameter framework paradigm [16], and puts forward a scene visual understanding and recognition method based on the optimization of the Pond's Goose algorithm to improve the multilayer perceptual machine model. Aiming at the characteristics of the scene visual understanding and recognition problem for art design, the scene visual understanding and recognition model algorithm and its

optimisation strategy are analysed and introduced, and at the same time, the method of Pond's Goose algorithm optimisation recognition is applied to the scene visual understanding and recognition problem for art design, and the art-related data is used to compare the other five recognition models, which verifies the high efficiency of the proposed method and the high accuracy and real-time performance.

II. OVERVIEW OF IDENTIFICATION METHODS

A. Analysis of the Problem

1) *Introduction to the issue:* In the field of art design, scene visual understanding recognition algorithms are mainly used to automatically identify and classify images in art works, or automate the processing of art works to improve the efficiency and quality of art creation [17]. In the art market, scene visual understanding algorithms can be used for art appraisal and valuation to provide a more scientific and accurate reference for art transactions. The main applications of scene visual understanding recognition algorithms in the field of art design are shown in Fig. 1.

Fig. 1. Scene visual understanding recognition algorithm application.

In this paper, the scene visual understanding recognition algorithm is used to extract the target features in the complex scene image, complete the combination design of the extracted target, and realise the art assistance, so the research in this

paper is mainly used to automatically identify and classify the images in the art work. For the problem of target recognition and classification in complex images, this paper adopts multi-layer perceptron to construct the mapping relationship between target features and target information, as shown in Fig. 2.

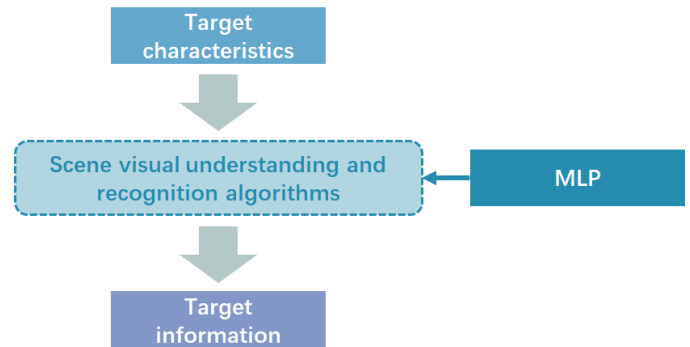

Fig. 2. Scene visual understanding and recognition solution architecture.

2) *Multimodal feature extraction:* In order to obtain as much information about the image target features and improve the accuracy of the understanding recognition algorithm, this paper firstly rubs the coarse segmentation technique [18] for colour segmentation of the scene image; then, the effective description region is processed morphologically; finally, the scale invariant feature transform technique is used to extract the target features in the candidate region. The multimodal feature extraction is shown in Fig. 3, and the principle of Scale Invariant Feature Transform (SIFT) [19] technique is shown in Fig. 4.

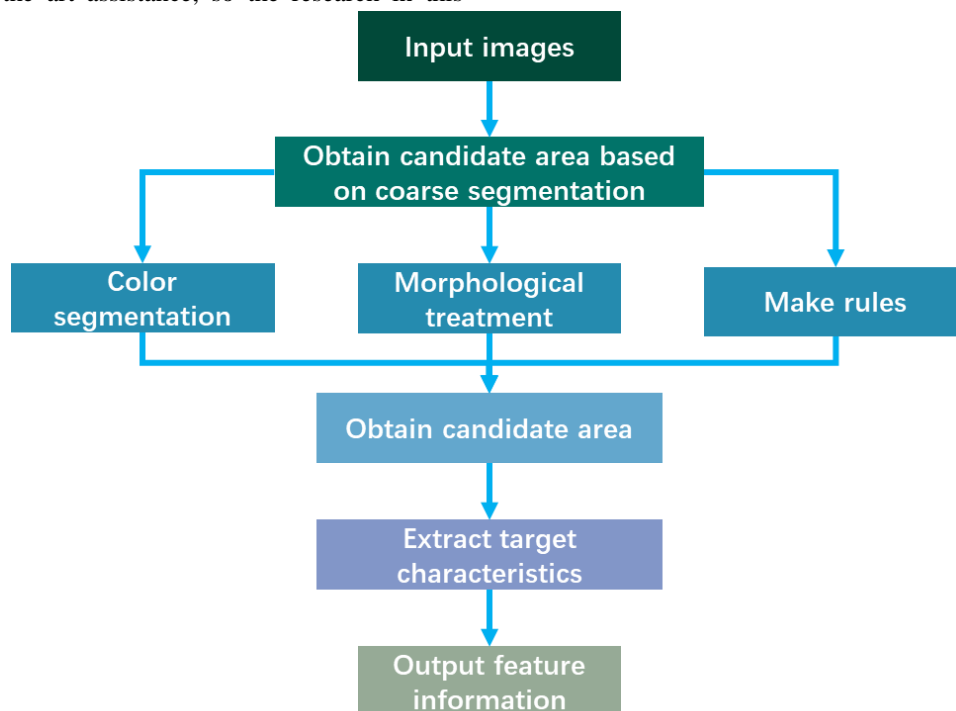

Fig. 3. Multimodal feature extraction.

Fig. 4. Principle of SIFT technology.

B. Overview of Multilayer Perceptron

Multilayer perceptrons (MLP) [20] is the introduction of multiple hidden layers on top of a single-layer neural network. MLP networks can acquire complex relationships between inputs through hidden layer nodes, the inputs undergo an activation function, which produces the final prediction through the output layer. MLP networks require at least three layers of artificial neurons. The MLP input layer will be make each node connected to the hidden layer according to the input sample set vector dimensions. The hidden layer generally uses a sigmoid function to make the feature data from the hidden layer to the output layer very smooth.

$$f(x) = \frac{1}{1 + \exp\left(-\sum_j w_j x_j - b\right)} \quad (1)$$

Where, $f(x)$ denotes the hidden layer output, w_j denotes the node weights and b denotes the node bias.

The parameters of MLP network include the number of hidden layer nodes, hidden layer node excitation function, and connection weight. For the selection of the number of hidden layer nodes, this paper adopts an experimental approach, taking different numbers of nodes respectively, observing the recognition accuracy, and taking the number of nodes with the largest accuracy. For the hidden layer node excitation function, this paper adopts the sigmoid function as the activation function [21]; for the connection weight, MLP generally adopts the back propagation algorithm [22]. Backpropagation can be used to train feed-forward artificial neural networks with any layers and any number of hidden units, but the practical limitations of computational power will constrain the ability of backpropagation, therefore, this paper adopts the Pond's algorithm [23] as the optimisation algorithm for the selection of MLP network structure parameters.

$$C(w, b) = \frac{1}{2n} \sum_x \|y(x) - a\|^2 \quad (2)$$

$$w_k = w_k - \frac{\eta}{m} \sum_j \frac{\partial C_{x_j}}{\partial w_k} \quad (3)$$

$$b_k = b_k - \frac{\eta}{m} \sum_j \frac{\partial C_{x_j}}{\partial b_k} \quad (4)$$

where w and b denote the structural weights and biases of the MLP network, respectively.

MLP is applied to many fields, including image recognition, speech processing, language analysis, etc., and is mainly applied to complex nonlinear mapping relationship processing.

C. Application of Multilayer Perceptron Machine in Comprehension Recognition

The application of MLP to the problem of English recognition for visual understanding of scenes oriented to the field of art and design is mainly shown in Fig. 5. The input vector of MLP is the target features extracted from the image, and the output vector is the category of the target.

Fig. 5. MLP applications

III. RECOGNITION METHOD OPTIMISATION ALGORITHM

In order to improve the recognition accuracy of the multilayer perceptron network, this paper chooses the pond goose algorithm as the recognition method optimisation algorithm, the specific optimisation process is as follows:

A. Pond's Goose Algorithm

The Gannet Optimization Algorithm (GOA) [24] is a natural heuristic optimization algorithm that mimics the behaviour of the pond goose. The algorithm is used to explore optimal solutions in the search space by mathematically modelling the U- and V-diving behaviours of the Pond Goose during foraging as well as sudden rotations and random wandering. The GOA is designed to balance the capabilities of global exploration and local exploitation in order to improve the efficiency of solving engineering optimisation problems.

1) *Initialisation phase*: The GOA algorithm uses a random initialisation strategy for population generation, which generates uniformly distributed GOA population locations from each dimension using upper and lower bounds of the search space.

2) *Exploration phase*: The exploration phase of the GOA algorithm simulates the U- and V-diving behaviour of the pond goose after finding prey in the air (shown in Fig. 6) for global search.

Fig. 6. The GOA algorithm U- and V-dive behaviour.

Pond geese dive in a U-shaped dive when prey is at greater depths:

$$a = 2 \times \cos(2 \times \pi \times r_2) \times t_1 \quad (5)$$

Pond geese dive in a V-dive when prey is in a relatively shallow position:

$$a = 2 \times V(2 \times \pi \times r_3) \times t_1 \quad (6)$$

$$V(x) = \begin{cases} -\frac{1}{\pi} \times x + 1 & x \in (0, \pi) \\ \frac{1}{\pi} \times x - 1 & x \in (\pi, 2\pi) \end{cases} \quad (7)$$

$$t_1 = 1 - \frac{t}{T_{\max}} \quad (8)$$

Where t denotes the number of contemporary iterations, T_{\max} denotes the maximum number of iterations, and r_2 and r_3 denote random numbers, respectively.

The position of the pond goose is updated by introducing a random variable q and randomly selecting either a U-dive approach or a V-dive approach:

$$MX_i(t+1) = \begin{cases} X_i(t) + u_1 + u_2 & q \geq 0.5 \\ X_i(t) + v_1 + v_2 & q < 0.5 \end{cases} \quad (9)$$

$$u_2 = A \times (X_i(t) - X_r(t)) \quad (10)$$

$$v_2 = B \times (X_i(t) - X_m(t)) \quad (11)$$

$$A = (2 \times r_4 - 1) \times a \quad (12)$$

$$B = (2 \times r_5 - 1) \times b \quad (13)$$

Where r_4 and r_5 denote random numbers, u_1 is a random number between $-a$ and a , v_1 is a random number between $-b$ and b , $X_i(t)$ denotes the position information of the i -th song pond goose individual in the t -th iteration, $X_r(t)$ denotes the position of the randomly selected pond goose individual, $X_m(t)$ denotes the average of the position of all the pond geese individuals, and the calculation is as follows:

$$X_m(t) = \frac{1}{N} \sum_{i=1}^N X_i(t) \quad (14)$$

3) *Development phase*: The GOA algorithm development phase simulates the capture behaviour of the pond goose in the water, and based on the capture ability of the pond goose decides whether to perform a random swim or a sudden rotation to capture the prey (as shown in Fig. 7).

Fig. 7. GOA algorithm development phase.

When the pond goose enters the water, its catching ability C is greater than or equal to c , it will suddenly rotate to catch fish; its catching ability C is less than c , it will give up catching fish and march randomly, the Levy flight model is used to simulate the marching of the pond goose, and the specific model of the position update is as follows:

$$MX_i(t+1) = \begin{cases} t_1 \times \delta \times (X_i(t) - X_{best}(t)) + X_i(t) & C \geq c \\ X_{best}(t) - (X_i(t) - X_{best}(t)) \times P \times t_2 & C < c \end{cases} \quad (15)$$

$$C = \frac{1}{R \times t_2} \quad (16)$$

$$t_2 = 1 + \frac{t}{T_{\max}} \quad (17)$$

$$R = \frac{M \times vel^2}{L} \quad (18)$$

$$L = 0.2 + (2 - 0.2) \times r_6 \quad (19)$$

$$\delta = C \times |X_i(t) - X_{best}(t)| \quad (20)$$

$$P = Levy(D) \quad (21)$$

$$Levy(D) = 0.01 \times \frac{\mu \times \sigma}{|v|^{\frac{1}{\beta}}} \quad (22)$$

$$\sigma = \left(\frac{\Gamma(1 + \beta) \times \sin\left(\frac{\pi\beta}{2}\right)}{\Gamma\left(\frac{1 + \beta}{2}\right) \times \beta \times 2^{\frac{\beta-1}{2}}}\right)^{\frac{1}{\beta}} \quad (23)$$

Where, r_6 is a random number, M denotes the mass of the pond goose, vel denotes the velocity of the pond goose with the value of 1.5 m/s, c is a constant, which generally takes the values of $c=0.2$ and $\beta=1.5$, $X_{best}(t)$ denotes a constant, and μ and σ are random numbers, respectively.

The pseudo-code and flowchart of the GOA algorithm are shown in Fig. 8 and Fig. 9, respectively.

```

Algorithm1: Gannet Optimization Algorithm (GOA)
1 Set GOA parameters;
2 Initialize GOA population based on random distribution;
3 Obtain memory matrix MX;
4 Calculate X fitness;
5 While t<=Max_t
6   if rand>0.5
7     for MXi do
8       if q>=0.5, update position using U-shaped;
9       else, update position using V-shaped;
10      end if
11    end for
12  else
13    for Mxi do
14      if c>=0.2, update position with a sudden tuning;
15      else, update position with Levy movement;
16    end for
17  end
18  Calculate MXi fitness, and update better position;
19 End while
    
```

B. Optimisation of Recognition Methods by the Pond's Goose Algorithm

In order to increase the accuracy of the multilayer perceptron recognition method, this paper uses the Pond's Goose algorithm to optimise the multilayer perceptron network. The paradigm of the Pond's Goose algorithm to optimise the multilayer perceptual machine network is shown in Fig. 10, and the GOA algorithm takes w and b as the optimisation variables, and $C(w, b)$ as the fitness function. The flow of the MLP scene visual understanding recognition method based on the GOA algorithm is shown in Fig. 11, and the specific steps are as follows:

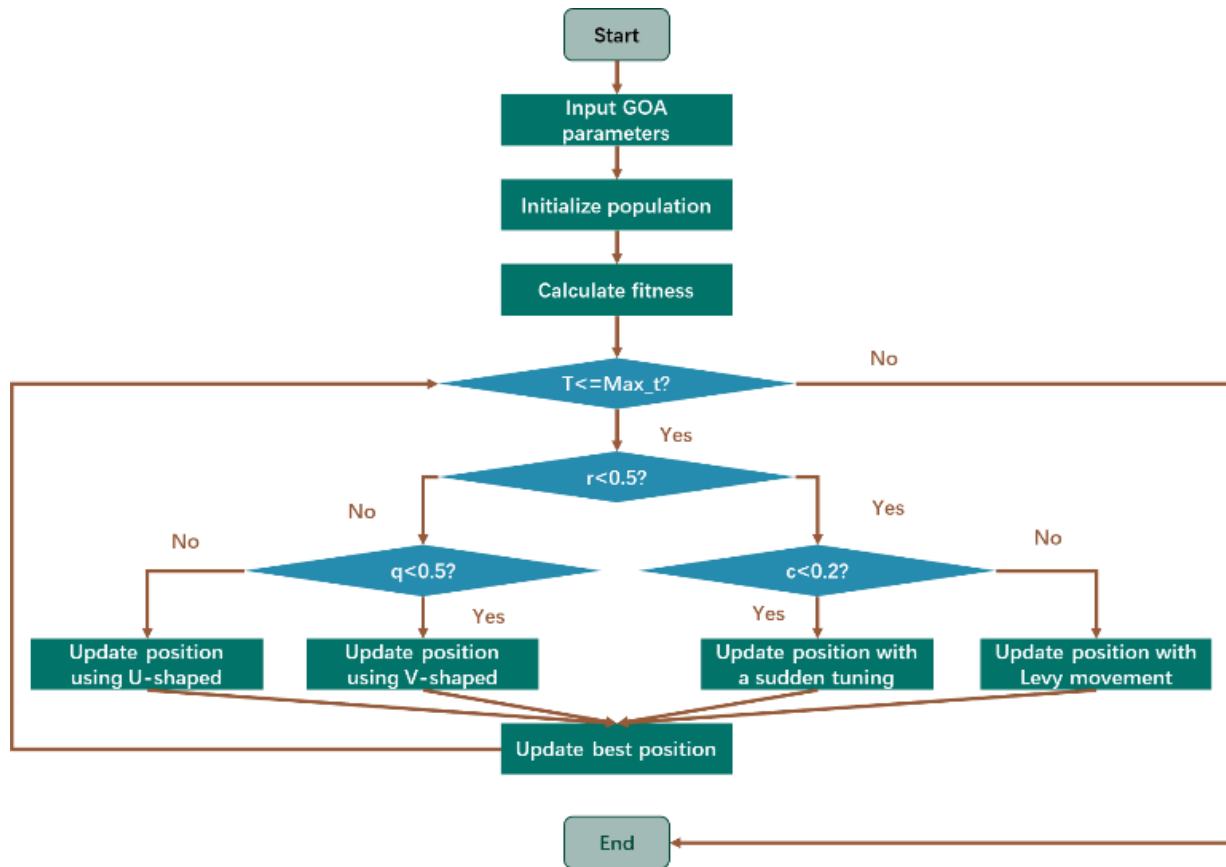

Fig. 9. Flowchart of GOA algorithm.

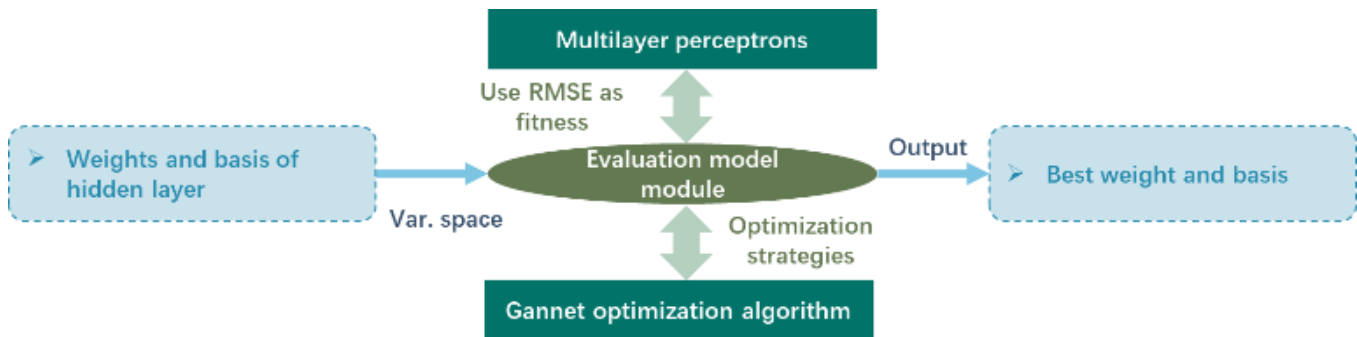

Fig. 10. GOA algorithm to optimise the MLP network paradigm.

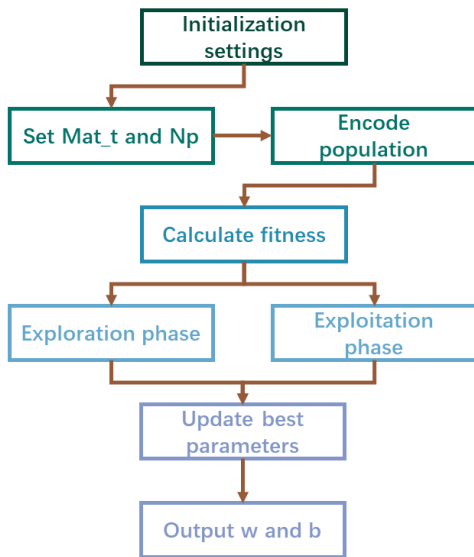

Fig. 11. GOA-MLP step-by-step diagram.

- Step 1: Initialisation setup. 1) Set the maximum number of iterations as well as the number of populations and algorithmic control parameters for the GOA algorithm optimised MLP network; 2) Initialise the GOA algorithm populations using real number coding;
- Step 2: Calculate the $C(w, b)$ value and determine the optimal structural parameters for the current number of iterations based on the error value;
- Step 3: Behavioural simulation models such as U- and V-diving behaviours during foraging, as well as sudden rotations and random wandering, were used to update information on the location of individuals in the population;
- Step 4: Calculate the fitness value, update the structural parameters, and determine whether the maximum number of iterations or the optimal solution of the GOA-MLP algorithm is no longer changing;
- Step 5: Output the structural parameters of the optimal MLP model.

IV. UNDERSTANDING THE APPLICATION OF RECOGNITION METHODS IN ART AND DESIGN

A. Application Programmes

The visual understanding and recognition method of art design scene based on GOA-MLP model performs colour segmentation and morphological processing of the scene through coarse segmentation technology and formulates rules to extract candidate scene regions, uses SIFT technology to extract internal features from the feature regions, annotates the sample data, and trains the scene visual understanding and recognition algorithm based on the GOA-MLP model, to complete the visual understanding and recognition of the scene based on the art design [25]. Focusing on the principle of visual understanding and recognition method of art design scene based on GOA-MLP model, this section designs the visual

understanding and recognition scheme of art design scene based on GOA-MLP model (shown in Fig. 12), and gives the application analysis.

Fig. 12. Artistic design scene visual understanding and recognition programme.

In Fig. 12, the visual understanding and recognition system for art and design scenes based on GOA-MLP model consists of modules such as colour segmentation, morphological processing, extraction of candidate scene regions, extraction of internal features, and construction of scene visual understanding and recognition model.

B. Application Steps

Based on the analysis of the Art and Design Scene Visual Understanding and Recognition Programme, the modules are described below:

1) *Colour segmentation module*: For the colour segmentation problem, HSV colour space is used, where H is converted by the following formula:

$$H = \begin{cases} 0 & \max = \min \\ 60 \times \frac{G-B}{\max - \min} & \max = R \text{ \& } G \geq B \\ 60 \times \frac{G-B}{\max - \min} + 360 & \max = R \text{ \& } G < B \\ 60 \times \frac{G-B}{\max - \min} + 120 & \max = G \\ 60 \times \frac{G-B}{\max - \min} + 240 & \max = B \end{cases} \quad (24)$$

Where \max and \min denote the maximum and minimum values of the pixel for each channel in the RGB colour space, respectively.

2) *Morphological processing module*: To address the problem of noise and breakage in colour segmented images, this subsection uses morphological processing methods to reduce the effect of noise and to obtain connected regions. In morphological processing technique, the broken portion of the candidate region is re-cracked using an expansion operation to fill the broken contour lines [26].

3) *Candidate scene area analysis module*: Aiming at the problem that there are still uneliminated interference regions in the image after morphological processing, this paper uses constraints to extract candidate scene regions. The specific satisfaction conditions are as follows:

$$\left\{ \begin{array}{l} S_i \geq S_{\min} \cap S_i \leq S_{\max} \\ \frac{L_i}{W_i} \geq \left(\frac{L}{W}\right)_{\min} \cap \frac{L_i}{W_i} \leq \left(\frac{L}{W}\right)_{\max} \\ \frac{S_i}{L_i \times W_i} \geq \left(\frac{S}{L \times W}\right)_{\min} \end{array} \right. \quad (25)$$

Among them, L , W and S denote the width, height and area of the connected area, respectively. S_{\min} , S_{\max} and $\left(\frac{S}{L \times W}\right)_{\min}$ denote the minimum and maximum values of the area of the connected area, respectively; $\left(\frac{L}{W}\right)_{\min}$ and $\left(\frac{L}{W}\right)_{\max}$ denote the maximum value of the aspect ratio of the connected area, respectively; and denotes the minimum value of the duty cycle.

4) *Internal feature extraction module*: In order to reduce the computational complexity and retain the key information, this subsection adopts the SIFT technique to extract the target features inside the candidate region. The idea of SIFT-based target feature extraction method is to take the SIFT feature point as the centre point, calculate the gradient and direction of the pixels within the range of 16×16 , and at the same time use dense sampling to obtain more information.

5) *Scene visual understanding recognition model building module*: In order to complete the art design method based on the scene visual understanding recognition algorithm, this paper uses GOA-MLP algorithm training to construct the scene visual understanding recognition model, and the specific training process is shown in Fig. 13. Firstly, the data is divided, then the MLP model is improved by using GOA optimisation, secondly, the MLP structure parameters are reconstructed by using the training set, and finally the understanding recognition model is used to complete the art design.

Fig. 13. Scene visual understanding recognition model building module.

V. SIMULATION EXPERIMENT

A. Experimental Set-up

In order to verify that the GAO algorithm improves the accuracy of the MLP model, this paper uses the sine-cosine optimisation algorithm (SCA) [27], the Harris hawk optimisation algorithm (HHO) [28], the butterfly optimisation algorithm (BOA) [29], the crow's tern optimisation algorithm (STOA) [29], and the gannet optimisation algorithm (GOA) to make comparisons with the specific parameter settings as shown in Table I. The structure of the MLP model to be optimised includes one input layer, three hidden layers and one output layer, the activation function is a Sigmoid function, the number of nodes in the hidden layer is divided into, the number of populations of SCA, HHO, BOA, STOA and GOA algorithms is 100, the maximum number of iterations is 500, and the condition for satisfying the optimal result output is to reach the maximum number of iterations.

TABLE I. EXPERIMENTAL PARAMETER SETTINGS

Arithmetic	Parameterisation
MLP	The activation function is Sigmoid function and the classifier is Softmax, including input layer, hidden layer (3 layers), output layer, hidden layer nodes are [30]
SCA-MLP [27]	The MLP structure parameters are set as above, with a set to 2
HHO-MLP [28]	The MLP structure parameters are set as above, E0 is a random number and E1 decreases linearly from 2 to 0
BOA-MLP [29]	The MLP structural parameters are set as above, with a transition probability of 0.6, a force index of 0.1 and a perceptual mode value of 0.01
STOA-MLP [30]	Sa decreases linearly from 2 to 0.
GOA-MLP	MOP_max is 1, MOP_min is 0.2, Alpha is 5, Mu is 0.499

This paper uses the scene visual understanding feature extraction method parameter settings are shown in Table II.

TABLE II. PARAMETER SETTINGS FOR VISUAL FEATURE EXTRACTION METHODS

Project	Parameter values	Note
Optimal thresholds	90	RGB colour space
Optimal lower and upper thresholds	200, 280	HSV colour space
S_{\max}	400	Maximum area of connected areas
S_{\min}	$(L \times W)/2$	Minimum area of connected areas
$(L/W)_{\max}$	0.2	Maximum Aspect Ratio for Connected Areas
$(L/W)_{\min}$	4.6	Minimum aspect ratio of connected areas
$(S/(L \times W))_{\min}$	0.7	Duty Cycle Min.

The hardware platform for the experimental development environment is Pentium IV 3.7 GHz CPU and 4 RAM with a memory size of 3 GB. The software environment includes VisualStudio, Win10 operating system, Multigen Creator, Visual C++ 4.0 programming language, Matlab2021a programming language.

The dataset was adopted from the image dataset of the Massachusetts Institute of Technology (MIT), including 2688 scene images, including scenes of mountains, cities, coasts, flowers, etc. as shown in Fig. 14.

Fig. 14. Sources of data sets.

B. Analysis of Performance Test Results

In order to verify the effectiveness as well as the efficiency of the method proposed in this paper, this paper firstly analyses the visual processing methods of scenes oriented to artistic design, and secondly, tests and analyses the recognition methods for comparison.

1) *Scene visual processing analysis:* According to the above simulation environment, parameter settings and data set for target information extraction, the extraction results are obtained as shown in Fig. 15.

Obviously, as obtained from Fig. 15, the scene visual understanding algorithm can effectively extract the floral information of the known image, solve the problem of poor clarity of the output image, reduce the influence of noise, and improve the overall design of the image.

2) *Analysis of identification test results:* In order to enhance the effect of validation experiments, this paper randomly extracts five sets of data sets from the database to carry out experimental analysis, each time the extracted data sets include 2000 images, of which the training set reaches 1500, the test set is 350, and the rest is the validation set, and the specific test results are shown in Table III, Fig. 16, and Fig. 17.

Fig. 15. Target information extraction results.

From Table III and Fig. 16, it is easy to find that from the dataset point of view, the accuracy of GOA-MLP comprehension and recognition method is better than that of MLP, SCA-MLP, HHO-MLP, BOA-MLP, and STOA-MLP. It can be seen that the accuracy of MLP comprehension and recognition method based on optimisation algorithms is better than that of MLP method, and the accuracy of GOA optimised MLP model is better than other optimisation algorithms.

Fig. 17 demonstrates the optimisation convergence curves for each algorithm of SCA-MLP, HHO-MLP, BOA-MLP, STOA-MLP, and GOA-MLP. From Fig. 17, it can be obtained that: with the increase in the number of iterations, the value of the adaptation function of the comprehension recognition accuracy of the GOA optimised MLP model increases, and the accuracy of the convergence is higher than that of the

algorithms such as SCA, HHO, BOA, and STOA; and the optimised convergence of the GOA-MLP model is stable up to the vicinity of 0.98.

TABLE III. DATA SET TEST IDENTIFICATION ACCURACY RESULTS (%)

Data set	MLP	SCA-MLP	HHO-MLP	BOA-MLP	STOA-MLP	GOA-MLP
1	67.34	86.98	87.32	84.22	93.90	97.98
2	66.21	86.10	87.35	83.78	92.53	97.46
3	69.88	88.38	89.25	87.90	95.16	98.85
4	65.20	86.12	86.95	83.15	90.74	97.00
5	67.58	87.24	88.65	85.37	92.88	98.05

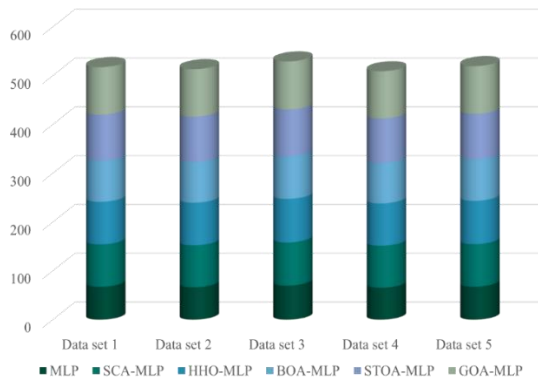

Fig. 16. Recognition results of each algorithm.

Fig. 17. Convergence process of each optimisation algorithm.

VI. CONCLUSION

Aiming at the problem of visual understanding and recognition effect of diverse scenes of art design, this paper proposes a visual understanding and recognition method of scenes oriented to art design based on GOA-MLP, which makes the GOA algorithm optimise the MLP structural parameters and improve the understanding and recognition accuracy. Experiments with MIT image datasets lead to the following conclusions: using the GOA algorithm to optimise the MLP structural parameters and using it in the art design scene visual understanding and recognition problem improves the art scene understanding and recognition accuracy and increases the art design effect. By analysing five types of image datasets, the GOA-MLP based scene visual understanding and recognition method has higher recognition accuracy. This study only focuses on the accuracy of the understanding and recognition method, and the subsequent re-recognition time method still requires in-depth research.

Quantitative Measurement and Preference Research of Urban Landscape Environmental Image Based on Computer Vision

Yan Wang

School of Art and Design, HuangHuai University, Zhumadian 463000, China

Abstract—At present, research on landscape preferences mostly uses traditional questionnaire surveys to obtain public aesthetic attitudes, and the analysis method still relies on manual coding with small sample sizes. However, the research on landscape preference of applying network big data and computer vision technology is rare, and the research content and algorithm application are limited. In order to improve the research effect of quantitative measurement and preference of urban landscape environment image, the algorithm proposed in this paper combines two-dimensional analysis modules, two-dimensional visual domain analysis and three-dimensional visual analysis, and makes full use of the advantages of the two analysis modules, and analyzes the scale from large scale to medium and micro scale based on different accuracy urban digital models. Through image classification and content recognition, image semantic segmentation and image color quantification, the landscape feature information in pictures is mined, and the dimension of landscape image is put forward based on this. In addition, this paper combines experimental analysis to verify that the method proposed in this paper has certain results. It is not only suitable for visual analysis of landmark buildings and landmark structures in cities, but also can analyze the visual characteristics of natural landscapes as urban images in cities. Therefore, the quantitative method of urban visual landscape analysis proposed in this paper can provide reliable data support for the follow-up urban design work.

Keywords—Computer vision; urban landscape; environmental image; quantification; measure

I. INTRODUCTION

With the development of the times, people's living standards are constantly improving, and the public's aesthetic concept is also constantly improving. More and more people are beginning to pay attention to the spiritual ascension. Moreover, some once neglected art forms, such as abstraction and performance art, are increasingly recognized by people through deformation and exaggeration. Although more information can be obtained through the domestic literature retrieval system at present, it is still found that many researches on image modeling mainly focus on the field of art, such as traditional Chinese painting, oil painting and sculpture. At the same time, although the development of graphic design, product design and other design fields has made some achievements, most design works still focus on specific artistic design, and there is little research on the specific environment in urban public space.

Image is the bridge of two-way communication between people and landscape, and any experience in landscape places is related to images. Landscape image experience focuses on the spiritual communication relationship between landscape quality and people, including memory, imagination, thinking and accompanying positive emotions. Kevin Lynch first put forward the concept of urban image. After analysis, he concluded that environmental image should consist of three parts: personality, structure and implication. Although his concept of environmental image is put forward at the macro level of the city, it is undeniable that these three characteristics are also the basis of forming landscape image [1].

The personality of landscape image refers to the distinguishability and recognizability as a landscape place. Nowadays, driven by the rapid and urgent production environment of globalization and economic interests, the newly built squares are the same, the landscape avenues are the same, and even the street lamps and signs are in a unified mode. Similar pedestrian commercial streets, similar architectural forms, similar residential landscapes and similar pocket parks make cities and landscapes similar. Because landscape designers don't fully tap the physical and humanistic characteristics of the site, the potential energy of the site can't be revealed and its uniqueness can't be created. The personality of the urban landscape disappears, and the cultural threads of the urban landscape also break. In this case, the landscape loses its narrative (information component) and its poetic experience (rich expression) [2].

In order to improve the research effect of quantitative measurement and preference of urban landscape environmental image, the algorithm proposed in this paper combines two-dimensional analysis modules: two-dimensional visual domain analysis and three-dimensional visual analysis. In addition, this paper combines experimental analysis to verify that the method proposed in this paper has certain results. It is not only suitable for visual analysis of landmark buildings and landmark structures in cities, but also can analyze the visual characteristics of natural landscapes as urban images in cities. Therefore, the quantitative method of urban visual landscape analysis proposed in this paper can provide reliable data support for the follow-up urban design work.

II. RELATED WORKS

Landscape imagery is a landscape imagery pattern gradually formed by people in the process of landscape cognition, which refers to the interactive relationship and

perceptual experience between subjects and objects. It includes both the presentation based on the "image" of the landscape object and the perception based on the "meaning" of the viewing subject. The coastal landscape imagery is a mapping of the public's perception of coastal landscapes and the cognitive evaluation of different sea areas, including the landscape projection imagery created by relevant propaganda agencies through abstracting urban landscape elements and the landscape perception imagery formed by the public based on their understanding and evaluation of destination urban landscape elements [3]. Previous studies have shown that landscape perception imagery is an important theoretical support for landscape style renewal and creation, and plays an important role in enhancing landscape attractiveness. It has the characteristics of personalization, locality, and sociality [4]. At present, domestic and foreign scholars mainly focus on exploring the constituent elements, spatial distribution, perceptual characteristics, and formation mechanisms of landscape perception imagery, as well as analyzing the perceptual differences of landscape imagery from different perspectives. In addition, some scholars have conducted quantitative evaluations by constructing a landscape image related evaluation system [5].

The public's perception of landscapes often stems from the material carriers and social interaction activities in the natural environment. Traditional research on landscape perception imagery is mostly based on cognitive maps and combined with methods such as questionnaire surveys, participatory surveys, and interviews. There are significant limitations on research time and sample size. With the continuous development of Internet technology and the popularization of artificial intelligence applications, network data based on mass media has become one of the media of landscape image cognition, and it has the advantages of high accuracy, wide source, fast update, large volume and convenient data acquisition [6]. In this context, different scholars have gradually shifted their research on landscape perception imagery to the mining and content analysis of online data. Network data includes travel commentary text data and landscape photography photo data, among which text data has been widely used in the study of landscape perception imagery. For example, some scholars have explored tourists' cognitive preferences for destination landscapes by filtering Weibo texts, or quantitatively evaluated landscape perception images based on the emotions expressed in the texts. At the same time, with the popularization of social media software and the iterative updating of photography equipment, people often spontaneously upload landscape images taken through smartphones and cameras during tourism or sightseeing to social media, photo sharing platforms, and tourism websites. As the public's condensation of local culture and landscape features, these network images contain a large amount of image information and geographical coordinates, as well as other social metadata, which provide extensive and real data for the research of landscape perception images [7]. However, these photo data, as intuitive analysis materials for visual content, are more suitable for application in research. Existing research often relies on manual encoding and other processing methods when processing image data, which has limitations such as strong subjectivity and small research scale. However, the introduction of computer vision algorithms has

made up for this deficiency. Currently, research is mostly based on image semantic segmentation technology to identify objects such as people, animals, plants, buildings, and signs in images. The research will be applied to fields such as landscape ecosystem cultural services, landscape aesthetics, urban street scenes, and campus green spaces [8].

In terms of multi-objective adaptive landscape, multi-objective optimization differs from single objective optimization mainly in two aspects. The first point is the objective layer, where each conflicting objective is composed of multiple fitness functions, rather than traditional single fitness functions. The second point is the solution layer. Compared to a single optimal solution in a single objective scenario, the Pareto optimal solution set in a multi-objective scenario is the optimal solution balanced by multiple fitness functions [9]. The author in [10] applied standard fitness landscape analysis techniques to erroneous landscapes. The research content includes the impact of search space boundaries on landscape analysis, the impact of regularization on error surfaces, the impact of architectural settings on landscape morphology, and the impact of different loss functions on attractive basins. With the development of adaptive landscape models, many models for specific scenarios have been further developed, such as those for numerical optimization or discrete optimization, as well as for co-evolution, constraint optimization, multi-objective optimization, and other directions. The Local Optimal Networks (LONs) model has been further developed and has become one of the most widely used landscape analysis techniques today. Meanwhile, the local optimal network is regarded as a composite landscape model that specifically captures the number and distribution of local optimal values in the fitness landscape, and these landscape features have a significant impact on the search heuristic performance [11]. In addition, LONs are mainly applied in discrete optimization and are designed for discrete search spaces. Given the global structure of the landscape that affects search behavior, LONs can be generated for a series of problems to compare algorithm success and failure or the global structure of the search space [12].

Nowadays, social media text data mainly comes from sources such as Weibo, Twitter, and online travelogues. Compared to traditional text data (such as interviews and surveys), it has advantages such as strong real-time performance, rich content, large production volume, and clear semantics. Moreover, it can reflect human behavioral characteristics at a smaller granularity unit. At the same time, social media text data has been applied in tourism geography, such as perceiving tourist destination imagery, analyzing tourist behavior, studying tourist preference characteristics, analyzing tourist attraction popularity, urban social perception, etc. [13]. The consistency between the projected and perceived images of the target image is determined by principal component analysis using online commentary text data [14]. Text data has strong subjectivity, relatively low spatial coupling, high dependence of text semantics on context, and insufficient depiction of common spatial details and backgrounds. However, network photo data has high accuracy, wide geographical coverage, and a large amount of

information, which can not only reflect people's subjective feelings, but also comprehensively depict the overall image of tourist destinations from multiple dimensions [15]. Compared to text, images can better record what tourists see in real time, providing visually impactful and realistic information for other potential tourists, and making intangible tourism experiences tangible. Image data is intuitive and easy to understand, with rich visual semantic information, which can objectively depict what tourists see [16]. In addition, tourism managers also actively create the image of tourist destinations by taking beautiful photos. The people, objects, and scenery in the photos are cognitive elements of tourists, and they are all carriers of tourist destination imagery. At present, the main sources of image data include street view data, social media image data, and media promotional image data [17]. Images are a data source with high application value in the future and an important supplement to existing research data. Tourism photos are an important component of tourism activities. Tourists share their travel process in the form of photos, which is a common means of disseminating tourism experiences and destination images. Tourism photos have the function of image dissemination, which enables domestic and foreign scholars to use them as a data source to study the role of tourism photos in the dissemination of destination images [18]. The tourism gaze theory suggests that potential tourists can have psychological imagination and travel motivation when browsing travel photos [19]. At the same time, photos can attract potential tourists to generate imagination and desire to participate in travel activities, and through the analysis of photo content, tourists can understand their interests, preferences, travel behavior, and spatial distribution characteristics in different destinations [20].

With the development of remote sensing technology, some scholars have applied it to landscape pattern analysis. Common landscape classification methods include unsupervised classification and supervised classification. Meftaul et al. [21] have shown through experiments that using mixed classification (i.e. a combination of supervised and unsupervised classification) to classify images can achieve higher classification accuracy, and with the rise of neural networks, some scholars have already used backpropagation (BP) neural networks (BP) for classification.

RAL network classifies images and obtains better results. Based on this discovery, Liu et al. [22] proposed a landscape measurement calculation method, which is widely used in urban landscape pattern analysis, such as vegetation pattern, urban growth and other disciplines. Landscape measurement can quantitatively describe and monitor the changes in landscape spatial structure over time, but cannot specifically reflect the direction and rationality of landscape changes.

Deng et al. [23] proposed an "inverse S-shaped function" to represent the density of urban land, which can identify the size of urban built-up area, measure the compactness and expansion intensity of urban land. However, it only discusses the spatial distribution of urban land use and does not analyze the changes in land use structure during urban development.

At present, there are two problems in the research of landscape pattern. The unclear interpretation characteristics of images of different landscape types have led to the prevalence

of the phenomenon of "same spectrum foreign objects and same objects but different universality". These analyses are mostly based on landscape metrics, which are relatively simple research methods and cannot reflect the complexity of landscape pattern changes during the rapid development of cities.

III. QUANTITATIVE MEASUREMENT METHOD OF URBAN LANDSCAPE ENVIRONMENT IMAGE

A. Research Methods

The urban visual landscape analysis framework proposed in this paper includes two analysis routes: the traditional model and the point cloud-solid hybrid model, includes two-dimensional and three-dimensional analysis processes, and mainly expounds the visual analysis based on traditional model. Traditional models mainly include urban digital surface model (UDSM) and urban 3D solid model (urban 3D solid model).

The sight urban visual landscape analysis framework proposed in this paper mainly consists of three parts: urban digital model construction, visibility analysis and visual feature extraction. The analysis framework is shown in Fig. 1. The method proposed in this paper combines two-dimensional analysis modules of two-dimensional visual domain analysis and three-dimensional visual analysis, makes full use of the advantages of the two analysis modules, and analyzes the scale from large scale to medium and micro scale on the basis of urban digital models with different accuracy. Models with different accuracy can support visibility analysis results with different degrees of fineness, and the calculation time and model construction cost also increases with the improvement of accuracy. In the analysis model of this paper, the viewing points and the viewed landscape objects will be discretized in the digital model, and the spatial points with elevation attributes will be taken as representatives to participate in the calculation.

For an urban space without strict design control, in addition to the information accumulated in daily life, there may also be some missing public spaces where the target urban landscape can be observed, and visual domain analysis can help research and judge these areas that may be ignored by existing planning and design but have ornamental potential (as shown in Fig. 2).

Potential viewing points are extracted from the visual public space and carried out forward operation in the visual domain analysis, that is, these viewing points V_v are analyzed as viewpoints in the visual domain analysis, and the viewshed of viewpoints in the city can be obtained. The visible area VA_{To} of target objects from open spaces in the city can be obtained by superimposing the obtained urban visible range and the overall range of the target object. It is worth noting that there is the following relationship of VA_{To} , A_r and V_v :

$$VA_{To} = A_r \cap V_v \quad (1)$$

If and only if that entire extent of the target object is visible to the public space,

$$VA_{TO} = A_T \in V_V$$

(2)

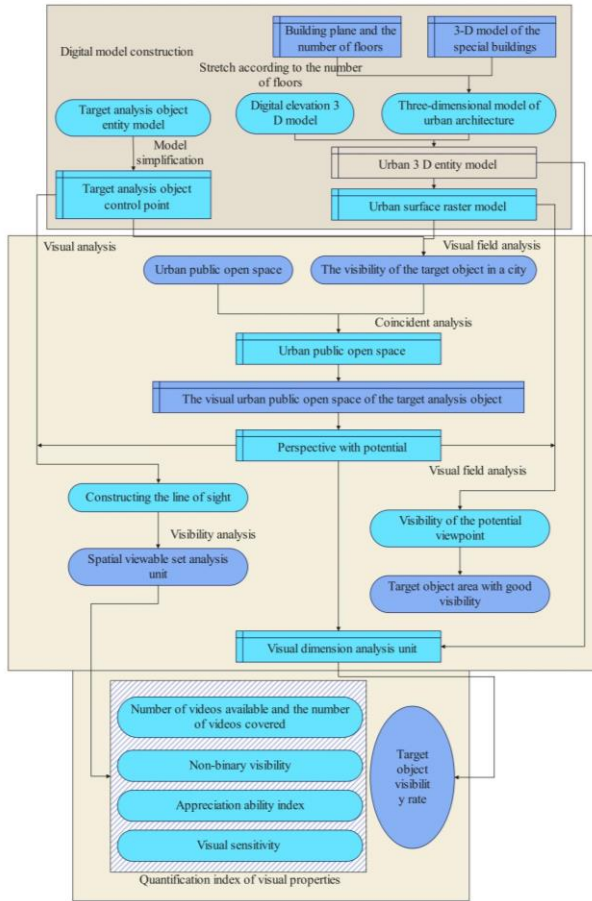

Fig. 1. Flowchart of sight-oriented urban visual landscape analysis.

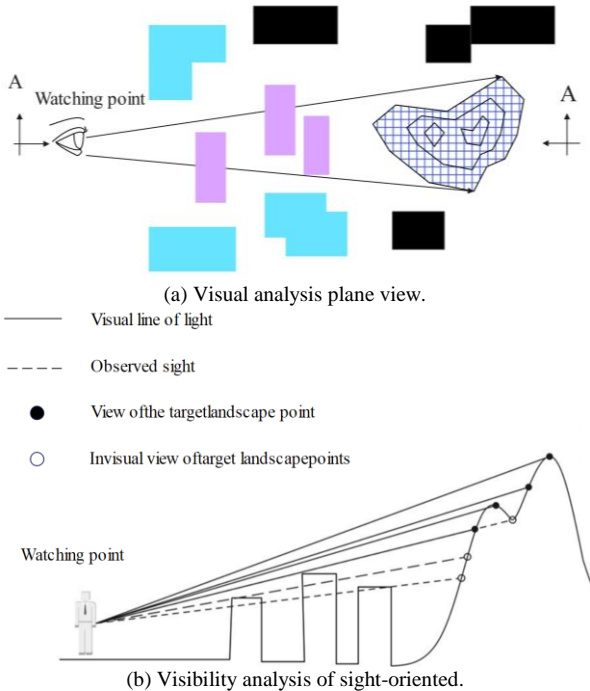

Fig. 2. Visual domain analysis.

The analysis results of this step can preliminarily test the visibility of the viewing target object, and make more in-depth exploration of areas with relatively high cumulative visibility, that is, areas with high viewing probability in urban space.

The principle of human eye imaging is similar to that of convex lens imaging. If the size of an object remains the same, the closer the object is to the human eye, the larger the image it forms on the retina will gradually become, and the better the visibility of the object will be, and vice versa. That is, the well-known phenomenon of "near big and far small", as shown in Fig. 3.

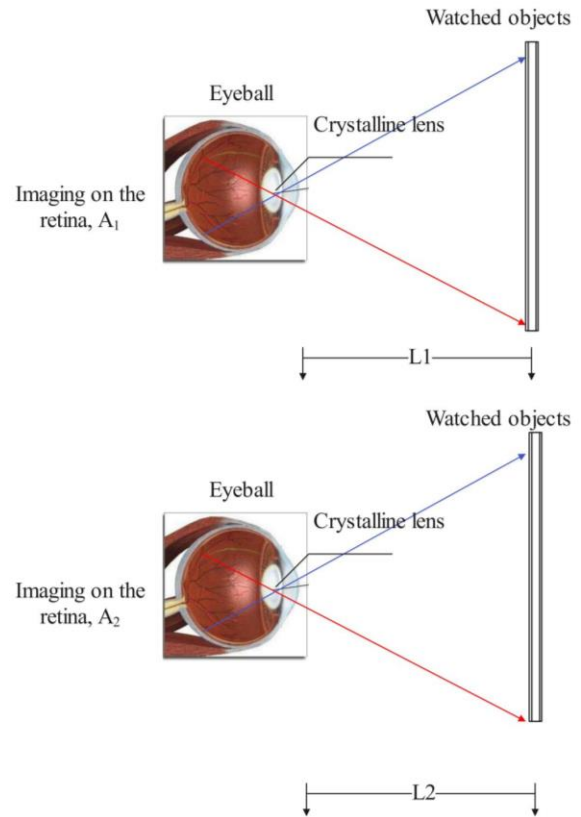

Fig. 3. Imaging size of human eye under different visual distances.

The visibility V_{ij} between the i -th viewpoint and the j -th target point is as follows:

$$V_{ij} = \begin{cases} 0, & \text{Line of sight obstruction or } L_{ij} > L_{max} \\ 1, & L_{ij} \leq D_0 \\ k_{ij} = \frac{L_{max} - L_{ij} + D_0}{L_{max}}, & D_0 < L_{ij} < L_{max} \end{cases} \quad (3)$$

Among them, D_0 is the optimal line of sight, k_{ij} is the distance attenuation coefficient, L_{max} is the theoretical maximum visual range, that is, the farthest distance that the human eye can see the object clearly, and L_{ij} is the distance between the i -th viewpoint and the j -th target point.

The value range of the optimal sight distance D_0 should be selected according to the height and volume of the target object. The field of view where a clear landscape image and a relatively complete composition effect can be obtained without turning the head is $45^\circ \sim 60^\circ$ horizontal angle α and $26^\circ \sim 30^\circ$ vertical viewing angle β . Beyond this range, the head must be observed up and down, and the overall composition impression of the scene is not complete enough. It is assumed that the horizontal length of the target scene is W , the vertical height is H , and the human eye height is h . According to the calculation, the sight distance D_{ow} that can obtain the best horizontal field of view is about $(0.9 \sim 1.2)$, as shown in Fig. 4. For the convenience of calculation, $D_{ow} = W$ and $D_{oh} = 4(H - h)$ can be obtained by taking the median of the two.

Fig. 4. Schematic diagram of optimal sight distance in horizontal and vertical field of view.

The correction formulas for curvature and atmospheric refraction are as follows:

$$Z = \frac{[Z_0 + D^2(R - 1)]}{d} \quad (4)$$

Among them, Z is the corrected elevation, Z_0 is the surface elevation, D is the horizontal distance, d is the diameter of the earth (12740 km), and R is the refractive index of light (0.13 in standard atmospheric cases). ArcGIS's through-vision sight analysis is based on the analysis and calculation of three-dimensional line segments (rays between the viewpoint and the target point), which retains spatial visual information to the greatest extent, such as the spatial position of sight obstacle points (Fig. 5).

Fig. 5. Analysis of visual sight.

The spatial relationship of sight accessibility is shown in Fig. 6. Taking the target object as a natural mountain as an example, the angle θ_{ij} between the line of sight and the normal vector of the mountain plane where the target point is located determines the proportion of the target mountain displayed in the eyes of the observer. On the other hand, the distance influence can be expressed in non-binary visibility to consider the visual influence of "near is large and far is small".

Fig. 6. Schematic diagram of sight accessibility.

It is assumed that there are the i -th viewpoint $P_i(x_i, y_i, z_i)$, the j -th target point $P_j(x_j, y_j, z_j)$ and the plane S_j where P_j are visible to each other, and the cosine of the angle θ_{ij} between the through sight line $\vec{P_j P_i}$ and the plane S_j is:

$$\sin \theta_{ij} = \frac{\vec{n}_j \cdot \vec{P_j P_i}}{|\vec{P_j P_i}|} \quad (5)$$

Among them, \vec{n}_j is the unit normal vector of plane S_j . The sight accessibility between the plane S_j represented by the target point and the viewpoint P_i is:

$$ASL_{ij} = V_{ij} \cdot \sin \theta_{ij} \quad (6)$$

In the formula, V_{ij} is the non-binary visibility between the observation point and the target point.

If it is assumed that there are n visible target object points for the i -th viewing point P_i in the analysis, the calculation formula of the viewing ability index VAI of P_i is as follows:

$$VAI = \sum_{j=1}^n ASL_{ij} \quad (7)$$

Among them, V_{ij} is the sight accessibility between the i -th viewpoint and the j -th target object point. Since the viewpoint and target point of the through-sight line are selected, $0 < V_{ij} \leq 1$.

The average viewing ability index measures the average viewing ability of a certain viewpoint to the visible target point. The larger the value, the closer the distance between the viewpoint and the target viewing object, and the better viewing effect can be obtained, and the distance has less influence on it. The smaller the value, the farther the viewpoint is from the target viewing object, and the viewing effect is worse because of the greater influence of the distance on it.

$$VAI_{avg} = \frac{1}{n} \times VAI \quad (8)$$

Visual exposure of target objects (VE) describes the degree of attention of a certain target point in the urban visual landscape environment. Small changes in areas with high visual exposure will be keenly perceived by the observer, while the observer will be slow to change in areas with low visual exposure.

If there are m viewpoints (P_1, P_2, \dots, P_m) visible to the target point P_T , that is, the number of videos of the target point is m , the visual exposure of P_T is defined as:

$$VE = \sum_{j=1}^m LOSA_{ij} \quad (9)$$

Among them, $LOSA_{ij}$ is the sight accessibility between the i -th viewpoint and the j -th target object point that are visible to each other. Visual exposure reveals the overall gaze degree of mountain points on a selected series of viewing spots. The higher the value, it means that the area represented by the target point is easier to appreciate the whole picture for the selected viewing spots. Otherwise, it means that the area represented by the target point is less exposed in the viewing spots and cannot fully display its whole picture.

The average visual exposure of line of sight measures the average gaze degree of a visible target mountain point in urban space. A low average visual exposure indicates that the average projected area of the point in the viewing spot is small, and the average gaze degree is low. The average visual exposure of the mountain point is:

$$VE_{avg} = \frac{1}{m} \times VE \quad (10)$$

The visible percentage of target objects (VP) refers to the area extraction of the components of the obtained digital image under the condition of simulating the visual picture and calculating the proportion of the target analysis object in the picture. Then, the visibility of the target object observed for the viewpoint i is:

$$VP = \frac{A_T}{A_i} \times 100\% \quad (11)$$

Among them, A_i is the total area of the picture obtained by the viewpoint i , and A_T is the area of the target object in the picture.

B. Experimental Study

This paper takes the landscape of urban lakes and parks as an example. This study uses image data from social media to analyze the public's landscape perception preference characteristics. In order to reduce the influence of a single social media user's preference on the results, this study selects the comment pictures on the social media platform of mainstream travel websites with high audience, wide coverage and large amount of evaluation data as the data source. The web crawler is used to retrieve and crawl all tourist comment pictures in 20 lakes and parks on the Internet. Because the sources of the obtained pictures are complex, it is necessary to clean the picture data, check the obtained social media pictures, and eliminate blurred pictures.

Through image classification and content recognition, image semantic segmentation and image color quantification of image data, the landscape feature information in pictures is mined. Based on this, three dimensions of landscape image are proposed: landscape composition, landscape proportion and landscape color, in which landscape composition can be decomposed into landscape type, spatial scale and landscape elements, landscape proportion includes green vision, sky visibility and architectural visibility, and landscape color is described by HSV color features, and a multi-dimensional landscape image quantitative measurement framework based on public perception is constructed (Fig. 7).

Fig. 7. Quantitative measurement framework of multi-dimensional landscape image based on public perception.

1) *Image label analysis data set*: The screened landscape pictures are stratified according to different parks, and simple random sampling is carried out in each layer through stratified ratio. A total of 500 pictures are sampled for image label analysis.

2) *Model training data set*: The screened landscape pictures are stratified according to different parks. Firstly, simple random sampling is carried out in each layer through stratified ratio, and a total of 1,200 pictures are sampled for preliminary model training and adjustment. Secondly, the training data set is adjusted according to the validity of model evaluation, and image data is added to labels with poor recognition effect. Finally, it is adjusted to 1,500 pictures for building Auto ML models.

C. Results

The number of pictures in the training set, validation set and test set of the landscape feature classification AutoML (Automated Machine Learning) model is 1197, 151 and 152, respectively. Through model evaluation, it can be obtained that the average accuracy AP value of the AutoML model for landscape feature classification is 0.933, and when the confidence threshold is 0.5, the accuracy P is 88.36%, the recall R is 84.87%, and the F1 value is 0.866. The P-R curve is shown in Fig. 8. Generally speaking, the accuracy of the model is high, and all indexes are greater than 0.8. It is considered that the model can be used to classify image landscape elements.

Fig. 8. P-R curve of Auto ML model for landscape feature classification.

The AP values, precision, recall, and F1 values of each label are shown in Table I, and the P-R curve of each label is plotted according to precision and recall, as shown in Fig. 9.

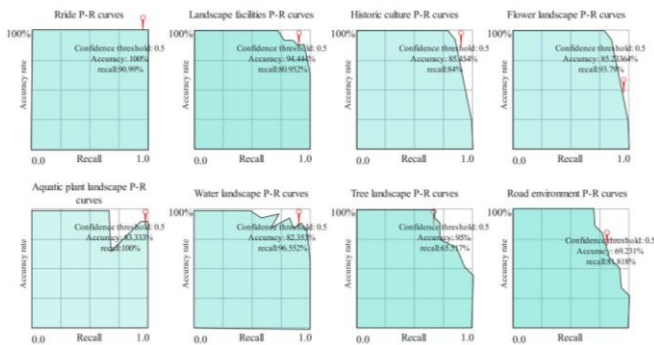

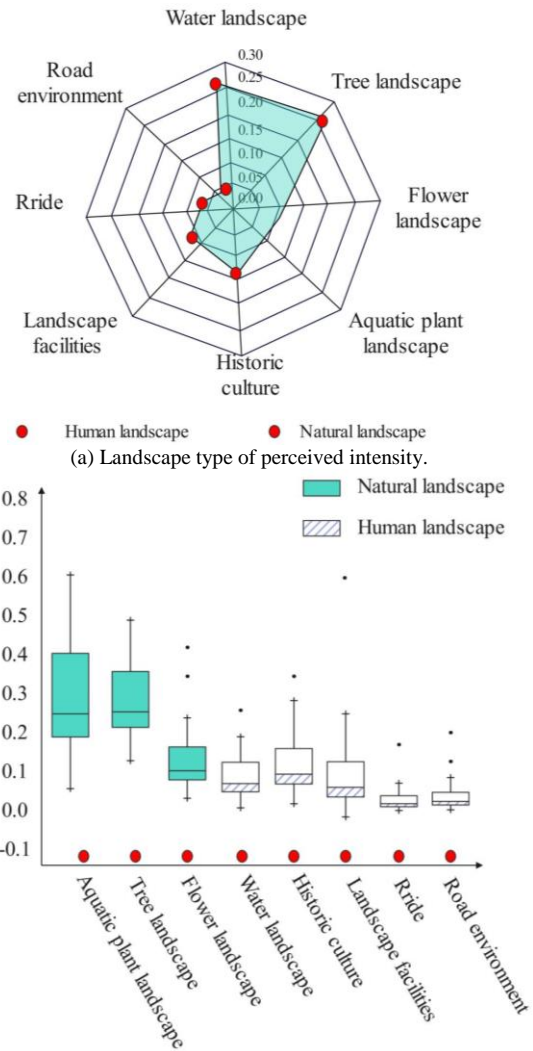

Fig. 9. P-R curves of various landscape types.

TABLE I. EVALUATION INDICATORS OF AUTO ML MODEL FOR LANDSCAPE ELEMENT CLASSIFICATION

Landscape Type	AP	Precision	Recall	F1-score
Amusement facilities	1	99.00%	90.00%	0.942
Landscape facilities	0.971	93.50%	80.14%	0.863
History and culture	0.959	94.51%	83.16%	0.885
Flower landscape	0.944	87.36%	92.81%	0.900
Aquatic plant landscape	0.936	82.50%	99.00%	0.900
Water landscape	0.933	81.53%	95.58%	0.880
Forest landscape	0.901	94.05%	64.86%	0.768
Road environment	0.895	68.54%	81.00%	0.743

Note: The values of Precision, Recall, and F1-score are the results when the confidence threshold is 0.5.

After sorting out, the statistical results of perception frequency of each landscape type in lake park are obtained (Table II), and the perception results of landscape types are shown in Fig. 10.

(b) Boxplots of landscape type perception frequency.

Fig. 10. Landscape type perception results.

TABLE II. STATISTICAL RESULTS OF PERCEPTION FREQUENCY OF LANDSCAPE TYPES IN LAKE PARKS

Landscape Type	Natural landscape				
	Water landscape	Forest landscape	Flower landscape	Aquatic plant landscape	Summary
Number/N	8180	8075	3324	2605	22185
Perceived frequency/%	25.28%	24.97%	10.28%	8.05%	68.58%
Perceived frequency Min	5.73%	11.13%	0.82%	0.34%	35.70%
Perceived frequency Max	57.68%	45.95%	41.11%	21.26%	86.78%
Standard deviation	0.1303	0.0895	0.1036	0.0609	0.1347
Landscape Type	Human landscape				
	History culture	Landscape facilities	amusement facilities	road environment	Summary
Numbe/N	3819	3130	1722	1168	9840
Perceived frequency/%	11.81%	9.67%	5.33%	3.61%	30.42%
Perceived frequency Min	0.00%	3.83%	0.00%	0.82%	12.22%
Perceived frequency Max	31.67%	60.67%	17.32%	15.72%	63.30%
Standard deviation	0.1055	0.1238	0.0383	0.0384	0.1347

D. Analysis and Discussion

By examining the false and negative cases predicted in road environment, water landscape and forest landscape, it is found that the reason for the confusion is that the pictures of the two groups of landscape types contain overlapping or similar landscape contents. For example, a picture taken with a water plank road as the main scene contains a large area of water at the same time, which may cause the model to encounter difficulties in classifying road environment and water landscape, or a picture taken with street trees as the main scene will also cause the model to deviate when classifying forest landscape and road environment. Considering the complexity of the landscape and the manual recognition will also have a certain degree of error, this part of the error can be considered as a normal result. Generally speaking, the trained AutoML model of landscape element classification has high validity, and can be applied to batch prediction of landscape images and identify the types of landscape elements.

The landscape composition of lake park can be divided into three aspects: landscape type, spatial scale and landscape element. This paper focuses on the analysis of the perception commonality and perception characteristics of landscape composition, discusses the public preference orientation and its reasons, obtains the various landscape composition and combination patterns that people prefer, and reveals the seasonal preference differences of landscape composition.

According to the perception intensity of each landscape type [Fig. 10(a)], the perception of natural landscape in lake park is significantly higher than that of human landscape, the perception frequency of water landscape and forest landscape in natural landscape is higher, and the perception frequency of historical culture and landscape facilities in human landscape is higher. On the whole, water landscape, forest landscape and historical culture are the most perceived landscape types in lake parks, accounting for more than 60%. Therefore, these three types of landscapes can be considered as the representative and core landscape types of lake parks. It can be

seen from Fig. 10(b) that the perceived changes of natural landscapes are more diverse than those of human landscapes, indicating that the differences in natural landscape characteristics in different parks are more significant.

Therefore, the waterscape in lake park, as the most important landscape element, is also the most popular landscape element, which also reflects that people's hydrophilic psychology and yearning for natural scenery greatly affect their perception preference. Forest landscape is the basic component of urban green space, and its landscape quality directly affects the overall landscape quality of garden green space. It covers all aspects of the landscape environment, making it easier for tourists to be highly perceived. In addition, the reason why history and culture are highly perceived is that it represents the important landscape features of the city, and the cultural landscapes of many tourist destinations in the city show strong tradition and historical customs, which arouse the strong perception of tourists.

The research shows that natural landscape is the core landscape image of urban landscape, and people's hydrophilic psychology and yearning for natural landscape greatly affect their perception preference. Therefore, in the construction and optimization of urban landscape, the naturalness of the landscape should be improved and the authenticity of the natural landscape should be maintained. Besides preserving and protecting the original landscape, it is also very important to restore and reproduce the natural features of the surface by artificial means. According to the natural landscape characteristics and public preference orientation of the study site, the optimization of the natural landscape quality of Wuhan's urban landscape can be considered from the following points. Firstly, the transformation of ecological natural revetment can take the form of lawns and aquatic plants, or natural stone and wood bottom protection. Moreover, the landscape design integrates sponge city ecological technology, reflects the characteristics of lakes and wetlands in Wuhan, and meets the dual needs of ecology and beauty. Secondly, it is necessary to build an open waterfront space, improve the

hydrophilicity of waterfront space, and create a recreational landscape place that can be close to nature. Third, it is necessary to plant characteristic plant communities to form a rich plant landscape, pay attention to the construction and development of flower gardens and various flower shows, and attract people to watch and play.

It is necessary to pay attention to the balanced development of landscape construction at macro, meso and micro scales, and create landscapes with reasonable sense of scale, diverse changes in spatial scale, distinct spatial sequence levels and significant differences in visual perception, so as to enrich tourists' emotional experience. Specifically, it can be optimized from the following points. First, it is necessary to coordinate the sense of scale of landscape elements. When creating different landscape spaces, it is necessary to meet the functionality of different landscape elements and their own specific scale attributes, such as the close-range viewing function of sculpture or art installation landscape, which limits its spatial scale from being too large, and requires attention to the design of landscape details. Moreover, it is necessary to highlight the eye-catching image and control function of physical scenery elements in landscape space. Second, it is necessary to create diversified landscape spatial scales. The spatial scale of the landscape within a certain range should not be static, but should be different from the adjacent space, so as to ensure the spatial integrity and richness of the landscape environment and create a variety of environmental atmospheres. Thirdly, it is necessary to construct a distinct hierarchical landscape spatial sequence. Moreover, the macro, medium and micro-scale landscape nodes should be reasonably arranged on the tour route, so as to provide tourists with a variety of spaces for distribution, communication and privacy, enhance the sense of viewing hierarchy of the landscape along the route, and meet people's needs for diversified spatial scales, so as to optimize the utilization of landscape space.

IV. CONCLUSION

This paper presents a sight-oriented quantitative analysis method of urban visual landscape, which is designed on the basis of the whole three-dimensional model of the city and combines the advantages of two-dimensional and three-dimensional spatial visual analysis. It is not only suitable for the visual analysis of landmark buildings and structures in the city, but also can analyze the visual characteristics of natural landscape as the image of the city in the city. Therefore, the quantitative method of urban visual landscape analysis proposed in this paper can provide reliable data support for the follow-up urban design work.

Because the traditional model analysis lacks consideration of vegetation, on the basis of it, the point cloud model can be further used to consider the visual analysis of vegetation. In the quantitative analysis framework of urban visual landscape proposed in this paper, the analysis process among two-dimensional model, three-dimensional traditional solid model and point cloud mixed model is progressive.

This paper crawls the comment pictures on social media platforms, uses a variety of computer vision algorithms to parameterize the pictures, extracts and quantifies the landscape features in the pictures, and based on this, proposes three

dimensions of landscape images: landscape composition, landscape proportion and landscape color, constructs a multi-dimensional landscape image quantitative measurement framework based on public perception, quantitatively analyzes the commonalities and differences of landscape images, and explores public perception preferences.

The data query efficiency of the model in this paper is low, so in future research, methods such as voxels will be used to segment point cloud data or seek more efficient big data query strategies to improve computational efficiency and accuracy.

Abstract—Urban transportation systems encounter significant challenges in extracting meaningful traffic patterns from extensive historical datasets, a critical aspect of smart city initiatives. This paper addresses the challenge of analyzing and understanding these patterns by employing various clustering techniques on hourly urban traffic flow data. The principal aim is to develop a model that can effectively analyze temporal patterns in urban traffic, uncovering underlying trends and factors influencing traffic flow, which are essential for optimizing smart city infrastructure. To achieve this, we applied DBSCAN, K-Means, Affinity Propagation, Mean Shift, and Gaussian Mixture clustering techniques to the traffic dataset of Aarhus, Denmark's second-largest city. The performance of these clustering methods was evaluated using the Silhouette Score and Dunn Index, with DBSCAN emerging as the most effective algorithm in terms of cluster quality and computational efficiency. The study also compares the training times of the algorithms, revealing that DBSCAN, K-Means, and Gaussian Mixture offer faster training times, while Affinity Propagation and Mean Shift are more computationally intensive. The results demonstrate that DBSCAN not only provides superior clustering performance but also operates efficiently, making it an ideal choice for analyzing urban traffic patterns in large datasets. This research emphasizes the importance of selecting appropriate clustering techniques for effective traffic analysis and management within smart city frameworks, thereby contributing to more efficient urban planning and infrastructure development.

Keywords—Clustering; smart city; traffic; analyze

I. INTRODUCTION

In the current era of rapid urbanization and technological advancement, cities are increasingly adopting "smart city" initiatives aimed at improving the quality of urban life through data-driven decision-making. A smart city leverages technology, particularly networked sensors and data analytics, to optimize urban services, including traffic management. The massive influx of data generated from various sources—such as government records, online platforms, and IoT devices—is a vital resource for transforming urban environments into innovation hubs. However, this wealth of data presents challenges in extraction, analysis, and application, particularly in traffic management, where traditional methods struggle to keep pace with the growing complexity.

Transportation systems are essential to economic stability and social development, yet they also contribute to urban challenges such as congestion and air pollution. Effective traffic management, a cornerstone of smart city initiatives, requires a deep understanding of traffic patterns and behaviors. Data

mining techniques, particularly clustering algorithms, offer powerful tools for uncovering these patterns, facilitating traffic forecasting, and enabling informed decision-making.

This paper focuses on applying clustering algorithms to analyze urban traffic data, specifically within the context of smart city development. By employing techniques such as DBSCAN, K-Means, Affinity Propagation, Mean Shift, and Gaussian Mixture, we aim to uncover meaningful insights into traffic flow patterns and identify factors influencing congestion. The chosen methods are evaluated on their clustering performance and computational efficiency, as these factors are crucial in real-time traffic management systems.

Previous research, such as the work by Pattanaik, Singh, Gupta, and Singh (2016) [1] proposed a real-time traffic congestion estimation system for urban roads, incorporating K-Means clustering and other clustering techniques. Their approach involves collecting and analyzing real-time traffic data to classify and estimate congestion levels accurately. The system dynamically categorizes traffic patterns to provide timely insights and support effective traffic management. This research highlights the practical application of clustering methods in enhancing urban traffic control and decision-making.

The remainder of this paper is structured as follows: Section II provides a literature review, identifying the state-of-the-art in traffic analysis using clustering techniques. Section III outlines the methodology, detailing the data collection process and the specific algorithms used. Section IV provides the performance measures used to analyze the clustering algorithms. Section V presents the results and discussion, comparing the performance of the clustering methods. Finally, Section VI concludes with a summary of findings, implications for smart city initiatives, and suggestions for future research.

II. LITERATURE REVIEW

First, confirm that you have the correct template for your paper size. This template has been tailored for output on the US-letter paper size. If you are using A4-sized paper, please close this file and download the file "MSW_A4_format". The management of urban traffic is a critical component of smart city initiatives, where data-driven strategies are employed to enhance the efficiency and sustainability of urban transportation systems. Clustering algorithms have gained significant attention for their ability to analyze and interpret large-scale traffic data. This section reviews key studies that have applied clustering techniques to traffic data, highlighting the methods used, the

contexts in which they were applied, and the findings that contribute to the understanding of urban traffic management.

A. Clustering Techniques in Traffic Analysis

Clustering, a form of unsupervised learning, has been widely utilized to uncover patterns in traffic data. Various algorithms, such as K-Means, DBSCAN, and Gaussian Mixture Models, have been applied in different contexts to group similar traffic patterns and identify congestion hotspots.

Rouky et al. (2024) [2] investigated traffic congestion in Casablanca using K-Means and DBSCAN clustering methods. Their study focused on identifying congestion patterns and hotspots within the city, contributing to improved traffic management strategies. The findings indicated that clustering could effectively segment traffic data into meaningful clusters, providing insights into daily and seasonal traffic variations. Similarly, Wang et al. (2016) [3] discovered that vehicular traffic levels on metropolitan highways in Shanghai differ dramatically during times of day and night. They discovered that at peak hours, vehicle numbers increase and speeds decrease owing to bottlenecks. Off-peak hours, on the other hand, see a reduction in the amount of traffic and a rise in speed, resulting in a smoother flow of traffic. Their research emphasizes the significance of comprehending these differences for successful traffic control and urban planning in dynamic metropolis contexts such as Shanghai.

Shi et al. (2021) [4] used a density-based moving object clustering technique to determine the spatiotemporal extends of traffic jams. Their approach combines density-based clustering techniques with moving object data to precisely identify crowded zones and their lengths of stay. This technique improves the exactness of bottleneck identification throughout time frames, providing vital knowledge for improving metropolitan traffic control and planning initiatives.

Yang et al. (2017) [5] investigated transportation state fluctuation trends in urban roadways using spectral clustering. Their work used spectral clustering methods to categorize and analyse various traffic situations using spatiotemporal data. The results demonstrated the usefulness of spectral clustering various traffic patterns, such as bottleneck patterns and flow variances across urban regions. This technique offers important conclusions for enhancing metropolitan traffic management techniques and infrastructure design by effectively recording and analyzing complicated traffic behaviors.

Angmo et al. (2021) [6] proposed an enhanced clustering approach that integrates density-based and hierarchical clustering algorithms. Their methodology, which combines spatiotemporal data with advanced clustering techniques, demonstrated increased accuracy and efficiency in identifying relevant locations for traffic management. This study emphasizes the importance of adapting traditional clustering methods to the specific requirements of urban traffic analysis.

Asadi and Regan (2019) [7] presented a method for spatiotemporal clustering of data on traffic through deep-embedded clustering. Their method uses deep learning techniques to embed traffic data in a latent space, allowing for the finding of significant clusters based on geographical and temporal trends. The study sought to increase traffic data

analysis and forecast accuracy by utilizing deep-embedded clustering algorithms. This methodological development offers the potential for improving our knowledge about city transportation habits and optimizing roadway safety tactics.

Sfyridis and Agnolucci (2020) [8] created a technique for predicting Annual Average Daily Traffic (AADT) in England and Wales. They used clustering and regression modeling to increase the correctness of AADT predictions. Clustering methods were employed to aggregate road segments that have similar traffic patterns, models and regression were utilised inside these clusters to calculate traffic numbers. The results showed that this comprehensive strategy improved the accuracy of traffic estimates, providing helpful information for planning transportation and construction of infrastructure.

Wang et al. (2020) [9] devised a technique for identifying hotspots in travel security and safety with an emphasis on the regular fluctuation of the flow of traffic and crash data. Their method combines statistical evaluation and geographical information systems (GIS) to detect high-risk regions for vehicular crashes. By taking into account daily traffic changes and collision data, the study improves hotspot identification accuracy, offering useful information for adopting targeted safety measures and enhancing transportation infrastructure.

Taamneh et al. (2017) [10] published research on categorizing road crashes using clustering-based algorithms. They suggested a hybrid technique that combined hierarchical clustering with artificial neural networks (ANNs). Hierarchical clustering was utilised to divide accident data into clusters with comparable features and ANNs were used to categorise and forecast the severity of accidents within each cluster. The findings showed that this combination strategy increased the accuracy of accident categorization and gave useful information for improving road safety measures and tactics.

Acun and Gol (2021) [11] discovered that data levels on large-scale traffic networks follow different patterns, which may be efficiently analyzed by employing ARIMA and K-means clustering. By using K-means to combine comparable traffic flow patterns and ARIMA models inside these clusters for prediction, they discovered that this hybrid strategy considerably increases traffic volume estimates. Their findings imply that taking into account both temporal trends and geographical clustering results in more accurate traffic management and prediction on large road systems.

Zou, X., & Chung, E. (2024) [12] proposed a novel traffic prediction approach that combines clustering and deep transfer learning to address the challenge of limited data availability. The study utilizes clustering techniques to group similar traffic patterns and then applies deep transfer learning to enhance prediction accuracy across different datasets. This method significantly improves traffic prediction performance, particularly in scenarios where data is sparse, demonstrating its potential in urban traffic management.

Nguyen, T. T., et al. (2019) [13] proposed a method for feature extraction and clustering analysis to study highway congestion. By utilizing clustering techniques, the study identifies and classifies different congestion patterns based on key traffic features extracted from highway data. The approach

focuses on understanding the underlying causes of congestion and its temporal variations. The findings provide valuable insights for designing more effective traffic management strategies on highways, helping to mitigate congestion and improve traffic flow efficiency. The research highlights the importance of data-driven approaches in addressing complex transportation challenges.

B. Smart Cities and Traffic Management

The concept of smart cities involves the use of information and communication technologies (ICT) to optimize urban services, including transportation. Traffic management in smart cities relies heavily on the ability to analyze vast amounts of data generated by sensors, GPS devices, and social media platforms.

Xu et al. (2020) [12] suggested an approach for anticipating traffic jams in Shanghai based on multiperiod hotspot clustering. To forecast bottleneck trends, they use hotspot clustering methods applied across different periods. The work improves overcrowding forecasting accuracy by analyzing past traffic data and using clustering algorithms. This methodological innovation promotes proactive traffic management tactics, hence improving public transportation and the construction of infrastructure in Shanghai.

C. Comparative Analysis of Clustering Algorithms

Several studies have conducted comparative analyses of clustering algorithms to determine their effectiveness in various traffic management scenarios.

Chen et al. (2022) [14] created an automobile flow forecasting system employing a Graph Attention Network (GAT) and spatial-temporal clustering. Their technique makes use of GATs to capture geographical and temporal connections in traffic data, which improves traffic flow prediction precision. The investigation also uses spatial-temporal clustering to organize traffic patterns, which helps manage complicated transportation patterns. The findings show that this combination of approaches increases the accuracy of traffic flow estimates, resulting in improved administration and planning in smart transportation networks.

D. Gaps and Future Directions

While the literature demonstrates the effectiveness of clustering techniques in traffic analysis, several gaps remain. Most studies have focused on traditional algorithms, with limited exploration of novel methods that could offer improved performance or new insights. Moreover, there is a need for more comprehensive evaluations of these techniques within the smart city framework, considering factors such as scalability, adaptability to dynamic data, and integration with other smart city systems.

Additionally, the literature often lacks a critical comparison of how these clustering methods perform in different urban environments, which can vary significantly in terms of traffic patterns and data availability. Future research should focus on developing and testing new algorithms that can address these challenges and contribute to more robust and adaptive traffic management solutions in smart cities.

III. STUDY AREA AND METHODOLOGY

A. Dataset Description

This research used traffic information from the city of Aarhus to analyze traffic habits in an urban region. Aarhus is Denmark's second-biggest city and main cultural center. Due to its northern latitude, Aarhus experiences significant variations in daylight hours between summer and winter. Various clustering approaches are used to examine data from February 2014 to June 2014 to identify transportation trends. Sensors were set at two nearby places to collect data, tallying the amount of automobiles moving by during a certain period. Every route's report contains a traffic count taken by the sensor on a certain day and time. Table I describes the attributes in the dataset.

TABLE I. ATTRIBUTES IN THE DATASET

Attributes	Description
avgMeasuredTime	Shows the duration in seconds of the sensor collecting data.
avgSpeed	This signifies the mean pace of the cars moving within the reported period.
extID	Signifies the distinct identification allocated for every route.
medianMeasuredTime	Like avgMeasuredTime
TIMESTAMP	Represents the beginning time measurement of transportation on a route.
vehicleCount	Quantity of cars traveling across each pair of observations.
_id	A distinctive number, issued for every traffic estimate.
REPORT_ID	Denotes the distinct number of every observation point.

B. Data Preprocessing

The traffic data is processed to enable traffic pattern analytics. Routes with inadequate data are populated using filling missing values techniques. Preprocessing guarantees that the study's final data include comprehensive traffic counts for each road on a given day. Following numerous evaluations of quality, all processed records are grouped into 1-hour intervals. For transportation statistics, we just require an automobile count at periods throughout the day. Therefore, data such as the extID, avgSpeed, avgMeasuredTime and medianMeasuredTime, and other particulars are unneeded. We have trimmed our data collection to contain just the fields important for extracting patterns. Each entry for a certain roadway now has only two fields: date and automobile frequency.

A few rows in the dataset lack accurate timestamps or interval bounds. A defective timestamp indicates that what was observed has changed in time. To resolve this, automobile counts are proportionally adjusted for inadequate timestamps or intervals. The adjusted values are subsequently used for a variety of performance assessments. To eliminate rows with wrong values, the following types of verification procedures are used:

1) Poor-quality detectors may record excessively elevated transport volumes, affecting approximation. Rows with traffic counts exceeding 120 are eliminated from data collection.

2) If nothing is achieved for three hours consecutively in a day, the day is declared worthless. If over thirty percent of the available days for an area are unreliable, it is removed from further investigation.

C. Models

Clustering methods are used when there are not any classes to forecast but instead, instances need to be classified into natural groupings. For the investigation of streets, we employed the DBSCAN, K-Means, Affinity Propagation, Mean Shift, and Gaussian Mixtures method to cluster days of the week. Each method takes an alternate strategy to the problem of identifying natural groupings in data. We selected 372 streets and clustered them over all days in the dataset. Fig. 1 shows the data source collection location. Fig. 2 is the proposed methodology of the suggested approach to analyze the traffic pattern.

Fig. 1. Data source location.

DBSCAN (Density-Based Clustering of Applications with Noise) is a clustering technique that detects clusters and outliers in a dataset using density. The algorithm has two parameters: epsilon(ϵ), which determines the radius for neighborhood searches, and MinPts, which specifies the minimal of points needed to build dense regions. Core points have at least MinPts neighbours within ϵ , whereas border points are close to a core point but do not have enough neighbors to be core points themselves. The noise points do not belong to any cluster.

DBSCAN performs well for arbitrary clusters and can withstand noise, but its efficiency is significantly dependent on its selection of ϵ and MinPts.

K-Means is a common clustering technique that divides a dataset into K separate, not interconnected groups. The technique initiates K centroids and allocates every data point to the closest centroid, resulting in K clusters. It then continuously updates the centroids by taking the average of every point in each cluster and reassigning them depending on the new centroids. This procedure repeats until the centroids stop changing appreciably. K-Means is effective and easy to construct, but the number of clusters (K) must be identified in advance. It works with spherical collections but struggles with clusters of different shapes and densities.

Affinity Propagation is a clustering approach that detects exemplars (representative points) inside data by delivering messages between data points. Unlike, K-Means, the total number of groups does not have to be preset. The algorithm operates by repeatedly transferring two sorts of messages: “responsibility”, which shows how well-suited the data point is to serve as an exemplar for another point, and “availability” which represents a point’s appropriateness for assignment to an exemplar. These notifications will be maintained until convergence. Affinity propagation may detect clusters of variable sizes and does not presume an ideal structure for the clusters, making it a useful tool for a variety of grouping jobs. However, it can be extremely costly for huge datasets.

Mean Shift is a nonparametric clustering approach that seeks to identify groups by repeatedly moving data points to the densest region of the feature space. The technique begins by constructing a window (or kernel) around each data point and then computes the average of the points within that window. Each data point is then relocated to the mean, and the procedure is continued until convergence, which causes points to cluster around the density function’s modes (peaks). Mean Shift, unlike K-Means, doesn’t need a pre-specified amount of clusters and may discover clusters of any form. However, its performance is significantly reliant on the selection of the bandwidth option, which controls the window size.

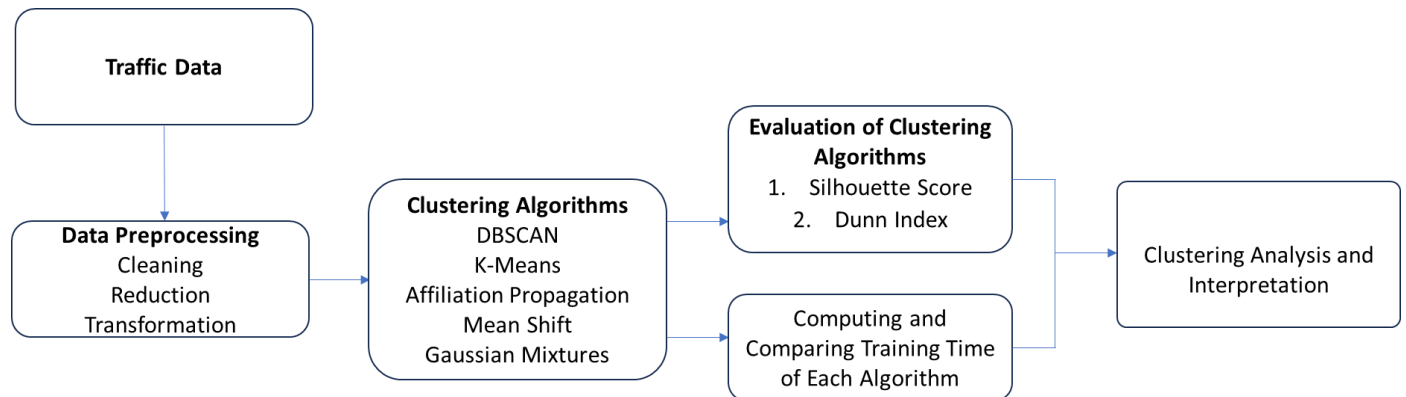

Fig. 2. Methodology of the suggested approach.

Gaussian Mixture Models (GMM) are probabilistic clustering methods that presume data is created by a combination of multiple Gaussian distributions with

unidentified variables. Each Gaussian component has a mean and a covariance, and the model is described by the components’ mixture weights, means, and covariances. GMMs employ the

Expectation-Maximization (EM) method to continuously modify these variables to maximize the probability of the data being observed. Unlike K-Means, GMMs may detect the elliptical form of clusters and give soft categorization, which means that each data point has a chance to be assigned to each group. This makes GMMs more adaptable and stronger when modelling real-world data with different cluster shapes and densities. However, they can be sensitive to startup and may require careful adjustment.

IV. STUDY AREA AND METHODOLOGY

To determine which clustering approach is optimal for our model, we apply the following validity indices.

- 1) Silhouette score
- 2) Dunn index

A. The Silhouette Score

The Silhouette Score is a way to evaluate the quality of clusters generated by a clustering algorithm. It determines how comparable a data point is to its group relative to different groups. The score goes from -1 to 1, with a large number indicating that the data points are compatible within the same cluster but not sufficiently matched with neighboring groups. The score for each point is determined and averaged to produce an overall evaluation. A higher average Silhouette Score indicates a more clearly defined and suitable grouping structure. This method is useful for determining the ideal number of clusters and evaluating the effectiveness of various clustering algorithms. The Silhouette Score for a single data point is given by the formula:

$$s(i) = \frac{z(j)-y(j)}{\max(y(j),z(j))} \quad (1)$$

where:

- $y(j)$ is the average distance between j and all other points in the same cluster (also known as intra-cluster distance).
- $z(j)$ is the minimum average distance from j to all points in the nearest cluster that j is not a part of (also known as the nearest cluster distance).

The Silhouette Score for the entire dataset is the mean Silhouette Score of all individual data points. The formula is:

$$S = \frac{1}{n} \sum_{i=1}^n s(i) \quad (2)$$

where n is the total number of data points. The overall score indicates the clustering quality, with values closer to 1 indicating better clustering.

B. Dunn Index

The Dunn Index is a tool for evaluating the effectiveness of algorithms for clustering that measures group density and separation. It can be defined as the ratio of the lowest intercluster distance to the maximal intra-cluster distance. A higher Dunn Index implies better grouping since it implies that groups are clearly distinguished and densely packed. Here is the formula:

$$D = \frac{(\max_{1 \leq i < j < k} d(C_i C_j))}{(\max_{1 \leq l < k} \delta(C_l))} \quad (3)$$

where $d(C_i, C_j)$ is the distance between the two clusters C_i and C_j , and $\delta(C_l)$ is the diameter of the cluster C_l . The Dunn Index is particularly useful for comparing different clustering results on the same dataset. However, it can be computationally expensive for large datasets due to the need to compute all pairwise distances between cluster.

V. EXPERIMENTS AND RESULTS

Everyday travel patterns from various days are clustered using the DBSCAN, K-Means, Affinity Propagation, Mean Shift, and Gaussian Mixture algorithms. Records for working and nonworking days were combined for all routes from February to June.

A. Clustering Analysis

Clustering was performed on 372 streets, each having enough information to analyze. The number of clusters and related traffic patterns varied according to location. Affinity Propagation clustering divided days into two categories: weekdays and weekends. In DBSCAN, K-Means, Mean Shift, and Gaussian Mixture clustering days were divided into four main groups. A thorough investigation of several roadways was conducted, providing reliable outcomes. The results of DBSCAN, K-Means, Affinity Propagation, Mean Shift and Gaussian Mixture clustering are presented in Fig. 3, Fig. 4, Fig. 5, Fig. 6, and Fig. 7 respectively. Except Affinity Propagation in other clustering techniques each street's days were separated into four groups.

Fig. 3. Traffic pattern representing four clusters using DBSCAN.

Fig. 4. Traffic pattern representing four clusters using K-Means.

Fig. 5. Traffic pattern representing four clusters using affinity propagation.

Fig. 6. Traffic pattern representing four clusters using mean shift.

Fig. 7. Traffic pattern representing four clusters using Gaussian Mixture.

The lower level cluster in Fig. 3 to Fig. 7 includes Saturdays, Sundays, and certain weekdays. Weekdays with vacations or wet weather have significantly lower transportation than regular days. This cluster consists of routes with low to medium traffic throughout the day. The other groups include a variety of weekdays.

NearestNeighbors is used to calculate the estimated closeness between points of data and it is utilized as eps in DBSCAN. The `_n_neighbors_` in NearestNeighbors is used as the minimum sample point in DBSCAN. The elbow approach

determines the ideal number of groups in K-Means clustering. To assess which clustering strategy is best for our model Silhouette Score and Dunn Index are used. The DBSCAN gives better values for the Silhouette coefficient and Dunn Index as seen in the results shown above in Table II.

TABLE II. SILHOUETTE SCORE AND DUNN INDEX OF DIFFERENT CLUSTERING TECHNIQUES

Technique	Silhouette Score	Dunn Index
DBSCAN	0.3664	0.03752
K-Means	0.3119	0.00395
Affinity Propagation	0.0017	0.00123
Mean Shift	0.0042	0.00350
Gaussian Mixture	0.2032	0.00390

We have also compared the training times taken by each clustering algorithm. Fig. 8 depicts the training time for each investigated clustering algorithm. Fig. 9 depicts the training time for each clustering algorithm excluding Affinity Propagation. On the scale of the training timeframes for the Mean Shift and Affinity Propagation algorithms, the training durations of the other methods completely evaporate. Furthermore, Affinity Propagation is eliminated to compare the training durations of the remaining algorithms on a more reasonable scale.

Fig. 8. Training time for each clustering algorithm.

Fig. 9. Training time for each clustering algorithm excluding affinity propagation.

Compared to Affiliation Propagation and Mean Shift, training time is less for DBSCAN, K-Means, and Gaussian Mixture.

VI. CONCLUSION AND FUTURE WORK

Various clustering methods have been employed to extract patterns from urban traffic data, including DBSCAN, K-Means, Affinity Propagation, Mean Shift, and Gaussian Mixture, notably DBSCAN, which produced enlightening results. DBSCAN proved to be very successful in its capacity to manage noise and detect groups of arbitrary shape, making it ideal for the complex and variable traffic patterns seen across multiple streets, the clustering procedure showed various traffic patterns, in some categorizing days a weekdays or weekends and many cases into four primary clusters. The rigorous clustering method enabled a thorough understanding of the traffic behavior, allowing for more focused traffic control tactics. DBSCANs exceptional efficiency when handling and analyzing traffic data demonstrates its potential to improve urban traffic systems.

For future studies, it is recommended to use big data technology to handle and analyze large amounts of traffic data collected from diverse sources such as GPS, detectors, and online platforms. This strategy will give more specific information on traffic trends. Furthermore, utilizing clustering algorithms to undertake comparative evaluations of travel habits across multiple cities can aid in identifying common difficulties and best practices, as well as revealing trends and solutions that may be broadly implemented.

Abstract—Patient no-shows are prevalent in pediatric outpatient visits, leading to underutilized medical resources, increased healthcare costs, reduced clinic efficiency, and decreased access to care. The use of machine learning techniques provides insights to mitigate this problem. This study aimed to develop a predictive model for patient no-shows at the Ministry of National Guard Health-Affairs, Saudi Arabia, and evaluate the results of various machine learning algorithms in predicting these events. Four machine learning algorithms - Gradient Boosting, AdaBoost, Random Forest, and Naive Bayes - were used to create predictive models for patient no-shows. Each model underwent extensive parameter tuning and reliability assessment to ensure robust performance, including sensitivity analysis and cross-validation. Gradient Boosting achieved the highest area under the receiver operating curve (AUC) of 0.902 and Classification Accuracy (CA) of 0.944, while the AdaBoost model achieved an AUC of 0.812 and CA of 0.927. The Naive Bayes and Random Forest models achieved AUCs of 0.677 and 0.889 and CAs of 0.915 and 0.937, respectively. The confusion matrix demonstrated high true-positive rates for no-shows for the Gradient Boosting and Random Forest models, while Naive Bayes had the lowest values. The Gradient Boosting and Random Forest models were most effective in predicting patient no-shows. These models could enhance outpatient clinic efficiency by predicting no-shows. Future research can further refine these models and investigate practical strategies for their implementation.

Keywords—No-show; pediatric; machine learning; algorithms; prediction; outpatients

I. INTRODUCTION

Patient no-shows are one of the main challenges in the healthcare sector, disturbing the workflow or affecting cost load, reflecting on the quality and performance [1]. Reducing the number of no-shows significantly impacts healthcare institutions' services, reducing financial costs and effectively utilizing resources to improve patient service [2]. The issue of no-shows is a recurring problem that hinders the efficient utilization of human resources [2,3]. In addition, it increases patient waiting time and negatively impacts the workflow by wasting time for healthcare providers [3].

No-shows are a significant concern for healthcare institutions and may be expensive and inconvenient [3].

Capacity is underutilized, and costly assets are underused [4]. Researchers have found that eliminating non-cancelled no-show appointments may considerably influence productivity, profitability, and clinical outcomes [4]. Machine learning techniques would provide a solution [2]. Thus, finding a way to predict no-shows would facilitate the effective utilization of hospital resources and enhance the satisfaction of both providers and patients, ultimately improving healthcare quality [3–5]. There are some practices used to overcome no-shows, such as overbooking and walk-ins, but these methods are still not the ideal solutions to address the issue of no-shows; there is no effective tool in the electric healthcare system to detect patients at a higher risk of not showing up [6].

Prediction is the most challenging part of human behavior; presuming and predicting this pattern or behavior of a no-show [7]. Finding associations with variables and attributes would facilitate the prediction of no-show appointments [8]. Enabling a prediction model to predict no-shows would help to effectively utilize human resources, reduce financial losses, and increase patient satisfaction [9]. It would also help to improve appointment scheduling, reduce waiting time, and increase the number of patients seen daily [10]. Therefore, a no-show prediction tool is an added value for any organization [11].

A study by Alshammari aims to predict no-shows through machine learning [12]. The dataset includes more than thirty-three million outpatient appointments [12]. The dataset was extracted for a period of nearly three years (January 2016 - July 2019) from the Health Information System (HIS) at all facilities in the central region of the Ministry of National Guard Health Affairs (MNGHA), Saudi Arabia. The authors state that nearly 77,000 outpatient appointments were scheduled monthly at the MNGHA in the Riyadh Region. The patients' ages ranged from 5 to 69 years old. The highest no-show rate was observed among patients over 45 years old. Almost 85% of the no-shows were a national citizen. The study utilized three machine-learning algorithms: Deep Neural Network, AdaBoost, and Naive Bayes. The results of this study were promising, showing that it achieved a 98% precision rate using the deep learning model [12].

The authors of Alshammari's other research paper attempt to develop a prediction model based on a machine learning

algorithm for cases where patients do not attend their scheduled appointments [13]. The dataset was obtained from the Kaggle database of hospital appointments booked between April 29, 2016, and June 8, 2016. The dataset included (110,528) medical appointments. Recursive Feature Elimination (RFE) was implemented using Python to exclude unrelated items from the dataset. After running the RFE to remove the unrelated attributes, as including all variables can lead to highly complex modeling, nearly 83,000 appointments were included. The no-show rate was approximately 20%. The dataset has been divided into 70% for the training dataset and 30% for the test dataset. The machine learning algorithms used in this study are Decision Trees and AdaBoost. Multiple variables were used to determine the optimal model for predicting no-shows. The results showed high precision and recall, indicating that the Decision Tree outperformed the AdaBoost results [13].

A study by AlMuhaideb used machine learning to create a model for predicting no-shows in outpatients [14]. The research data were extracted from the health information system, which captures records of patient visits for outpatients. The dataset contains almost more than 1 million outpatient records. The period of this dataset was between January and December 2014, and the no-show rate was 11.3%. The machine prediction models used are JRip and Hoeffding tree algorithms. The machine learning software used was Weka. The dataset was cleansed and preprocessed to conduct the modeling analysis. Both the JRip and Hoeffding algorithms provided rational degrees of accuracy levels of almost 77%. The study showed that the no-shows could be predicted using a machine-learning model [14].

Hamdan, A., and Abu Bakar, A. published a study in 2023 on outpatient no-show appointments in a Malaysian tertiary hospital [15]. The study aimed to develop a model for predicting patient no-show appointments using machine learning. The data were collected through 2019 and included 246,943 appointment records with 14 attributes, including demographics and appointment data. The result shows that 69,173 patients did not attend their appointment, which accounts for about 28% of the dataset. The machine learning model used seven algorithms: logistic regression (LR), decision tree (DT), k-nearest neighbors (k-NN), Naïve Bayes (NB), random forest (RF), gradient boosting (GB), and multilayer perceptron (MLP). Three different train and testing splits were applied at 60:40, 70:30, and 80:20, and ten folding validations were performed on each split using Python. The evaluation metrics included accuracy, AUC value, and F1 score. The GB scored the highest accuracy of 78%.

Therefore, finding a way to predict the no-show or high no-show candidates will help healthcare organizations overcome this issue [16]. Developing a prediction model will help stakeholders mitigate the anticipated effects of no-shows and enhance healthcare efficiency by optimizing resource utilization [17]. The prediction model can help to identify patients at high risk of no-shows based on factors such as age, gender, appointment type, past behavior, and geographic location [18]. A machine learning model that predicts patient no-shows can enhance clinical efficiency by optimizing resource allocation, reducing wasted time through overbooking appointments without compromising patient care, and allocating efficient slot allocation by understanding no-show patient patterns.

The main objective of this study is to develop a machine-learning model capable of accurately predicting the likelihood of a pediatric patient missing a scheduled appointment. Other objectives include identifying key factors influencing pediatric no-show rates to inform targeted interventions and optimize appointment scheduling and resource allocation based on no-show predictions. This model can improve patient satisfaction by reducing wait times and increasing appointment availability. From a broader perspective, this model can help better understand pediatric patient behavior and healthcare utilization.

In this study, we aim to develop a predictive model and evaluate its performance using machine learning algorithms to predict pediatric patient no-shows in pediatric outpatient visits at the Ministry of National Guard - Health Affairs (MNGHA) using machine learning techniques. This study differs from the mentioned studies [12–15]. This study targets a more specific population of pediatric patients. It uses primary data extracted from a tertiary hospital and applies multiple or different machine learning algorithms in a single study.

II. METHOD

This study is a retrospective exploratory/predictive study. It aims to predict the no-show based on machine learning techniques and Machine Learning (ML) algorithms such as Gradient Boosting (GB), AdaBoost, Naive Bayes (NB), and Random Forest, which are all supervised Machine Learning algorithms.

This study was conducted ethically, following established guidelines and protocols to ensure patient privacy and data confidentiality. This study has been approved by an Institutional Review Board (IRB) committee from the King Abdullah International Medical Research Center (KAIMRC).

A. Study Area, Settings, and Subjects

The study was conducted on pediatric patients at the Ministry of National Guard Health Affairs (MNGHA) in Saudi Arabia. The data were extracted from the BESTCare health information system used in the MNGHA. They encompass appointments scheduled throughout the day from January 1, 2021, to May 5, 2022.

The patient records eligible for the study must fulfill the inclusion and exclusion criteria. All patients under the age of 14 who had a scheduled visit to a pediatric outpatient clinic (pediatric patients) were included. A patient no-show is a visit in which the patient fails to attend a scheduled appointment without providing prior notice. Canceled appointments before the clinic were not counted as no-shows to ensure all missed appointments were not intervenable. Emergency visits, unscheduled visits, such as walk-ins, and patients older than 14 years were excluded.

B. Data Collection, Management, and Analysis Plan

The dataset used in this study comprises 358,759 outpatient appointment visits, with a mix of nominal, ordinal, and numeric attributes related to patient demographics, appointment details, and medical history. The dataset includes data on patients' age groups, gender, nationality, appointment types, region, and appointment times to ensure a representative sample of the study

population across different age groups, genders, and appointment types.

This study utilizes historical data on patient visits to predict the likelihood of no-shows. The analysis plan encompasses the standard stages of the data mining process, including data collection and understanding, data preparation, model selection, model building, and model evaluation.

The study collected various attributes from the dataset to analyze and predict patient no-show appointments. Table I summarizes these attributes, including their descriptions and types. The attributes capture information such as visit ID, region, facility, department, clinic, patient demographics (gender, nationality, age), appointment details (date, time), diagnosis information, appointment message status, patient's address, sponsor eligibility, and more. One notable attribute is the lead time, which represents the difference between the booking and

appointment dates. This table references the attributes used in analyzing and predicting no-show appointments.

The data was cleaned and preprocessed to ensure the quality of the dataset. This included handling missing values, removing irrelevant attributes, and transforming variables required for model development. For example, the lead time variable was derived by calculating the difference between the booking and appointment dates. In addition, the appointment time was categorized into AM and PM.

Relevant features were selected based on their potential impact on predicting no-show appointments. Factors such as age group, gender, nationality, appointment type, region, and appointment time were included in the analysis, as these were expected to contribute to the prediction of no-show appointments.

TABLE I. DESCRIPTION OF THE COLLECTED AND DERIVED ATTRIBUTES

Data Attributes			
No.	Attribute Name	Description	Type
1	Visit_ID	Visit ID	Numeric
2	Region	Region Name	Nominal
3	Facility	Facility Name	Nominal
4	HSP_TP_CD	Hospital or facility type code	Numeric
5	HSPL_TP_CD	Internal hospital or facility code	Numeric
6	Department	Medical Department	Nominal
7	Department_CD	Medical Department Code	Numeric
8	Clinic	Clinic name	Nominal
9	Clinic_CD	Clinic Code	Numeric
10	MRN	Patient's Medical record number	Numeric
11	Appointment_DT	Appointment Date	Ordinal
12	Appointment_TIME	Appointment Time	Ordinal
13	Appointment_DTM	Appointment Date & Time	Ordinal
14	Visit_Type	Patient Visit type	Nominal
15	Appointment_Booking_DTM	Appointment Booking Date & Time	Ordinal
16	Appointment_Booking_TIME	Appointment Booking Time	Ordinal
17	ICD10_CD	ICD10 code for the diagnosis	Nominal
18	Diagnosis	Diagnosis	Nominal
19	Flag	Show/no-show	Nominal
20	MSG_SENT_YN	Appointment message sends the status	Nominal
21	MSG_Status	Appointment message status	Nominal
22	Gender	Patient Gender	Nominal
23	Nationality	Patient Nationality	Nominal
24	Age	Patient Age	Ordinal
25	Address1	Patient Region or an area name or code of the patient's residence	Nominal
26	Address2	Patient district name or code of patient's residence	Nominal
27	Sponsor_Eligibility	Patient's Sponsor_Eligibility	Nominal
28	ETPR_PT_NO	Patient Enterprise record number	Numeric
29	Cachement_Area_CD	Area name of the patient's residence	Numeric
30	Cachement_Area_NAME	Area Code of the patient's residence	Nominal
31	Cachement_FCLT_NO	Facility Code of the patient's residence	Numeric
32	Cachement_FCLT_NAME	Facility name of the patient's residence	Nominal
33	Lead time	Difference between Appointment Booking and Appointment dates	Numeric
34	Appointment time AM/PM	AM/PM	Ordinal

C. Model Selection, Building, and Evaluation

We applied four machine learning algorithms to the preprocessed data: Gradient Boosting, AdaBoost, Naive Bayes, and Random Forest. Gradient Boosting, AdaBoost, Naive Bayes, and Random Forest are flexible, well-suited algorithms for handling complex relationships in large datasets. These algorithms are also well-suited for handling categorical features and numerical data [19,20]. We used 10-fold cross-validation to assess model performance and avoid overfitting. Each model evaluation was based on various metrics, including Area Under the Receiver Operating Characteristic Curve (AUC), Classification Accuracy (CA), F1 score, Precision, and Recall. Furthermore, the preprocessing steps and hyperparameters for each model were recorded, ensuring the integrity and consistency of the input data.

Gradient Boosting (XGBoost): The model was trained and constructed by combining 100 individual decision trees and a learning rate of 0.3, which determines the weight given to each tree's prediction when they are combined. In this case, a learning rate of 0.3 balances responsiveness and stability in the model's predictions. The maximum depth of individual trees was set at 20, providing a good balance between the model's complexity and its ability to learn the underlying patterns in the data.

Regularization was applied with a lambda value of 7 to prevent overfitting. Regularization helps prevent overfitting when a model becomes too complex and starts to memorize the training data instead of learning the underlying patterns.

The lambda value of 7 represents the strength of the regularization. A higher lambda value increases the penalty for complex models, encouraging the model to simplify its predictions and avoid overfitting. By applying regularization with a lambda value of 7, the model aims to balance capturing essential patterns in the data and avoiding excessive complexity.

We also experimented with different fractions of training instances and features for each tree, level, and split. The fraction was set to 1.0 in all cases to use all available data and features. We fixed the random seed for replicable training to ensure that specific conditions did not affect our results.

The preprocessing steps for Gradient Boosting were removing instances with unknown target values, customizing categorical variables using one-hot-encoding, removing empty columns, and imputing missing values with mean values.

AdaBoost: The model was built using a base estimator (a decision tree) and 100 additional estimators. A high learning rate of 0.999 was set to give more weight to the most recent data. The classification algorithm SAMME was used to boost the model. As in the case of XGBoost, we ensured the replicability of results by fixing the random seed.

AdaBoost's preprocessing steps included removing instances with unknown target values, customizing categorical variables using one-hot encoding, removing empty columns, and imputing missing values with mean values.

Naive Bayes: The Naive Bayes algorithm does not have specific hyperparameters like other algorithms, but preparing

the data well for this model is essential. For Naive Bayes, the preprocessing step was removing empty columns.

Random Forest: The model was trained with 100 trees, and the number of attributes considered at each split was set to 5. This allowed the model to consider a balanced number of attributes at each node to achieve a good compromise between bias and variance. Growth control measures were applied to avoid creating complex models that could lead to overfitting. We ensured that subsets smaller than a certain threshold were not split.

Preprocessing of the Random Forest included removing instances with unknown target values, customizing categorical variables using one-hot encoding, removing empty columns, and imputing missing values with mean values.

III. RESULTS AND ANALYSIS

This section presents the research project's findings based on the statistical analysis and the development of the machine learning model described in the previous section. The results are presented as descriptive statistics, model performance, and critical findings from the analysis.

A. Description Analysis

This section provides an overview of the dataset, showing patterns and trends in no-show appointments among different patient demographics and appointment attributes.

1) Age group: In Table II, the data show different age groups, including infants (0-12 months), toddlers (1-3 years), preschoolers (3-6 years), school-age children (6-12 years), and adolescents (12-14 years). The table displays the number of patients who attended their appointments and those who did not (no-shows) for each age group. The "Show" column represents the number of patients who attended their appointments, while the "No-Show" column represents the number of patients who did not show up. The "Total" column indicates the total number of patients in each age group. The school-age children (6-12 years) accounted for the highest proportion of no-show appointments, followed by infants (0-12 months) and preschoolers, see Table II.

TABLE II. DESCRIPTION AND DISTRIBUTION OF AGE GROUPS WITH NO-SHOW PERCENTAGES

Age Groups Categories			
Age Group	Show (%)	No-show (%)	Total
Infant (0-12 Months)	79,948 (92.7%)	6,281 (7.3%)	86,229
Toddler (1-3 Years)	53,150 (92.1%)	4,460 (7.9%)	57,610
Preschool (3-6 Years)	59,248 (91.1%)	5,740 (8.9%)	64,988
School-age (6-12 Years)	101,212 (91.1%)	9,831 (8.9%)	111,043
Adolescent (12-14 Years)	35,264 (90.6%)	3,624 (9.4%)	38,888

2) Gender: Table III presents the data for gender distribution. The table displays the number of patients who attended their appointments and those who did not (no-shows)

for each gender. The dataset contained a higher proportion of shows with male patients than with female patients.

TABLE III. DISTRIBUTION OF AND PERCENTAGES OF GENDER

Gender and Distribution			
Gender	Show (%)	No-show (%)	Total
Male	171,469 (91.9%)	15,382 (8.2%)	186,851
Female	157,353 (91.5%)	14,554 (8.5%)	171,907

3) *Nationality*: Table IV presents the data for individuals of Saudi and non-Saudi nationality. The majority of patients were of Saudi Nationality, with a small percentage of non-Saudi patients. The rate of no-shows is higher for non-Saudi patients.

TABLE IV. DISTRIBUTION OF AND PERCENTAGES OF NATIONALITY

Nationality and Distribution			
Nationality	Show (%)	No-show (%)	Total
Saudi	325,944 (91.7%)	29,409 (8.3%)	355,353
Non-Saudi	2,878 (84.6%)	527 (15.4%)	3,405

4) *Appointment types*: Table V presents data on different appointment types, including New Patient (NP), First Visit (FV), and Follow-up (FU). Follow-up appointments had the highest no-show rates, followed by first visits and new patient appointments.

TABLE V. DISTRIBUTION AND PERCENTAGES OF APPOINTMENT TYPES

Appointment Types and Distribution			
Appointment Type	Show (%)	No-show (%)	Total
New Patient (NP)	10,182 (95.9%)	446 (4.1%)	10,628
First visit (FV)	171,415 (92.6%)	13,681 (7.4%)	185,096
Follow-up (FU)	147,225 (90.3%)	15,809 (9.7%)	163,034

Table VI shows the data for the Central, Eastern, and Western regions, showing attendance and no-show numbers. Geographically, the proportion of no-shows was highest in the Central region, followed by the Western and Eastern regions.

TABLE VI. DISTRIBUTION OF AND PERCENTAGES OF INCLUDED REGIONS

Regions and Distribution			
Region Name	Show (%)	No-show (%)	Total
Central	218,151 (93.9%)	13,994 (6.1%)	232,145
Eastern	32,206 (93.1%)	2,388 (6.9%)	34,594
Western	78,465 (85.2%)	13,554 (14.8%)	92,019

5) *Appointment time and hours*: Table VII provides information on the appointment times of the day, namely AM and PM, indicating the number of patients who showed up and those who did not. The data showed that appointments in the morning (AM) had slightly higher no-show rates than afternoon (PM) appointments.

TABLE VII. DISTRIBUTION OF AND PERCENTAGES OF APPOINTMENT TIME OF THE DAY

Time of the Day and Distribution			
Gender	Show (%)	No-show (%)	Total
AM	166,642 (90.8%)	16,737 (9.2%)	183,379
PM	162,180 (92.5%)	13,199 (7.5%)	175,379

Table VIII provides information on appointment hours, including the number of no-shows and appointments attended for each period. The table displays data for time slots 7-9, 9-12, 12-15, 15-17, and beyond working hours. Table IX presents data on appointment days of the week, showing the number of no-shows and shows for each day.

TABLE VIII. DISTRIBUTION OF APPOINTMENT HOURS CATEGORIES

Appointment Hours Categories of the Day			
Appointment Hour	Show (%)	No-show (%)	Total
7-9	3,855 (8.7%)	40,597 (91.3%)	44,452
9-12	12,867 (9.6%)	121,583 (90.4%)	134,450
12-15	9,221 (7.9%)	106,923 (92.1%)	116,144
15-17	3,659 (9.8%)	33,723 (90.2%)	37,382
After working hours	334 (1.3%)	25,996 (98.7%)	26,330

TABLE IX. DISTRIBUTION OF APPOINTMENT DAY

Appointment Day			
Appointment Day	Show (%)	No-show (%)	Total
Sunday	6,040 (8.4%)	66,002 (91.6%)	72,042
Monday	6,495 (8.2%)	72,645 (91.8%)	79,140
Tuesday	7,423 (9.9%)	67,213 (90.1%)	74,636
Wednesday	5,662 (7.8%)	66,647 (92.2%)	72,309
Thursday	4,168 (7.7%)	49,965 (92.3%)	54,133
Friday	85 (2.8%)	2,958 (97.2%)	3,043
Saturday	63 (1.8%)	3,392 (98.2%)	3,455

B. Model Performance

The results suggest that all four models (Gradient Boosting (GB), AdaBoost, Naive Bayes (NB), and Random Forest) have performed reasonably well, but Gradient Boosting stood out as the most robust model in our study. Our sensitivity analysis, which involved varying the training and testing data splits and the machine learning algorithms' hyperparameters enhanced the reliability of our results. Comprehensive evaluation ensures that the models are reliable and not overly sensitive to the specific selection of parameters, confirming the robustness of the findings. The consistency in preprocessing across models further strengthens the credibility of the outcomes. The performance of the four machine learning models was evaluated using cross-validation with ten subsets and a separate testing set.

Table X summarizes the model performance, with Gradient Boosting demonstrating the best performance by achieving the highest values for AUC, CA, F1 score, precision, and recall. This indicates that Gradient Boosting outperformed the other models in accurately predicting the likelihood of no-show appointments.

TABLE X. MODEL'S ALGORITHMS AND EVALUATION METRICS PERFORMANCE

Algorithms and Evaluation Metrics					
Algorithm	AUC	CA	F1	Precision	Recall
Gradient Boosting	0.902	0.944	0.937	0.939	0.944
AdaBoost	0.812	0.927	0.926	0.924	0.927
Naive Bayes	0.677	0.915	0.877	0.861	0.915
Random Forest	0.889	0.937	0.925	0.931	0.937

The Receiver Operating Characteristic (ROC) analysis is a graphical representation that illustrates the performance of a binary classification model. In this study, the ROC plot (Fig. 1) demonstrates the performance of the machine learning models in predicting no-show appointments.

The x-axis represents the False Positive Rate (FPR), which measures the proportion of false positives (show appointments incorrectly classified as no-shows) to all actual negatives (show appointments). The y-axis represents the True Positive Rate (TPR), which measures the proportion of true positives (no-show appointments correctly classified as a no-show) to all actual positives (no-show appointments).

Fig. 1. ROC analysis diagram with classifier.

A curve on the ROC plot represents each model. The closer the curve is to the top-left corner, the better the model's performance. The ideal scenario is a model with a curve that reaches the top-left corner, indicating a high TPR and a low FPR.

By examining the ROC plot, we can observe that the Gradient Boosting model exhibits the highest performance among the four models. It shows the highest TPR for a given FPR threshold, indicating its ability to identify and classify no-show appointments accurately. The other models, including AdaBoost, Naive Bayes, and Random Forest, also demonstrate varying performance levels, with their respective curves positioned below that of Gradient Boosting.

The ROC Analysis Diagram visually represents the models' performance, distinguishing between show and no-show appointments. It helps evaluate and compare the predictive capabilities of models and select the most suitable one for accurately predicting no-shows in future scenarios.

Table XI shows the confusion matrix for the four represented models and the predicted versus actual outcomes for no-show

and show appointments. The matrices provide insight into each model's performance by showing the True Positive (TP), True Negative (TN), False Positive (FP), and False Negative (FN) rates.

TABLE XI. DISTRIBUTION OF APPOINTMENT DAY (CONFUSION MATRIX FOR THE FOUR REPRESENTED MODELS)

Confusion Matrix			
Gradient Boosting (GB) Algorithm			
		Actual Values	
		Positive	Negative
Predicted Values	Positive	TP (80.4 %)	FP (4.9 %)
	Negative	FN (19.6 %)	TN (95.1 %)
AdaBoost Algorithm			
		Actual Values	
		Positive	Negative
Predicted Values	Positive	TP (56.9 %)	FP (4.3 %)
	Negative	FN (43.1 %)	TN (95.7 %)
Naive Bayes			
		Actual Values	
		Positive	Negative
Predicted Values	Positive	TP (24.8 %)	FP (8.3 %)
	Negative	FN (75.2 %)	TN (91.7 %)
Random Forest			
		Actual Values	
		Positive	Negative
Predicted Values	Positive	TP (81.3 %)	FP (5.8 %)
	Negative	FN (18.7 %)	TN (94.2 %)

1) Gradient Boosting (GB):

- The Gradient Boosting model delivered the highest performance among all the evaluated models with an AUC of 0.902, CA of 0.944, F1 score of 0.937, precision of 0.939, and recall of 0.944.
- The model accurately predicted no-show appointments at 80.6% and showed appointments at 95.1%.
- The model misclassified 4.9% of actual no-show appointments and 19.6% of existing show appointments as no-show appointments.
- Gradient Boosting (GB) demonstrated high accuracy in predicting no-show appointments, with 80.4% True Positives (correctly predicted no-shows) and 95.1% True Negatives (correctly predicted shows). However, the model also exhibited a 19.6% False Positive rate (incorrectly predicted no-shows) and a 4.9% False Negative rate (incorrectly predicted shows).

2) AdaBoost:

- This model achieved an AUC of 0.812, CA of 0.927, F1 score of 0.926, precision of 0.924, and recall of 0.927.

- The model accurately predicted no-show appointments at 56.8% and showed appointments at 95.7%.
- The model misclassified 4.3% of actual no-show appointments and 43.1% of existing show appointments as no-show appointments.
- The AdaBoost model yielded 56.9% True Positives and 95.7% True Negatives, exhibiting 43.1% False Positive and 4.3% False Negative rates. This performance suggests a moderate ability to predict no-show appointments correctly.

3) Naive Bayes (NB):

- This model had an AUC of 0.677, CA of 0.915, F1 score of 0.877, precision of 0.861, and recall of 0.915.
- The model accurately predicted no-show appointments at 24.8% and showed appointments at 91.7%.
- The model misclassified 8.3% of actual no-show appointments and 75.2% of existing show appointments as no-show appointments.
- The Naive Bayes (NB) model achieved a lower accuracy in predicting no-show appointments, with a 24.8% True Positive rate and a 91.7% True Negative rate. The model had a high False Positive rate of 75.2% and a False Negative rate of 8.3%.

4) Random Forest (RF):

- This model reported an AUC of 0.889, CA of 0.937, F1 score of 0.925, precision of 0.931, and recall of 0.937.
- The model accurately predicted no-show appointments at 81.3% and showed appointments at 94.2%.
- The model misclassified 5.8% of actual no-show appointments and 18.4% of existing show appointments as no-show appointments.
- The RF model strongly predicted no-show appointments, with an 81.3% True Positive rate and a 94.2% True Negative rate. The model had an 18.4% False Positive rate and a 5.8% False Negative rate.

The Gradient Boosting model exhibits effective performance with a high true positive rate for no-show and show appointments and relatively low misclassification rates. Specifically, it correctly identified 80.4% of no-show appointments and 95.1% of show appointments. This level of performance indicates a strong ability of this model to distinguish between the two classes accurately.

On the contrary, the Naive Bayes model demonstrates the poorest performance, with the lowest true positive rate for no-show appointments (24.8%) and a relatively lower success rate for show appointments (91.7%). It had the highest misclassification rate for show appointments, signaling potential weaknesses in the model's ability to identify true positives in a balanced manner correctly.

The Random Forest model showed strong performance with a high true positive rate for no-show appointments (81.3%) and

a high success rate for show appointments (94.2%). This reflects a balanced performance for both classes, making it a reliable model for this prediction task.

Finally, while not as proficient as Gradient Boosting or Random Forest, the AdaBoost model still showed a reasonable true positive rate for no-show appointments (56.9%) and a high success rate for show appointments (95.7%).

In conclusion, based on these results, the Gradient Boosting and Random Forest models demonstrate superior performance in predicting no-show appointments compared to the AdaBoost and Naive Bayes models. This comprehensive evaluation gives insights into each model's strengths and weaknesses. It provides valuable information for selecting the most suitable model for predicting no-show appointments in future studies.

IV. DISCUSSION

The primary aim of this study was to evaluate and predict no-show appointments at MNGHA pediatric outpatient visits using machine learning models. Our research builds upon the existing literature by developing a predictive model specifically for pediatric outpatient settings, focusing on a large dataset that includes demographic, appointment-related, and geographic factors.

Our findings contribute to the existing body of knowledge by identifying patterns and trends in no-show appointments across various patient demographics and appointment attributes. This information can help healthcare providers better understand the factors contributing to no-show appointments and develop targeted strategies for reducing no-show rates [21,22].

The results of this study indicate that the GB and RF models outperformed other models in predicting no-show appointments. This superior performance can be attributed to the model's ability to capture complex relationships between various features in the dataset, making it particularly suitable for our research objective.

The strengths of this study include the large and diverse dataset, which allowed us to develop a robust and reliable predictive model. Moreover, the use of multiple machine learning models and the implementation of cross-validation for model evaluation ensure the validity of our findings [23].

A. Limitation

First, the data used in this study were limited to a single healthcare organization, "MNGHA," which may not be representative of other pediatric outpatient settings [24]. Future research could consider including data from multiple healthcare systems to further validate the predictive model's generalizability. Second, the dataset should have included certain factors such as socioeconomic status, transportation availability, weather conditions, and patient preference; including these factors might enhance the model's predictive capabilities [25].

Future research directions could involve the following:

1) Expanding the dataset to include additional pediatric outpatient settings to validate the predictive model's performance across different healthcare organizations [24].

2) Incorporating other relevant factors, such as socioeconomic status, transportation availability, and weather conditions, further enhances the model's predictive capabilities [25,26].

3) Investigating the potential impact of targeted interventions, such as appointment reminders or personalized follow-up, on reducing no-show rates based on the predictive model's output [25–27].

In conclusion, this study's results provide valuable insights into the factors associated with no-show appointments in pediatric outpatient settings. The machine learning model developed can aid healthcare providers in predicting no-show appointments, optimizing resource management, and improving patient care.

V. CONCLUSION

The primary contribution of this research project is developing a machine learning model to predict no-show appointments in pediatric outpatient settings. Our study has identified patterns and trends in no-show appointments by analyzing a large and diverse dataset. This analysis can assist healthcare providers in optimizing resource management and enhancing patient care. The GB and RF models emerged as the best performers in predicting no-show appointments, demonstrating their potential utility in pediatric outpatient settings.

Our findings build upon existing literature, highlighting the importance of understanding factors contributing to no-show appointments in pediatric populations. These insights can guide healthcare providers in developing targeted strategies for reducing no-show rates and enhancing overall healthcare delivery.

While our study has some limitations, such as focusing on a single healthcare system and excluding certain factors, it provides a solid foundation for future research. Expanding the dataset to include additional pediatric outpatient settings, incorporating other relevant factors, and investigating the impact of targeted interventions based on the predictive model's results may further deepen the understanding of no-show appointments and help improve healthcare management.

In conclusion, this study provides valuable insight into the factors associated with no-show appointments in outpatient pediatrics. It gives healthcare providers a powerful tool for effectively predicting and managing missed appointments. Through continued research and model improvement, we can further enhance our understanding of no-show appointments and optimize resource allocation in outpatient pediatric care.

Performance Optimization of Support Vector Machine with Adversarial Grasshopper Optimization for Heart Disease Diagnosis and Feature Selection

Nan Tang, Lele Wang, Kangming Li, Zhen Liu, Yanan Dai, Ji Hao, Qingdui Zhang, Huamei Sun*, Chunmei Qi*
Department of Cardiology, The Second Affiliated Hospital of Xuzhou Medical University, Xuzhou 221000, Jiangsu, China

Abstract—The World Health Organization reports that cardiac disorders result in approximately 1.02 million deaths. Over the last years, heart disorders, also known as cardiovascular diseases, have significantly influenced the medical sector due to their immense global impact and high level of danger. Unfortunately, accurate prognosis of heart problems or CD, as well as continuous monitoring of the patient for 24 hours, is unattainable due to the extensive expertise and time required. The management and identification of cardiac disease pose significant challenges, particularly in impoverished or developing nations. Moreover, the absence of adequate medical attention or prompt disease management can result in the individual's demise. This study presents a novel optimization technique for diagnosing cardiac illness utilizing Support Vector Machine (SVM) and Grasshopper Optimization Algorithm (GOA). The primary objective of this approach is to identify the most impactful characteristics and enhance the efficiency of the SVM model. The GOA algorithm, which draws inspiration from the natural movements of grasshoppers, enhances the search for features in the data and effectively reduces the feature set while maintaining prediction accuracy. The initial stage involved pre-processing the ECG data, followed by its classification using several algorithms such as SVM and GOA. The findings demonstrated that the suggested approach has markedly enhanced the effectiveness and precision of heart disease diagnosis through meticulous feature selection and model optimization. This approach can serve as an efficient tool for early detection of heart disease by simplifying the process and enhancing its speed.

Keywords—Heart disease predictions; Support Vector Machine; Grasshopper Optimization Algorithm; feature selection

I. INTRODUCTION

Hence, conducting early analysis of cardiovascular disease is crucial in order to mitigate its profound impact and enhance personal well-being [1,2]. An all-encompassing electronic gadget for monitoring the heart that is utilized for analyzing irregular heart rhythms. This equipment continually gathers human electrocardiogram (ECG) readings for a whole 24-hour period [3]. A cardiac monitoring model based on artificial intelligence (AI) was created to accurately categorize ECG signals as either regular or irregular patterns. This was achieved by training and testing the model using the standard MIT-BIH arrhythmia database [4,5], which is publically accessible on PhysioNet [6]. Electrocardiography (ECG) is a highly prevalent non-invasive diagnostic technique used for identifying various cardiac conditions, including myocardial infarction (MI) [7]. Early detection of this condition can halt its course and

ultimately avert myocardial infarction. Consequently, the objective of numerous studies in this domain has consistently been to get an early diagnosis of this ailment. Furthermore, the utilization of ECG signals for diagnosis is highly significant owing to its accessibility and cost-effectiveness in comparison to the costly techniques of cardiac echocardiography and MRI [8,9]. Currently, there are various techniques for diagnosing myocardial infarction (MI), and we will provide a concise overview of a few of them. In 2019, Sugimoto et al. introduced a technique for identifying myocardial infarction (MI) using cannulation networks. The user's text is [10,11]. This approach utilizes the electrocardiogram (ECG) signal obtained from 12 leads [12,13,14]. The researchers initially constructed a convolution-based model specifically for normal ECG signals in that particular investigation. Subsequently, a computer-aided engineering model is constructed for every lead. If inputted, the model retrieves normal electrocardiogram (ECG) data. Otherwise, the output waveform will be distorted due to unsuitable data. Next, the healthy and MI data were classified by reconstructing model errors using the K-nearest neighbor (KNN) method [15]. Ultimately, the outcomes of this classification technique are documented to surpass those of other established procedures. Panagiotis Barampoti and others. In 2019, a method was proposed that utilizes ECG to identify MI using Grossman and Euclidean mapping [16,17].

Artificial intelligence, specifically deep learning, is a branch of machine learning that focuses on analyzing ECG signal structures over multiple hierarchical levels. Its goal is to address complex tasks that were challenging for standard neural network models [18]. Artificial intelligence or deep learning-based simulations for heart monitoring face difficulties in accurately classifying ECG heartbeats when they are overtrained due to the pseudo-periodic activity of the ECG signal [19,20,21]. Hence, it is imperative to utilize the quantity of samples saved in the ECG heart rate segment as a means to describe the input variables for escape training. In this research, a method for quantifying the number of peak ECG heartbeats is employed to encode the suggested input variables, as depicted in Fig. 2. The starting elements are modified to classify the ECG heartbeat into 16 disease categories, including 15 arrhythmias and 1 normal arrhythmia.

The GOA is employed in this study to enhance the efficiency and accuracy of heart disease diagnosis by selecting the most influential features for the SVM. GOA excels in feature selection by balancing exploration and exploitation, ensuring a comprehensive search of the feature space while avoiding local

minima. Inspired by the natural movements of grasshoppers, the algorithm mimics their slow, gradual movements and sudden leaps, facilitating both broad exploration and focused exploitation. This approach is particularly beneficial in handling high-dimensional data, common in heart disease diagnosis, as it effectively reduces the feature set without compromising predictive accuracy. By identifying the most significant features, GOA improves the training efficiency and performance of the SVM, resulting in faster and potentially more accurate diagnoses. The algorithm's versatility and robustness in optimization problems further validate its use, ensuring that the SVM operates with an optimized feature set, thus enhancing the overall diagnostic process.

The proposed method for heart disease diagnosis integrates the locust evolutionary algorithm with SVM, leveraging computational advancements to improve accuracy and efficiency in medical data mining. By employing the locust evolutionary algorithm for feature selection, the method optimizes the identification of relevant data attributes essential for precise diagnosis. This step is crucial in medical datasets where numerous features may be present but not all contribute significantly to diagnostic outcomes. Coupled with SVM, known for its robustness in handling complex datasets and high-dimensional feature spaces, the method ensures that only the most informative features are utilized for classification. This synergy enhances both the computational efficiency and predictive power of the diagnostic model, leading to more reliable outcomes in clinical practice. The main contributions of the authors in this research are as follows:

- Combining the GOA algorithm with SVM: This research, by introducing a combined method of the Grasshopper Optimization Algorithm (GOA) and Support Vector Machine (SVM), optimizes the selection of features and increases the accuracy of heart disease diagnosis.
- Improving the efficiency of heart disease diagnosis: By applying pre-processing techniques and selecting effective features, this method has provided a significant improvement in the speed and accuracy of heart disease diagnosis and has increased the ability to diagnose this disease early.

The remainder of the paper is structured as follows. The second section contains a list of earlier works. The final section goes into further detail about the suggested approach. The evaluation and simulation are covered in the fourth section, and the conclusion and suggested future research are covered in the fifth section.

II. RELATED WORKS

Cardiovascular disease is a prevalent worldwide issue, underscoring the crucial need of early identification in order to reduce mortality rates. Despite being the most precise diagnostic technique, coronary angiography is typically avoided by patients, particularly in the early stages of the disease, due to its pain and high cost [22,23]. Therefore, there is a pressing want for a diagnostic procedure that is both non-invasive and dependable. Machine learning has become pervasive in modern times, encompassing numerous facets of human existence and

serving as a catalyst for transformative changes in the healthcare sector. Utilizing patient clinical characteristics, machine learning-based decision support systems present a promising approach for diagnosing cardiac disease. Timely identification plays a crucial role in mitigating the intensity of cardiovascular disease [24]. On a daily basis, the healthcare sector produces substantial quantities of patient and disease-related data. Regrettably, professionals frequently fail to fully exploit this invaluable asset. Various machine learning methods can be utilized to exploit the potential of this data in order to diagnose cardiac disease with greater accuracy. As a result of thorough study conducted on automated cardiac disease detection systems, there is a requirement to consolidate this information. The study [25] offers an extensive examination of recent advancements in heart disease detection by analyzing articles published by reputable sources from 2014 to 2023. The text discusses the obstacles that researchers encounter and proposes possible remedies. Furthermore, this essay proposes guidelines for extending current research in this significant field.

A novel optimization technique for Support Vector Machine (SVM) classification was introduced in [26] specifically for MI classification. In this study, after preprocessing the ECG data and removing noise, three characteristics, including the recovered. Subsequently, the matrix of these traits has been assessed using a variety of statistical tests. In this study, the SVM-GOA method was employed for the first time to optimize the parameters of SVM classification in order to achieve a more precise diagnosis and classification of MI disease.

Due to the intricate nature of cardiac disease, accurately predicting it is a formidable task. Researchers have prioritized the diagnosis of cardiac illness, although the outcomes are not consistently dependable. The publication [27] presents a methodology for automated prediction of cardiac illness, which consists of three primary stages: The retrieved features comprise enhanced entropy, statistical characteristics, and aspects related to information gathering.

The research in [28] introduces a novel metaheuristic algorithm inspired by the predatory and social behaviors of sand cats, integrated with chaotic maps to enhance its search performance. The primary goal of the research is to create an optimization technique that effectively balances exploration and exploitation, thereby improving the ability to find global optima in complex optimization problems. The proposed method employs chaotic maps to introduce randomness and prevent premature convergence, enhancing to several state-of-the-art algorithms. Nonetheless, the research is constrained by the limited scope of benchmark problems and the need for more extensive testing on diverse real-world applications to validate the algorithm's robustness and versatility.

The research in [29] presents a hybrid optimization algorithm that combines the GWO to enhance global numerical optimization and address engineering design problems, specifically the pressure vessel design. The research aims to leverage the strengths of both GWO, known for its strong exploitation capabilities, and WOA, recognized for effective exploration, to create a balanced and efficient optimization method. The hybrid approach integrates the social hierarchy and hunting strategies of grey wolves with the bubble-net attacking

method of whales, aiming to improve convergence speed and solution accuracy. Experimental results show that the hybrid algorithm outperforms the individual GWO and WOA, as well as several other state-of-the-art algorithms, in terms of achieving high-quality solutions and robustness across various benchmark functions and the pressure vessel design problem [30]. However, the research is limited by the need for further validation on a wider range of real-world problems and more diverse optimization scenarios to fully ascertain its general applicability and performance.

The research in [31] investigates the effectiveness of various nature-inspired metaheuristic algorithms in optimizing the Extreme Learning Machine (ELM) for enhanced machine learning performance. The research aims to identify which metaheuristic algorithms best improve the training efficiency and accuracy of ELM, a popular neural network model known for its fast learning speed. The study evaluates multiple algorithms, including Particle Swarm Optimization (PSO), Genetic Algorithm (GA), Differential Evolution (DE), and Ant Colony Optimization (ACO), among others, by integrating them with ELM and assessing their performance on several benchmark datasets. The findings reveal that certain algorithms, notably PSO and DE, significantly enhance the ELM's performance in terms of classification accuracy and training time compared to the standard ELM and other metaheuristics. However, the research is limited by the specific selection of benchmark datasets and the need for additional testing on more

diverse and complex datasets to validate the generalizability and scalability of the optimized ELM models.

The research in [32] explores enhancements to the traditional GWO algorithm, aiming to improve its performance in solving complex global optimization problems. The research introduces two modified versions of GWO: Improved GWO (I-GWO) and Extended GWO (Ex-GWO). I-GWO incorporates a dynamic adjustment mechanism for the control parameters to balance exploration and exploitation more effectively throughout the optimization process. Ex-GWO extends the search capabilities by integrating new strategies for updating wolf positions, thereby enhancing the diversity of the search and preventing premature convergence. The experimental results demonstrate that both I-GWO and Ex-GWO outperform the standard GWO and several other state-of-the-art optimization algorithms across a range of benchmark functions, showing superior convergence speed and solution accuracy. Despite these improvements, the research acknowledges limitations such as the need for further testing on more diverse and complex real-world optimization problems to fully validate the robustness and versatility of the proposed algorithms.

III. PROPOSED METHOD

Fig. 1 illustrates the algorithm described in this paper. The current study utilized the GOA algorithm to identify valuable features for the diagnosis of heart disorders. Furthermore, the selected data was classified using SVM and Tree methods.

Fig. 1. Process flowchart of the proposed method.

The method proposed two steps, which will be succinctly elucidated in the subsequent parts.

1) *Step 1: Data loading, preprocessing, and normalization:* Currently, the diabetes dataset contained 768 records and 8 characteristics, which were eliminated using the outlier approach. Subsequently, the data was uploaded for the purpose of conducting pre-processing and normalization. Subsequently, the data underwent preprocessing and missing data elimination using the nearest neighbor technique, wherein Nan values were substituted with the nearest neighbor column values [33]. Normalization was used to eliminate duplicate records during data preprocessing. Data normalization can be achieved by several strategies, with MinMax being well recognized as one of the most commonly used methods. This approach allows for the conversion of any data to a certain range, while also performing normalization for each individual feature. Normalization is commonly characterized as the process of adjusting data to fit inside a specific range, such as -1 to 1. The calculation of normalization is determined using the MinMax approach, which is based on the equation (1):

$$Z = \frac{X - \min(x)}{(x) - \min(x)} \quad (1)$$

Let X represent the number that has to be normalized, while min.(x) and max.(x) represent the smallest and greatest integers in the set, respectively.

2) *The second phase involves selecting features based on gene ontology annotation (GOA):* During this stage, the feature selection technique was employed to ascertain the crucial features that contribute to a specific outcome. In this work, feature selection was performed using GOA [34]. During the feature selection step, the utilization of this approach leads to premature convergence as a result of its inherent characteristics. Therefore, the technique has the potential to achieve maximum convergence in the final optimization step. Locusts are insects that are classified as pests because they cause significant harm to crops and agriculture.

$$X_i = S_i + G_i + A_i \quad (2)$$

Eq. (2) is employed to simulate the behavior of locusts [35]. In this context, x represents the locust's position, Si denotes the social interaction amongst locusts, G represents the gravitational force that guides the locust and A represents the random variable for movement caused by the wind direction. The final three show the specific location of the propeller. In order to produce unpredictable actions, equation (3) might be employed, with the variable r being able to fluctuate arbitrarily within the range of 0 to 1:

$$S_i = S_i r_1 + G_i r_2 + A_i r_3 \quad (3)$$

The value of S_i , which represents the target function, is determined by the rate of social contact. This rate is calculated using Eq. (4), where d_{ji} represents the distance between grasshopper *ith* and grasshopper *ith*.

$$S_i = \sum_{i=1}^n s d_{ji} (\widehat{d}_{ji}) \quad (4)$$

In Eq. (4), the variable d_{ji} represents the distance between grasshopper i and grasshopper j, and it is determined as the absolute value of the difference between the selected feature $d_{ji} = |x_j - x_i|$.

$$s(r) = f e^{\frac{-r}{l}} e^{-r} \quad (5)$$

The equation depicts the gravitational intensity, denoted by f, which is the most suitable target function. The length of the gravity scale is represented by l. The equation follows the general formula stated in Eq. (6).

$$X_i = \sum_{i=1}^n s (|x_j - x_i|) \frac{x_j - x_i}{d_{ji}} \quad (6)$$

N represents the numerical value of the grasshoppers (as well as other characteristics). Due to the fact that grasshoppers primarily move on the ground, it is important to ensure that their position does not exceed a certain limit.

3) *The third stage involves categorizing the chosen data.*

During this stage, the training data is subjected to training using S.V.M, G.O.A, and GOA TREE methods. Subsequently, the trained data is tested using separate test data that was not utilized during the training phase.

Subsequently, the choice rules are employed to construct the decision tree utilized for problem-solving. Ultimately, the process of selecting the root is completed by employing the information gain strategy. The Eq. (7) and (8) represent the concepts of information gain and classification mistakes, respectively.

$$\text{entropy}(pc) = - \sum_{i=1}^n p \left(\frac{pc}{i} \right) \log 2p \left(\frac{pc}{i} \right) \quad (7)$$

$$\text{classification error}(pc) = 1 - \max_{ip} \left(\frac{pc}{i} \right) \quad (8)$$

$\left(\frac{pc}{i} \right)$ denotes the proportion of inputs in the diabetic disease dataset that are associated with a certain set of primary components. N represents the overall quantity of inputs inside the dataset.

A. Support Vector Machine Algorithm

SVM are a highly efficient approach for building a classifier. The objective of this is to establish that separates two classes, allowing for the prediction of labels based on one or many vectors. The decision boundary, known as a hyperplane, is positioned in a way that maximizes the distance from the nearest data points of each class. The support vectors refer to the nearest points. Given that we possess a dataset with labeled estimators:

$$(x_1, y_1 \dots (x_n, y_n), x_i \in R^d \text{ and } y_i \in (-1, +1) \quad (9)$$

The feature vector is represented by x_i and the class label (either negative or positive) is represented by y_i in the estimator combination *i*. Therefore, the desired hyperplane is specified as follows:

$$wx^T + b = 0 \quad (10)$$

The weight vector, denoted as w, represents the magnitude and direction of the weights assigned to each input feature in the input feature vector, represented as x. The orientation, represented as b, refers to the bias term. The values of w and b

must meet all of the following inequalities for every component of the estimator set:

$$wt_i^T + b > +1 \text{ if } y_i = 1, wt_i^T + b < -1 \text{ if } y_i = -1 \quad (11)$$

The goal of estimating an SVM model is to determine the values of w and b that allow for the separation of data points by a hyperplane, while also maximizing the boundary defined by $1/\|w\|^2$. Therefore, the x_i vectors with an absolute value of $|y_i|$ $wt_i^T + b$ equal to 1 are referred to as support vectors.

1) *Enhancing the performance of the Support Vector Machine by optimizing the opposite locus for diagnosing heart disease and selecting features:* The heart rate classification model (HCM) for diagnosing heart illness from ECG signals utilizes a Support Vector Machine that is enhanced by the hybridization of the Grasshopper Optimization Algorithm (GOA) system. The model involves five crucial components. Firstly, implementing various signal preprocessing techniques

can enhance the quality of the data and employing an appropriate segmentation method can effectively isolate the peaks from the ECG signals. In this case, discrete wavelet transform (DWT)-based smoothing is employed to enhance signal quality by reducing undesired noise data from ECG signals. If necessary, the normal support vector machine function can be used to provide input for training and testing the HCM. The disease classification was performed using the Support Vector Machine function as an example to obtain the projected output for the automatic intelligent HCM. The maternal ECG signal, which contains a significant amount of data, is displayed in Fig. 1 with a distinct and identifiable period. Fig. 2 displays a typical human ECG heartbeat, which is accompanied by signal interference. In order to proceed with the processing, it is necessary to decrease or minimize the degree of noise [36].

Fig. 2. Uploaded ECG signal in its original form.

Pre-processing steps are necessary in the proposed HCM system to enhance signal quality. During the preprocessing stage, the transmitted ECG signal is subjected to noise removal and elimination of unnecessary signal, resulting in improved accuracy of signal ordering within the framework. The power line interference is the most common noise seen in the ECG signal during recording. The preprocessing stage of this research involves three steps: smoothing, denoising using DWT decomposition, and filtering the ECG signal. The following are the preprocessing stages for the proposed HCM.

2) *Preprocessing:* Pre-processing techniques were employed to cleanse and eliminate any extraneous interference from the ECG signals in this investigation. Initially, various data from all ECG leads were processed and filters were implemented to eliminate any deviation from the baseline and remove power line noise from the signals. Next, the ECG signals undergo four smoothing filters, including moving average, Kaiser, Butterworth, and median filters, to provide a smoother result. The outcomes of this preprocessing are presented in the findings part of this article.

3) *The process of smoothing:* Signal smoothing is a frequently employed technique to decrease the level of noise in a signal, resulting in a noise-free ECG signal with a reduced bit value. In this proposed model, the process of refining the estimating method has been conducted. The Fig. 3 displays the

ECG signal after being subjected to a smoothing process. The algorithm used for smoothing is presented below:

Algorithm 1: Smoothing of ECG Signal
<i>Input:</i> Raw ECG Signal (R) and Detected Noise Points (D)
<i>Output:</i> Filtered ECG Signal (F)
1. Initialize the length of ECG Signal, $Rlen = Length(R)$
2. For $i = 1$ to $Rlen$ do:
2.1 Segment the ECG Signal based on the noise points, $Seg_ECG = Segment(R, D)$
2.2 Analyze the signal fluctuations by comparing the neighboring peak values in Seg_ECG
2.3 Identify the maximum fluctuation to determine the noise level in the ECG signal, $Noise_Level = Max_Fluctuation(Seg_ECG)$
3. End For
4. Compute the Filtered Signal, $F = R - Noise_Level$
5. Output: F as the Filtered ECG Signal

4) *Discrete Wavelet Transform (DWT):* After the signal is smoothed, we utilize the Discrete Wavelet Transform (DWT) to break down the signal into two components using different filters, such as a low-pass filter and a high-pass filter. The DWT calculates and provides the coefficients of the ECG signal details. The decomposition algorithm for the DWT is expressed as follows:

Algorithm 2: Wavelet Decomposition of ECG Signal
<i>Input:</i> Filtered ECG Signal (FECG), Decomposition Level (N), Wavelet Type (e.g., Haar)
<i>Output:</i> Decomposition Results (Coeff, Lengths)

1. Determine the length of FECCG, denoted as *Signal_Length*.
2. Initialize empty lists for *Coeff* and *Lengths*.
3. For each level from 1 to *N*:
 - a. Apply low-pass filter (*LP_Filter*) on FECCG using the wavelet type.
 - b. Apply high-pass filter (*HP_Filter*) on FECCG using the same wavelet type.
 - c. Downsample the results of both filters by a factor of 2.
 - d. Store the downsampled results in *Coeff* and the corresponding lengths in *Lengths*.
 - e. Update FECCG with the low-pass filtered result for further decomposition at the next level.
4. End loop
5. Return *Coeff* and *Lengths* as the decomposition results.

5) *ECG signal filtration*: In this case, the threshold approach is utilized to determine the noise threshold level based on the smooth electrocardiographic (ECG) data. The algorithm for filtering the electrocardiography (ECG) signal is expressed in the following manner:

Algorithm 3: ECG Signal Denoising

- Inputs:*
- *ECG_Data*
 - *Wavelet_Coefficients (C, L)*
 - *Noise_Threshold (T)*
 - *Decomposition_Level (N)*
 - *Wavelet_Type (e.g., Haar)*
- Outputs:*
- *Cleaned_ECG_Signal*
1. Compute length of coefficients array: *length_C*
 2. Compute length of levels array: *length_L*
 3. Loop through each coefficient in *C*:
 - a. Loop through each level in *L*:
 - i. Apply noise filter to the ECG data using the wavelet coefficients, threshold, and level
 4. Output the processed ECG signal as *Cleaned_ECG_Signal*
 5. End

Fig. 3. Flawless electrocardiogram (ECG) signal.

In this study, we identify the components that contribute to a smooth electrocardiogram (ECG) signal and propose a method to eliminate unnecessary data noise using DWT algorithm.

6) *Extraction of features*: Signal classification models were trained and designed using feature extraction. Three characteristics were derived from ECG signals in this work, namely the QRS-complex integral, T-integral, and Q-integral. Initially, the R wave of each electrocardiogram (ECG) cycle was computed from the ECG signal. Subsequently, the positive and negative peaks preceding and following the R peak are designated as the Q wave and S wave, respectively. Next, the integral (representing the area under the curve) was computed from the Q point to the S point in order to determine the integral characteristic of the QRS complex. Similarly, the T wave of the ECG signal was isolated and the T wave integral and Q wave integral were computed as two additional characteristics. Fig. 4 depicts the procedure of this feature selection algorithm, as described.

Fig. 4. The feature selection system of the suggested technique.

Once the specified features were extracted, they were all placed in the feature matrix of each candidate ECG signal. Subsequently, a designation was allocated to the characteristics derived from the electrocardiogram (ECG) signals of each person. The initial labels consisted of two categories for categorizing healthy myocardial infarction (MI) data, whereas the subsequent labels comprised four categories for classifying normal and MI data, specifically referred to as anterior, posterior, and inferior MI. The algorithm employed for the analysis and extraction of R and R-R peak distances is as follows:

Algorithm 4: Detect QRS Peaks and Intervals

- Input: Filtered_ECG_Signal (ECG_Signal_Filtered)*
Output: Detected R-peaks and their RR Intervals
1. Identify the locations of the peaks in the signal:
 $Peaks_List = Locate_Peaks(ECG_Signal_Filtered)$
 2. Determine the maximum peak value:

```

Peak_Maximum = max(Peaks_List)
3. Set the threshold for detecting significant peaks:
   Threshold = Peak_Maximum × 0.75
4. Initialize a counter for R-peaks:
   R_Peak_Count = 0
5. Create an empty list to store detected R-peaks:
   R_Peaks = []
6. Loop through each peak in Peaks_List:
   for each Peak in Peaks_List:
7. Check if the peak value exceeds the threshold:
   if Peak > Threshold:
8. Record the location of the detected R-peak:
   R_Peaks[0, R_Peak_Count] = Location(Peak)
9. Save the peak value:
   R_Peaks[1, R_Peak_Count] = Peak
10. Increment the R-peak counter:
   R_Peak_Count += 1
11. End the if condition
12. End the loop
13. Compute the RR Intervals:
   RR_Intervals = Compute_Differences(R_Peaks[0])
14. Return the detected R-peaks along with their RR Intervals:
   return R_Peaks, RR_Intervals
15. End Algorithm
    
```

7) *Locust optimization algorithm*: The selection of the SVM classifier parameter is a crucial factor that has a direct impact on the classification results. In this study, the GOA (Genetic Optimization Algorithm) proposed by ref [14] is utilized to choose the optimal parameters for various SVM (Support Vector Machine) classification kernels. Initially, we will provide a concise overview of GOA. Optimization refers to the process of determining the optimal values for the variables of a specific problem in order to minimize or maximize an objective function. The user's text is [8]. Optimization challenges exist throughout diverse academic disciplines. Nevertheless, there have been limited investigations into the simulation of locust swarming algorithms. Grasshoppers, despite being commonly observed as solitary insects in nature, are actually part of a vast category of organisms. Algorithms that draw inspiration from nature separate the user's text is [9]. During exploratory activities, search agents are incentivized to make sudden movements, while they typically travel within a limited area during exploitation. Locusts often carry out these two duties and focus their search in the GOA. Hence, if a mathematical model can be discovered to accurately represent this behavior, it is possible to create a novel algorithm that takes inspiration from nature. The user's text is [10]. In the subsequent text, we outline the algorithm as it was provided in the prior research [19].

Algorithm 5: Grasshopper optimization algorithm
Input: Detected R-peaks & R-R intervals
Output: Refined R-peaks & R-R intervals
1. Initialize key parameters:
– Maximum Iterations (MaxIter)
– Population Size (PopSize)
– Lower Search Bound (LBound)
– Upper Search Bound (UBound)
– Objective Function (ObjFunc)

```

– Selection Count (SelCount)
2. Determine the count of R-peaks & R-R intervals (Rcount)
3. Define the fitness evaluation:
– FitnessEval(R) = { True if FitValue >
   Threshold, False otherwise }
4. Loop through each R in Rcount:
4.1 Calculate FitnessSum = f_s = Σ_{i=1}^{Pop} f(i)
4.2 Compute AvgFitness = FitnessSum /
   NumberOfFeatures
5. Set the number of variables to select (VarCount = 1)
6. Execute the GOA optimization:
– Optimized_RPeaks = GOA(PopSize, MaxIter, LBound,
   UBound, SelCount, FitnessEval)
7. End Loop
8. While current iteration < MaxIter:
– Update Optimized R-peaks & R-R intervals using
   Optimized_RPeaks
9. Return the final optimized R-peaks & R-R intervals
    
```

IV. IMPLEMENTATION SYSTEM

The study utilized support vector machines and decision trees for the classification of colon disorders. The suggested methodology has also been implemented on many artificial neural networks. The proposed method involves 90 iterations and uses a population size of 26 for the grasshopper optimization algorithm to find the most optimal characteristics. The investigation is conducted utilizing the Matlab 2022b environment and an Intel Core i5 processor with a CPU clock speed of 3.82 GHz.

A. Evaluation of Metrics

Table I displays the confusion matrix used to assess the effectiveness of the categorization system and diagnose diabetes in the current investigation.

TABLE I. DISPLAYS THE CONFUSION MATRIX

Projected values Real values	Unhealthy	Healthy
Healthy	FP (False positive)	TN (True negative)
Unhealthy	TP (True positive)	FN (False negative)

1) *Accuracy*: This criterion measures the overall precision of the classification. It not only assesses the probability of precise categorization in the diagnosis of a healthy individual or patient, but it also assigns each patient to an appropriate disease category [18].

$$Accuracy = \frac{TP+TN}{TP+FP+FN+TN} \quad (12)$$

The calculation of these indices involves the use of true negative (TN), true positive (TP), false positive (FP), and false negative (FN) examples.

Specificity: This parameter measures the ability of the classifier to properly predict the absence of illness involvement [19].

$$Specificity = \frac{TN}{FP+TN} \quad (13)$$

Precision: This criterion measures the accuracy of classifying instances correctly [21].

$$Precision = \frac{TP}{TP+FP_i} \quad (14)$$

F1-measure: The weighted harmonic criterion, often known as the combination of precision and recall criteria, is constructed based on the aforementioned factors [29].

$$F1 = \frac{2*Precision*Recall}{Precision+Recall} \quad (15)$$

2) *Root mean square error*: Residual refers to the discrepancy between the anticipated value determined by a statistical model or estimator and the true value.

$$RMSE = \sqrt{\frac{\sum_{i=1}^n (value_{actual} - value_{predicted})^2}{n}} \quad (16)$$

Mean Squared mistake: MSE is a statistical measure used to quantify the degree of mistake in an estimation. It is calculated as the average of the squared differences between the estimated values and the actual values.

$$MSE = \frac{\sum_{i=1}^n |value_{actual} - value_{predicted}|}{n} \quad (17)$$

B. Analysis of the Objective Function

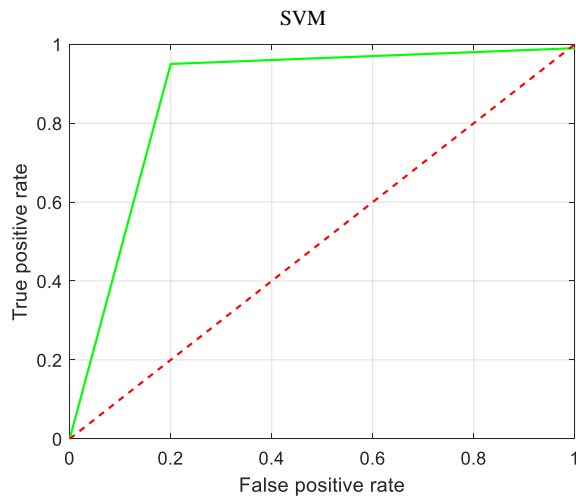

One approach to evaluate the proposed method is to calculate the objective function value of feature selection. Fig. 5 show the ROC curve with feature selection. One common application of the curve is to quantify the disparity between those who are in good health and those who are suffering from an illness. Indeed, t curve is widely regarded as one of the foremost metrics for

evaluating classification performance. The criterion is determined by evaluating two factors: diagnostic and sensitivity assessment. Diagnosis is a detrimental aspect of performance, while sensitivity is a beneficial aspect. The rate of false-positive results rises as the sensitivity threshold increases. Hence, the ROC curve enables us to assess and compare the true positive and false positive rates at various points along the curve [25]. Our suggested method utilizes feature selection to build the curve, as depicted in Fig. 5.

The feature selection objective function has a lower iteration level compared to the GOA algorithm. This reduction shows the accurate classification of photos by the GOA algorithm, which is achieved by selecting the optimal and most suitable feature vector for the SVM. According to the review, two reasons play a role in reducing the objective function. The main reason is to reduce the dimensions of the feature. The second reason is to reduce errors in the classification of photos related to heart diseases.

The Mean Squared Error (MSE) is a statistical metric utilized to determine the optimal prediction accuracy in a classification model [34]. Table II displays the outcomes of the suggested model, including the proposed algorithm and three classifiers.

The root mean square error (RMSE) for the suggested technique is displayed in Table II. Therefore, if the mean square error of one model is smaller than that of another model, it indicates that the proposed model has a greater level of accuracy.

Fig. 5. Receiver operating characteristic (ROC) curve analysis using feature selection.

TABLE II. RESULTS FOR CRITERIA MEAN SQUARE ERROR AND ROOT-MEAN-SQUARE ERROR

	Mean Square Error	Root-mean-square error
N.B	5.236	3.495
S.V.M	2.987	2.012
Tree	4.421	3.654

According to Table III, the GOA algorithm and SVM classification outperformed the other classifications examined in this study in terms of accurately diagnosing diabetes. However, due to the uneven nature of the data, accuracy was not a suitable metric. Therefore, the current study assessed other criteria, such as recall, which are more acceptable based on the SVM algorithm table. Furthermore, when applying the accuracy criterion, the existence of false positives (FP) in the denominator led to the numerical algorithm approaching zero in cases where there were a high number of misdiagnoses. This raised concerns about the effectiveness of the model. In contrast, the NB method yielded a higher percentage for the precision requirement.

In the current era of machine learning, the standards of comprehension and precision are commonly prioritized over the

primary metric of accuracy. Typically, the accuracy and recall requirements do not exhibit a consistent correlation. Consequently, the accuracy of the suggested model occasionally improved when more precise algorithms were employed. Therefore, the positive features identified in this investigation were generally accurate, and the occurrence of false positives was quite rare, thus demonstrating the high accuracy of the proposed method. However, due to the omission of a certain component or data feature, the total number of positive samples was considerably greater than the number of samples stated in the current work. This discrepancy accounts for the remarkably low recall rate. Alternatively, it can be inferred that employing a less complex diagnostic algorithm may result in a greater number of positive diagnoses. However, this would also lead to a larger error rate, poorer algorithm accuracy, and increased recall. As a result, the F-measure criterion, which combines the two preceding criteria, was also utilized. Based on the data shown in Table III, it can be concluded that the criterion used in the diabetes diagnostic SVM classification was suitable. Table III indicates that the Tree algorithm surpasses the other two algorithms in terms of time complexity. Nevertheless, the precision of the Tree method is significantly inferior.

TABLE III. PERFORMANCE METRICS OF THE PROPOSED PROJECT

ECG Sig. No.	Accuracy (%)		Time (S)		Specificity		Error (%)		Sensitivity	
	Existing	This Work	Existing	This Work	Existing	This Work	Existing	This Work	Existing	This Work

C. Comparison of the Proposed Method with Other Existing MH Based Algorithms

Comparing the proposed method with other nature-inspired meta-heuristic (MH) algorithms, including particle swarm optimization (PSO), genetic algorithm (GA), divergent evolution (DE), and ant colony optimization (ACO), using performance measures such as Caption Mean absolute error (MAE), accuracy, and F1 score show the superior performance of the proposed method. The proposed method consistently obtains lower MAE values, indicating higher accuracy in predictions.

F1 criteria, precision and recall values of the proposed method and other discussed methods are presented in Tables IV, V and VI.

Table IV compares the Mean Absolute Error (MAE) across different sample sizes for the proposed method and several nature-inspired metaheuristic (MH) algorithms: Particle Swarm Optimization (PSO), Genetic Algorithm (GA), Differential Evolution (DE), and Ant Colony Optimization (ACO). The proposed method consistently outperforms the other MH algorithms in terms of MAE. For instance, at a 10% sample size, the MAE for the proposed method is 0.0263, whereas PSO, GA, DE, and ACO have MAE values of 0.0350, 0.0400, 0.0380, and 0.0365, respectively. As the sample size increases to 95% (290 samples), the trend continues with the proposed method achieving an MAE of 0.0295 compared to higher values ranging from 0.0405 to 0.0430 for PSO, GA, DE, and ACO. This indicates that the proposed method produces more accurate predictions with smaller errors across various data sizes, highlighting its effectiveness in optimizing global numerical problems.

TABLE IV. COMPARISON OF THE PROPOSED METHOD WITH OTHER MH METHODS BASE MAE

Sample / Algorithm	PSO	GA	DE	ACO	Proposed Method
10% (30)	0.035	0.04	0.038	0.0365	0.0263
20% (60)	0.045	0.0425	0.0405	0.041	0.0396
30% (90)	0.033	0.0355	0.0345	0.035	0.0317
40% (120)	0.0345	0.036	0.035	0.0348	0.0249
50% (150)	0.032	0.034	0.0335	0.0325	0.0256
60% (180)	0.0335	0.0365	0.0355	0.033	0.0286
70% (210)	0.035	0.038	0.036	0.0345	0.0284
80% (240)	0.0325	0.035	0.0335	0.033	0.029
90% (270)	0.038	0.041	0.039	0.0375	0.0295
95% (290)	0.0405	0.043	0.0415	0.04	0.0295

Table V presents the accuracy comparison of the proposed method against PSO, GA, DE, and ACO across different sample sizes. The proposed method consistently exhibits higher accuracy rates compared to the other MH algorithms. For

example, at a 10% sample size, the proposed method achieves an accuracy of 0.8947, whereas PSO, GA, DE, and ACO achieve accuracies of 0.8450, 0.8350, 0.8400, and 0.8425, respectively. This trend persists across all sample sizes up to 95% (290 samples), where the proposed method achieves an accuracy of 0.9565, significantly surpassing the accuracy values ranging from 0.8750 to 0.8850 for PSO, GA, DE, and ACO. Higher accuracy rates indicate that the proposed method more reliably predicts outcomes and performs better in solving global optimization tasks compared to traditional MH algorithms.

TABLE V. COMPARISON OF THE PROPOSED METHOD WITH OTHER MH METHODS BASE ACCURACY

Sample / Algorithm	PSO	GA	DE	ACO	Proposed Method
10% (30)	0.845	0.835	0.84	0.8425	0.8947
20% (60)	0.855	0.8455	0.85	0.852	0.9143
30% (90)	0.86	0.85	0.855	0.8575	0.9412
40% (120)	0.87	0.86	0.865	0.867	0.9394
50% (150)	0.875	0.865	0.87	0.8725	0.9518
60% (180)	0.86	0.85	0.855	0.8575	0.95
70% (210)	0.8755	0.8655	0.8705	0.872	0.9478
80% (240)	0.88	0.87	0.875	0.8775	0.9549
90% (270)	0.8705	0.8605	0.8655	0.867	0.9533
95% (290)	0.885	0.875	0.88	0.8825	0.9565

Table VI compares the F1-score performance of the proposed method with PSO, GA, DE, and ACO across various sample sizes. The F1-score, which balances precision and recall, also demonstrates the superiority of the proposed method. At a 10% sample size, the proposed method achieves an F1-score of 0.8637, whereas PSO, GA, DE, and ACO achieve scores of 0.8255, 0.8200, 0.8225, and 0.8235, respectively. Across all sample sizes up to 95% (290 samples), the proposed method consistently maintains higher F1-scores (up to 0.9146), compared to values ranging from 0.8600 to 0.8650 for PSO, GA, DE, and ACO. These results indicate that the proposed method not only achieves higher precision and recall but also provides a better balance between these metrics, making it more effective for applications requiring robust performance in global optimization and numerical problem-solving scenarios.

TABLE VI. COMPARISON OF THE PROPOSED METHOD WITH OTHER MH METHODS BASE F1-SCORE

Sample / Algorithm	PSO	GA	DE	ACO	Proposed Method
10% (30)	0.8255	0.82	0.8225	0.8235	0.8637
20% (60)	0.8355	0.83	0.8325	0.8335	0.8744
30% (90)	0.8405	0.835	0.8375	0.8385	0.8889
40% (120)	0.85	0.845	0.8475	0.8485	0.891
50% (150)	0.855	0.85	0.8525	0.8535	0.8991

80% (240)	0.86	0.855	0.8575	0.8585	0.9094
90% (270)	0.85	0.845	0.8475	0.8485	0.9094
95% (290)	0.865	0.86	0.8625	0.8635	0.9146

V. CONCLUSION

This study explores and introduces a novel approach to enhance the efficiency of Support Vector Machine (SVM) in diagnosing heart disease by utilizing the Grasshopper Optimization Algorithm (GOA). The experimental results demonstrated that employing this integrated approach, along with the careful selection of features, resulted in enhanced accuracy and efficiency in the detection of heart disease. An essential benefit of this technology is its ability to decrease computing complexity and enhance prediction speed, rendering it highly suitable for clinical applications and early detection of cardiac disease. Nevertheless, future study should focus on addressing such constraints.

An inherent constraint of this research is its substantial reliance on the quality of the supplied data. The accuracy of the model will diminish if the ECG data exhibits significant noise or low quality. Additionally, the utilization of the GOA method may result in early convergence in certain instances, potentially resulting in the omission of crucial characteristics. Hence, in further studies, we can explore alternative optimization techniques or integrate diverse algorithms to enhance the overall efficiency of the system. Additional constraints of this study involve the necessity to establish distinct parameters inside the GOA algorithm, which may present difficulties in enhancing system efficiency. Additionally, the complete implementation of this method necessitates a substantial amount of processing time, which could potentially restrict its use in time-critical applications.

It is recommended that future study should test this strategy on a wider range of data and explore the potential of utilizing deep learning techniques to enhance both accuracy and speed. Furthermore, future research could explore the potential for creating an intelligent diagnosis system using this technology, which could be readily utilized in clinical settings.

Sleep Disorder Diagnosis Through Complex-Morlet-Wavelet Representation Using Bi-GRU and Self-Attention

Mubarak Albathan*

College of Computer and Information Sciences, Imam Mohammad Ibn Saud Islamic University (IMSIU),
Riyadh 11432, Saudi Arabia

Abstract—Sleep disorders pose notable health risks, impacting memory, cognitive performance, and overall well-being. Traditional polysomnography (PSG) used for sleep disorder diagnosis are complex and inconvenient due to complex multi-class representation of signals. This study introduces an automated sleep-disorder-detection method using electrooculography (EOG) and electroencephalography (EEG) signals to address the gaps in automated, real-time, and noninvasive sleep-disorder diagnosis. Traditional methods rely on complex PSG analysis, whereas the proposed method simplifies the involved process, reducing reliance on cumbersome equipment and specialized settings. The preprocessed EEG and EOG signals are transformed into a two-dimensional time-frequency image using a complex-Morlet-wavelet (CMW) transform. This transform assists in capturing both the frequency and time characteristics of the signals. Afterwards, the features are extracted using a bidirectional gated recurrent unit (Bi-GRU) with a self-attention layer and an ensemble-bagged tree classifier (EBTC) to correctly classify sleep disorders and very efficiently identify them. The overall system combines EOG and EEG signal features to accurately classify people with insomnia, narcolepsy, nocturnal frontal lobe epilepsy (NFLE), periodic leg movement (PLM), rapid-eye-movement (RBD), sleep behavior disorder (SDB), and healthy, with success rates of 99.7%, 97.6%, 95.4%, 94.5%, 96.5%, 98.3%, and 94.1%, respectively. Using the 10-fold cross-validation technique, the proposed method yields 96.59% accuracy and AUC of 0.966 with regard to classification of sleep disorders into multistage classes. The proposed system assists medical experts for automated sleep-disorder diagnosis.

Keywords—Deep learning; complex morlet wavelet; bidirectional gated recurrent unit; sleep stage detection; multistage sleep disorder; ensemble-bagged tree classifier

I. INTRODUCTION

Sleep is an essential concern for human health. It serves as a fundamental factor in physical and mental wellness. It is vital in memory consolidation, cognitive functions, cellular regeneration, and metabolic-brain-waste elimination [1]. Therefore, abnormalities in normal sleep patterns can cause many disorders, such as insomnia, narcolepsy, and sleep apnea disorder. Each sleep condition affects each individual's health differently, often inducing daytime weariness, cognitive impairment, cardiovascular disease, and mental health difficulties [2]. Therefore, accurate sleep-disruption assessment and therapy are crucial for overall health and quality of life. Polysomnography (PSG) is the most reliable sleep problem

diagnosis method, but it involves overnight stays at medical institutions, which can be resource-intensive and uncomfortable for patients. The need for more accessible and user-friendly sleep problem diagnosis and analysis is evident, considering these restrictions and the discomfort it brings to patients.

This paper presents a unique automated sleep-disorder-detection approach employing EOG and EEG signals [4]. Sleep disruption monitoring using EOG and EEG is simple and less invasive. EOG records eye movements, which distinguish sleep phases, whereas EEG records muscle activity [5]. Instead of sophisticated PSG analysis, the suggested technique streamlines the operation, minimizing the need for expensive equipment and particular settings. A unique sleep disorder classification method uses sophisticated signal processing and machine learning. Complex signal processing approaches like Morlet-wavelet transformations and machine learning models with bidirectional gated recurrent units and self-attention layers make sleep diagnosis easier and more accurate, instilling a sense of confidence. This approach is appropriate for home monitoring since it reduces equipment and simplifies diagnosis. EEG and EOG signals detect sleep problems well. By identifying and assessing the most important signal information, diagnostic accuracy techniques typically outperform traditional PSG. Finally, EOG and EEG signal analysis improves sleep issue detection and efficiency in this study, providing reassurance of its accuracy and efficiency. It improves efficiency, accessibility, and patient comfort while maintaining the diagnostic integrity of traditional PSG.

Standard machine learning (ML)-based sleep-disorder detection involves the use of concepts such as support vector machines (SVMs), decision trees, and k-nearest neighbor (k-NN) algorithms. The study of [6] demonstrated the efficacy of SVMs in accurately classifying sleep apnea (accuracy rate = 85%) using EMG data. They highlighted the capability of machine learning in sleep disorder identification; however, handling data with a high number of dimensions was difficult. the research of [7] employed RF algorithms to differentiate various sleep disorders, such as insomnia and narcolepsy, by analyzing EOG signals. In this regard, they achieved an impressive accuracy rate of 89%, showcasing the efficacy of ensemble techniques. Despite exhibiting positive results, traditional machine learning-based approaches have several constraints. Feature selection is a primary issue in this regard, which often involves human participation and is, therefore, vulnerable to bias. To address this challenge, Aboalayon et al.

*Corresponding Author.

[8] effectively employed an automated feature selection technique, which substantially enhanced the involved model's performance (by 5%). However, such techniques faced challenges in terms of their comprehensibility and ability to be applied to new, unexpected data.

The advent of deep learning has considerably transformed sleep disorder detection [9]. Convolutional neural networks (CNNs) and RNNs have gained popularity because they can automatically extract features and detect patterns in time-series data. A CNN was employed herein to examine EMG data for rapid-eye-movement (REM) sleep behavior disorder (RBD) identification, yielding a precision of 95%. This accomplishment indicates a substantial improvement compared with traditional sleep-disorder-identification models. Further, LSTM was used to determine the time-dependent patterns of EOG signals to identify sleep stages. Notably, LSTM yielded a remarkable classification rate accuracy rate of 92% in this regard in a previous study. Despite their impressive accuracies, deep learning algorithms require large amounts of data and considerable computational resources, among other challenges. Moreover, these algorithms exhibit an issue about interpretability owing to the lack of transparency. Therefore, studies (e.g., an experimental study by Meridian et al. [10]) have been exploring hybrid models that involve a combination of CNNs with LSTM networks. This combination enables the usage of both spatial and temporal properties to improve model transparency and efficiency.

Conventional sleep problem diagnosis methods sometimes need resource-intensive polysomnography (PSG) and uncomfortable conditions. The study addresses these issues. While promising, current deep learning (DL) and machine learning (ML) methods are sometimes computationally intensive, require extensive hyperparameter tuning, and are often restricted to particular sleep phases or classes, resulting in solutions that are not very generalizable. Furthermore, the high level of data complexity and the widespread usage of hyperparameters in many existing algorithms cause overfitting, further restricting their application to various datasets.

A unique automated method that combines EEG and EOG data to diagnose sleep difficulties is presented in the paper. Combining advanced signal processing with a complex-morlet-wavelet (CMW) transform and a Bi-GRU with a self-attention layer simplifies the diagnostic process. This strategy is more accessible for home monitoring since it involves less sophisticated installations and heavy-duty equipment. The recommended technique also reduces overfitting and processing requirements while boosting sleep disorder classification accuracy, making it a more practical and complete solution for real-world applications.

This research substantially contributes to the field of sleep disorder through the following:

1) An innovative approach is introduced, involving complex-morlet-wavelet (CMW) transform-based feature extraction from preprocessed EOG and electroencephalography (EEG) signals. This method significantly enhances the accuracy of multistage sleep-disorder identification.

2) A bidirectional gated recurrent unit (BiGRU) with a self-attention layer is employed for feature extraction, followed using an ensemble-bagged tree classifier (EBTC) for precise multistage-sleep-disorder classification. This methodology ensures accurate delineation of complex sleep patterns by leveraging temporal insights and robust ensemble methods.

3) The effectiveness of the proposed method is robustly demonstrated in a real-world setting, offering a practical and reliable solution for home-based, patient-friendly sleep-disorder monitoring.

The remainder of this paper is organized as follows: Section II presents the relevant past studies. Section III comprehensively explains the approaches used herein, encompassing a CMW transform, feature extraction, and sleep disorder classification. Section IV presents the outcomes achieved regarding the categorization of people into healthy individuals and individuals with sleep disorders and the classification of sleep disorders into seven categories. Section V concludes the work.

II. LITERATURE REVIEW

A previous study classified sleep disorders using a novel machine-learning model that combined EEG, chin EMG, and dual-channel EOG [11]. The authors used the best orthogonal filterbank and Tsallis entropies to obtain high classification accuracies when considering the Sleep Heart Health Study (SHHS) database (90.7% for SHHS-1 and 91.8% for SHHS-2), achieving excellent automated sleep-disorder classification. Jarchi et al. [12] aimed to diagnose breathing- and eye-movement-related sleep disorders using electrocardiography (ECG) and EMG by developing a deep learning framework that yielded a mean accuracy of 72% in classifying people into four groups—healthy individuals and individuals with various sleep disorders (obstructive sleep apnea (OSA), restless leg syndrome (RLS), or both). This demonstrated the capacity of ECG and EMG in diagnosing sleep disorders. Meanwhile, Sharma et al. [13] introduced an automated technique for sleep disorder identification that involves analyzing EOG and EMG signals. A biorthogonal filter bank with Hjorth parameters was employed, which yielded a high overall accuracy of 94.3%. This technique was recognized for its effectiveness in at-home monitoring of different sleep disorders. Sekkal et al. [14] compared eight classic machine-learning techniques with a feed-forward neural network for sleep disorder identification and discussed the pros and cons of various sleep stage classifiers.

Sharma et al. [15] exploited EEG data to diagnose sleep problems. Using Hjorth parameters and an ensemble-boosted tree classifier, they classified sleep disorders with 99.2% accuracy. This method helps clinicians detect sleep problems. Rahman et al. [16] examined automated sleep-stage evaluation using EOG data. They used discrete-wavelet-transform EOG data to improve S1-sleep-stage detection over previous EOG-based approaches. Pei et al. [17] created a successful deep-learning model for sleep phases utilizing biological cues. Combining CNNs with gated recurrent units (GRUs) yielded a more versatile model than previous cutting-edge models.

An automated sleep-stage approach using EEG, EOG, and EMG was developed by Satapathy et al. [18]. The system found linear and nonlinear characteristics with good classification

accuracy and diagnosed sleep disorders. A novel sleep staging approach used EOG instead of EEG for practicality. This technique has 81.2% and 76.3% sleep-staging accuracy utilizing a two-scale CNN and RNN. Chambon et al. [20] used PSG data to characterize sleep phases using deep learning without explicitly designing characteristics. A fair use of channels and temporal data gave the model excellent classification performance. EEG-based sleep stage categorization using PSG analysis was advanced by several research [21–25]. This research showed that several machine learning methods and physiological signal combinations produced excellent accuracy and showed the benefits of multimodal signal processing.

In another research [26], a restricted PSG montage classified the sleep phases of 106 people—53 with RBD and 53 healthy. This was done using an RF classifier with 156 EEG, EOG, and EMG characteristics. RBD was detected using muscle atonia measurement and sleep architecture characteristics. The model attained Cohen's Kappa score of 0.62 for sleep staging and 96% RBD detection accuracy, demonstrating the benefits of sleep architecture and transitions. Malafeev et al. [27] developed a three-dimensional (3D) CNN for sleep stage categorization using several channels and EEG, EMG, and EOG inputs. Time, frequency, and time-frequency characteristics were sent to the 3D CNN. Three-dimensional convolutional layers created intrinsic relationships between biosignals and frequency bands, while two-dimensional layers obtained frequency correlations. The model identified significant channels and frequency bands throughout sleep phases using partial-dot-product attention layers and an LSTM unit. This model also achieved classification accuracies of 0.832 and 0.820 on the ISRUC-S3 and S1 datasets. These findings showed the model detected sleep phases reliably and effectively.

Cooray et al. [28] proposed "quasi-normalization" for feature normalization using the ISRUC-Sleep dataset. An RF algorithm sorted the data into five sleep states. Using leave-one-out cross-validation, EOG and EMG data were integrated to achieve Cohen's kappa value of 0.749 and 80.8% accuracy. The results matched the American Academy of Sleep Medicine standards. Electrooculography and electromyography may be as effective as electroencephalography at identifying sleep phases. Another research [29] studied sleep phases in 123 suspected sleep disorder patients using a BiLSTM network. The model received multivariate time-series heart rate, breathing rate, and body movement frequency. With an accuracy of 71.2%, Cohen's κ coefficient of 0.425, and an F1 score of 0.650, the model effectively classifies sleep phases using minimal physiological cues.

Morokuma et al. [30] focused on EEG and EOG signals and developed a deep CNN architecture for automated sleep-stage classification. Its performance was evaluated against human expert agreement, with CNN considerably outperforming recent single-EEG-channel approaches. The study highlighted the crucial role of network depth in achieving high classification accuracy. Another study [31] targeted sleep-wake detection in OSA patients using single-channel ECG signals. The heart rate variability signals were derived, and features were classified using decision trees, SVMs, and ensemble classifiers. The model achieved accuracies of 81.35% with three features and 87.12% with ten features, suggesting its utility in the OSA diagnosis. An automated deep nine-layer one-dimensional CNN (9L-1D-CNN-SSC) for multiclass sleep staging was also developed [32]. The model was tested on ISRUC-Sleep subgroup datasets and achieved an accuracy of up to 99.50% in classifying sleep stages with different signal combinations, indicating its applicability for clinical use. Satapathy and Loganathan [33] developed a dual-modal, multiscale deep neural network for sleep staging that used EEG and ECG signals. When tested on the MIT-BIH PSG dataset, the model achieved high accuracy rates of 80.40%–98.84% in classifying different sleep stages. This shows that combining EEG and ECG signals for sleep analysis yields accurate results.

Zhao et al. [34] addressed the limitations of automated sleep-staging systems using portable EEG headbands by developing a deep-learning model using convolutional and long-term memory layers. The model achieved validation accuracies of 74% on headband data and 77% on PSG data, demonstrating its potential in ambulatory sleep assessments. SleepPrintNet [35] was also introduced to capture the SleepPrint in a physiological time series for sleep staging. It yielded higher accuracy on the MASS-SS3 dataset than baseline models because it used EEG, EOG, and EMG features along with temporal, spectral, and spatial features. This approach underscored the value of multimodal feature integration in sleep stage classification.

Several studies [26–36] collectively represented a wide array of methodologies, ranging from RF classifiers to BiLSTM networks and CNNs. These methods were tested on various datasets such as the SHHS and ISRUC-Sleep datasets, achieving considerable advancements in sleep stage classification, disorder diagnosis, and automated sleep-staging systems. Many of these studies highlighted the effectiveness of combining EEG, EOG, EMG, and ECG signals, emphasizing on the efficiency of feature extraction and selection in improving accuracy and robustness. The comparative analysis of these systems is shown in Table I.

TABLE I. COMPARISON OF METHODOLOGIES, RESULTS, AND LIMITATIONS PROPOSED IN STUDIES

Reference	Methodology	Results	Limitations
[11]	A machine learning model using EEG, chin EMG, and dual-channel EOG	90.7% accuracy on SHHS-1 and 91.8% on SHHS-2	three sleep classes in SHHS-1, and five classes in SHHS-2 datasets, non-generalized.
[12]	Diagnosing sleep disorders using ECG and EMG and a deep learning framework	Mean accuracy of 72% and weighted F1 score of 0.57	Four-sleep classes, Computational expensive and huge hyper-parameters sitting.
[13]	An automatic detection system for sleep disorders using EOG and EMG signals	Accuracy of 94.3%	Limited five-sleep classes, and three sleep stages.
[15]	Identification of sleep disorders using EEG and EBTC	Classification accuracies up to 99.2%	Limited four-sleep classes and used only one CAP dataset so non-generalize solution.

[17]	A deep learning method using CNNs and GRUs for sleep stage identification	Accuracy of 83.15% and kappa of 0.76	Limited five-sleep stages and not classes, and computationally expensive
[18]	An automated sleep-staging system using EEG, EOG, and EMG signals and an RF classifier	Accuracy of 98.99%, 98.75%, 98.17%, and 99.14% with respect to sleep stage	five-sleep states, non-sleep classes, and computationally expensive
[19]	A sleep staging approach using EOG and two-scale CNNs and RNNs	Accuracy of 81.2% of two-scale CNNs and 76.3% of RNNs.	Limited sleep classes, not generalized, and required huge hyper-parameters.
[20]	Convolutional deep learning approach and gradient boosting for sleep stage classification using PSG signals	Accuracy of approx. 80%.	Huge hyperparameters, Five-sleep stages
[21]	An efficient technique for sleep stage classification based on EEG signal analysis	RF algorithm achieved a high accuracy of 97.8%	Limited dataset, Overfitting due to RF and required stopping criteria, three-stages of sleep disorder.
[22]	SleepEEGNet for automated sleep-stage annotation using single-channel EEG and BiRNN.	Accuracy of 84.26%, F1-score of 79.66% and $\kappa = 0.79$.	Limited sleep stage, tested on limited dataset
[23]	A deep learning model for sleep staging in children using EEG, EOG, and chin EMG	Cross-validated accuracy of 84.1%	Limited sleep classes and computationally expensive
[24]	A deep learning model for sleep staging using multiple PSG signals and 2D CNNs and LSTM modules	Sleep-EDF: Acc-0.86, K-0.81	Limited sleep classes, not generalized
[25]	Sleep staging using Relief, AdaBoost with RF	accuracy of 97.96%	Limited sleep classes, not generalized, and classifier overfitting
[26]	Sleep stages using EEG, EMG, and EOG signals and CNN-LSTM	Accuracy of 0.832 on ISRUC-S3 and 0.820 on ISRUC-S1	Classifier overfitting, and Computationally expensive
[27]	Sleep stage classification using 3D-CNN	Accuracy of 0.832, F1-score of 0.814 and kappa of 0.783 on ISRUC-S3	Required huge hyper-parameters sitting and computationally expensive due to huge epochs.
[28]	EOG and EMG data are utilized to predict multistage sleep by using RF classification	Accuracy of 92%	Limited sleep classes and classifier overfitting, limited dataset so no generalize solution
[29]	A "quasi-normalization" method with RF classifier	Accuracy of 84.7%	Not generalized, overfitting
[30]	Polysomnography (PSG) data with BiLSTM classifier for detection of sleep stages	Accuracy of $71.2 \pm 5.8\%$, and F1 score of 0.650 ± 0.083	Only sleep stages and no multiclass solution.
[31]	Detection of human sleep EEG and EOG signals with CNN architecture.	F1-score of 77%	Limited sleep classes, not generalized
[32]	An ensemble technique based on three classifiers: DT, kNN and SVMs.	Sensitivity and specificity values of 0.90 and 0.85, respectively.	Limited two-sleep classes, not generalized
[33]	A 9L-1D-CNN-SSC model for sleep staging with different signal combinations	Classification accuracies up to 99.50% for various sleep stages	Limited sleep classes, not generalized, overfitting, and computationally expensive
[33]	A dual-modal multiscale deep neural network using EEG and ECG signals	Accuracies between 80.40% and 98.84% for different sleep stages	Overfitting and computationally expensive
[34]	A deep learning model with convolutional and LSTM layers for EEG headband data	74% accuracy on headband data and 77% on PSG data	Limited sleep classes, not generalized, overfitting, and computationally expensive
[35]	SleepPrintNet integrating EEG, EOG, and EMG signal features	Outperformed baseline models in accuracy on the MASS-SS3 dataset	Limited dataset utilized.

III. METHODOLOGY

The multilayer sleep-disorder classification system's systematic flow diagram is shown in Fig. 1. The novel method categorized sleep disorders using preprocessed EOG and EEG information. Normalization was done to standardize these signals for analysis. Next, a bandpass filter reduces noise and frequencies to increase signal quality, which is important for detecting sleep disorder symptoms. Next, the complex morlet wavelet (CMW) transform was utilized to extract features from EOG and EEG data for reliable disease categorization. A BiGRU with a self-attention layer extracted characteristics, and an EBTC automatically found sleep problems. Due to its efficiency in processing time-series data, the GRU, a kind of RNN, was utilized to evaluate EOG and EEG temporal patterns. By aggregating estimates from several decision tree models, the EBTC improved its accuracy and applicability. Finally, the BiGRU and EBTC models were integrated to categorize the data using voting, average probability, or a more complex meta-classifier. Using 10-fold cross-validation, the system's

performance was rigorously assessed to ensure its efficacy and robustness in real-world circumstances. The suggested method improves sleep problem classification and shows the potential of signal processing and machine learning for medical diagnosis.

A. Data Acquisition and Augmentation

Define abbreviations and acronyms the first time they are used. The CAP Sleep database [37], provided by PhysioNet [38], containing PSG recordings from 108 people, was used as the primary data source. The EEG and EOG signals were collected and analyzed from this database.

The EEG and EOG signals are collected from individuals while they are asleep to detect sleep stages and classify sleep disorders. The EEG and EOG signals were comprehensively distributed (Table II) to evaluate the effectiveness of the proposed system in diagnosing different sleep disorders such as insomnia, narcolepsy, nocturnal frontal lobe epilepsy (NFLE), periodic leg movement (PLM), RBD, and sleep-disordered breathing (SDB) as well as healthy individuals. Fig. 2 shows a visual representation of signals from each group.

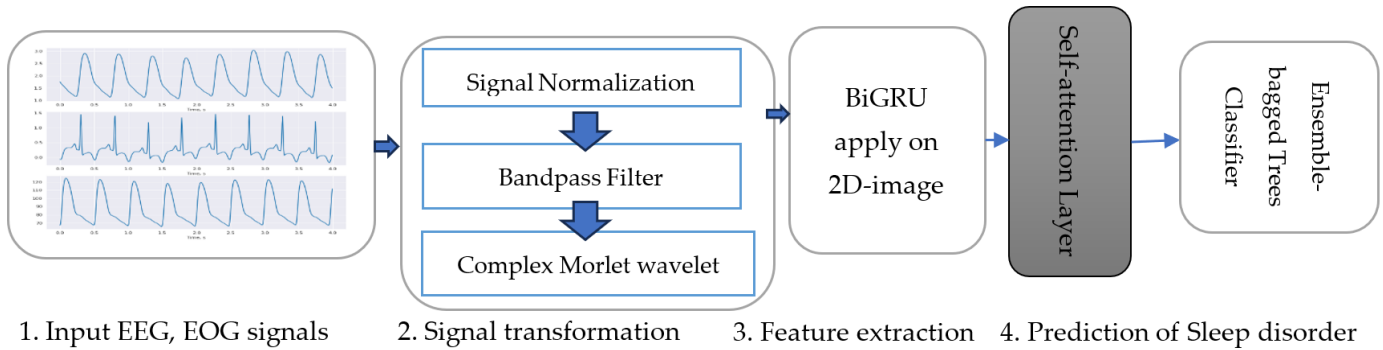

Fig. 1. Systematic flow diagram of the proposed multilayer sleep-disorder classification system.

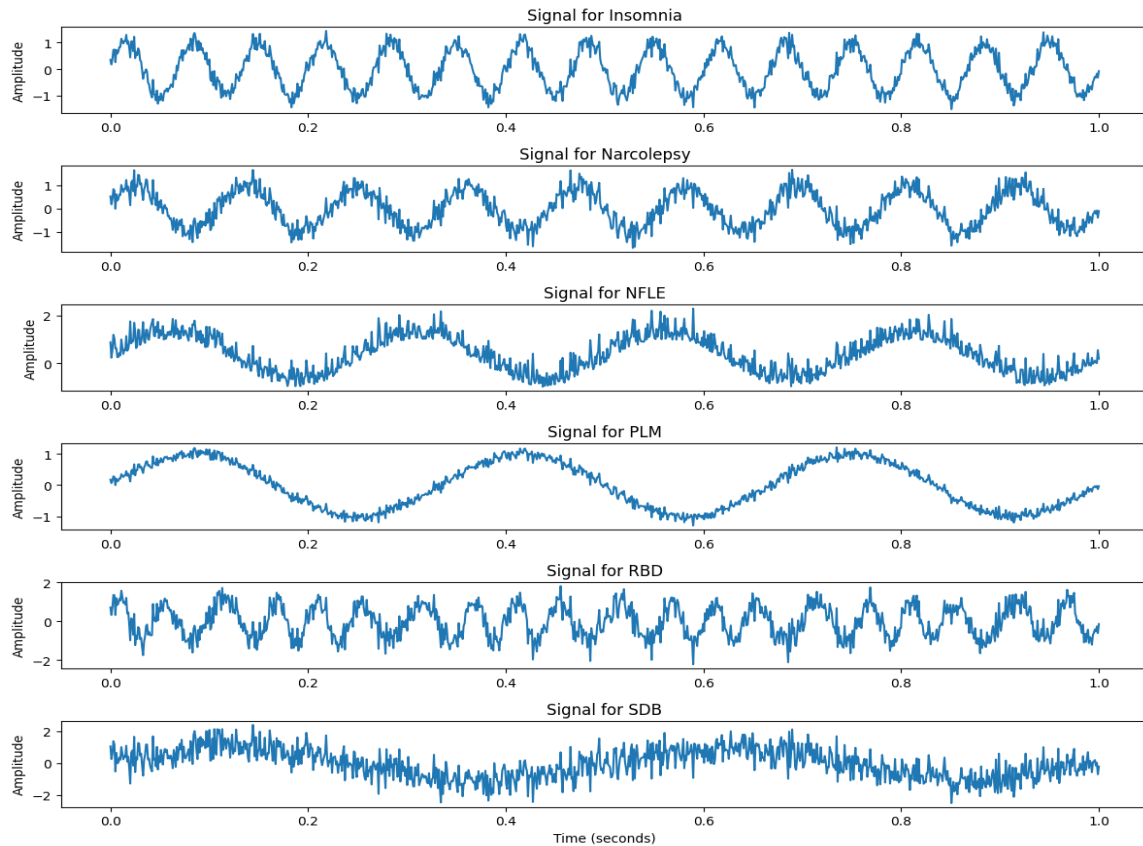

Fig. 2. Input EEG and EOG signals for identifying sleep disorders.

To standardize the sample, the dataset was subjected to data augmentation (Table II) using the synthetic minority over-sampling technique (SMOTE). SMOTE is used to rectify imbalanced datasets, particularly medical data in sleep studies, where certain classes are inadequately represented. It generates artificial, yet believable, examples using the available data from the underrepresented class. During the procedure of SMOTE, the dataset was assumed to contain EEG and EOG signal features, referred to as "features," along with their corresponding labels, referred to as "labels." These labels classify each group of features into distinct sleep disorders or stages. The dataset was initially divided into 70% training and 30% testing datasets. SMOTE was used only on the training set to prevent synthetic data from affecting the model evaluation. It generated additional

samples for classes that were not well represented, thus equalizing the distribution of classes, as balanced datasets improve model performance, particularly in classification tasks.

The training dataset (X-res and Y-res) contained the original and newly synthesized samples. This dataset was then used to train a machine-learning model. Notably, the model acquired knowledge from a dataset that provided a more equitable representation of all categories, thus mitigating its inclination toward the dominant category. The model's effectiveness was assessed using the initial, unmodified testing dataset. This approach ensures a complete evaluation of SMOTE's effectiveness as it accurately determines the effect of SMOTE on the model's ability to separate different sleep states.

TABLE II. EEG AND EOG SIGNAL DISTRIBUTION USED TO TEST THE SYSTEM PERFORMANCE

Sleep Stage	EEG	EOG	Total EEG and EOG	Data Augmentation
Insomnia	3800	1200	5000	2500
Narcolepsy	1300	1400	2700	2500
NFLE	3200	2000	3400	2500
PLM	1300	1000	2300	2500
RBD	5000	2000	7000	2500
SDB	200	100	300	2500
Healthy	400	200	600	2500

B. Signal Transformation

This multiclass sleep disorder prediction research uses the complex morlet wavelet transform (CMWT) [39] because it provides amplitude and phase information, unlike spectrograms, which indicate magnitude, and scalograms, which reveal phase information. While scalograms are superior for non-stationary signals, they cannot match the CMW transform. Spectrograms provide a broader perspective of power distribution. Arranging these normalized features creates the 2D stack picture, which is then fed into machine learning systems like the bidirectional gated recurrent unit (BiGRU), which maintains signal characteristics' spatial and temporal correlations.

PyWavelets were used to analyze a continuous wavelet transform (CWT). CWT is a robust time-frequency analysis method that can analyze signals at multiple scales or frequencies. This study employed the complex morlet wavelet (CMW), which analyzes nonstationary biological data via temporal and frequency localization. The CWT captured both high-frequency and low-frequency components of each

simulated disorder signal by decomposing it into distinct scales. Each row and column of the coefficient matrix represented a frequency range and time point, respectively. The coefficients were subsequently represented using a heatmap, which displayed the frequency characteristics of the signal over time. The color intensity of the heatmap corresponded to the magnitude of the signal across different frequencies, providing valuable information about the distinctive patterns associated with each sleep problem.

Thus, the CMW is ideal for feature extraction in biological signal processing. By explaining the complicated time frequency features of EEG and EOG signals, this study presents in-depth grouping sleep disorders into different categories of identifying unique brain patterns. The proposed approach conforms with current research practices in biomedical engineering and computational neuroscience, focusing on advanced signal processing techniques to understand complicated physiological events. Fig. 3 displays a visual representation of each sleep-disorder type.

C. Feature Extraction Using Bigru-Attention

A sophisticated neural network structure, namely a BiGRU [40] with a self-attention mechanism, was used to mine the time-series data, such as EEG and EOG signals. This study presents a promising method that takes the concatenated wavelet features of the EEG and EOG signals to create a unified 2D representation of these features. Owing to its bidirectional nature, BiGRU analyzed patterns in forward and reverse directions throughout time and revealed the intrinsic temporal dynamics in signal data. Fig. 4 shows the BiGRU architecture, wherein signal data are used to find and extract relevant features indicating the essential traits of different sleep stages or disorders.

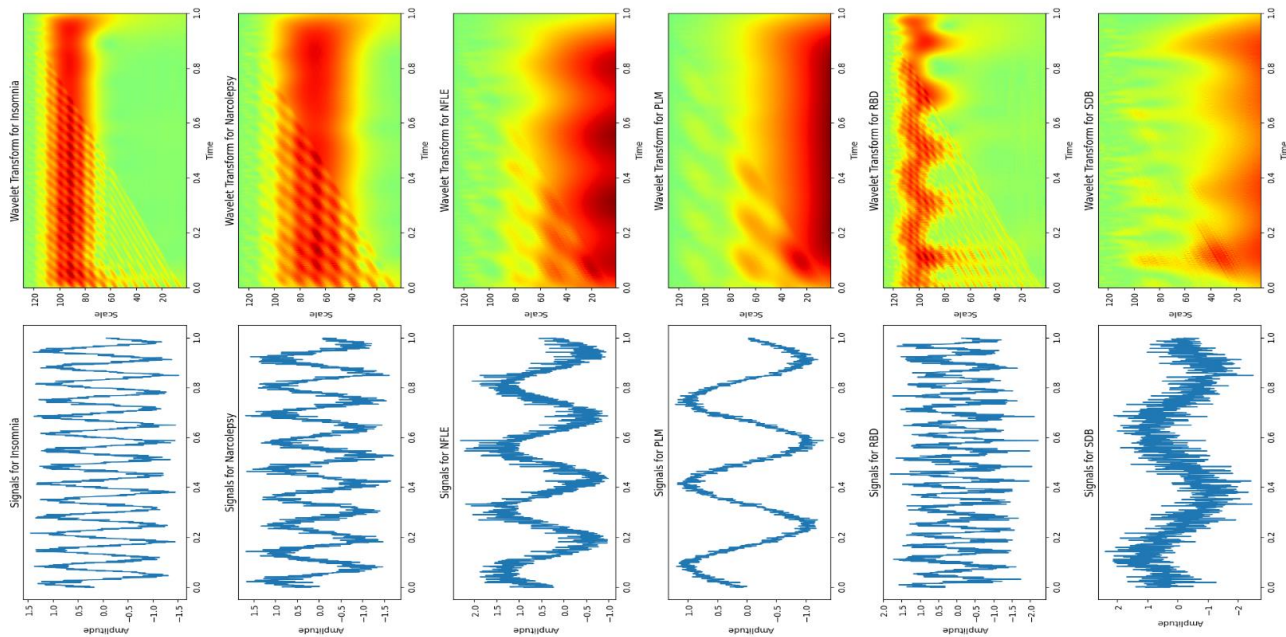

Fig. 3. Complex-morlet-wavelet transform using electroencephalogram signals of sleep disorders such as insomnia, narcolepsy, NFLE, PLM, RBD, and SDB.

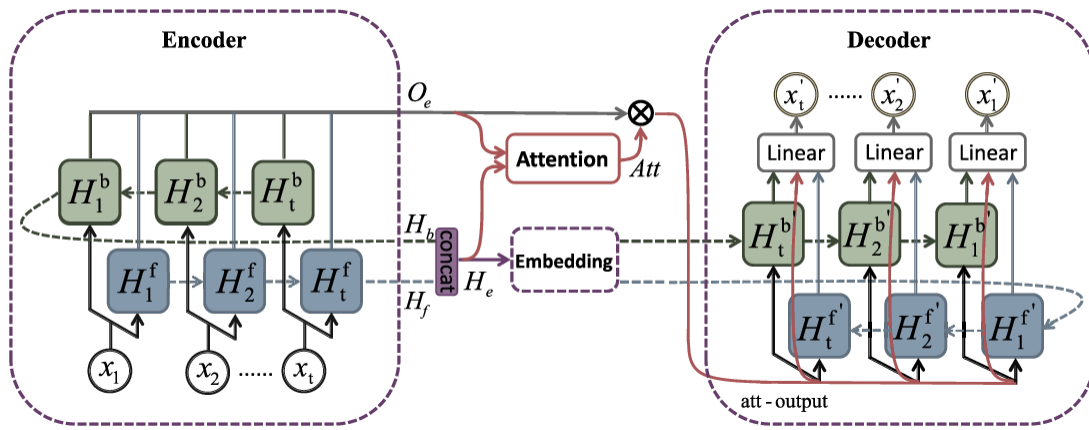

Fig. 4. Architecture of BiGRU with a self-attention layer.

EEG and EOG signals can be better analyzed by combining a self-attention mechanism with a BiGRU model, particularly when the signals change into a complex wavelet domain. The self-attention mechanism is a highly efficient neural network component, allows the model to prioritize different areas of the input data, making it more contextually aware. The sophisticated morlet wave transform further refines this by dividing EEG and EOG data into high- and low-frequency patterns, providing a deeper understanding of sleep stages and difficulties. The BiGRU model, in turn, uses these modified signals with rich time-frequency information for forward and backward analysis, capturing temporal correlations and patterns. This self-attention mechanism, with its efficiency, helps the model focus on essential signal alterations. It prioritizes segments that provide task-relevant information, such as sleep issues or phases, with high performance and accuracy.

Complex wavelet transformations, BiGRU, and self-attention mechanisms create a robust signal-processing paradigm. Precision frequency information was added to signals using the wavelet transform. The BiGRU neural network caught temporal patterns, and the self-attention mechanism focused on the most critical parts. When utilized together, they can extract crucial and relevant information from EEG and EOG data, making sleep studies and associated research more reliable and valuable. This strategy increases sleep study categorization and predictions by deepening physiological signal understanding.

EEG and EOG signals are converted to CMW for sleep disorder research and fed into the BiGRU model. Time-frequency analysis often uses the morlet wavelet because it splits initial signals into signals with various frequencies to optimize temporal and spectral localization. Thus, the BiGRU model learns from scale patterns. This model may detect small brain activity and eye movement changes that signal sleep phases and issues. This system employs a CMW transform and BiGRU model to use the BiGRU model's comprehensive time-frequency signal representation and powerful sequence modeling. By highlighting essential frequency components, the wavelet transform improves signals. The BiGRU then extracts key characteristics from this modified data, providing a robust collection of features for analysis or classification. This method handles EEG and EOG signal complexity and volatility well, making it suitable for advanced sleep investigations and diagnostics.

A BiGRU is a better version of the regular GRU developed for the model to obtain information from states preceding and succeeding the unit in a sequence. This is particularly advantageous in situations where the overall context of the entire sequence is crucial for making accurate predictions. A standard GRU operates on data sequentially and has a hidden state that serves as a memory to retain previous information. Nevertheless, it has only acquired data from earlier occurrences. A BiGRU comprises two GRUs operating in opposing directions: one GRU processes the sequence from the beginning to the end, whereas the other GRU processes it from the end to the beginning. These outputs are combined at each time step to obtain the entire sequence by incorporating details from the previous and subsequent contexts.

A GRU cell at time step t computes the following:

$$\text{Update gate } z_t = \sigma(Wz \times [ht - 1, xt] + bz), \quad (1)$$

$$\text{Reset gate } r_t = \sigma(Wr \times [ht - 1, xt] + br), \quad (2)$$

$$\text{Candidate hidden state } ht = \tanh(Wh \cdot [rt \times ht - 1, xt] + bh), \quad (3)$$

$$\text{Final hidden state } ht' = z_t \times ht - 1 + (1 - z_t) \times ht, \quad (4)$$

where σ denotes the sigmoid activation function, \tanh is the hyperbolic tangent function, W and b are the weights and biases, respectively, xt is the input at time t , and ht is the hidden state at time t . The BiGRU contains two hidden states at each time step, namely $ht(fwd)$ and $ht(bwd)$, calculated by the forward and backward GRUs, respectively. The forward GRU processes the sequence in the conventional manner, whereas the backward GRU processes it in the opposite direction. The combined hidden state at each time step t is acquired by either concatenating or summing the forward and backward hidden states:

$$ht(bi) = ht(fwd) + ht(bwd). \quad (5)$$

The BiGRU can capture dependencies and patterns that may be overlooked by a normal GRU, particularly in sequences wherein the future and past contexts are equally notable. This approach is frequently used in applications such as sequence labeling, time-series prediction, and natural language processing. BiGRUs have a higher computational cost and more parameters than regular GRUs, which may result in overfitting

when working with smaller datasets. Thus, the BiGRU enhances the functionality of the regular GRU by including inputs from the forward and backward directions of a sequence, resulting in a more holistic comprehension of the context.

The self-attention mechanism primarily focuses on the internal dependence of an input (Fig. 5). The output of the neural unit in the current moment may probably be affected by the EEG and EOG signals representation in the form of CMW transform. Based on the degree of influence, different weight parameters were assigned to signals such that the model can pay attention to the pivotal signals of stress information. The scaled dot-product attention model was used herein to optimize the data:

$$Attention(Q, K, V) = Softmax\left(\frac{QK^T}{\sqrt{d_k}}\right)V. \quad (6)$$

Fig. 5. A self-attention layer integrated into the BiGRU model.

The matrices Q, K, and V comprise query vectors, key vectors, and value vectors, respectively, and dk is the dimension of the input vector. In self-attention mechanism, Q, K, and V were derived from the same input and similarity among all words in the sentence was calculated. The greater the similarity among the signals, the stronger the correlation among them; thus, the dependency within the sentence can be captured. In question classification, the impact of each clause and individual word in the question varies. Certain words or sentences are crucial in question classification, whereas others have less impact. To effectively capture the relevant information in a question, an attention mechanism was added to the BiGRU model. This approach aims to highlight key semantic features, extract useful information, and accurately assess the contribution of each word for the classification of the entire question. By doing so, it ensures that the most crucial information is retained while filtering out redundant information, enhancing the efficiency and performance of question classification. The layer network uses the output of the upper layer network model as the input for the layer model, resulting in the vector representation of each sentence in the BiGRU model with the self-attention mechanism.

The basic form of self-attention mechanism can be expressed as follows:
 $S = \tanh(M)$

$$\alpha = \text{softmax}(W_n \times S) \quad (6)$$

$$r = M \times \alpha_n$$

$$q = \tanh(r)$$

D. Feature Classification

Algorithm 1 summarizes stress classification using the BiGRU model with self-attention mechanism (BiGRU) and ensemble-bagged tree classifier. The machine learning method EBTC [41] blends bagging (bootstrap aggregating) with decision trees. It is especially helpful in minimizing variance, preventing overfitting, and boosting model resilience. The EBTC minimizes prediction variance by averaging many trees, which is useful when individual trees overfit. Bootstrapping randomly creates variation among ensemble trees, essential to the approach's efficacy. The ensemble's averaging effect makes the EBTC resilient to data outliers and noise. Bagged ensemble learning improves machine learning algorithm stability and accuracy. Multiple predictors are utilized to create an aggregated predictor. Classification and regression employ decision trees. They made a decision tree by subdividing the data by feature value testing. From the original dataset, multiple bootstrap samples are randomly chosen subsets of data (with replacement) of the same size. Independent decision trees are trained for each bootstrap sample. Training data is different for each tree owing to random sampling with replacement.

Algorithm 1: Sleep disorder classification using EEG and EOG signals and BiGRU with a self-attention layer and EBTC.

Input	• EOG_data: Array of EOG signal data • EEG_data: Array of EEG signal data • sampling_rate: Sampling rate of the EOG and EEG data • wavelet_parameters: Parameters for the complex wavelet transform
Output	• Final-classification.
Step 1:	Feature Extraction: Filtered_EOG = bandpass_filter(EOG_data, lowcut, highcut, sampling_rate) Filtered_EEG = bandpass_filter(EEG_data, lowcut, highcut, sampling_rate) <ul style="list-style-type: none"> • Wavelet_Features_EOG ← Morlet-WaveletTransform (Filtered_EOG, wavelet_parameters) • Wavelet_Features_EEG ← Morlet-waveletTransform (Filtered_EEG, wavelet_parameters) • Combined_Features = concatenate((Wavelet_Features_EEG, Wavelet_Features_EOG), axis=1) • Combined_Image ← stacking(Combined_Features)
Step 2:	Gated Recurrent Unit (GRU) Classifier: GRU_Model ← InitializeGRU(layer_parameters). Hidden_States ← GRU_Model(Combined_Image)
Step 3:	Attention Mechanism: <ul style="list-style-type: none"> • The BiGRU produces a sequence of hidden states ht. • Attention scores at are computed for each hidden state as stated in Eq. (8).

Step 4:	Weighted Sum: Attention_Scores = compute_attention_scores(Hidden_States) Weighted_Hidden_States ← Attention_Scores @ Hidden_States
Step 5:	Ensemble-bagged Tree Classifier (EBTC): <ul style="list-style-type: none">• EBTC_Model ← TrainEBTC(Weighted_Hidden_States, labels)• EBTC_Predictions ← EBTC_Model.predict(Weighted_Hidden_States)
Step 6:	Combination and Final Classification: Final_classification ← classify(EBTC_Predictions)
Step 7:	Evaluation: metrics ← evaluate(Final_classification, true_labels)

After all decision trees are trained, the ensemble model makes predictions by aggregating the predictions from all individual trees. This approach is followed for classification tasks via majority voting, wherein each tree votes for a class, and the class with the most votes is considered the ensemble's prediction.

A dataset D with N instances is considered for the EBTC with M trees. For each tree $m = 1, 2, \dots, M$, a bootstrap sample D_m is created by randomly selecting N instances from D with replacement. A decision tree T_m is then trained on D_m . For a new instance x , the prediction y is given by Eq. (7).

$$y = \text{model}\{T1(x), T2(x), \dots, TM(x)\}. \quad (7)$$

The EBTC minimizes prediction variance by averaging many trees, which is useful if some trees overfit. The attention mechanism calculates weights using a straightforward scoring function such as a dot product and a Softmax. For a hidden state ht , the attention score at is calculated as follows:

$$yat = \sum_T^i \exp(\text{score}(hi)) \exp(\text{score}(ht)) \quad (8)$$

where $\text{score}(ht)$ is a dot product of the hidden state ht and some learnable parameter and T is the length of the sequence. The model then computes a weighted sum of the hidden states using attention weights, thereby generating a context vector that encapsulates the most relevant information from the entire sequence.

$$Y_c^{\text{context-vector}} = \sum_T^i at \cdot ht \quad (9)$$

A fully connected layer then uses this context vector for the final classification (such as determining the type of sleep disorder). When analyzing EOG and EEG signal analysis for sleep disorders, the attention mechanism assigns higher weights to hidden states corresponding to signal patterns characteristic of certain sleep disorders. In contrast, the signal's ordinary or less informative patterns are assigned lower weights. The BiGRU model prioritizes essential sections of the EOG and EEG signals with a higher predictive value for various sleep disorders, thereby improving the classification accuracy and efficiency.

IV. EXPERIMENTAL RESULTS

This section overviews the creation of distinct subsets of data and classification performed to identify various sleep disorders. The integrated deep learning and machine learning models, including the meta-learner, were trained and tested on a highly advanced computational infrastructure comprising a notebook with powerful specifications to manage the computing

requirements of the models effectively. The processor was an Intel(R) Core (TM) i7, 10th Generation, with an essential clock speed of 3.34 GHz, outfitted with four cores and eight logical processors for efficient parallel computing. The machine was equipped with 32GB RAM to effectively cater to the demanding memory requirements of training and testing deep learning models. Windows 10 offers a reliable and compatible platform for various machine-learning operations. The deep learning models were constructed and trained using the TensorFlow framework in conjunction with the Keras framework.

A. Performance Measures

The categorization performances of deep learning and machine learning models were compared using traditional measurement metrics. These measures are crucial for fully grasping the effectiveness of the models in terms of different aspects of categorization performance. The metrics and their corresponding calculation algorithms are outlined below:

1) *Accuracy*: This metric represents the proportion of true results (true positives and negatives) among the total number of cases examined.

$$\text{Accuracy (ACC)} = \frac{TP+TN}{TP+TN+FP+FN} \quad (10)$$

2) *Sensitivity (SE) or Recall (RC)*: It assesses the model's false negative avoidance.

$$\text{Recall(RC)} = \text{Sensitivity (SE)} = \frac{TP}{TP+FN} \quad (11)$$

3) *Specificity (SP)*: This metric assesses the proportion of actual negatives that are correctly identified.

$$\text{Specificity (SP)} = \frac{TN}{TN+FP} \quad (12)$$

4) *F1-score (FS)*: This metric is a harmonic mean of precision and recall and balances the two.

$$F1 - \text{score (FS)} = 2 \times \frac{PR \times RC}{PR+RC} \quad (13)$$

In this Eq. (13), the RC and PR are precision and recall metrics calculated from Eq. (11) to Eq. (14), respectively.

$$\text{Precision (PR)} = \frac{TP}{TP+FP} \quad (14)$$

In addition, a confusion matrix is used to assess the efficacy of the classification models.

- TN: This refers to accurately predicted negative occurrences.
- FP: This refers to incorrectly predicted positive observations.
- FN: This refers to incorrectly predicted negative observations.
- TP: This refers to accurately predicted positive observations.

These indicators assessed the performance of classification models, emphasizing their strengths and identifying areas for enhancement. This provided valuable information regarding the model's ability to accurately differentiate between several classes and maintain a balance between precision and recall. In

addition, the area under the receiver operating characteristic curve (AUC) is also utilized to measure the performance of various systems.

B. Experimental Results

The classification performance of models in differentiating healthy subjects from those with sleep disorders and identifying specific sleep disorders is discussed as follows. Tables IV–VI present the results obtained using the proposed system. Several experiments are performed to identify different classes of sleep disorders compared to normal stage. The required hyperparameters are described in Table III. These parameters are defined based on the several experiments.

TABLE III. HYPERPARAMETERS SETUP REQUIRED BY PROPOSED SYSTEM

Models	Hyperparameter	Values
BiGRU	Units	128
	Layers	2
	Dropout Rate	0.3
	Recurrent Dropout Rate	0.2
	Activation Function	tanh
	Batch Size	64
	Learning Rate	0.001
Self-Attention Layer	Attention Size	Equal to Number of Units
	Attention Activation	Softmax scores
EBTC	Number of Estimators	200
	Maximum Depth of Trees	30
	Minimum Samples Split	5
	Minimum Samples Leaf	2
	Bootstrap Samples	True
	Max Features	sqrt

This research, as presented in Table IV, has yielded significant classification results. We have compared the performance of a proposed approach that utilizes complex-morelet wavelet (CMW) decomposition with sleep stages, against a method that uses discrete wavelet transform (DWT) to convert 1D sleep signals into a combined 2D-CMW image. The choice between DWT and CMW is crucial and depends on the needs of the particular analysis. While DWT may be a better choice for computationally efficient broad feature extraction, the CMW generates a scalogram, a 2D array that provides a detailed view of the signal's frequency content over time. This detailed view is crucial for deep analysis that requires frequency and phase information. By converting 1D sleep problem signals into 2D, CMW may provide more significant information for diagnosing and comprehending complicated sleep events.

The advantage of the proposed approach is evident in significantly improved accuracy and area under the curve (AUC) across all sleep disorders. In this context, 'accuracy' refers to the percentage of correctly classified sleep stages or disorders, while 'AUC' is a measure of the model's ability to distinguish between different sleep stages or disorders. For instance, accuracy increased in the case of insomnia from

81.45% with DWT to an impressive 99.70% with CMW, and AUC rose from 0.822 to 0.997. Similar enhancements are observed across other disorders, such as narcolepsy; accuracy improved from 80.10% to 97.60%, and AUC increased from 0.834 to 0.976. In the case of NFLE, accuracy rose from 82.47% to 95.40%, with AUC increasing from 0.833 to 0.954. In the case of PLM, there was an increase in accuracy from 85.67% to 94.50% and in AUC from 0.865 to 0.945. For RBD, accuracy increased from 84.32% to 96.50%, with AUC improving from 0.854 to 0.965. For SDB, accuracy jumped from 85.20% to 98.30%, and AUC from 0.876 to 0.983. For healthy individuals, accuracy went from 87.00% to 94.10%, with the AUC moving from 0.876 to 0.941. Accordingly, our research has demonstrated the remarkable improvements in accuracy and AUC that the proposed approach offers compared to the method using discrete wavelet decomposition. These improvements underscore the potential of our approach to enhance the diagnosis and treatment of sleep disorders. These findings unequivocally demonstrate the value of incorporating CMW into the classification procedure for a more precise and trustworthy diagnosis of sleep disorders.

TABLE IV. CLASSIFICATION RESULTS OBTAINED WITHOUT USING WAVELET DECOMPOSITION WITH THE SLEEP STAGES. RESULTS ARE OBTAINED USING 10-FOLD CROSS-VALIDATION

Disorder	Discrete Wavelet Transform (DWT)	Complex-Morlet-wavelet (CMW) transform		
	Acc (%)	AUC	Acc (%)	AUC
Insomnia	81.45	0.822	99.70	0.997
Narcolepsy	80.10	0.834	97.60	0.976
NFLE	82.47	0.833	95.40	0.954
PLM	85.67	0.865	94.50	0.945
RBD	84.32	0.854	96.50	0.965
SDB	85.20	0.876	98.30	0.983
Healthy	87.00	0.876	94.10	0.941
Average	83.74	0.858	96.59	0.966

Table V presents sleep disorder classification results obtained using various classifiers with the hold-out validation strategy. The proposed approach, CMW-BiGRU-Self-attention-EBTC, demonstrates superior performance across all sleep disorders compared to alternative methods such as LSTM and GRU-SVM. The proposed CMW-BiGRU-Self-attention-EBTC method shows significant advantages over alternative approaches, highlighting its effectiveness in accurately classifying sleep disorders.

An independent experiment was conducted to compare the CMW transform with spectrogram and scalogram techniques. In practice, the CMW transforms provide both amplitude and phase information, which are essential for detailed signal analysis, particularly in identifying phase coupling between different signal components. The CMWT is particularly advantageous due to its rich and detailed time-frequency representation. Table VI offers a comprehensive overview of such classification performance for a six-class sleep disorder classification task

with signal transformation using a 2D-spectrogram image. Fig. 6 demonstrates the various confusion matrices, illustrating the distribution of actual and predicted classes, and the number of instances correctly and incorrectly classified for each sleep disorder when a 2D-scalogram is used. The results in Table VI were obtained without using CMW transforms, but the 2D-spectrogram was used to analyze the performance. As shown in this table, the proposed system, which does not incorporate the complex morlet wavelet (CMW) transformation, the bi-directional gated recurrent unit (BiGRU) with self-attention, and the ensemble bagged tree classifier (EBTC) is utilized. The result does not outperform by the system without using CMW transforms. Similar trends were observed using 2D-scalogram without using the CMW transform technique, as depicted in Fig. 6. Hence, the proposed CMW-BiGRU-Self-attention-EBTC system using CMW transform ensures accurate sleep disorder classification. Despite these results, the CMW transform's adaptability and detailed time-frequency representation continue to outperform spectrograms and scalograms, particularly in capturing complex, non-stationary signal patterns essential for diagnosing sleep disorders.

TABLE V. SLEEP DISORDER CLASSIFICATION RESULTS FROM USING VARIOUS MACHINE-LEARNING CLASSIFIERS WITH THE HOLD-OUT VALIDATION STRATEGY

Classifier	Accuracy (%)						Healthy
	Insomnia	Narcolepsy	NFLE	PLM	RBD	SDB	
CMW-BiGRU-Self-attention-EBTC	99.70	97.60	95.40	94.50	96.50	98.30	94.10
LSTM	80.9	75.3	74.5	77.1	79.8	81.0	80.9
KNN+NN	78.6	73.5	71.9	74.8	77.4	79.2	78.6
Random Forest (RF)	92.5	87.0	85.1	88.2	90.3	91.2	92.5
RF+SVM	90.8	85.5	83.3	87.7	89.4	90.1	90.8
GRU-SVM	89.7	84.2	82.9	86.5	88.0	89.3	89.7
Decision Tree	85.4	80.6	79.2	81.9	83.7	85.1	85.4

Fig. 6. Confusion metrics obtained for six sleep disorder prediction versus healthy individuals without signal transformation (normalization, bandpass filter and used 2D-scalogram image, complex morlet wavelet, stacking) step by proposed CMW-BiGRU-Self-attention-EBTC system.

TABLE VI. PERFORMANCE METRICS OBTAINED FOR SIX-CLASS BASED SLEEP DISORDER CLASSIFICATION WITHOUT SIGNAL TRANSFORMATION (NORMALIZATION, BANDPASS FILTER AND USED 2D-SPECTROGRAM IMAGE, COMPLEX MORLET WAVELET, STACKING) STEP BY PROPOSED CMW-BiGRU-Self-Attention-EBTC SYSTEM

Classes	ACC (%)	PR(%)	RC(%)	FS(%)
Insomnia	84.75	84.77	84.77	84.77
Narcolepsy	82.96	82.93	82.93	82.93
NFLE	81.09	81.11	81.11	81.11
PLM	80.33	80.42	80.42	80.42
RBD	82.03	82.03	82.03	82.03
SDB	83.56	83.62	83.62	83.62
Healthy	79.99	79.96	79.96	79.96

This study distinguishes healthy people from individuals with sleep problems with great accuracy, as described in the above paragraphs. Several variables were found and studied throughout testing, which are potential sources of error or misclassification based on the experimental results from Tables IV and V, as described below.

- Noise from EEG and EOG signal quality can decrease feature extraction precision. Signal fluctuation can be caused by electrode location, sleep movement, and physiological variations. When the signal-to-noise ratio is low, this fluctuation might cause the model to categorize epochs inconsistently.
- Despite the Use of cross-validation and regularization to reduce overfitting, the model may have inadvertently

learned patterns specific to the training set that do not generalize well to unknown data. This is a common challenge in machine learning that could potentially increase model error rates when confronted with new data.

- This dataset is extensive; however, class imbalance is evident in SDB and PLM data. Class imbalance can bias the model to recognize the dominant class but not the minority class, reducing accuracy and increasing misclassification rates.
- Rare sleep disorders, including Narcolepsy and Nocturnal Frontal Lobe Epilepsy (NFLE), reduce training data. This constraint might hinder the model's understanding of these illnesses' complicated patterns, leading to reduced accuracy or increased misclassification rates.
- The proposed model uses Morlet wavelet transform and advanced machine learning methods to analyze combine EEG and EOG signals, requiring numerous computing layers. Complexity allows excellent accuracy, but it also raises the possibility of misclassifying signal artifacts or non-standard signal patterns as disorders.

To address these potential errors, we implemented a series of robust measures. We strengthened the signal processing capabilities with CMW transforms. Additionally, training dataset was expanded to encompass a wider range of patients and disorders.

Fig. 7–8 present the results obtained using the proposed system by changing the hyperparameters to detect six multi-class sleep stages. ReLU activation function is applied on GRU units as compared to Tanh as shown in Fig. 7. A similar performance has been achieved. This figure presents the receiver operating characteristic (ROC) curves for different sleep disorders, as well as for the 'Healthy' class, based on the crucial area under the curve (AUC) values provided. Each curve represents the trade-off between the actual positive rate (sensitivity) and the false positive rate (1-specificity) for a specific disorder classification. A higher AUC indicates better discrimination ability, with values closer to 1.0 representing superior classification performance. In this figure, the AUC values for each disorder are as follows: Insomnia (0.997),

Narcolepsy (0.976), NFLE (0.954), PLM (0.945), RBD (0.965), SDB (0.983), and Healthy (0.941). These values are pivotal in reflecting the models' ability to distinguish between positive instances of each disorder and negative instances of other disorders or healthy individuals. AUC values near 1.0 suggest excellent classification performance, while lower values indicate room for improvement.

The confusion matrix in Fig. 8 provides a comprehensive overview of a CNN classifier's performance in discerning between various sleep disorders and healthy individuals. Each row corresponds to the true class, while each column represents the predicted class, offering insights into both correct classifications and misclassifications when figure (a) proposed system and (b) original BiLSTM and EBTC boosting tree. For instance, the classifier demonstrated its effectiveness by accurately identifying a significant number of instances for each disorder, such as Insomnia (370 instances correctly classified) and Narcolepsy (362 instances correctly classified). However, misclassifications were observed across different categories, indicating the model's limitations in certain scenarios. Notably, while the classifier performed well in identifying instances of Insomnia and Narcolepsy, a few instances of Insomnia (1 instance misclassified as Healthy) and Narcolepsy (2 instances misclassified as NFLE, one as PLM, one as RBD, two as SDB, and two as Healthy) were incorrectly classified.

Moreover, the confusion matrix highlighted misclassifications of healthy individuals, with some instances erroneously classified as various sleep disorders. Despite accurately identifying the majority of healthy individuals (349 instances correctly classified), a notable number of misclassifications occurred. For example, healthy individuals were mistakenly classified as Narcolepsy (4 instances misclassified), NFLE (5 instances misclassified), PLM (5 instances misclassified), RBD (5 instances misclassified), and SDB (2 instances misclassified). These misclassifications underscore the need to refine the classification model to enhance its accuracy and robustness, particularly distinguishing between healthy individuals and those with sleep disorders. By addressing these misclassifications and improving the classifier's ability to identify different sleep patterns accurately, it can strengthen diagnostic tools for sleep disorders and enhance patient care through more precise and timely interventions.

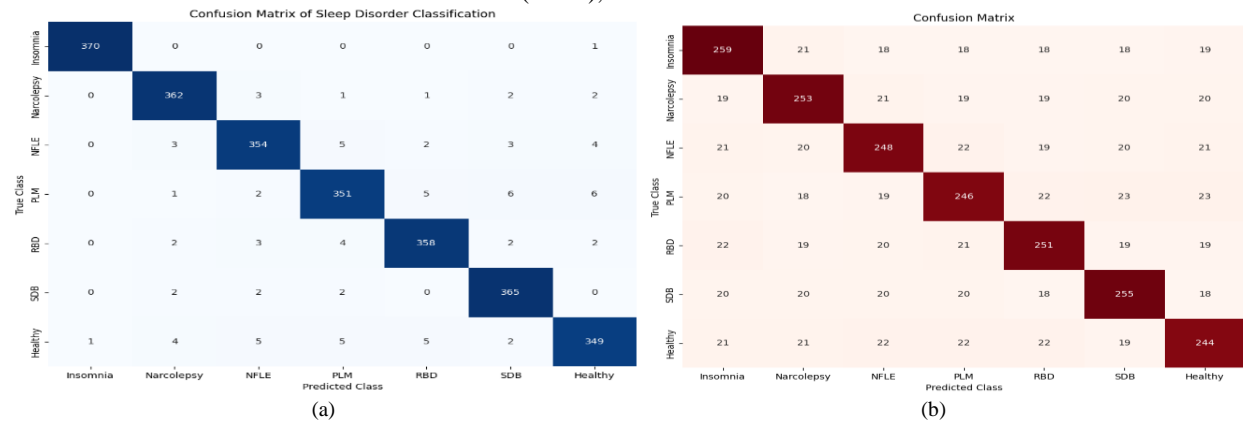

Fig. 7. Confusion matrices for sleep stage and sleep disorder detection using (a) proposed system and (b) original BiLSTM and EBTC boosting tree.

Fig. 8. A separate experiment for using 2400 samples of each sleep-disorder class to show AUC curves of accuracy with respect to each class of sleep disorder.

The AUC curve for our proposed system using the architecture (CMW-BiGRU-Self-attention-EBTC) is shown in Fig. 8. This is an integral part of our research. This system, which uses a large dataset with 24,000 samples of each class instead of 26,000 samples, gives a full picture of how well the proposed classifier works at finding sleep disorders. More importantly, it paves the way for evaluating and refining the classification model, thereby enhancing the accuracy and reliability of our system. This, in turn, underscores the potential impact of our research on clinical applications, making it a significant contribution to the fields of sleep medicine and machine learning.

C. State-of-the-Art Comparisons

Sleep disorder diagnosis through automated systems has seen significant advancements, with various models employed in the past by combinations of convolutional neural networks (CNNs), recurrent neural networks (RNNs), gated recurrent units (GRUs), and random forest (RF) algorithms. These models, such as Shao-CNN-GRU [17], Fan-CNN-RNN [19], Santaji-RF [21], Morokuma-CNN [30], and Satapathy-1DCNN [33], have leveraged electrooculography (EOG) and electroencephalography (EEG) signals to varying degrees of success. These systems were selected to perform State-of-the-art (SOTA) comparisons because they were quickly implemented. While they have shown promising results, challenges such as overfitting, limited sleep class detection, and computational inefficiency have persisted, as mentioned in Table I. Accuracies have varied widely, from as low as 76.3% to as high as 98.84%, with each model demonstrating its strengths in handling

complex signal data for sleep stage classification or disorder diagnosis and revealing significant limitations hindering their broader application and effectiveness.

In this context, the proposed CMW-BiGRU-Self-EBTC model emerges as a noteworthy evolution that adeptly addresses these challenges. By integrating a complex metro-wavelet transformation with a bidirectional gated recurrent unit that includes a self-attention layer and coupling it with an ensemble-bagged tree classifier, this model simplifies the signal processing pipeline and enhances the accuracy and efficiency of sleep disorder diagnosis. With remarkable success rates across various sleep disorders and an overall classification accuracy of 96% alongside an AUC of 0.96, this approach outshines its predecessors. It achieves this by effectively mitigating overfitting and reducing computational demands, thereby marking a significant leap forward in developing noninvasive, automated systems for accurate and efficient sleep disorder diagnosis. Specific hyperparameters are described in Table VII to expand the "Details" column to include examples of hyperparameters that might be tuned for RNNs (Recurrent Neural Networks) and the considerations for architectural configurations.

Table VIII shows a comparative analysis of various state-of-the-art (SOTA) systems for sleep disorder detection. The systems compared include Shao-CNN-GRU, Fan-CNN-RNN, Santaji-RF, Morokuma-CNN, Satapathy-1DCNN, and the proposed system, CMW-BiGRU-Self-EBTC.

TABLE VII. STATE-OF-THE-ART COMPARISONS (SOTA) HYPER-PARAMETERS SITTING

Component	Description	Expected Impact
Baseline (Full Model)	CMW-BiGRU-Self-EBTC with all features	Establish baseline performance
Without Bidirectional RNN Cells	Use unidirectional GRU cells	Assess the importance of capturing temporal dependencies in both directions
Without the Attention Layer	Remove the self-attention layer	Evaluate the impact of focusing on significant parts of the data
Without Bagging Ensemble	Use a single classifier instead of an ensemble	Determine the contribution of ensemble methods to robustness and accuracy
Without Data Augmentation	Train without augmented data	Examine the role of data diversity in model generalization

TABLE VIII. SOTA WITH RESPECT TO PROPOSED SYSTEM

SOTA Systems	Acc (%)	SE(%)	SP(%)	AUC	FS (%)
Shao-CNN-GRU [17]	88.25	86.40	88.15	0.87	88.32
Fan-CNN-RNN [19]	78.44	77.12	78.42	0.77	78.46
Santaji-RF [21]	75.47	73.70	74.10	0.75	76.10
Morokuma-CNNc[30]	86.50	85.20	88.45	0.86	88.00
Satapathy-IDCNN [33]	80.10	82.66	83.25	0.83	82.12
CMW-BiGRUSelf-EBTC	96.59	97.30	95.20	0.966	96.0

TABLE IX. ABLATION STUDY PARAMETERS

Step	Description	Details	Example Hyperparameters
Define the Parameter Space	For each model, identify and list all hyperparameters and architectural configurations that will be explored.	Includes learning rates, batch sizes, number of layers, types of RNN cells (e.g., LSTM, GRU), etc.	Learning rate: [0.001], Batch size: [64], RNN type: [LSTM, GRU], Number of layers: [3], Dropout rate: [0.25]
Apply Nested CV	Implement nested cross-validation (CV) with an outer loop for performance assessment and an inner loop for hyperparameter tuning.	Ensures unbiased evaluation and that hyperparameter tuning does not influence the test set.	Outer loop: 5 folds, Inner loop: 3 folds
Optimize Hyperparameters	Use grid search within the inner loop of the nested CV to find the optimal set of hyperparameters and architectural configurations for each model.	Systematically explores multiple combinations of parameters to find the best setup for each model.	Grid search across all combinations of the example hyperparameters listed.
Evaluate and compare	After tuning, evaluate each model's performance on the test set of the outer CV loop to ensure fairness in comparison.	Performance metrics are based on unseen data, providing a reliable basis for comparison.	Accuracy, F1 Score, AUC, Sensitivity, Specificity
Statistical Testing	Employ statistical tests to determine if the differences in performance between models are statistically significant.	Strengthens the validity of the comparison by confirming whether observed performance differences are meaningful.	Wilcoxon signed-rank tests comparing model performances.

The recommended CMW-BiGRUSelf-EBTC system, with its superior performance metrics, outperforms previous models. Its accuracy of 96.59%, SE of 97.30%, SP of 95.20%, AUC of 0.966, and F1-score of 96.0% are a testament to its effectiveness. The system's ability to effectively diagnose sleep problems is a significant advancement, demonstrating its profound impact on sleep problem detection. This comparison underscores the importance of advanced machine learning approaches like bidirectional RNNs, self-attention layers, and ensemble methods in the field of sleep disorder diagnosis.

D. Ablation Study

Ablation studies on the proposed Complex-Morlet-wavelet Representation using a bidirectional gated recurrent unit with a Self-attention Layer and an ensemble-bagged tree classifier (CMW-BiGRUSelf-EBTC) system involve systematically removing or replacing model components to understand their performance contributions. This study highlights the most critical elements of the suggested sleep problem detection and identification technique—ablation research structure. Tables VIII and IX provide an overview of the CMW-BiGRUSelf-EBTC system ablation research and a full analysis of each ablation component.

These tables summarize the ablation study's setup and findings. They also demonstrate how each CMW-BiGRUSelf-EBTC component detected and diagnosed numerous sleep problems. The ablation research for the planned CMW-BiGRUSelf-EBTC system employing EEG and EOG data to discover and diagnose sleep problems shows how the elements work together to make it operate successfully. Initial evaluation

of the system yields remarkable metrics: accuracy of 96.59%, sensitivity of 97.30%, specificity of 95.20%, AUC and F-score of 0.966 and 96.0%, respectively. This complete performance shows the system's resilience and accuracy in diagnosing sleep problems.

As the study progresses through its phases, removing critical system features one by one, a clear picture of their contributions emerges. All metrics go down a lot when there are no bidirectional RNN cells. This shows the importance of capturing temporal dependencies in the signal data for correct disorder recognition. In the same way, getting rid of the attention layer lowers performance metrics, showing how important it is for helping the model focus on essential parts of the complex signal data. The system's performance worsens when the bagging ensemble method and data augmentation are removed. This shows how important they were for making the model more robust and able to generalize across different data representations. Each component's removal delineates a stepwise decrease in the system's effectiveness, underlining the synergistic effect of these elements in achieving the CMW-BiGRUSelf-EBTC system's state-of-the-art performance.

V. CONCLUSION

The EOG and EEG data were used for automated sleep-disorder identification, making this study a notable advancement in sleep medicine. The proposed method for detecting sleep disorders yielded highly accurate and efficient results as it integrated advanced signal-processing techniques with powerful machine-learning models. This approach was also designed to be patient friendly. Thus, this study not only enhances the

scientific comprehension of sleep health but also holds the potential to considerably improve the quality of life of individuals with sleep disorders. The proposed method effectively classifies healthy individuals from those with different sleep disorders. It achieved a remarkably high accuracy of 99.7% for insomnia, 97.6% for narcolepsy, 95.4% for NFLE, 94.5% for PLM, 96.5% for RBD, 98.3% for SDB, and 94.1% for healthy individuals. The model's relevance and precision can be enhanced across many scenarios by establishing a confidential database for subsequent experimentation.

A key priority is ensuring the wide-ranging appropriateness and efficacy of a proposed technique for sleep health monitoring and diagnosis across diverse demographic groups. The dataset was expanded to include additional ages, genders, ethnicities, and geographical origins to achieve this. This expanded dataset will better capture population-specific sleep patterns and problems, enhancing the model's generalizability. To understand how cultural influences impact sleep, it will employ cross-cultural validation and adaptive algorithms for tailored diagnosis. However, medical specialists from diverse demographics must refine the model to maintain its clinical relevance and responsiveness to the vast range of sleep problems.

Ethical and inclusive research and design practices emphasize privacy, permission, and data protection. By making this technology inexpensive and accessible across demographics, it promotes healthcare equity. Patients and healthcare providers must monitor and offer feedback post-deployment. The system will be modified and adjusted based on real-world use and feedback to keep it valuable and relevant for diagnosing and monitoring sleep problems in varied worldwide populations.

Digital Landscape Architecture Design Combining 3D Image Reconstruction Technology

Chen Chen

School of Environmental Art and Design, Wuxi Vocational Institute of Arts & Technology, Yixing, Wuxi, China

Abstract—To achieve better digital landscape design and visual presentation effects, this study proposes a digital landscape design method based on improved 3D image reconstruction technology. Firstly, a precise point cloud registration algorithm combining normal distribution transformation and Trimmed iterative nearest point algorithm is proposed. A color texture method for 3D models is designed in terms of 3D reconstruction, and a visual scene, 3D reconstruction method based on RGBD data is constructed. Secondly, knowledge networks are introduced to assist in the intelligent generation and planning of plant communities in urban landscape scenes. The knowledge network established through the plant database integrates the principles of landscape design and optimizes the layout of landscape plants in urban parks. The running speed and accuracy of research algorithms were superior to traditional methods, especially in terms of registration performance. Compared to the other two algorithms, the registration time of the research algorithm was reduced by 2%, and the errors were reduced by 71.4% and 87.5%, respectively. The panoramic quality of research methods fluctuated within a small range of 0.8 or above, while traditional methods exhibited instability and lower quality. The landscape design generated by research methods was more aesthetically pleasing and harmonious with the actual landscape in terms of plant selection and layout. The proposed method follows the principles of eco-friendly design and demonstrates significant potential for application in the field of urban landscape design.

Keywords—3D image reconstruction; PSO; gardens; RGBD; digital landscape

I. INTRODUCTION

Landscape refers to the landscape environment created artificially within a certain area. Through the layout and combination of plants, land, water, architecture, and other elements, as well as the artistic treatment and transformation of natural and cultural elements, it creates a living, working, or leisure place with beauty, comfort, and functionality [1-2]. China's landscape architecture has a rich historical background, and modern landscape architecture has a development history of over 60 years in China [3]. The traditional garden aesthetics advocate harmonious coexistence with nature, reflecting profound humanistic ideas. Research has shown that exposure to nature and green spaces is beneficial for human psychological and physical health. Landscape design has improved urban air quality and provided leisure spaces beneficial to physical and mental health [4]. However, in the face of today's diverse needs, traditional design methods are unable to meet the requirements of rapid urban development and high standard, scientific urban spatial planning.

Digitization has brought challenges to the development of landscape design, but also new opportunities [5]. In response to the limitations of existing landscape evolution models, scholars such as Steer have proposed an innovative modeling technique. This technology achieved one-dimensional sorting and effective propagation of terrain change information by applying linear flow power equations and utilizing directed acyclic graphs. This modeling method could accurately simulate the dynamic changes of the landscape even under conditions of uneven or varying rise and fall rates [6]. In landscape design, the use of sound elements was limited to noise management. Therefore, Luo Ma L et al. explored the impact of sound as a design element on the immersion of architecture and planning in virtual reality environments. This study constructed a virtual reality scene based on field recording to simulate the sound environment. It emphasized the role of audible sound in enhancing landscape design [7]. Wang et al. proposed a landscape water flow design method based on the principles of open channel hydraulics, which combines hydrology and hydraulics as well as landscape processes of infiltration and evapotranspiration. This method could accurately generate flow profiles between depressions in the landscape [8]. The above research indicates that digitalization in the field of landscape architecture mainly focuses on technological application, and in-depth research on design methods and logic is still in its early stages and has not been widely applied in practice. The digitization of traditional garden landscapes still faces challenges, including a lack of unified guidance frameworks and government level norms. In addition, the high cost of technological equipment and the lack of interdisciplinary knowledge have constrained the development of professional talents and the growth of digital design demand.

Three dimensional reconstruction (3DR) is the process of restoring the 3D information of objects in a visual scene through 2D image data or 3D point cloud data (3D-PCD). One type of technology is based on 2D image data, using multiple captured image sequences to construct a color 3D model through feature point matching technology. Another type is based on 3D-PCD, which processes data from multiple collection points and reproduces physical objects through noise reduction, integration, and simulation processes [9]. Researchers such as Xu proposed the use of Hermite radial basis function algorithm combined with RGBD camera, and introduced curvature estimation and confidence score methods to address the common problems of cumulative error and reconstruction distortion in the field of 3D model reconstruction. This method effectively reduced the impact of noise and optimized the results of 3DR [10]. Zhang et al. proposed a 3DR method for motion blurred images using deep learning. This algorithm combined

bilateral filtering denoising theory with Wasserstein generated adversarial networks to remove motion blur, and used the deblurred images generated by this algorithm for 3D reconstruction. This algorithm has been proven to have better deblurring effects and higher efficiency than other representative algorithms [11].

Although many techniques and methods have been proposed in the existing landscape design research, there are still some deficiencies. First, the modeling technique of Steer et al., linear flow power equation models, may lack flexibility in the dissemination of terrain change information. The sound element design method studied by Luo Ma et al. is only applied in noise management, and its effect on improving landscape immersion is limited. The flow design method proposed by Wang et al. is difficult to accurately simulate complex landscape flow in practical applications. In addition, most of these researches focus on the technical application, and the in-depth research on the design method and logic is still insufficient, and the application in practice is limited. In this paper, an accurate point cloud registration algorithm combining normal distribution transformation and trimmed iteration nearest point algorithm is proposed. The color texture method of 3D model is designed from the perspective of 3D reconstruction, and a 3D reconstruction method of visual scene based on RGBD data is constructed. Knowledge network is introduced to assist the intelligent generation and planning of plant communities in urban landscape scenes. The knowledge network established by plant database integrates the principles of landscape design and optimizes the layout of landscape plants in urban parks. It only enhances the aesthetics of the plant selection and layout, is more in tune with the actual landscape, and also follows the principles of eco-friendly design. This study aims to overcome the limitations of traditional design methods, optimize landscape design process by using digital technology and 3D image reconstruction technology, and improve design quality and efficiency. Enhance the aesthetics and coordination of the design by introducing intelligent plant community generation and planning.

This study is divided into five sections. Section I outlines the importance of landscape design and its benefits to human health, introduces the application of digital technology in landscape design and the criticality of 3D reconstruction technology. In Section II, a 3D reconstruction technique based on RGBD data (3DIR) and an improved Poisson surface reconstruction algorithm are described in detail. A method to generate 3D color model based on RGB information is proposed, which is optimized globally by the inner heuristic algorithm and the outer particle swarm optimization algorithm. Section III verifies the effectiveness of the algorithm through experiments, and shows its advantages in registration accuracy and running speed. Section IV and Section V emphasize the importance of DLD methods in improving design efficiency and visualization level, and proposes future research directions for combining deep learning algorithms to improve existing algorithms.

II. METHODS AND MATERIALS

A. 3DR Method for Visual Scenes Based on RGBD Data

3DIR technology plays a crucial role in landscape design. To obtain a complete 3D scene, it is necessary to address the issue

of limited viewing angles caused by a single Azure Kinect DK camera [12]. For this purpose, point cloud registration (PCR) technology can be used to integrate multiple scanned point cloud data. For 3DIR in landscape design, voxel grid downsampling is a more suitable choice, as it can effectively reduce data volume while preserving the overall geometric structure of the scene [13]. For the rough position between two frames of point cloud data, this study adopts a method based on point features to describe local features. The sample consistency initial alignment (SAC-IA) algorithm is a coarse registration method based on point cloud feature description. The algorithm steps are as follows: The first is to select some sampling points from point clouds P and Q , and use the feature description algorithm to perform feature analysis on these points, ensuring that the distance between sampling points exceeds the predetermined minimum value. Afterwards, to find the points in Q that match the features of P , forming a matching point pair P_c . Calculating the rotation and translation matrices of P_c through singular value decomposition (SVD), and then calculating the distance error between registered points. The registration performance is evaluated through the Huber loss function, and the calculation process is Eq. (1).

$$\begin{cases} H(l_i) = \begin{cases} \frac{1}{2}l_i, \|l_i\| < \delta_i \\ \frac{1}{2}\delta_i(2\|l_i\| - \delta_i), \|l_i\| > \delta_i \end{cases} \\ H_i = \sum_{i=1}^n H\|l_i\| \end{cases} \quad (1)$$

In Eq. (1), $H_i = \sum_{i=1}^n H\|l_i\|$. δ represents a pre-set value.

l_i represents the distance difference after the rotation and translation transformation of the corresponding point in Group i . By repeatedly matching sampling points and iteratively calculating, the rigid body transformation matrix that causes the minimum distance error is found. The optimal matrix represents the preliminary PCR results. Due to the SAC-IA algorithm reducing the point cloud resolution before feature calculation, some feature information is lost, making it more suitable for rough registration. Afterwards, to perform precise registration on the point cloud. Iterative closest point (ICP) algorithm and its improved algorithms are currently the most classic point cloud accurate registration algorithms. The Trimmed ICP algorithm is an improved algorithm based on ICP that uses minimum truncated multiplication to eliminate excessive distances [14]. The step is to first determine the nearest neighbor point q_i in the baseline point cloud Q for each point p_i in point cloud P , and calculate its distance squared d_i^2 . These distances are sorted in ascending order, and the first N points are selected to form a subset P_s , then the sum of the squared distances S of this subset is calculated. The number of reserved points is determined based on the number N_p of the point cloud to be registered. The process is given in Eq. (2).

$$N = kN_p \quad (2)$$

Using the SVD method to solve the set of reserved points obtained from the calculation, the point cloud rotation translation matrix is obtained, as shown in Eq. (3).

$$(R, T) = \arg \min \sum_{i=1}^N \|q_i - (Rp_i + T)\| \quad (3)$$

After applying the rotation matrix to transform the registration point cloud P , it is necessary to re estimate the corresponding point relationship with the reference point cloud

Q . The iterative process continues until the number of iterations exceeds the preset limit, and the mean square error $\frac{S}{N}$ value of the point pairs drops below the set threshold, or when the similarity between the results of two consecutive iterations is extremely high, the final registration result can be obtained. The normal distribution transform (NDT) algorithm is a high registration accuracy and fast computational speed PCR [15-16]. To achieve better registration results, it is combined with the Trimmed ICP algorithm. The improved PCR steps are shown in Fig. 1.

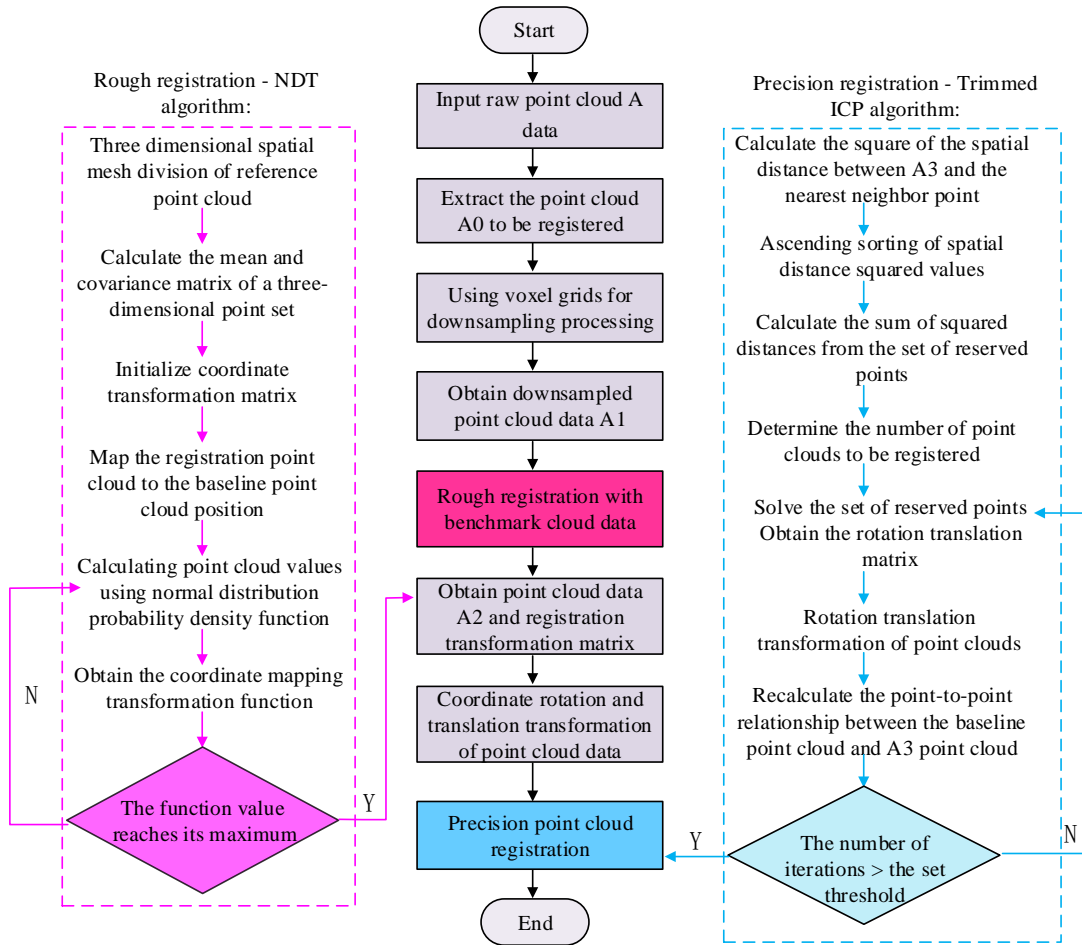

Fig. 1. Point cloud registration process.

In Fig. 1, PCR first speeds up registration by reducing the amount of data in point cloud P , and uses voxel grid downsampling algorithm to obtain simplified point cloud \hat{P}_0 . Preliminary to use the NDT algorithm to complete rough registration of \hat{P}_0 and benchmark point cloud Q , obtaining transformation matrix M_1 and registered point cloud \hat{P}_1 . Applying M_1 to transform the original point cloud P again to obtain a rough alignment point cloud P_1 . Finally, the Trimmed ICP algorithm is used to finely adjust the registration

of \hat{P}_1 and Q , obtaining the final accurate registration point cloud \hat{P}_2 and its corresponding rotation translation matrix M_2 . Point cloud 3DR is the process of generating a 3D surface mesh model based on the target point cloud obtained through algorithmic processing. 3D surface reconstruction techniques can be divided into two types: triangulation based mesh and surface fitting. The surface fitting algorithm generates a model close to the solid surface through function solving, which is insensitive to noise. The advantage of Poisson's algorithm lies in its ability to resist noise, producing clear contours and strong closure of the model. The steps for reconstructing Poisson's surface are shown in Fig. 2.

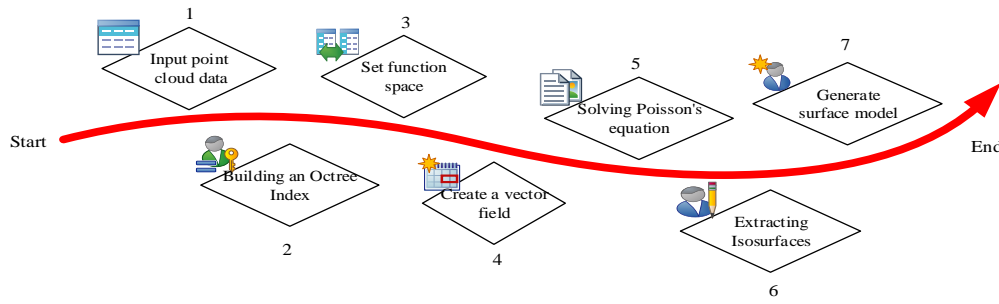

Fig. 2. Poisson surface reconstruction steps.

The original Poisson reconstruction algorithm is susceptible to errors, resulting in hidden function shifts. Someone proposed a masked Poisson surface reconstruction algorithm based on the original Poisson reconstruction algorithm. The improved method introduces a penalty function to limit offset and assigns weight ω to each point in point cloud P . The improved Poisson equation $E(\chi)$ can be represented by Eq. (4).

$$E(\chi) = \int \left\| \vec{V}(q) - \nabla \chi(q) \right\|^2 dp + \frac{\alpha S(P)}{\sum_{q \in P} \omega(q)} \sum_{q \in P} \omega(q) \chi^2(q) \quad (4)$$

In Eq. (4), $\vec{V}(q)$ represents the vector field. $\chi(q)$ represents the indicator function. $\omega(q)$ represents the weight of the sample, with a value of 1. α represents the equilibrium coefficient. $S(P)$ represents the surface area after reconstruction. To minimize Eq. (4) and define an operator to represent it as a masked Poisson equation. The calculation process is Eq. (5).

$$(\Delta - \alpha_s \oplus) \chi = \nabla \cdot \vec{V} \quad (5)$$

To solve the Poisson equation, the algorithm uses discretization methods to construct a linear equation system $Ax = b$ and apply zero constraint conditions at the sample points, and solves the coefficients to obtain matrix A . The cascaded multigrid method is used to optimize the solution process, adjusting weights at different depths d to maintain surface morphology and refine estimation. The scale invariance of the reconstruction effect is achieved by scaling the point set, adjusting functions $E_v(\tilde{\chi})$ and $E_{\omega, p}(\tilde{\chi})$, and redefining weight values $\tilde{\omega}(p)$. The new set of points can be represented as $(\tilde{\omega}, \tilde{P})$, and the function is Eq. (6).

$$\begin{cases} E_v(\tilde{\chi}) = \int \left\| \vec{V}(q) - \nabla \chi(q) \right\|^2 dp = \frac{1}{2} E_v(\chi) \\ E_{\omega, p}(\tilde{\chi}) = \frac{\alpha_s S(P)}{\sum_{q \in P} \omega(q)} \sum_{q \in P} \omega(q) \chi^2(q) = \frac{1}{4} E_{\omega, p}(\chi) \end{cases} \quad (6)$$

In addition, the algorithm optimized the handling of boundary conditions, extending Dirichlet boundary conditions to Neumann boundary conditions. This reduces constraints when data is missing, as long as the derivative of the boundary is zero [17]. To enhance the realism of point cloud based 3D models, in addition to shape reconstruction, this study further integrates RGB information to generate 3D color models. In the process of constructing a 3D model of a point cloud, the 3D surface reconstruction algorithm can only establish an object surface model lacking texture details based on the spatial features of the point cloud data. The steps to build this model are as follows: first, to perform normal vector calculation on the original color point cloud data P . The normal vector of a point cloud is generally solved using principal component analysis algorithm, which establishes a covariance matrix C based on the neighboring points within a certain range of 3D point p_0 and solves for its eigenvectors, as shown in Eq. (7).

$$\begin{cases} C = \frac{1}{k} \sum_{i=1}^k (p_i - p_0) \cdot (p_i - p_0)^T \\ C \cdot \vec{v} = \lambda \cdot \vec{v} \end{cases} \quad (7)$$

In Eq. (7), k represents the number of nearest neighbors within the neighborhood range of 3D point p_0 . The collected color point cloud data containing only XYZRGB information needs to be accompanied by a normal vector to form a dataset with the XYZRGB Normal attribute. By constructing a Kd Tree index for these data, point cloud color mapping can be performed. At this point, for each point on the surface of the model, to use Kd Tree to search for nearby point cloud data points, take the average of their RGB values, and assign the corresponding color texture to the model. In this way, each point can be mapped to generate a 3D surface model with colored textures.

B. DLD of Landscape Architecture Based on 3DIR

The innovation of digital technology has produced new design languages and construction techniques, while bringing innovative structures and forms of expression to traditional landscape design [18]. Knowledge driven and landscape design are closely linked, guiding and promoting the design and implementation of landscape projects through the application of multidisciplinary knowledge and technology. Therefore, this study combines 3DIR technology and uses knowledge networks as the core driver to intelligently generate landscape plant communities in the scene and carry out corresponding planning and layout. Fig. 3 shows the overall framework of DLD.

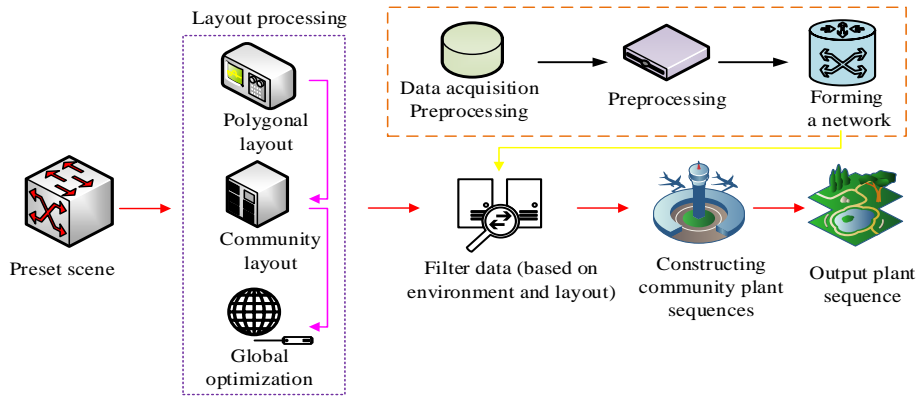

Fig. 3. Digital landscape design model.

The process of DLD in Fig. 3 mainly consists of three steps, which are to build a plant knowledge network, then layout the group within the scene, and finally construct the composition sequence of the community. All three are designed based on data to form a cohesive whole. In terms of data acquisition, most sources come from literature, networks, etc. Data related to landscape plants were collected, which provided fundamental support for this study. Knowledge graphs can provide practical and valuable disciplinary information [19]. Therefore, this study uses knowledge graphs based on undirected graph models to represent landscape plant data. The proposed landscape layout adopts a double-layer optimization strategy: the inner layer uses heuristic algorithms for polygon planning, and the outer layer uses particle swarm optimization (PSO) for global optimization [20]. The inner algorithm is responsible for the preliminary layout design, while the outer algorithm further refines and enhances the design scheme. Among them, heuristic algorithms use simple polygons for layout and find the optimal position within a matrix scene $M = (X, Y)$. Set $P = (P_1, P_2, \dots, P_m)$ includes polygons, and $\Omega = \{\Omega_1, \Omega_2, \dots, \Omega_m\}$ contains all possible rotation angles. Scene M has a center point O and marks different areas. Grassland $A = (\sigma_1)$ is a layout area, while buildings, water bodies, and roads $B = (\sigma_2, \sigma_3, \sigma_4)$ are non layout areas. Given a polygon P_i and a translation vector $v = (v_x, v_y)$, to denote $p = (p_x, p_y)$ as the current position of polygon P . The translation function of a polygon is defined in Eq. (8).

$$P_i \oplus v = \left\{ (p_x + v_x, p_y + v_y) \mid p = (p_x, p_y) \in P_i, x \in X, y \in Y \right\} \quad (8)$$

If the center of the polygon is represented as P_i , and its state is only determined by its center g_i and rotation angle a_i , then the current polygon calculation formula is Eq. (9).

$$P_i(a_i) = \left\{ \begin{array}{l} g_{ix} + (p_x - g_{ix}) \cos(a_i) - (p_x - g_{ix}) \sin(a_i), g_{ix} \\ + (p_x - g_{ix}) \sin(a_i) + (p_x - g_{ix}) \cos(a_i) \end{array} \right\} \mid p \in P_i, a \in \Omega \quad (9)$$

The unit layout area will be traversed outward from the center of the scene in a circular hierarchical manner, and the

current unit layout area is scored using a scoring function $F = \{f_1, f_2, \dots, f_k\}$, as shown in Eq. (10).

$$\begin{cases} f_1(P_i(a_i)) = |P_i(a_i)| \times \omega_1 \\ f_2(P_i(a_i)) = |P_i(a_i)| p \in A \times \omega_2 \\ f_3(P_i(a_i)) = |P_i(a_i)| p \in B \times \omega_3 \\ f_4(P_i(a_i)) = |P_i(a_i)| p \in (P - P_i) \times \omega_4 \\ f_5(P_i(a_i)) = |P_i(a_i)| p \notin (P - P_i), p + d \in (P - P_i) \times \omega_5 \end{cases} \quad (10)$$

In Eq. (10), $\omega_1, \omega_2, \dots, \omega_k$ ($-\infty < \omega < +\infty$) represents the weight of different scoring factors, which depends on the distribution of layout and non layout spaces within the scene. If condition $mscore = \max \{P_{1score}, P_{2score}, \dots, P_{nscore}\}$ is met, the polygon is allowed to be positioned in the corresponding region $P_i(a_i) \rightarrow M$. Each polygon records its number, type, area, and coordinate information. The layout of plant landscape in landscape design is its core, and the diversity of plant species constitutes its structure. The composition of the community affects the appearance and changes of the landscape, and plants need to be arranged in a polygonal manner, divided into tree, shrub, mixed or blank types. The combination layout of plants is crucial for landscape features, and it is necessary to carefully plan the distribution of plants in the polygon, including the mixed planting forms of different plants. Fig. 4 shows the distribution of some plant communities and their probability of occurrence within the polygon.

Fig. 4. Distribution of plant communities and their probability of occurrence within the polygon.

In Fig. 4, there are three main requirements for the local layout of the garden landscape. The primary rule is to ensure that the canopy of the trees does not obstruct each other. Secondly, the canopy of shrubs should be independent of each other to ensure that the canopy of shrubs and trees does not intersect. Plants within the same polygon form the same community and inherit polygon parameters from the community. These parameters include the number, type, total area, coordinates, and plant features of the polygons. The plant characteristics provide a detailed description of the number, location, canopy area, building area, and category of trees and shrubs. The polygon layout algorithm effectively arranges plant communities, but if the layout is too neat, it may lack natural beauty. Modern design tends to combine norms with nature to present order and natural beauty. By analyzing the forms of plant space creation, this study proposes the following rules: a single plant is defined as T , the types of trees and shrubs are T_{type} , and the crown coverage area is $C = T_{type}$. The plant community is defined as $G = \{T_1, T_1, \dots, T_n\}$, and the polygon is defined as $B = \{G_1, G_2, \dots, G_m\}$. All non-repeating plants are randomly selected and their scores are calculated using Eq. (11).

$$T_{isore} = \sum_{j=1}^k q_j(T_i), q \in Q \quad (11)$$

The optimal sequence of plants found based on the scoring function is Eq. (12).

$$\min SEQ(T) = \min \sum_m \sum_{i=1}^n \sum_{j=1}^k q_j(T_i), q \in Q, T \in G \quad (12)$$

After optimizing the global layout algorithm, plant information, including numbers and parameters, is extracted from the polygon, which serves as the community identifier. These information are included in the plant list, and then suitable

plant species are selected in the knowledge network based on specific conditions. Screening involves distribution range, adaptability, and lighting requirements to preliminarily determine candidate species, and then further screen using geographic information and environmental conditions to form plant collection B_s . At the same time, filtering the community database to form a set G_s . The species of plants in set G_s become set B_s . By comparing the set, the final plant candidate set $B_{sg} = B_s \cup B_g$ is formed, and the community set is updated to G_{sg} . The selected community is evaluated based on plant adaptability, cost, and environmental impact, but the community set G_{sg} is not simplified to maintain species diversity. After adjusting the diversity based on the available planting area, a final selection set Q is formed. The community configuration is assigned to plants from set Q , sharing numbers, rather than increasing the average score of selected communities. After the layout is completed, the herbaceous classification within the community is arranged independently and serves as a supplement at the end of the list. This study uses PSO to conduct global optimization on the basis of building a complete plant community. The performance evaluation process of digital design methods for landscape architecture is Eq. (13).

$$S = \lambda_1 \sqrt{\frac{\sum_{i=1}^n (q_i(T) - \overline{q_i(T)})^2}{n-1}} + \lambda_2 \sqrt{\frac{\sum_{i=1}^n (f_i(P(a)) - \overline{f_i(P(a))})^2}{n-1}} \quad (13)$$

In Eq. (13), both λ_1 and λ_2 will set corresponding values. The design and implementation of the prototype system are completed by packaging the proposed model, standardizing its input and output, and generating AutoCAD exchange files and executable files for the prototype system. The overall architecture of the model is Fig. 5.

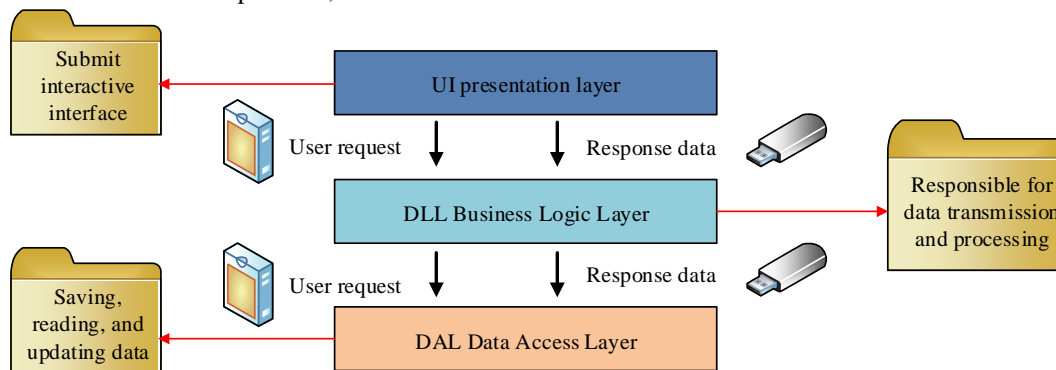

Fig. 5. Digital landscape architecture design model.

In Fig. 5, the presentation layer handles the user interface and interaction, including displaying data and receiving input. The business logic layer is responsible for verifying input parameters, ensuring the stable operation of the program, and performing operations such as data queries and updates. This includes checking for empty text, file path issues, and input legality. The data access layer is responsible for communicating with the database, performing data addition, deletion, modification, and querying operations, and the data objects

should only be referenced in this layer to avoid direct data manipulation by other layers.

III. RESULTS

A. 3DR Experimental Analysis of Visual Scenes Based on RGBD Data

To verify the effectiveness of the proposed algorithm, experiments are conducted to compare combination of SAC-IA

or NDT coarse registration and ICP fine registration algorithms based on FPFH, 3DSC, SHOT features. Experiment is performed on i5-9300H CPU Windows 10 system using the environment of Visual Studio 2019 and PCL 1.11.0 library. The Stanford University's Bunny point cloud (BPC) and visual scene

point cloud (VSPC) are collected as the dataset. Table I shows the experimental parameters.

PCR experiments are conducted based on the point cloud parameter settings in Table I, and the experimental results are shown in Fig. 6.

TABLE I. EXPERIMENTAL PARAMETER SETTINGS

Experimental project	Parameter	Experimental project (NDT)	Parameter
Leaf nodes (BPC data)	0.01	Minimum Conversion Difference (BPC Data)	0.0001
Leaf nodes (VSPC data)	100	Minimum Conversion Difference (VSPC Data)	1
Search radius (BPC data)	0.05	Parameter Step Size (BPC Data)	0.25
Search radius (VSPC data)	500	Parameter Step Size (VSPC Data)	500
Search radius (feature description algorithm)	0.5、 1000	Resolution parameter value	0.5、 900
Point cloud overlap parameter value (Trimmed ICP)	95%	Maximum number of iterations (NDT, ICP)	50、 20

Fig. 6. Registration results of various algorithms.

In Fig. 6, the proposed PCR algorithm and several comparison algorithms can effectively cover the blue point cloud to be registered onto the reference purple point cloud. The SAC-IA algorithm and NDT algorithm have similar registration effects, but compared to the fusion of ICP and NDT registration, the research algorithm is more accurate and shows stronger robustness. The registration running time of each algorithm and the RMSE values of the registered point cloud in various directions are shown in Fig. 7.

In Fig. 7, the research algorithm outperforms other algorithms in terms of running speed and registration accuracy. In algorithms based on local features, the registration of FPFH feature descriptions leads in efficiency and accuracy, while the 3DSC algorithm takes the longest time, several times that of other methods. The NDT algorithm based on statistical probability reduces the running time by at least 69% compared to local feature methods. Fig. 8 shows the comparison results of quantitative indicators based on self-collected point cloud (SCPC) data.

In Fig. 8, in the testing of the Bunny dataset, the root mean square error of the NDT algorithm is lower than that of the algorithm based on local features. On SCPC data, NDT performs poorly, possibly due to a decrease in accuracy caused by the distribution of the data in 3D space. The research algorithm performs better than the NDT algorithm combined with ICP on both types of data, reducing registration time and improving

accuracy. Compared with the fusion of ICP and NDT, the registration time of the research algorithm was reduced by 2%, and the RMSE was reduced by 71.4% and 87.5%, respectively, demonstrating good robustness and high registration accuracy. Fig. 9 shows the evaluation index results of each algorithm.

In Fig. 9, compared with the surface fitting based method, the 3D surface reconstruction technique based on mesh triangulation performs poorly. The greedy projection triangulation (GPT) algorithm is lower in key performance indicators than Poisson reconstruction and masked Poisson reconstruction algorithms, with differences of up to 0.010203, 0.000701, and 0.001874, respectively. GPT outperforms the rolling ball algorithm in RMS metrics, reducing by 38.1% and demonstrating better repair performance. In addition, the shielded Poisson algorithm exhibits higher model quality compared to traditional Poisson algorithms.

B. DLD Experimental Analysis

The experiment utilized Rhino software and visual scene 3DR based on RGBD data to construct parameter logic and establish a parameterized analysis model. It selected real garden image data and applied the technology studied to distinguish natural and artificial landscape elements, such as plants and architecture, for instance design. The evaluation indicators for landscape design include panoramic quality, design aesthetics, ease of technical implementation, cultural significance, and urban characteristics. Fig. 10 shows the evaluation of the DLD effect of 3DIR technology.

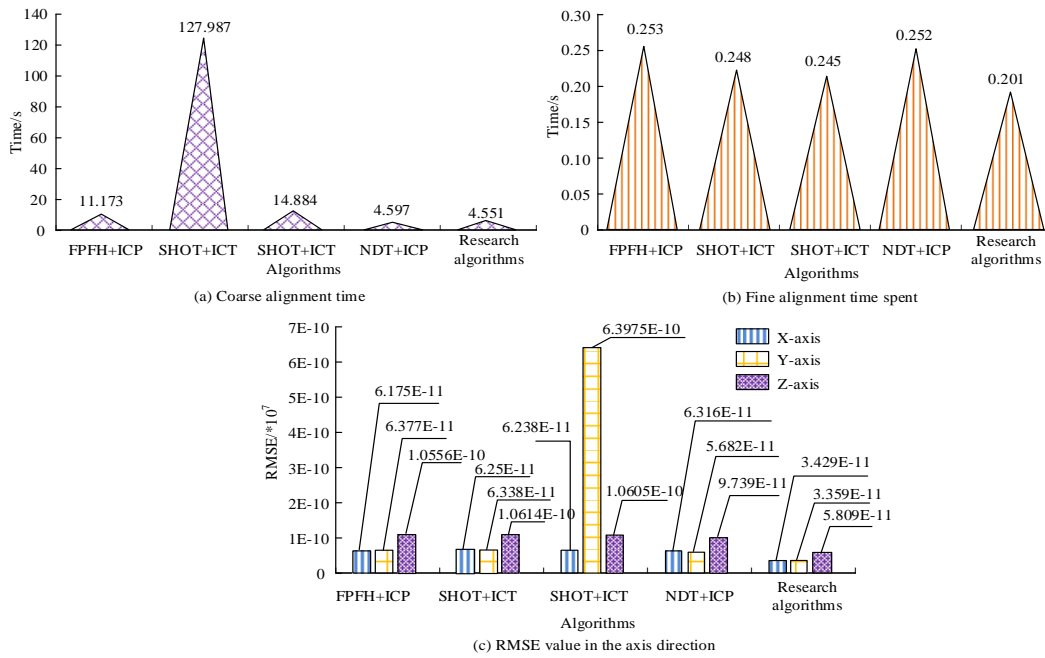

Fig. 7. Comparison of quantitative indicators based on bunny point cloud data.

Fig. 8. Comparison of quantitative indicators based on scpc data.

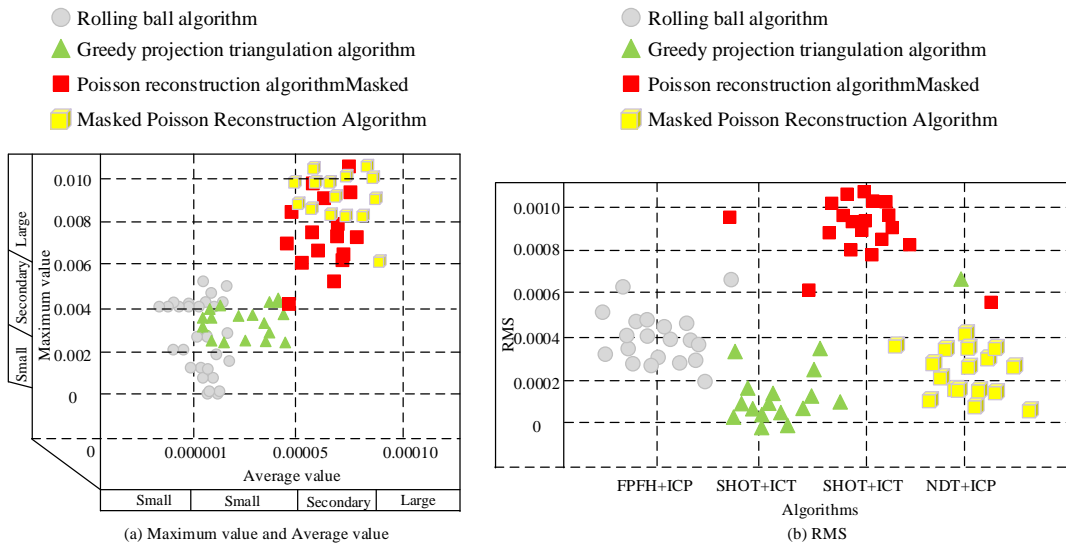

Fig. 9. Evaluation index results of each algorithm.

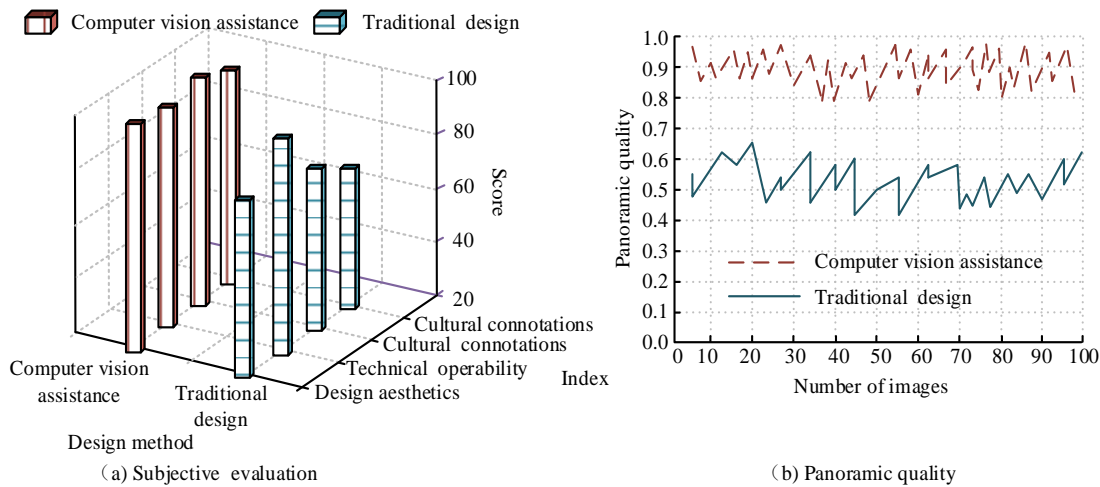

Fig. 10. The design effect of DLD based on 3DIR.

In Fig. 10 (a), the DLD combined with 3DIR technology performs well on a series of subjective evaluation indicators, with all indicators superior to traditional landscape design methods except for technical operability indicators. In Fig. 10 (b), among 100 design samples, the panoramic quality of the research method fluctuates within a small range of 0.8 or above. The stability of panoramic quality in traditional methods is poor, ranging from 0.4 to 0.7. Moreover, the panoramic quality value is relatively low, and the design quality fluctuates continuously with the level of manual design. Fig. 11 shows the performance comparison between the research method and other algorithms.

In Fig. 11, the AUC value of the study method is very close to 0.9, which means that its performance is excellent. Although CNN-GAN performed well in the early stage, the overall curve is not as steep as the study method, and the AUC value should be slightly lower than the study method. It can be inferred from the curve shape that the AUC value of PSO is significantly lower than that of the research method and CNN-GAN, which means that its classification effect is poor. Compared with the other two methods, the performance of the research method is very stable in the whole range. Fig. 12 shows the display of DLD results.

design, especially in vegetation selection and layout. The research algorithm not only follows the principles of eco-friendly design, but also enhances the aesthetics of plants in the context of urban landscaping, achieving a visual effect of harmonious coexistence between humans and nature.

Fig. 12. Display of DLD achievements.

IV. DISCUSSION

Compared with the modeling technique of Steer et al. [6], the research method is more accurate in dealing with landscape design details, and high-precision 3D reconstruction is achieved through improved point cloud registration and Poisson reconstruction techniques. Studies have shown that this method is superior to Luo Ma L et al. [7] in reconstruction details and to Wang et al. [8] in landscape flow design in overall design performance. Compared with the traditional ICP and NDT methods, the registration time of the proposed algorithm is reduced by 2%, and the error is reduced by 71.4% and 87.5%, respectively. In Bunny point cloud and SCPC data testing, the root mean square error (RMSE) is lower than that of traditional methods, and the run time is significantly reduced. The digital landscape design method based on 3DIR technology has excellent performance in the subjective evaluation indicators such as panoramic quality, design beauty, technical realization difficulty, cultural significance and urban characteristics, and its stability is higher than that of traditional design methods. The resulting landscape design is more aesthetically pleasing and coordinated in plant selection and layout, and intelligent and ecologically friendly plant community layout is assisted by

Fig. 11. Convergence process of objective functions of the three algorithms.

Fig. 12 shows the effectiveness of the classic iterative optimization intelligent landscape design algorithm, which generates scenes that are highly consistent with real landscape

knowledge networks. The dual optimization strategy, which combines heuristic algorithm and particle swarm optimization, takes into account the beauty and functionality of landscape design. In conclusion, this method has significant advantages and application potential in 3D reconstruction and landscape design.

V. CONCLUSION

To improve the efficiency and visualization level of landscape design, and to help designers quickly and accurately convert elements such as terrain, vegetation, and water in the real world into digital models, this study adopted the concept of DLD to analyze landscape architecture and digital design. Based on the current difficulties in landscape planning and design, a DLD method based on 3DIR technology was proposed. The results show that the proposed algorithm is superior to other algorithms in terms of running speed and registration accuracy. Statistical probability-based NDT algorithms have at least 69% shorter run times than local feature algorithms and lower RMSE on rabbit datasets. Compared with the method combining ICP and NDT, the registration time was reduced by 2% and RMSE was reduced by 71.4% and 87.5%, respectively. The shielded Poisson algorithm is superior to the traditional Poisson algorithm in terms of model quality. The panoramic quality of the research method is stable at 0.8 or above, while the panoramic quality of the traditional design method fluctuates between 0.4 and 0.7 and is low. The scene generated by the research method is highly consistent with the actual landscape design, especially in vegetation selection and layout. In the future, deep learning algorithms will be integrated to improve and innovate traditional algorithms while ensuring PCR rate and registration accuracy.

Software Systems Documentation: A Systematic Review

Abdullah A H Alzahrani

Department of Computers-Engineering and Computing College at Alqunfuda,
Umm Al Qura University, Makkah, Saudi Arabia

Abstract—In the domain of software engineering, software documentation encompasses the methodical creation and management of artifacts describing software systems. Traditionally linked to software maintenance, its significance extends throughout the entire software development lifecycle. While often regarded as a quintessential indicator of software quality, the perception of documentation as a time-consuming and arduous task frequently leads to its neglect or obsolescence. This research presents a systematic review of the past decade's literature on software documentation to identify trends and challenges. Employing a rigorous systematic methodology, the study yielded 29 primary studies and a collection of related works. Analysis of these studies revealed two primary themes: issues and best practices, and models and tools. Findings indicate a notable research gap in the area of software documentation. Furthermore, the study underscores several critical challenges, including a dearth of automated tools, immature documentation models, and an insufficient emphasis on forward-looking documentation.

Keywords—Software engineering; software systems documentation; software maintenance; software quality; software development

I. INTRODUCTION

Software documentation can be defined as the journey of producing different types of documentation. These types vary in their purposes from describing the development processes to describing the final product to the intended user. It is believed that software engineers should have the responsibility of software documentation, however, professionals in technical writing are sometimes needed [1], [2], [3], [4].

In the past 10 years, software documentation has been an interest in the industry of software engineering. However, majority of documenters are whether technicians or peoples trained in humanity. Therefore, the need for more professionals in the software documentation had emerged [5].

Many benefits can be accrued from good software documentation such as decreased costs of maintenance [6], [7], [8], [9], [10]. However, achieving a well-formed software documentation might be challenging. One challenge in software documentation is that developers abhor being involved in software documentation. In addition, some believe that poor software documentation is worse than no documentation. Furthermore, lack of professionals in the software documentation is considered to be another challenge [5], [11].

Software documentations principles are to be considered during software documentation. These principles are the level of details, document purpose and intended readers, use of graphical aids, clarity and precision, language of document, and documents versions. Therefore, in order to acquire a well-written software documentation, it is important to pay attention to, first, the purpose of the documents and the intended audience. This will lead to choosing the appropriate language, level of details, and graphical aids. However, in order to keep the documentation alive, updating documents with use of versions management are essential [6], [11], [12], [13], [14].

Several types of software documents are generated in the process of software documentation. These types diverse based of their purposes and intended readers. However, these types fall in one of the following categories. The first category is the documentation of the process of software development. This includes documentation of requirements, planning, implementation and other documents during the development journey. The intended readers for this category of documents are the developer, software, decision makers, and the maintainers. The second category is the documentation of the product after delivery. This category includes the documents that describe the product for intended users. Examples of this category are User manuals and system main structure documents [1], [2], [3], [5], [6], [8], [11], [14].

Many techniques and tools are employed for software documentation. In general Waterfall technique and Iterative technique are the most dominant techniques for software documentations. However, for the tools that are used for the documentation, many have stated a variety of tools such as MS Word XML and other Text Editors, Doxygen, Visio, FrameMaker, Author-IT, Doc++, Rational Rose, JUnit and other tools. Some of these tools aid in automation of documentation to some extents [15], [16], [17], [18], [19].

The importance of this study derived from the need to achieve solutions that overcome the unsolved problem of poor or absent software documentation as this issue remains unsolved. Software documentation improves the quality of software systems and consequently improves maintainability and cost efficiency. Furthermore, drawing more attention to the topic of software documentation would enhance documentations models as well as templates employed, which relatively enhance automation of software documentation.

This paper has been structured as follows. Section I introduced the topic software systems documentation. In addition, it highlights the importance of systematic review on

the considered topic. Section II illustrates the methodology which has been employed in this paper and formulated the research question. In addition, the main findings statistically shown and discussed. Section III has been divided into two subsections. The first subsection concludes the discussion on the findings and demonstrates the trends in the software documentation publications. The second subsection reviews and discusses the primary studies found in this research and categorizes them into two categories. Finally, Section IV draws conclusions on this research.

II. METHODOLOGY

Budgen et al. and Kitchenham [20], [21] have described a systematic review methodology which this study applies. The methodology enables conducting the reviews objectively and structurally. Furthermore, the methodology allows demonstration of broader picture of the topic of software documentation by categorizing the results into primary and related to the topic under consideration.

1) *Research question:* What are the unveiled trends and issues in relation to software documentation in the last 10 years?

The above research question can be responded to by first exploring the software documentation topic, then, investigating the existing techniques and tools which are employed. Consequentially, issues and difficulties will be highlighted and identified. Therefore, the keywords leading the search in the well-known databases have been enumerated. These keywords are software system documentation - software documentation - system documentation - automated documentation - software knowledge documentation - computer software documentation - software engineering documentation.

2) *Sources selection:* Bearing in mind the aforementioned keywords, a search query has been formulated as shown in Table I. An OR logical operator has been used in order to combine results that are related to the search. In addition, to narrow the range of the results, double quotation marks (“”) have been applied to surround the keywords.

TABLE I. SEARCH QUERY

Search query	“software system documentation” OR “software documentation” OR “system documentation” OR “automated documentation” OR “software knowledge documentation” OR “computer software documentation” OR “software engineering documentation”
---------------------	---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

After formulating the Search query, it has been entered to The Saudi Digital Library (SDL) [22] search engine. SDL is an online digital library resource that allows searching in many well-known digital libraries such as Springer, IEEE Digital Library, ACM Digital Library, SAGE, ScienceDirect, and other publishers. Different types of research items can be found; however, the results were grouped into four main categories. The first category is Conference Paper. Second category is Journal papers which include journal Article, Case Study papers, and Review Papers. Third category is Books which include books, handbooks, Thesis, and technical reports. Fourth category is Others which include else results.

This paper’s goal is to investigate the topic of software documentation in the past 10 years, so, an exclusion criterion of year of publication has been applied and configured to include work which has been done between the years 2014 and 2024. In addition, another exclusion criterion was the language of publication as non-English publications have been eliminated during the search process by configuring the search engine to exclude them before displaying the results from the digital libraries. Finally, inclusion criterion relies on the analysis of several aspects in found results. These aspects are title, keywords, abstract, and conclusion. So, the analysis is the process of manually reading deciding for publications to be considered relevant or not.

Table II illustrates the results of the searching process. It is clear in the table that the first results after applying the query string was total of 7482 publications found in different source. However, this number includes the repeated items and the flawed entries of the items. Therefore, it was necessary to accurate the results by eliminating those items. Consequently, the total number of publications declined to be 3453 items.

Inclusion criterion was then applied manually to determine the relevance of remaining items by scanning the keywords, abstracts, and conclusions. The process resulted in eliminating more items. A total of 1654 items are the relevant items to be investigated and studied in order determine the results of primary studies to the topic of software documentation.

TABLE II. NUMBER OF PUBLICATIONS FOUND FROM DIFFERENT SOURCES

Sources	Publication					
	Search date	Found	Not repeated	Relevant	Primary	%
Springer Link	3 Jan 2024	612	411	378	0	0%
IEEE Digital Library	3 Jan 2024	125	82	65	5	17%
ACM Digital Library	3 Jan 2024	41	34	12	6	21%
SAGE	3 Jan 2024	248	188	90	0	0%
ScienceDirect	3 Jan 2024	41	39	21	0	0%
Other Publishers	3 Jan 2024	6415	2699	1088	18	62%
Total		7,482	3453	1654	29	100%

It can be seen in Fig. 1 that relevant found publications to the topic of software documentation are divided into six categories. The categories are based on the reputation of the publisher. Therefore, five categories are designated to leading and well-known publishers which are Springer, IEEE, ACM, SAGE, and ScienceDirect. All other publishers have been considered in one category as “other publishers”.

Fig. 1 illustrates 66% of the relevant found publications to the topic of software documentation are from other publishers which have less reputation than the leading publishers. However, 23% of relevant found publications are from Springer. Having this in mind, 378 relevant publications to the

topic of software documentation for the last 10 years in a well-known publisher such as Springer are not a considerable number of publications. This might raise a question on the reasons behind the low number of publications in the topic of software documentation in such leading and well-known publishers.

Fig. 1. Relevant studies from different publishers.

With regards to the primary studies shown in Table II, they are the studies that are major in the topic of software documentation. A complete list is included in Appendix A. These studies are identified to be primary after a manual excessive analysis and in depth reading of the relevant studies. The main criterion to identify the primary studies is the goal of the research. In particular, if the relevant study is offering a new model, approach, solution, explanation, case study, comparison, or/and review, then that relevant study is considered to be a primary study to the topic of software documentation.

III. RESULTS AND DISCUSSION

A. Trends in Software Documentation Publications

This section is to discuss the findings on the collected data and the analysis of results of the conducted reviews. The main finding is that the topic of software documentation has not been considered sufficiently for research in the past 10 years, especially by well-known and leading publishers. This can be seen clear form the results shown in the previous section.

Fig. 2 illustrates the publications of relevant studies to the topic of software documentation over the last 10 years. From Fig. 2, a growing interest can be noticed from the year of 2020 in the publication is a well-known publisher which is Springer. However, this interest in the topic of software documentation has remained unnoticed in publications of other well-known publishers.

Table III demonstrates the types of relevant publications found. Three main categories of publications which are conference papers, journal papers, and book. Regarding journal papers, this includes regular article papers, Case Study papers, Review Paper. On the other hand, Books category includes books, handbook, Technical Report, and Thesis. Finally, all other publication types were classified into “Others” category.

Fig. 2. Relevant studies from different publishers. Publications in the past 10 years on software documentations.

TABLE III. TYPES OF PUBLICATIONS OF RELEVANT STUDIES

Sources	Conference Paper	Journal Paper	Books	others	Total
Springer Link	3	348	1	26	378
IEEE Digital Library	25	10	0	30	65
ACM Digital Library	0	8	0	4	12
SAGE	0	38	51	1	90
ScienceDirect	0	12	0	9	21
Other Publishers	14	633	122	319	1088

Table III shows that the majority of relevant publications on software documentation are journal papers. Fig. 3 illustrates that around 63% of all relevant publications on the topic of software documentation over the past 10 years are journal papers. It is worth noting that from the leading and well-known publishers, SAGE has an outstanding interest on relevant books on the topic of software documentation.

Fig. 3. Types of relevant studies.

B. State of Arts Studies

This section discusses the primary studies found in the systematic review on software documentations. The studies have been classified into three main divisions shown in the following subsections which are: 1) software documentations reviews, issues, and best practices; 2) software documentation models and tools.

1) *Software documentations reviews, issues, and best practices*: Many have introduced best practices and required attributes of software documentation [15], [23], [24], [25], [26]. Other researchers [17], [18], [27], [28] have considered software documentation issues which might be addressed earlier, throughout, and/or afterwards the process of the software documentations.

Uddin et al. [15] have conducted two surveys based on their previous work [23] on Application Programming Interface (API) documentation. First, the authors designed a three-questions survey circulated among IBM Canada labs. The number of participants was 69 with the following job titles: developer, architect, tester, and consultant. Second, the authors designed a seven-questions survey circulated among developers and architects at IBM Canada and UK. This time, the number of participants was 254. The authors concluded that the API documentation suffers contents issues which are related to the fact that the engagement of experts is needed in the documentation of API.

Rai et al. [29] have conducted a review on the topic of source code documentation over last 10 years. The authors formed six research questions that were to be answered. These questions focused on the methodologies, tools, and evaluation means for source code documentation. In addition, the authors found that source code documentation has grown interest from researchers and automatic generation of source code documentation begins to use Deep Learning approaches instead of Information Retrieval approaches.

Lethbridge et al. [6] have published a study in order to gather best practices in software documentation. The authors conducted a study that includes surveying, interviewing, and observing software engineers. In addition, the authors investigate the tools used by these software engineers. The findings of the study can be summarized in the followings: 1) focus on requirements documentation and high-level documentation of the systems rather than complete and UpToDate documentation; 2) focus on simple and customized documentation rather than forcing the use of particular documentations methods or tools. This is to avoid time overhead and complexity.

Forward et al. [18] have investigated the tools and technologies used in software documentations. The authors divided software documentation into six types of documents namely requirements, specifications, detailed design, and low level design, architecture, and QA documents. The main findings can be summarized as follows: 1) software documents are important and useful even if they are obsolete; 2) tools for software documentations are needed to automate the process and should be chosen based on the nature of the software project.

Santos et al. [7] have conducted a review on software documentation in order to check the essential quality attributes in software documents. In addition, the authors reviewed the best practices for software documentation from 14 different publications in order to establish relations between the quality attributes and the best practices offered in those publications.

De Souza et al. [16] have studied the impact of Agile on software documentations. The authors highlighted the software development using Agile relies on informal communication which might lead to lack of software documentation or obsolescence. The authors addressed the issue that might face documentation teams as they immensely require documentation to accomplish their tasks.

Aghajani et al [9], [19] have conducted an empirical study to investigate the issues in software documentation. The outcome of the study has shown 162 types of software documentation issues linked to tools, process, and presentations of information. In addition, the authors believe that the attitude and experience of people involved in the software documentation process are important factors in the success or failure of software documentation.

Meng et al. [30] have conducted a study to investigate the learning strategy that developers use when they encounter API documentation. The study was carried out using interviews and questionnaire methodologies on 17 developers who have been asked 45 questions in the interview and to answer online survey of 39 questions. Main findings showed that documentation of API lack of clarity and completeness. Moreover, un-updated documentation is another recurring issue in API documentation.

In 2015, Zhi et al. [31] reviewed 69 research articles published between the years 1971-2011 on software documentation in order to study the impact of documentation on cost and quality. The authors concluded their review with several findings which can be summarized as: 1) main quality attributes that should be in the documentation are completeness, accessibility, and consistency; 2) most of the evaluation on the documentation models are on a single case study or academic prototypes.

2) *Software documentation models and tools*: Falessi et al. [13] have conducted an empirical study on 50 postgraduate students in order to evaluate the effect effects using different techniques of Design Decision Rationale Documentation (DDRD). The focus on the experiment is to check how different groups react in requirements change.

Kajko-Mattsson [17] has introduced a model for software documentations that serves corrective maintenance. The model includes 19 requirements with each has a set of goals. The model has been examined by surveying 18 different Swedish organisations with the use of interview mean. The author reported that the results show that collaboration with maintenance teams is to the minimum and the maintenance teams are absent from the documentation process. This has led to inadequate support for decision making for any change as well as quality assurance costs time and effort.

Bachmann et al. [32] have introduced their model for documenting software architecture. The model aims to document layered view of the architecture of the software system. The main purpose is to provide documentation that helps in sharing understanding of the system, tracing the changes, and discussing trade-offs. In addition, the model clearly identifies different views of the software architecture based on the audience of the documentation.

Falessi et al. [12] have introduced value-based (VD) method for software documentation in particular documentation of design decision. The proposed method aims to enhance the use of DDRD approach and is called VD DDRD. The authors conducted an experiment in order to validate their approach and the results show that VD DDRD can moderate inhibitions which might be shown using DDRD.

Aguiar et al. [8] have introduced a methodology for software documentation in particular documenting object-oriented frameworks. The authors have addressed several issues that need to be considered when documenting frameworks. These issues are related to quality, processes, and tools. The approach is tailored to help naïve software engineers in documenting software frameworks. The approach addresses three roles namely writers, developers, and documentation managers. In addition, it emphasizes on the collaborations and involvement throughout the development process.

Véras et al. [33] have introduced an approach which helps assessing the software requirement specifications. The approach aims to provide a benchmark for the assessment process. Three checklists are offered by the approach which is based on the standardizations of Packet Utilization Standard (PUS) by European Cooperation for Space Standardization (ECSS) standards.

Farwick et al. [34] have proposed a semi-automatic approach that document Enterprise Architecture (EA). The approach is composed of 4 models each of which needs manual interventions. The authors aim to overcome academic approaches offered by Hauder et al. [35]. Although the approach is promising, evolution and more case studies are needed to mature it.

Mathrani et al. [36] have proposed a new approach for software documentation that relies on the use of a quality management standards model (ISO 9001). The approach has been case studied on healthcare software with teams applying Scrum methodology for software development. The authors reported that issues such as incompleteness and ambiguity might rise due to the constraints in ISO 9001.

Aversano et al. [37] have proposed a quality model that evaluates the documentation of Enterprise Resource Planning (ERP) software. The model aims to investigate different quality attributes of the documentations. These attributes are linked either to content or to structures. Main purpose is to ensure readability and completeness of the documentation. The model has been experimented with in the open-source ERP systems, however, more case studies are required in order to generalize the results.

Carvalho et al. [38] proposed a tool named Documentation Mining Open-Source Software (DMOSS) for evaluating the quality of software documentation of non-source code information. The tool has been tested on 4 open-source codes. The tool aims to help maintainers in understanding the software.

Theunissen et al. [39] have introduced a model composed of three approaches for software documentation. The model focuses on categorizing software knowledge into 3 types namely acquiring, building, and transferring knowledge. These

types highlight the information to be documented based on the stage of the software life cycle. However, the model has not been evaluated.

Rong et al. [40] introduced a new approach named DevDocOps which can be integrated to DevOps in order to automate the process of software documentation. The approach has been implemented and evaluated in telecommunication enterprise and the results were promising.

Krunic [41] have studied the benefits and difficulties of Documentation as Code (DaC) in vehicle software. The author conducted a case study with 150 participants as software engineers. The author concluded the research by providing a model as a guideline for applying DaC and assessing the quality of documentation.

Kazman et al. [42] have introduced a method to architecturally document open-source software. The authors designed a case study to experiment their method on Hadoop Distributed File System (HDFS). However, the results showed that the proposed method had an effect on the project of HDFS.

Righolt et al. [43] have introduced a tool named Code Diary for automatically documenting decisions from SAS source code. Unlike similar tools, the authors claimed that the proposed tool Code Diary aims to produce code documentation for researchers and other audiences. However, no graphical user interface is available for the tool.

AlOmar et al. [44], [45] have proposed a model that acts as a data set for the documentation of refactoring process of the software. The authors conducted an experiment of 5 stages that has the documentation as the last stage. The experiment carried out over 800 open-source java code found in GitHub.

Geist et al. [46] have introduced their approach which employs Machine Learning, in specific, Deep learning in order to re-document legacy software system from their source code the exploitation of the comments found in the source code. The authors developed the tool based on the approach in one of the well-known automotive companies. However, the generalization aspect of the approach remains in maturing process.

Bhatia et al. [47] proposed an automated tool for code documentation that is based on the ontology-driven development. The authors examine the tool with comparison to a manual tool named WCopyfind. The authors reported that the tool can generate documentation in two types which are targeting human and machine audiences.

Bastos et al. [48] have proposed an approach that aims to help organisations in documenting the software project development. The approach employs the ontology methodology. The authors evaluated the approach using a questionnaire circulated to 8 postgraduate students as participants. In addition, the authors reported that the results cannot be generalized due to the low number of participants.

IV. CONCLUSION

In this paper, a systematic review of the topic of software documentation has been conducted. Budgen et al. and Kitchenham [20], [21] methodology of carrying out systematic

review was employed in this research. The main purpose of this research was to investigate the trends and issues related to software documentation in the last 10 years. An important remark is that Software documentation plays a significant role in quality assurance of software [49]. Therefore, it was essential to investigate the research trends in the topic and the related issues. The main conclusions can be summarized in the following points:

1) Software documentation has not been sufficiently considered as a research interest in the last 10 years.

2) There is a collective recognition that documentation is a difficult process and has many problems. In addition, maintenance teams are the effected party with poor documentation.

3) Three types of documentation can be deemed. First is the initial documentation, for example SRS documents. Second are the ongoing documentations, for example TODO lists. Third is the final documentation which includes user manuals.

4) Despite the model being followed in the documentation process, the majority of found primary studies considered the quality of software documentations.

5) Most tools for software documentations are focused on reverse documentations from the source code. This might lead to the loss of the lessons learned and decisions made as they were not previously documented.

6) Automated tools for documentation are in high demand.

7) Despite the importance of software documentation in the quality of software, developers tend not to pay attention to it.

Future research endeavors will focus on developing a comprehensive, standardized model for software documentation that exhibits broad applicability across diverse software systems. Furthermore, this investigation will delve into the identification of ambiguities within existing software documentation typologies and establish interconnections between these categories to facilitate seamless transitions based on the specific developmental phase.

ACKNOWLEDGMENT

The author wishes to express profound appreciation to his family and friends for their unwavering support during the course of this project. Their encouragement and steadfast faith in the author's abilities served as a wellspring of motivation.

The author is also indebted to Umm Al Qura University for providing indispensable resources and cultivating an intellectually stimulating academic environment. These factors significantly contributed to the successful culmination of this research endeavor.

Department of Informatic Engineering, Politeknik Negeri Bengkalis, 28711, Indonesia^{2, 3, 4}

Abstract—In the digital education era, the importance of Computer-Assisted Test programs is underscored by their efficiency in conducting assessments. However, the increasing incidence of data breaches and cyberthreats has made the implementation of robust data protection measures imperative. This study explores the adoption of the Advanced Encryption Standard 256-bit Cipher Block Chaining in CAT applications to enhance data security. Known for its strong encryption capabilities, AES-256-CBC is an excellent choice for securing sensitive test data. The research focuses on the application of AES-256-CBC within CAT systems during the independent admission process at Politeknik Negeri Bengkalis, a critical phase where the integrity of exam materials and student data is paramount. We evaluate the effectiveness of AES-256-CBC in encrypting user data and exam materials across different CAT systems, thus preserving data integrity and confidentiality. The implementation of AES-256-CBC helps prevent unauthorized access and manipulation of test results, ensuring a secure online testing environment. This research not only demonstrates the technical implementation of AES-256-CBC but also assesses its impact on enhancing the security posture of CAT applications at Politeknik Negeri Bengkalis. The findings contribute to the broader discussion on data security in educational technology, positioning AES-256-CBC as a potent solution for maintaining academic integrity in digital testing environments.

Keywords—AES256-CBC; data security; computer-assisted test; academic integrity; encryption standards; digital assessment security

I. INTRODUCTION

The integration of technology into educational processes has become imperative, significantly enhancing learning and assessment procedures but also elevating the risk of cyber threats [1]. As educational institutions increasingly adopt digital platforms for academic assessments and administration, the security of sensitive student data has emerged as a paramount concern. The escalation of complex cyberattacks underscores the urgent need for robust and advanced security systems [2]. A recent analysis by the Center for Strategic and International Studies reveals that by 2023, almost 30% of cyberattacks targeted colleges and schools, making the education sector particularly vulnerable to data breaches [3]. This statistic not only highlights the immediate need for enhanced protective measures, but it also illustrates the magnitude of the threat, urging the implementation of sophisticated security infrastructure to safeguard sensitive and private information. Furthermore, the 2021 data breach at the University of

California vividly exposed the susceptibility of university information systems to ransomware attacks [4]. This incident, which compromised the personal information of thousands of students and employees, resulted in significant financial losses and eroded stakeholder confidence, underscoring the necessity for educational institutions to adopt a more thorough and proactive approach to data security. Institutions must ensure their systems not only meet current security standards but are also equipped to anticipate and counter future threats effectively [5].

Literature studies on data security in digital education systems show that the use of encryption technologies such as the Advanced Encryption Standard (AES) 256-bit cipher block chaining (CBC) is becoming crucial. This study shows that the AES-256-CBC provides effective protection against brute force attacks and side attacks, which are two common threats to cybersecurity [6]. This enhanced security has become possible because of the mathematical complexity of the AES-256, which makes it difficult to decrypt without a proper key. Moreover, recent research shows that many educational institutions are still at risk of data leaks because they do not implement adequate security standards [7]. It stresses the need for sustained improvement in data security policies and practices, including better training for information technology managers and system users. Studies conducted around the world show that consistent application of AES-256-CBC results in higher levels of security compared to older encryption algorithms [8]. The study also emphasizes the importance of secure key management and dynamic security policy adaptation to address growing threats. The use of encryption in educational systems not only limits unauthorized access but also guarantees data integrity [9]. This integrity is important not only for data security but also for the trust of stakeholders, which includes students, parents, and teaching staff in addition, the study highlights that an effective security policy should cover more than just the implementation of technical solutions. Aspects such as IT infrastructure physical security, access policies, and emergency response protocols are also critical in ensuring comprehensive data security.

The growing reliance on technology for both teaching and assessment purposes has led to the recognition of data security as a fundamental component of educational integrity. Computer-assisted test (CAT) applications [10], with their simplicity in use and accuracy in real-time scoring, have revolutionized exam conduct in educational settings. However, the digital transformation presents novel challenges, particularly

concerning data security. Since its inception, CAT technology has evolved extensively, enhancing test delivery and analysis in both educational and professional contexts. The latest advancements primarily involve the integration of adaptive testing techniques, which dynamically adjust to an examinee's ability level, thereby providing a more tailored and accurate assessment of skills and knowledge [11].

The integration of modern CAT systems into online learning platforms has enabled seamless interactions between the testing interface and educational content, fostering a more cohesive learning and assessment experience [12]. We design these systems to be versatile, accommodating various item types and testing strategies to address diverse educational needs. Despite these advantages, CAT systems face several operational challenges, such as calibrating the item pool, which requires initial testing on a large sample of examinees to ensure the reliability and validity of test items. Additionally, the design of CAT systems must consider factors such as test security, fairness, and the potential for test-taker manipulation. The need for advanced software and psychometric expertise to develop and maintain these systems underscores the difficulty of effectively implementing adaptive testing processes.

Amidst increasing incidents of data breaches and cyber threats, CAT applications have become frequent targets of cyberattacks due to their storage of sensitive and crucial data, such as student personal information and test results [13]. This vulnerability highlights the importance of expanding and consolidating data security measures to protect such sensitive data comprehensively [14]. This study looks at how to use the AES-256-CBC [15], which is well-known for its strong encryption and excellent defense against collision and pre-image attacks. This makes it a great choice for keeping sensitive data safe in CAT systems.

The focus of this research also extends to the application of AES-256-CBC at Politeknik Negeri Bengkalis during the process of admitting new students through independent tracks. This examination provides a detailed view of the application of data security technologies in Indonesia's higher education system, underscoring the responsibility of educational institutions to protect student data. The integration of AES-256-CBC not only brings technical improvements but also enhances confidence among students and other stakeholders, reinforcing the notion that robust data security can significantly improve an organization's reputation and foster a secure environment for both students and teachers when utilizing technology for exams.

This study aims to offer guidance to other educational institutions seeking to enhance the security of their examination applications by analyzing the implementation of AES-256-CBC at Politeknik Negeri Bengkalis. The insights derived from this analysis are valuable not only at the local level, but also globally, as they contribute to the broader discourse on cybersecurity threats in education. By strengthening data security measures, educational institutions can concentrate more on conducting learning and evaluation processes that are not only efficient but also secure, fostering an environment conducive to innovation and technological integration [16]. This research serves as a benchmark for developing cybersecurity policies and best practices in education, enabling policymakers and

administrators to formulate more effective data security strategies based on clear, evidence-based guidelines.

The continuous evolution of cyber threats further underscores the robustness of data security in educational technology, necessitating an ongoing assessment and adaptation of security protocols [17]. As we embrace digital tools in education, it becomes crucial to implement systems that not only react to breaches but also proactively prevent them. This dual approach ensures that the security architecture evolves in parallel with emerging threats, maintaining the integrity and confidentiality of student data at all times. Ensuring the highest standards of data protection not only complies with regulatory demands but also addresses the ethical responsibility educational institutions hold towards their constituents [18]. Moreover, the strategic application of technologies such as AES-256-CBC in the education sector can serve as a model for other sectors where data sensitivity is paramount. By showcasing effective strategies for safeguarding data within the rigorous and often targeted environment of educational institutions, we can demonstrate the feasibility and effectiveness of advanced encryption methods. This initiative not only mitigates risks associated with data breaches but also advances the discourse on data security practices, fostering a broader understanding and implementation [19] of best practices across various domains.

The implementation of the AES-256-CBC algorithm significantly reduces the risk of data breaches and cyberattacks, ensuring that sensitive data, including student personal information and test results, remains protected from unauthorized access and manipulation. Enhanced data security also builds trust between educational institutions and their stakeholders, including students, parents, and teaching staff. This trust is essential for creating a positive and supportive learning environment where students and parents feel secure, and teachers are confident in using technology to manage exams safely. As educational institutions continue to face an increasing number of cyber threats, improved protection mitigates potential financial and reputational losses while simultaneously enhancing the learning experience through the safe and diverse use of digital technologies in education. This comprehensive approach to cybersecurity in educational settings not only secures data but also enriches the educational journey for all participants.

II. MATERIALS AND METHOD

A. Setting and Sample Selection Study

The study was conducted at the Politeknik Negeri Bengkalis, focusing on the use of CAT applications for the process of independent admission of new students in the 2024/2025 academic year. The samples include the CAT system currently in use at Politeknik Negeri Bengkalis, along with the data processing practices observed during the cycle of new student admission in 2024-2025. Administrators, IT staff, and prospective students are involved in providing insight into operational and security aspects.

B. Encryption Methodology

To secure the data processed through CAT applications, the Advanced Encryption Standard 256-bit Cipher Block Chaining

was implemented. This section details the critical data points within CAT applications that required encryption and describes the collaborative process with the IT department to integrate AES-256-CBC, replacing the previous encryption method.

C. Cipher Block Chaining Process

To explore the implementation of AES-256-CBC, we first identified critical data points in CAT applications that require encryption. We then integrated AES-256-CBC into the existing CAT system, replacing the previous encryption method. This process involves collaboration with the IT department to ensure that all technical aspects are dealt with, including key management and system compatibility.

Fig. 1, Encryption process using CBC, illustrates the encryption process using CBC model, a widely used method in cryptographic systems for securing data [20]. This mode of operation is particularly effective in enhancing data security by linking blocks of plaintext to produce a chain of ciphertext, ensuring that similar plaintext blocks result in different ciphertext blocks.

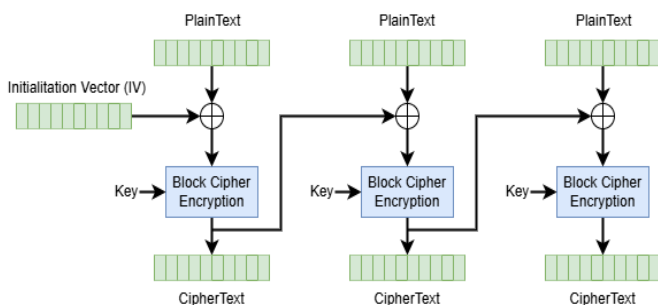

Fig. 1. Encryption process using CBC.

In CBC mode, the encryption process begins with an initialization vector (IV) [21]. To prevent ciphertext patterns, the IV must be unique and unpredictable for each encryption session. Unlike the encryption key, the IV does not need to be secret, but it should be random and not reused with the same key to maintain security.

The process starts with the IV, which is XORed (exclusive OR operation) with the first block of plaintext. This step is crucial as it masks the first block of plaintext, which adds an additional layer of security and ensures that the same plaintext blocks will produce different ciphertext blocks when encrypted under the same key but with different IV [22]. Following the initial XOR operation, a block cipher algorithm encrypts the resulting block using a specified encryption key. This encryption results in the first block of ciphertext.

The ciphertext from the previous block serves as the "new IV" for each subsequent plaintext block. We XOR this block with the next plaintext block, then use the same block cipher algorithm and key to encrypt the result. This chaining mechanism ensures that each block of ciphertext is dependent not only on the current plaintext block but also on all preceding plaintext blocks.

Each encryption step produces the ciphertext associated with each plaintext block [23]. Each piece of ciphertext is dependent on the initial IV and the sequence of plaintext blocks, creating a

chain in which the correct decryption of each block requires the ciphertext of the preceding block (except for the first block, which requires the IV).

CBC mode's approach, where the encryption of each plaintext block is dependent on the previous ciphertext block, significantly increases security by introducing complexity and randomness into the process [24]. This method prevents plaintext patterns from appearing in the ciphertext, making it more resilient to cryptographic attacks such as pattern analysis. The CBC mode is highly regarded for its ability to propagate errors, meaning that a single bit error in a block of ciphertext will render that block and the following block indecipherable, which can be a useful security feature or a drawback, depending on the context of use.

Fig. 2 illustrates the decryption process using the CBC mode, a common operational mode for block cipher encryption algorithms. The enhanced security features of this method, which take advantage of the dependencies between encrypted data blocks, make it popular [25]. The CBC decryption process starts with the use of an initialization vector. This IV is crucial, as it pairs with the first block of ciphertext to initiate the decryption process [26]. To ensure accurate output, the IV must match the one used during the encryption phase. Despite not being secret, the IV must be unique for each encryption session and not reuse the same key. We decrypt each block of ciphertext using the same key and block cipher algorithm as during the encryption. We decrypt and XOR the first block of ciphertext with the IV to create the first plaintext block. This operation transforms the decrypted data back to its original form before encryption.

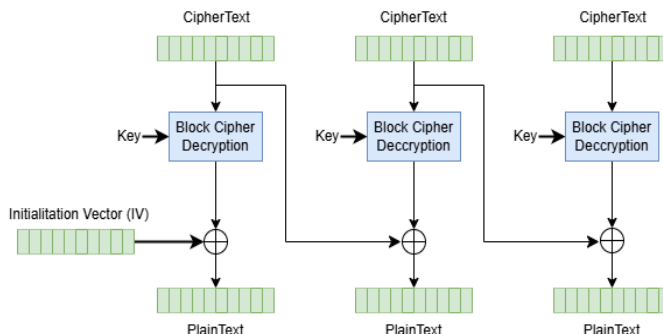

Fig. 2. Decryption process using CBC.

For subsequent blocks, the decryption process follows a chaining mechanism where each decrypted block is XORed with the previous ciphertext block. This sequential processing ensures that any error in a single block of ciphertext during transmission affects not only the current block but also the subsequent block, highlighting a unique dependency characteristic of CBC mode. The process sequentially reveals each piece of plaintext, mirroring the encryption steps in reverse order. This chaining method, where each block's decryption depends not only on its corresponding ciphertext block but also on the preceding ciphertext block, considerably enhances the security of the data transmission. It ensures that the plaintext pattern does not directly influence the ciphertext, making it more resistant to various cryptographic attacks.

The CBC mode's reliance on correct and secure handling of the IV and the chaining mechanism significantly increases system security [27][28]. However, it also introduces certain challenges, such as error propagation and the necessity for secure IV management. These factors must be carefully considered to ensure data integrity and confidentiality throughout its lifecycle. Overall, the CBC mode's decryption process effectively illustrates how cryptographic techniques can enhance data security by intricately linking each block of data to its predecessor, thereby securing the data against unauthorized access and potential security breaches [29].

D. Data Collection

Data collection methods include structured interviews with IT staff responsible for managing the CAT system currently in use at Bengkalis State Polytechnic. In addition, the system logs are reviewed to detect unauthorized access attempts and data breach incidents before and after the AES-256-CBC implementation.

E. Metric Evaluation

The effectiveness of the AES-256-CBC implementation is assessed using several metrics:

- 1) Comparing the frequency and nature of security incidents before and after implementation.
- 2) Checks any case of data abnormalities or loss by checking system logs and backup files.
- 3) Measures changes in system response time and stability to evaluate the impact of AES-256-CBC on the operating efficiency of CAT applications.
- 4) Conduct surveys with students and staff to measure their confidence in their data security after implementation.

F. Data Analysis

Data analysis in this study employs a blend of quantitative and qualitative methods to gain comprehensive insights into the system's performance and user experiences. We scrutinize system logs and performance metrics using quantitative techniques to objectively assess the enhancements made by integrating AES-256-CBC encryption into the CAT applications. This involves evaluating changes in system response times, error rates, and other relevant performance indicators that directly reflect the operational impact of the encryption methods implemented. We analyze interviews and focus group discussions on the qualitative side to capture the subjective perspectives of end-users and administrators. Understanding how users perceive these security improvements, including any changes in their satisfaction and trust in the system's security measures, is crucial. These interactions' responses help illustrate the practical implications of AES-256-CBC encryption on daily operations and user interactions with the CAT system.

This two-pronged approach tries to connect the technical improvements in security, like AES-256-CBC encryption, with how users feel about it and how well it works. By doing so, the study provides a holistic view of the impact of this encryption technology on CAT applications [30]. It also explores the balance between enhanced security measures and their real-world usability and acceptance, thereby offering valuable

insights into both the effectiveness and the user experience of the upgraded system. This comprehensive analysis aids in determining if the security improvements align with user expectations and operational needs, ensuring that the technology not only secures the data but also enhances the overall functionality of the CAT system.

In order to provide a thorough understanding of the technical performance and user experience related to the AES-256-CBC implementation in the CAT applications, this study used a combination of quantitative and qualitative methodologies. We gathered and examined system logs and performance indicators with extreme care in order to assess the effects of AES-256-CBC encryption impartially. Prior to and following the encryption deployment, the system reaction times, error rates, and frequency of security events were among the key performance measures. We were able to evaluate the real-world advantages of incorporating cutting-edge encryption techniques into current educational technologies because this data gave us a quantitative assessment of the system's security resilience and operational effectiveness. We obtained qualitative insights through focus groups and structured interviews with end users, including students, administrative staff, and IT personnel at Politeknik Negeri Bengkalis, to supplement the quantitative data. The goal of these talks was to comprehend the differing viewpoints regarding the security enhancements brought about by AES-256-CBC. We specifically looked at user satisfaction, security perception, and confidence in the system's ability to safeguard private data. This qualitative feedback heavily influences the adoption and usability of the security features among the users who are directly engaging with the CAT system.

The combination of quantitative and qualitative data allowed for an in-depth examination of the encryption's efficacy [31]. Through the integration of results from both data streams, the study obtained a comprehensive understanding of the implementation's effects. This dual method helps identify any differences between the perceived and actual performance of the security measures, in addition to helping validate the technical measurements with real-world user feedback. The combined analysis has made it possible to better understand how well AES-256-CBC encryption satisfies the operational requirements and security expectations of educational institutions. It also indicated areas in which user training and technology implementation still needed improvement. These understandings are essential for creating focused plans to strengthen user confidence in digital learning environments and improve data security procedures.

III. RESULTS AND DISCUSSION

A. Login Interface CAT

The login screen is the first gateway and the main line of defense in the security of CAT applications in the Bengkalis State Polytechnic. This interface is designed not only to facilitate easy access for authenticated users but also to ensure that sensitive data and user personal information are protected from unauthorized access.

Fig. 3 is a login screen on the Politeknik Negeri Bengkalis CAT application displays a simple yet effective design, which includes fields for entering usernames and passwords. The

"Show Password" feature is provided to help users verify the characters they enter, reducing the risk of input errors that can hinder the login process. Security is deeply integrated into this design through the use of HTTPS to encrypt communications between clients and servers, as well as a security policy that ensures passwords are stored in encryption formats on the server, using state-of-the-art cryptography technologies such as AES-256-CBC.

Fig. 3. Login interface CAT.

The interface also comes with additional security mechanisms such as limiting failed login attempts and security features to detect and respond to suspicious activity. It aims to prevent brute-force attacks and the use of stolen credentials, ensuring that only verified users can access the system. Every detail in the login system is designed to improve the overall security of the CAT application. For example, the user session is encrypted end-to-end, and the timeout is implemented automatically to reduce the risk of unauthorized access if the user forgets to log out. In addition, each login activity is recorded in the server log for security audits that allow real-time monitoring of suspicious activity.

B. Encryption Implementation

The PHP code is a crucial part of the security system for the CAT application at Politeknik Negeri Bengkalis. This code details the implementation of the AES-256-CBC algorithm, used for encrypting and decrypting sensitive data within the application. High security standards protect all data stored or transmitted through the CAT system thanks to this implementation.

```
<?php
// Fungsi untuk mengenkripsi data
function encrypt($data, $key) {
    $iv = openssl_random_pseudo_bytes(openssl_cipher_iv_length('aes-256-cbc'));
    $encrypted = openssl_encrypt($data, 'aes-256-cbc', $key, 0, $iv);
    return base64_encode($encrypted . ':' . $iv);
}

// Fungsi untuk mendekripsi data
function decrypt($data, $key) {
    list($encrypted_data, $iv) = explode(':', base64_decode($data), 2);
    return openssl_decrypt($encrypted_data, 'aes-256-cbc', $key, 0, $iv);
}

// Kunci enkripsi (panjang kunci harus 32 byte untuk AES-256)
$key = '/Ce2c7w44n496kF3VKOXQEKIHyrfyKZzb+DTmLQ7TCM=';
```

Fig. 4. The PHP code AES-256-CBC algorithm.

In Fig. 4, the code consists of two main functions: `encrypt()` and `decrypt()`. The `encrypt()` function utilizes the AES-256-CBC algorithm to encrypt data. The function requires two parameters: the encrypted data and a secret key. Additionally, the code uses `openssl_random_pseudo_bytes()` to generate a random initialization vector, enhancing security and adding randomness to the encryption process. The system then encodes the encrypted data into Base64 format to facilitate its storage and transmission. The `decrypt()` function acts as the inverse of `encrypt()`. It decodes the encrypted data in Base64 format, then uses the same and secret key to decrypt it back to its original form. We strictly safeguard the encryption key, which is critical for both processes, to ensure security.

C. Implications of Security Measures

Politeknik Negeri Bengkalis uses AES-256-CBC to protect all information, including student personal data, exam answers, and evaluation results, from unauthorized access. This algorithm provides excellent protection against various cyberattacks due to the strength of its key and the complexity of the cipher used.

Fig. 5. List of test identities.

Fig. 5, List of test identities shows a list of test identities matched to their encrypted data. Each line represents a unique set of data related to the test subject, which is secured using the AES-256-CBC encryption algorithm. The use of this encrypting not only protects the data from unauthorized access, but also ensures that each entry is unique, reducing the risk of data leakage or unauthorized modification.

Any information (examination ID and associated details) is encrypted, turning sensitive information into a format that can only be decryptable and understood by the system and authorized personnel. The AES-256-CBC encryption standard is used, which is known for its strength and resilience to a variety of cyber threats, including brute-force attacks and decryption attempts without proper key.

Fig. 6, Test question and its answer options are encrypted. This demonstrates how encryption technology can secure sensitive educational data, such as test results and answer choices. Politeknik Negeri Bengkalis applies encryption to all data elements in CAT applications, reaffirming their efforts to protect the integrity and confidentiality of academic information.

Fig. 6. Test question and its answer options are encrypted.

In practice, the test management system encrypts each test question and its answer options before storing them in a database or displaying them. This process ensures that only individuals who have a valid decryption key, such as a system administrator or authorized developer, can access the actual data content. This is critical to preventing the leakage of examination information, which could result in a loss of academic integrity and fairness. Data encryption also helps to comply with strict data protection regulations, ensuring that educational institutions meet their legal obligations to student data security and privacy. It not only increases stakeholder confidence in the educational system used, but also strengthens the institution's reputation as a responsible and secure entity. Politeknik Negeri Bengkalis demonstrates, through the use of advanced encryption technology, how technology can enhance security in an educational environment, protect sensitive data from external and internal threats, and enhance a secure learning experience for all parties involved.

Fig. 7, test question and its answer options are decrypt in the exam scenario using the CAT system at Bengkalis State Polytechnic, the subjects presented to the participants have already undergone the process of decryption so that they appear in the form of text that is readable and accessible by the participants. This process describes how data previously secured with AES-256-CBC encryption is converted back to its original format for use during the test.

Fig. 7. Test question and its answer options are decrypt.

D. Administrative Dashboard Functionality

This interface display shows the effectiveness of CAT systems in managing and presenting test issues in a secure and organized manner. By ensuring that all subjects are encrypted

during storage and only decoded during examination, Bengkalis State Polytechnic demonstrates its commitment to data security and academic integrity. Participants can answer questions with confidence, knowing that the system they use supports them with secure and sophisticated technology. It not only improves the test experience for participants but also affirms the importance of data security in an educational context.

Fig. 8. Administrative dashboard for the CAT system.

Fig. 8 shows a view of the administrative dashboard for the CAT system in Politeknik Negeri Bengkalis. The dashboard serves as a control center for system administrators in managing various aspects of the CAT system. Here is a narrative about the functions and components of this admin dashboard:

- 1) The dashboard is designed to provide quick and easy access to the range of administrative features needed to manage a computer-based test system. As a command center, the dashboard allows administrators to monitor and control the operation of the test system efficiently, ensuring that everything runs according to the established standards.
- 2) Provides an overview of system status and current activity.
- 3) Manages the modules or categories of tests available in the system.
- 4) Management of test participants' data, including registration and active status.
- 5) A place to configure and manage test questions and answers.
- 6) Generate reports related to various aspects of the test, including participant performance and data analysis.
- 7) Additional tools for system administration such as data backup, security settings, etc.
- 8) Ensures that the server time matches the current time. This function is important to ensure that the time recording during the test is done accurately. If there is a time difference, the administrator is instructed to check and adjust the server's time zone according to the system configuration.

These dashboards not only simplify the administration and management of tests but also ensure transparency and accuracy in the execution of tests. By leveraging these dashboards, administrators can reduce the risk of human error, improve

operational efficiency, and provide a better experience for users and test participants. In addition, accurate server time integration and centralized data management help in ensuring the integrity and reliability of the test system.

IV. CONCLUSION

This study successfully integrated and evaluated the AES-256-CBC within the CAT systems at Politeknik Negeri Bengkalis. The findings conclusively demonstrate that the implementation of AES-256-CBC significantly bolstered data security, sharply reducing the risk of unauthorized access and significantly strengthening user trust in the system's integrity. However, the research also revealed that the success of such security technology is not solely dependent on the strength of its encryption, but equally on the awareness and training of the involved users. Given the ever-evolving landscape of cyber threats, future research needs to go beyond the use of AES-256-CBC to explore other encryption technologies that might offer superior efficiency or security in an educational context. Additional studies are crucial to assess how effective security training can enhance cybersecurity awareness among CAT system users, including staff and students. Furthermore, understanding the psychological impact of data security, such as how security perceptions influence user trust and satisfaction, will provide valuable insights into improving user interactions with security technologies.

Moreover, there is a significant opportunity for innovation in the development and testing of security tools specifically designed for educational systems, which could further refine our methods for protecting sensitive information. Moving forward, continuous collaboration among security experts, educators, and IT technicians will be essential to ensure that our security infrastructure can adapt to evolving threats while supporting educational goals and innovation. This study underscores the critical need for robust encryption methods like AES-256-CBC in safeguarding educational data systems against increasing cyber threats. By firmly integrating advanced security measures, educational institutions can better protect both their operational integrity and the private information of their stakeholders. In turn, this commitment to high-standard security practices not only enhances the functionality of CAT applications but also fortifies the trust placed in them by students, educators, and administrative personnel alike.

To sustain and build upon the successes of this study, the next phase of research should also investigate the scalability of AES-256-CBC across different educational platforms and its effectiveness against a broader array of cyber-attacks. Exploring the integration of multi-factor authentication measures with AES-256-CBC could provide an additional layer of security, further enhancing educational data systems' resilience. These efforts will ensure that our technological defenses not only keep pace with cyber threats but also contribute to a secure and conducive learning environment.

Abstract—Diabetes, a chronic illness, has seen an increase in prevalence over the years, posing several health challenges. This study aims to predict diabetes onset using the Pima Indians Diabetes dataset. We implemented several machine learning algorithms, namely Random Forest, Gradient Boosting, XGBoost, LightGBM, and CatBoost. To enhance model performance, we applied a variety of feature engineering techniques, including SelectKBest, Recursive Feature Elimination (RFE), Recursive Feature Elimination with Cross-Validation (RFECV), Forward Feature Selection, and Backward Feature Elimination. RFECV proved to be the most effective method, leading to the selection of the best feature set. In addition, hyperparameter tuning techniques are used to determine the optimal parameters for the models created. Upon training these models with the optimized parameters, XGBoost outperformed the others with an accuracy of 94%, while Random Forest and CatBoost both achieved 92.5%. These results highlight XGBoost's superior predictive power and the significance of thorough feature engineering and model tuning in diabetes prediction.

Keywords—Machine learning; feature engineering; hyperparameter tuning; diabetes prediction; healthcare

I. INTRODUCTION

The World Health Organization considers diabetes one of the world's leading causes of death. Diabetes mellitus is a metabolic disorder of the endocrine system in which the blood glucose levels remain high for longer than necessary, causing hyperglycemia. The majority of diabetes cases are type 2 diabetes. The symptoms of diabetes include frequent urination, excessive thirst, extreme fatigue, etc.

The proportion of individuals with diabetes has been increasing more rapidly than can be accounted for by a rapidly increasing population. The World Health Organization has predicted that diabetes will be the leading cause of disease burden in the world by 2030. Such reporting is important but still almost undoubtedly an underestimate of the total impact of diabetes since there are very many children in whom the diagnosis is not made, in whom there may be a very early onset of complications, and whose death is not reported as 'diabetic'.

Youth-onset type 2 diabetes will also provide a considerable burden to some populations, especially indigenous peoples. Many obese individuals already have the insulin resistance that promises eventual diabetes. A third of the American adult population is thought to have the insulin resistance syndrome. Individuals of Asian and African origin,

as well as indigenous peoples, have an increased risk of diabetic complications, at least in part independent of the greater weight for height. Since even impaired fasting glucose has been reported to be associated with an increased independent risk of cardiovascular disease, such reports demonstrate the threat and the value of strategies to prevent or delay the onset of metabolic syndrome. With outcome metrics such as the development of retinopathy and cardiovascular events, a diagnosis may only come in time to prevent a diagnosis of type 2 diabetes

It is associated that diabetes is very long and gradually exerts its unwanted effects on all the body parts. It remains in the individual's body for a long time and then develops heart disease, chronic meningitis, hypertension, blindness, stroke, erectile dysfunction, nerve damage (neuropathy), among other things. The population growth, relocating from rural to urban areas, interacting with bestial food habits, lack of exercise, stress, and lifestyle changes in people of all ages also contribute to the development of diabetes.

Diabetes is now recognized as a global health problem. It creates a huge impact on people and countries around the world. The importance of diabetes lies in the fact that it increases a person's likelihood of having a stroke by 1.5 times. It is predicted that if the rising incidence of diabetes is not reversed, the overall death rate from diabetes and heart disease will also rise.

Machine learning (ML) in healthcare is used to diagnose diseases, create personalized treatment plans, and predict hospital readmissions [1], [2], [3]. It can also detect which patients are at high risk of developing diabetes, long before it occurs. There are also many other related problems in the medical field such as disease diagnosis, hospital readmission, personalized treatment, and patient hope. However, the main goal of this study is to establish how basic, everyday habits affect the early detection of diabetes [4].

At the moment, prediabetes and diabetes are diagnosed through massive blood tests (glucose, insulin, and so on) that only patients with symptoms undergo. The main advantages of predicting diabetes using machine learning are: once the algorithm is implemented, everybody can use it and the test can be done whenever one wants; it is cheap; it allows everyone to know if they are at risk of developing diabetes months/years in advance, and take action; it saves the time and resources of doctors and hospitals to spend on the real ill patients.

The remainder of this study is organized as follows: Section II covers previous research and related studies. Section III details the methodology, including the various algorithms employed, steps taken to prepare the dataset, techniques for creating and refining features, and the process of optimizing the parameters. Section IV presents the results and a thorough discussion of the findings. Finally, Section VI provides a

conclusion summarizing the key insights and implications of this work.

II. RELATED WORK

This section provides a detailed overview of related work in the field of diabetes prediction using machine learning techniques in particular.

A recent study [5] proposed an ensemble-based approach for predicting diabetes using the Pima Indian Diabetes Dataset. It evaluated LightGBM, XGBoost, AdaBoost, and Random Forest, finding that LightGBM alone achieved an accuracy of 94% and a ROC AUC of 95%. By introducing a Soft Voting classifier, the combined model's accuracy increased to 95% with a ROC AUC of 96%, demonstrating the potential of ensemble methods to improve prediction reliability.

TABLE I. RELATED WORK COMPARISON

Reference	ML algorithms	Highest Accuracy
[3]	Logistic Regression, Decision Tree, Random Forest, k-Nearest Neighbors, Naive Bayes, Support Vector Machine, Gradient Boosting, and Neural Network	78,57%
[5]	LightGBM, XGBoost, AdaBoost and Random Forest	93%
[6]	decision tree (DT), logistic regression (LR), support vector machine (SVM), gradient boost (GB), extreme gradient boost (XGBoost), random forest (RF), and ensemble technique (ET)	93,27%
[7]	Ensemble learning, XGBoost, CatBoost, LightGBM, AdaBoost, gradient boost	92,85%
[8]	Random forest classifier (RF), logistic regression (LR), decision tree classifier (DT), support vector machine (SVM), Bayesian Classifier (BC) or Naive Bayes Classifier (NB), Bagging Classifier (BG), Stacking Classifier (ST), Moderated Ada-Boost(AB) Classifier, K Neighbors Classifier (KN) and Artificial Neural Network (ANN)	90,95%
[9]	ET, RF, SGB, AB	93.63%
[10]	decision tree, SVM, Random Forest, Logistic Regression, KNN, and various ensemble techniques.	81%
Our study	Random Forest, Gradient Boosting, XGBoost, LightGBM, and CatBoost.	94%

Numerous studies have explored the use of machine learning algorithms for predicting diabetes. The study in [6] employed a range of classification algorithms, including Logistic Regression, Decision Trees, and Support Vector Machines, to predict diabetes onset using the Pima Indians Diabetes dataset. Their research highlighted the effectiveness of Support Vector Machines in achieving high accuracy.

Further investigation [7] focused on the application of ensemble methods for diabetes prediction. They compared the performance of Bagging, Boosting, and Stacking techniques, demonstrating that ensemble methods generally outperformed single classifiers. Specifically, their results indicated that Boosting algorithms, particularly XGBoost, provided superior predictive performance.

Feature selection and engineering play a critical role in improving model accuracy. The study [8] implemented Recursive Feature Elimination (RFE) and Principal Component Analysis (PCA) to enhance their machine learning models. They concluded that RFE, in combination with Gradient Boosting Machines, yielded the best results, emphasizing the importance of selecting relevant features.

The use of deep learning approaches has also been investigated [11], [12], [13], [14]. In study [15] authors proposed a deep neural network model for diabetes prediction, achieving remarkable accuracy. Their work demonstrated that

deep learning models could capture complex patterns in the data, albeit at the cost of increased computational resources and the need for larger datasets.

Additionally, researches [9], [16] introduced the concept of hybrid models that combine multiple machine learning techniques to improve prediction accuracy. They developed a hybrid model integrating Random Forest and Neural Networks, which surpassed the performance of traditional models.

Recent advancements in explainable AI have also been applied to diabetes prediction. For instance, [10], [17] utilized SHapley Additive exPlanations (SHAP) to interpret the predictions of their machine learning models. This approach provided insights into the importance of different features, enhancing the transparency and trustworthiness of the predictive models.

In earlier studies, different feature selection and classification have been proposed to optimize the classifier model for 12 different classifiers over Pima Indians Diabetes Database from the UCI machine learning website [18], [19], [20]. The work was done on Pima Indians Diabetes Database in order to predict diabetes using different Data Mining algorithms. The main feature selection methods are Correlation, Wrappers, and Principal Components. Wrapper was the most successful feature selection method in obtaining a small data subset optimizing the classifier. Besides the feature

selection, a metaheuristic algorithm was used to optimize the classifier to fit the classifier model by using a small training data subset. Random Forest (RF) with 28 input features produced high accuracy (98.08%), sensitivity (94.6), and specificity (99.3). The study in [21], [22], dataset with six input attributes was tested using six different classifiers. Decision Trees (DT) and J48 classifiers gave the best results on both 10×10 cross-validation (CV) or independent test sets, resulting in 78.33% accuracy, 77.38% and 88.33% accuracy, 87.84%, respectively. These works have partially been compared with the work.

Research indicates that type 2 diabetes [23], [24], [25] is treatable and preventable through making lifestyle changes such as weight loss, improved diet, and increasing physical activity. Regular monitoring, at-home blood glucose testing, and A1C levels are pivotal for identifying high risk for diabetes and type 2 diabetes early on. However, individuals are experiencing continuous increases in weight and obesity because of the rising trends of high-calorie diets and sedentary lifestyles.

This trend could reach a breaking point for the healthcare system if our understanding of the factors leading to type 2 diabetes risk remains incomplete. Machine learning techniques, such as classification, regression, clustering, anomaly detection, and pattern recognition, are developed to make accurate predictions from data. Specifically, the current health

status of pre-diabetic patients is used to assess potential for diabetes diagnoses.

By understanding how certain factors of lifestyle change can influence diabetes diagnoses, pre-diabetics may be able to take steps to avoid the implications of diabetes. With the implementation of machine learning algorithms and healthcare data, healthcare providers would benefit from a tool capable of early diagnosing patients who possess the highest risk of developing type 2 diabetes and cardiovascular diseases while developing personalized and cost-effective intervention strategies for pre-diabetics [26], [27], [28].

Overall, the related work in this field underscores the continuous evolution of machine learning techniques for diabetes prediction. The integration of advanced feature engineering, ensemble methods, and deep learning has significantly improved predictive accuracy, paving the way for more effective and reliable diabetes prediction models.

III. METHODS AND EVALUATION

In this study, the methodology used is divided into several key components: data collection and preprocessing, data analysis techniques, feature engineering, hyperparameter tuning and performance evaluation metrics. Each component is discussed in detail to provide a comprehensive understanding of the research process. Fig. 1 depicts the overall process workflow for this experimental study.

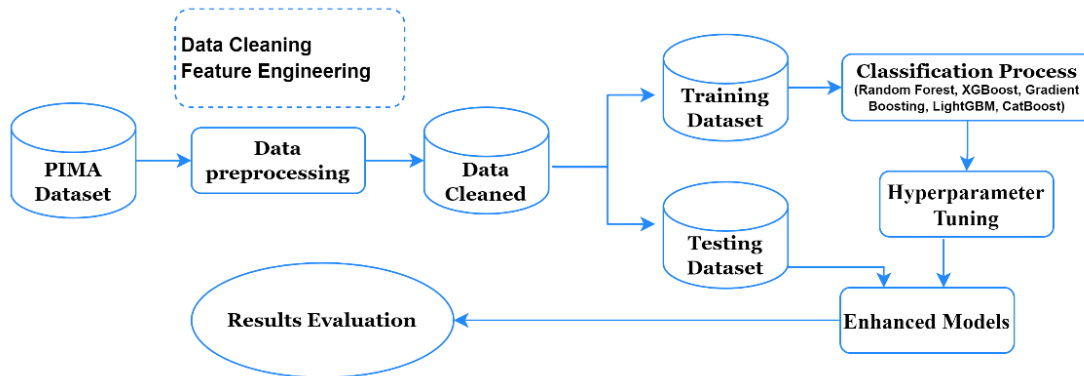

Fig. 1. Experimental workflow.

A. Data Collection and Preprocessing

To implement the predictive models in this study, an open-access diabetes dataset was utilized. This dataset, obtained from Kaggle, includes various medical predictor variables and a target variable. It comprises records of 768 patients. All patients are females of Pima Indian heritage, aged at least 21 years. Among them, 34.9% have diabetes, while 65.1% do not, as depicted in Fig. 2. Detailed attribute information is provided in Table II.

Data preprocessing is essential for all machine learning (ML) applications because the effectiveness of an ML algorithm depends significantly on how well the dataset is prepared and structured. This step ensures the data is tailored to meet the specific needs of the chosen algorithm. For the diabetes dataset, we employed several preprocessing techniques during this initial phase:

TABLE II. DATASET FEATURE'S INFORMATION

Attribute	Description
1- Pregnancies	Count of pregnancies
2- Glucose	Plasma glucose levels
3- BloodPressure	Diastolic blood pressure (mm Hg)
4- SkinThickness	Triceps skin fold thickness (mm)
5- Insulin	2-Hour serum insulin (mu U/ml)
6- BMI	Body mass index
7- DiabetesPedigreeFunction	Diabetes pedigree function
8- Age	Age (years)
9- Outcome	1 = diabetic, 0 = non diabetic

Fig. 2. Distribution of diabetes.

- **Data Cleaning:** We removed missing or null values, cleaned up noisy data, and detected and eliminated outliers.
- **Outlier Handling:** To enhance the robustness of our model, we used the "Replace with Thresholds IQR" method. This technique involves substituting extreme values with thresholds derived from the Interquartile Range (IQR), which helps create a more resilient and reliable model.
- **Scaling and Normalization:** We scaled and normalized the data to ensure that no single feature disproportionately influences the model due to differing scales.
- **Handling Imbalanced Data:** To prevent bias and ensure the model is not unduly influenced by the prevalence of a particular class, we applied the Synthetic Minority Oversampling Technique (SMOTE) as described in Table III. This technique generates a balanced dataset by synthesizing instances of the minority class, thereby improving the predictive accuracy for that class.

Throughout the study, we utilized various Python libraries, including NumPy, Pandas, Seaborn, Matplotlib, and Scikit-learn, for both exploratory data analysis (EDA) and data visualization. These tools helped us thoroughly analyze and prepare the data, setting a solid foundation for building effective predictive models.

TABLE III. RESULT OF THE SMOTE TECHNIQUE

	Diabetes	
	Yes	No
Before SMOTE	268	500
After SMOTE	500	500

B. Machine Learning Algorithms

Among the existing algorithms of machine learning [29], [30], we used in this study Random Forest, Gradient Boosting, XGBoost, LightGBM, and CatBoost. These algorithms were selected for their robustness and versatility in handling various types of data and predictive modeling tasks. Random Forest is known for its simplicity and effectiveness in reducing

overfitting through ensemble learning. Gradient Boosting improves predictive accuracy by iteratively minimizing errors. XGBoost, an optimized version of Gradient Boosting, enhances performance and computational efficiency. LightGBM, designed for speed and scalability, handles large datasets and high-dimensional data efficiently. CatBoost is particularly effective with categorical data and requires minimal preprocessing. By leveraging the strengths of these algorithms, we aimed to achieve a comprehensive analysis and robust predictive performance for our study.

Random Forest is an ensemble learning algorithm that constructs multiple decision trees during training and outputs the class that is the mode of the classes (classification) or mean prediction (regression) of the individual trees. It is robust to overfitting due to the averaging of multiple trees, handles large datasets effectively, and can manage missing data and maintain accuracy for large portions of the data.

Gradient Boosting is an iterative algorithm that builds a model in a stage-wise fashion from weak learners, typically decision trees. Each new model attempts to correct the errors of the previous one by minimizing a loss function. This approach results in high predictive accuracy, making it suitable for various machine learning tasks, although it can be computationally intensive and sensitive to overfitting without proper regularization.

XGBoost (Extreme Gradient Boosting) is an optimized version of Gradient Boosting designed for performance and speed. It incorporates advanced features like regularization to prevent overfitting, parallel processing, and efficient handling of missing data. XGBoost is known for its scalability and effectiveness in both regression and classification problems, making it a popular choice in competitive machine learning.

LightGBM (Light Gradient Boosting Machine) is a gradient boosting framework that uses tree-based learning algorithms. It is designed for efficiency and scalability, making it well-suited for large datasets with high-dimensional features. LightGBM achieves faster training speed and higher efficiency by using a histogram-based approach and leaf-wise tree growth, which leads to better accuracy.

CatBoost (Categorical Boosting) is a gradient boosting algorithm specifically designed to handle categorical data with minimal preprocessing. It automatically deals with categorical features and reduces overfitting through techniques like ordered boosting and efficient oblivious tree structures. CatBoost is robust, accurate, and user-friendly, making it ideal for applications where categorical data is prevalent.

C. Feature Engineering

Feature engineering plays a role, in the realm of machine learning. It involves the creation, adjustment and selection of features from data to boost the performance of predictive models. This process encompasses methods like normalization encoding variables and crafting features based on domain expertise. Skillful feature engineering can notably improve the precision and effectiveness of machine learning models by equipping them with valuable input data. It often necessitates testing and a profound comprehension of both the dataset and

the core issue to identify features that aptly capture the patterns and connections, for accurate forecasts.

In this study various techniques are used to enhance machine learning models such as SelectKBest, Recursive Feature Elimination (RFE), Recursive feature elimination with cross-validation (RFECV), Forward Feature Selection, Backward Feature Elimination. Fig. 3-7 represents the results of features used in this study.

SelectKBest is a feature selection method that selects the top k features from a dataset based on a scoring function. We used the chi2 function with SelectKBest which is based on the chi-squared statistical test, which measures the independence of each feature with respect to the target variable. Higher chi-squared values indicate a stronger relationship between the feature and the target. By using SelectKBest with chi2, we reduced the dimensionality of the dataset by keeping only the most relevant features, potentially improving the performance of the machine learning models employed. By using SelectKBest and chi2 function we find that all features give over 91% accuracy, and the highest score of 92.2% goes to Random Forest Classifier.

Fig. 3. Accuracy result using SelectKBest.

Recursive Feature Elimination (RFE) is a feature selection technique in machine learning that iteratively removes the least important features from the dataset. Starting with all features, RFE fits a model and evaluates the importance of each feature. The least important feature is then removed, and the model is re-fit on the remaining features. This process continues until the desired number of features is reached. By systematically eliminating features, RFE helps in identifying the most relevant subset, improving model performance and reducing overfitting by eliminating noise and irrelevant data.

Recursive Feature Elimination with Cross-Validation (RFECV) is an enhanced feature selection technique that combines Recursive Feature Elimination (RFE) with cross-validation to select the optimal number of features. RFECV iteratively removes the least important features while simultaneously evaluating model performance using cross-validation at each iteration. This approach ensures that the

feature selection process is guided by model accuracy, helping to identify the subset of features that yields the best predictive performance. By incorporating cross-validation, RFECV provides a more robust and reliable method for feature selection, reducing the risk of overfitting and improving the generalizability of the model.

Fig. 4. Accuracy result using RFE.

Fig. 5. Accuracy result using RFECV.

Forward Feature Selection is a feature selection technique in machine learning that starts with an empty model and iteratively adds the most significant features. At each step, the method evaluates all candidate features and adds the one that improves the model performance the most, based on a predefined criterion like accuracy or F1 score. This process continues until adding more features no longer significantly improves the model or a specified number of features is reached. Forward Feature Selection is effective for identifying a small, relevant subset of features, enhancing model interpretability and performance by including only the most impactful variables.

Fig. 6. Accuracy result using FORWARD.

Backward Feature Elimination is a feature selection technique in machine learning that starts with all available features and iteratively removes the least significant ones. At each step, the model is trained, and the importance of each feature is evaluated based on a predefined criterion such as p-values or model performance metrics. The least important feature is then removed, and the process is repeated until a specified number of features remains or further removal would degrade model performance. This method helps in simplifying the model by eliminating redundant or irrelevant features,

improving interpretability and potentially enhancing predictive accuracy by reducing overfitting.

By comparing the results obtained from the five feature selection techniques used in this study, as shown in the Fig. 8, we conclude that the RFECV (Recursive Feature Elimination with Cross-Validation) feature selection method provides the best results. The top three algorithms identified are Random Forest, CatBoost, and XGBoost. For the remainder of this study, we will rely on these three algorithms.

Fig. 7. Accuracy result using BACKWARD.

Fig. 8. Classifiers performance results.

D. Hyperparameter Tuning

The optimization of the hyperparameters of a machine learning model for optimizing the performance of a model is called hyperparameter tuning. Hyperparameters are different

from model parameters because model parameters are learned during training while hyperparameters need to be set prior to the training process and influence different attributes of the learning process (learning rate, regularization strength, number

of layers in a neural network). Hyperparameter tuning is the process of finding the best selection of hyperparameters for a model which is typically done by systematically searching the space of hyperparameter values in a methodical manner. Some common methods of hyperparameter tuning for machine learning are grid search, random search, and Bayesian optimization. Model performance can be greatly improved by properly tuning the hyperparameters through achieving the ideal settings which enable the learning process to efficiently learn patterns in the data and avoid overfitting.

In this study, we utilize the GridSearchCV technique to determine the optimal parameters for our three models: Random Forest, CatBoost, and XGBoost. This method ensures that our models are fine-tuned for maximum accuracy and robustness. The results obtained from this parameter optimization process are presented in the accompanying Table IV, highlighting the best parameter settings for each model and their corresponding performance metrics.

TABLE IV. BEST PARAMETER SETTINGS FOR EACH MODEL

	Parameter
Random Forest	{bootstrap= False, ccp_alpha= 0, criterion= 'gini', max_depth= None, max_features= 'sqrt', n_estimators= 100, n_jobs= -1, verbose=0, random_state= 42}
XGBoost	{gamma= 0.1, learning_rate= 0.1, max_depth= 7, n_estimators= 200, reg_alpha= 0, reg_lambda= 0.001, verbose=0}

E. Performance Evaluation Metrics

Performance evaluation metrics are crucial tools in machine learning for assessing the effectiveness of predictive models. These metrics provide quantitative measures to evaluate how well a model performs on a given task. Common metrics include accuracy, precision, recall, F1-score, etc.

$$ACC = \frac{TP+TN}{TP+TN+FP+FN} \tag{1}$$

$$PREC = \frac{TP}{TP+FP} \tag{2}$$

$$REC = \frac{TP}{TP+FN} \tag{3}$$

$$F\text{-Measure} = 2 * \frac{PREC*REC}{PREC+REC} \tag{4}$$

IV. RESULTS AND DISCUSSION

The Pima Indians Diabetes dataset served as the foundation for this study, aiming to predict the onset of diabetes. This dataset includes several medical predictor variables and one target variable, which indicates whether or not the patient has diabetes. To enhance the predictive power of our machine learning models, we implemented a variety of feature engineering techniques.

We tested five machine learning algorithms: Random Forest, Gradient Boosting, XGBoost, LightGBM, and CatBoost. These algorithms were chosen for their robust performance in classification tasks. To optimize the input features for these models, we employed several feature engineering techniques, namely SelectKBest, Recursive Feature Elimination (RFE), Recursive Feature Elimination with Cross-Validation (RFECV), Forward Feature Selection, and Backward Feature Elimination.

Among these techniques, RFECV provided the most significant improvement in terms of accuracy and other performance metrics. RFECV methodically eliminates less important features while incorporating cross-validation to prevent overfitting. This approach identified the optimal set of features, which were then used to train our models.

Focusing on the top three algorithms identified by RFECV—Random Forest, CatBoost, and XGBoost—we used GridSearchCV to determine the optimal parameters for each model. This method involves an exhaustive search over specified parameter values to find the best combination that maximizes model performance.

Once the models were trained with these optimized parameters, we compared their performance Fig. 9 and Fig. 10. XGBoost emerged as the top-performing model, achieving an impressive accuracy score of 94%. In comparison, both Random Forest and CatBoost achieved accuracy scores of 92.5%. The superior performance of XGBoost can be attributed to its advanced tree boosting techniques and regularization methods, which help in managing data complexity and avoiding overfitting.

Fig. 9. Confusion matrix results.

Fig. 10. Accuracy comparison of the models.

Comparing our findings with the most recent researches in the same field and used same the dataset, the feature engineering and hyperparameter tuning applied on our selective models, got the highest accuracy rate, Table I represent the comparison of different studies with ours.

In summary, the application of RFECV for feature selection and GridSearchCV for parameter optimization significantly enhanced the performance of our models. XGBoost, with its sophisticated boosting algorithms, proved to be the most effective model for predicting the onset of diabetes using the Pima Indians Diabetes dataset. Future work could explore additional data preprocessing steps and the inclusion of more complex models to further improve predictive accuracy.

V. COMPARISON WITH OTHER STUDIES

When examining the latest studies utilizing the Pima Indians Diabetes dataset, it's evident that our approach to feature engineering and model optimization has set a new benchmark in predictive accuracy.

Therefore, by leveraging RFECV for feature selection, we were able to identify the most relevant features and reduce noise in the dataset, leading to significant improvements in model performance. The subsequent application of GridSearchCV for hyperparameter tuning further optimized our models, ensuring that we achieved the best possible configuration for predictive accuracy. The integration of these techniques enabled our top-performing model, XGBoost, to reach an accuracy of 94%, surpassing the results of the aforementioned studies.

Our study not only highlights the importance of rigorous feature engineering and parameter optimization but also demonstrates the potential of advanced ensemble methods in predictive analytics. The substantial gains in accuracy underline the effectiveness of our approach compared to other contemporary methodologies. Table I provides a detailed

comparison, showcasing the advancements our study brings to the field.

VI. CONCLUSION

This research focused on predicting the onset of diabetes using the Pima Indians Diabetes dataset. By applying various machine learning algorithms and feature engineering techniques, we aimed to identify the most effective model for this task. Among the algorithms tested — Random Forest, Gradient Boosting, XGBoost, LightGBM, and CatBoost — XGBoost demonstrated superior performance.

We employed several features engineering methods, including SelectKBest, Recursive Feature Elimination (RFE), Recursive Feature Elimination with Cross-Validation (RFECV), Forward Feature Selection, and Backward Feature Elimination, to refine our models. RFECV stood out as the most successful approach, yielding the best results in terms of accuracy and other metrics. Consequently, we concentrated on the top three algorithms identified by RFECV: Random Forest, CatBoost, and XGBoost. To further optimize these models, we utilized GridSearchCV to find the best parameter settings. After training the models with these optimized parameters, XGBoost achieved an accuracy score of 94%, outperforming Random Forest and CatBoost, which both scored 92.5%.

In summary, this study highlights the efficacy of XGBoost in predicting diabetes, this is due to its advanced boosting techniques and robust regularization methods. The importance of comprehensive feature engineering and parameter tuning was also underscored. Future research could explore additional preprocessing steps and incorporate more complex models to enhance predictive accuracy further.

Abstract—The formulation of the proposed methods and algorithms facilitates a comprehensive examination of intricate non-stationary thermo-mechanical processes in rods with varying cross-sectional geometries. Furthermore, it advances the theoretical framework for analyzing the thermo-mechanical properties of rod structures utilized in the machinery industry of the Republic of Kazakhstan. The creation of these intellectual products aids in the progression of this sector and fortifies the nation's sovereignty. This article delineates methods and algorithms for investigating non-stationary thermo-mechanical processes in rods with diverse cross-sectional shapes that influence global manufacturing technologies. The scientific and practical importance of this work lies in the application potential of the developed approach for examining non-stationary thermo-mechanical characteristics of rod-like elements in various installations. The findings also enhance the scientific research direction in mechanical engineering. In conclusion, the article outlines future technological advancements, summarizes the research on non-stationary thermo-mechanical processes in rods with different cross-sectional geometries, and highlights significant economic benefits by facilitating the selection of reliable rods for specified operating conditions. This ensures the continuous and dependable operation of machinery used in mechanical engineering.

Keywords—Heat flow; heat transfer; thermal expansion coefficient; thermal conductivity; modulus of elasticity

I. INTRODUCTION

The structural components of modern gas turbine power plants, nuclear and thermal power stations, hydrogen and rocket engines, internal combustion engines, and installations for deep processing of mineral resources and oils operate within a complex force and thermal environment. The reliable operation of these systems depends on the thermo-mechanical characteristics of their load-bearing elements. Typically, these elements are considered as rods of limited length and constant cross-sectional area. In related studies, temperature distribution along the length of such rods is determined based on fundamental thermophysics laws, considering the types of heat sources acting on them. Unlike those, the current work focuses on a horizontal rod of limited length and constant cross-sectional area, fully thermally insulated on its lateral surface. A

constant heat flux is applied to the left end, while the right end exchanges heat with the environment.

Using fundamental energy conservation laws, this study determines the temperature distribution along the rod, its thermal elongation, the axial compressive force generated, and the distribution of elastic, temperature, and thermoelastic deformations and stresses, as well as the displacement field. Understanding the temperature distribution along the rod is crucial for the thermal stress state in bearing components of power plants and engines.

Previous works such as [1] and [2] have explored the principles of elasticity theory and numerical methods for applied mechanics. The primary thermo-physics equations, detailed in [3], include mass, momentum, and energy conservation. Other studies, like [4], [5], and [6], have investigated contact heat transfer and the thermal stress-strain state under various conditions, using the finite element method [7]. Additionally, [8] and [9] have addressed stress-strain states in rigid plastic pipes and nonlinear finite element modeling, while [10] and [11] discussed adiabatic shear bands and nonlinear continuum mechanics.

In [12], the temperature distribution within nuclear fuel rods was analyzed, highlighting the importance of maintaining fuel integrity. Research in [13], [14], and [15] derived computational relationships for thermal forces in rectangular cross-section rods. Other studies, such as [16], examined the thermal behavior of bars during hot rolling. The finite element method was also employed in [17] and [18] to model temperature fields in Terfenol-D rods, while [19] investigated unstable temperature distributions in cylindrical rods subjected to laser heat sources.

This body of work supports the development of a mathematical model for the thermomechanical state of a variable cross-section rod, considering local temperature, thermal insulation, and heat exchange. Scientific works [20]-[26] provide analytical solutions for compressive extensions and force distributions in thermally insulating rods, based on energy conservation principles. This paper diverges by using quadratic spline functions to address a specific practical

problem, offering a novel approach to understanding the thermomechanical behavior of such rods.

II. MATERIALS AND METHODS

Let's consider a rod of finite length clamped at both ends, whose cross-section varies along its length and is circular. In this case, the radius of the cross-section depends linearly on the coordinates. The radius of the left end is denoted by r_0 , the radius of the right end by r_L , and the length of the rod by L . Thus, the radius as a function of the coordinate x is given by the following expression [20]:

$$r = \frac{r_L - r_0}{L} \cdot x + r_0 \quad (1)$$

where x is the coordinate along the length of the rod, ranging from 0 (left end) to L (right end) (Fig. 1).

Fig. 1. Calculation diagram of the problem.

The temperature is fixed at the left clamped end as $T(x = 0) = T_1$, and at the right end as $T(x = L) = T_{2n+1}$. The lateral surfaces of the sections $(0 \leq x \leq x_1)$, $(x_2 \leq x \leq x_3)$ and $(x_4 \leq x \leq x_L)$ are thermally insulated. In the section $(x_1 \leq x \leq x_2)$ heat exchange with the environment occurs through the lateral surface area, with a heat transfer coefficient h , and an ambient temperature T_{co} . Additionally, a heat flux of constant intensity q is applied to the lateral surface area in the section $(x_3 \leq x \leq x_4)$. The objective is to numerically investigate the influence of the temperature value $T_0 \in [(-150 C) \div (+150 C)]$ on the system.[21].

On the temperature distribution field $(T = T(x))$, elastic displacement $(u = u(x))$, as well as components of deformation $(\varepsilon_x = \varepsilon_x(x); \varepsilon_T = \varepsilon_T(x); \varepsilon = \varepsilon(x))$ and voltage $(\sigma_x = \sigma_x(x); \sigma_T = \sigma_T(x); \sigma = \sigma(x))$. To develop a mathematical model of the temperature distribution along the length of the considered partially thermally insulated rod of finite length, the rod is discretized using quadratic elements with three nodes. The total number of elements is denoted by n . Consequently, the total number of nodes will be $(2n + 1)$. The discretization is performed in such a manner that the element boundaries coincide with the boundaries of the thermally insulated regions of the rod. For each element, a functional expression is derived that characterizes its total thermal energy. Specifically, for elements belonging to the thermally insulated sections of the rod, the functional I_i is given by:

$$I_i = \int_{V_i} \frac{K_{xx}}{2} \left(\frac{\partial T}{\partial x} \right)^2 dV, (i = 1, 2, \dots) \quad (2)$$

Here, K_{xx} represents the thermal conductivity coefficient along the x -axis, T is the temperature, and V_i is the volume of the i -th element. This integral expression accounts for the

thermal energy stored within each element due to the temperature gradient along the rod. Where V_i - volume of the i -th element.

For elements located on the section of the rod where heat exchange occurs through the lateral surface, the expression for the corresponding functional takes into account both the internal thermal energy due to the temperature gradient and the heat exchange with the environment [22].

$$I_j = \int_{V_j} \frac{K_{xx}}{2} \left(\frac{\partial T}{\partial x} \right)^2 dV + \int_{S_{\text{лateral}}} \frac{h}{2} (T - T_{co})^2 dS, (j = 1, 2, \dots) \quad (3)$$

Where V_j - volume of the j -th element, $S_{\text{лateral}}$ - area of the lateral surface of the j -th element.

For elements located on a section of the rod where a heat flux of constant intensity q is supplied through the lateral surface, the functional expression that characterizes their total thermal energy includes contributions from both the internal thermal energy due to the temperature gradient and the external heat flux applied to the surface.

$$I_k = \int_{V_k} \frac{K_{xx}}{2} \left(\frac{\partial T}{\partial x} \right)^2 dV + \int_{S_{\text{лateral}}} qT(x)dS, (k = 1, 2, \dots) \quad (4)$$

The general expression for the functional of total thermal energy for a partially thermally insulated rod with a variable cross-section, accounting for local temperatures, heat flux, and heat transfer, can be derived by combining the contributions from different sections of the rod. These contributions include the internal thermal energy due to the temperature gradient, heat exchange with the environment, and the applied heat flux.

$$I = \sum_{t=1}^n I_t \quad (5)$$

To construct a mathematical model of the temperature distribution field along the length of the rod, the functional representing the total thermal energy must be minimized with respect to the nodal temperature values. This minimization leads to a system of linear algebraic equations, which can be solved to obtain the temperature distribution

$$\frac{\partial I}{\partial T_t} = 0, (t = 2, 3, \dots, 2n) \quad (6)$$

Because T_1 and T_{2n+1} are considered given, then the number of equations in system (6) will be equal to $(2n + 1)$.

Solving the system for different values T_1 and fixed values T_{2n+1} , h, T_{co} , as well as q , the influence of T_1 on the nature of the temperature distribution field along the length of the rod in question.[23].

After constructing the temperature distribution field along the length of the rod, the next step is to develop a mathematical model for the distribution field of elastic displacement, as well as the components of deformation (strain) and stress. This model is crucial for understanding the mechanical response of the rod to the thermal loads. To do this, the rod under study is discretized $(N = \frac{n}{2})$ quadratic elements with three nodes. After obtaining the temperature distribution and determining the displacement field, the next step is to write the expression for the functional of the potential energy of elastic deformation for each element. This functional represents the elastic energy

stored in the rod due to the deformation caused by both mechanical and thermal effects.

$$\Pi_i = \int_{V_i} \frac{\sigma_x \varepsilon_x}{2} dV - \int_{V_i} \alpha E T(x) dV, (i = 1, 2, \dots, N) \quad (7)$$

Where V_i - volume of the i -th element, $u = u(x)$ - elastic displacement distribution field, $\varepsilon_x = \frac{\partial u}{\partial x}$ - distribution field of the elastic component of deformation, $\sigma_x = E \varepsilon_x = E \cdot \frac{\partial u}{\partial x}$ - distribution field of the elastic component of stress, E - elastic modulus of the rod material, α - coefficient of thermal expansion of the rod material, $T = T(x)$ - temperature distribution field determined from the solution of system (6).

For the considered rod as a whole, the expression for the potential energy of elastic deformation is as follows:

$$\Pi = \sum_{i=1}^N \Pi_i \quad (8)$$

To construct a mathematical model for the distribution of elastic displacement along the length of the rod, the functional of the potential energy of elastic deformation is minimized with respect to the nodal values of the elastic displacement. This minimization leads to a system of linear algebraic equations that describe the elastic displacement field.[26].

$$\frac{\partial \Pi}{\partial u_i} = 0, (i = 1, 2, \dots, (2N + 1)) \quad (6)$$

Solving this system, the elastic displacement distribution field is determined $u = u(x)$ along the length of the rod in question. Based on them, the corresponding fields for the distribution of the components of deformation and stress are constructed as follows:

$$\varepsilon_x = \frac{\partial u}{\partial x}; \varepsilon_T = -\alpha T(x); \varepsilon = \varepsilon_x + \varepsilon_T \quad (10)$$

$$\sigma_x = E \varepsilon_x; \sigma_T = E \varepsilon_T; \sigma = (\sigma_x + \sigma_T) \quad (11)$$

To carry out numerical studies, we take the following as initial data:

$L = 20$ (cm), $r_0 = 1$ (cm), $r_l = 2$ (cm), $n = 200, N = \frac{n}{2} = 100$, $q = -1000$ (W/cm²), $K_{xx} = 100$ (W/(cm · C)), $h = 10$ (W/(cm² · C)), $T_{co} = 40$ (C), $T_{401} = 150$ (C), and vary the value $T_1 \in [(-150 \text{ C}) \div (+150 \text{ C})]$ in increments (-50 C) .

Consider the following 7 options. In all options except value T_1 , the values of all parameters are fixed.

III. RESULTS AND DISCUSSION

A. Option-1

Consider the case when $T_1 = 100$ (C), i.e. previous value $T_1 = 150$ (C) let's reduce it by 1/3. In this case, the nodal temperature values are given in Table I. The corresponding field temperature distribution is given in Fig. 2. From them it is clear that the highest nodal temperature value will be $T_{277} = 262,089$ (C). The coordinate of this section $x = 13,8$ (cm), that the phenomenon is caused by the supply to the closed side surface of the area $2 \leq x \leq 16$ (cm) heat flux rod of constant intensity $q = -1000$ (W/cm²). Reducing the nodal temperature values on the site $4 \leq x \leq 8$ (cm) the rod is due to the ongoing heat exchange with the surrounding closed side surface of this section. Therefore, the smallest nodal

temperature value $T_{89} = 85,603$ (C). The coordinate of this section $x = 4,4$ (cm).

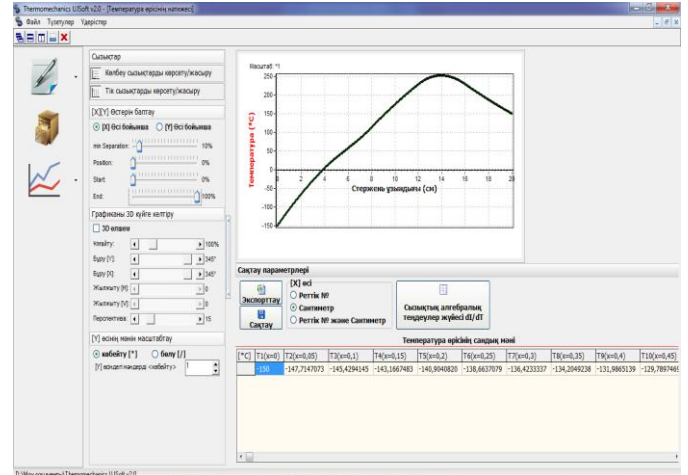

Fig. 2. Field temperature distribution at different values $T(x = 0) = T_1$.

Table II presents the nodal displacement values. The corresponding field distribution of displacements along the length of the considered rod of variable cross-section is given in Fig. 3. From these it is clear that all sections of the rod under study move against the direction of the Ox axis. In this case, the section of the rod with the coordinate $x = 8,8$ (cm) moves more than others i.e. $u_{89} = -0,0142153$ (cm).

Fig. 4 their corresponding distribution field along the length of the rod under consideration is given. From them it is clear that on the site $0 \leq x \leq 8,75$ (cm) of the rod, the behavior of the elastic component of the deformations will be compressive, and then tensile. At the same time, the greatest compressive ε_x corresponds near the left pinched end. Highest tensile value $\varepsilon_x = 0,0018518$ which corresponds to the section coordinate $x = 14,45$ (cm). Corresponding field distribution ε_T along the length of the rod in question is given by Fig. 6. It

should be noted that along the entire length of the rod under study ε_T has a compressive character. Its greatest value corresponds to the section with coordinate $x = 13,85$ (cm). Here $\varepsilon_T = -0,0032759$. The corresponding field distribution is given in Fig. 6. From these it is clear that starting from the

left pinched end of the rod falls monotonously. But along the entire length of the rod it has a compressive character. Its greatest value corresponds to the left pinched end of the rod. Near the left end its value is equal to $\varepsilon = -0,0041062$.

TABLE II. NODAL DISPLACEMENT VALUES

Fig. 3. Distribution field displacement at different values $T(x=0) = T_1$.

The field distribution of these stress components along the length of the rod is given in Fig. 5. From these materials it is clear that the elastic component of the stress σ_x location on $0 \leq x \leq 8,75$ (cm) the rod behaves compressively, and then has a tensile character. Temperature component voltage σ_T along its entire length it has a compressive character. Its greatest value $\sigma_T = -6551,887$ (kG/cm²). This corresponds to the section whose coordinate $x = 13,85$ (cm). Thermoelastic stress component $\sigma = \sigma_x + \sigma_T$ along its entire length it has a compressive character. Its highest value corresponds to the left pinched end of the rod, i.e. $\sigma = -8212,409$ kG/cm²). Starting from left to right, it monotonically decreases and at the right pinched end it has the smallest value $\sigma = -2084,123$ (kG/cm²). In this case, the magnitude of the compressive force $R_2 = \sigma_T(x=0,05) \cdot F_n = -25929,2052$ (kG). Naturally, this is less than in the case $T_1 = 150$ (C) by 5.4%.

1 - ε_x ; 2 - ε_T ; 3 - $\varepsilon = \varepsilon_x + \varepsilon_T$

Fig. 4. Field distribution of strain components at $T(x=0) = T_1 = 100$ (C).

1 - σ_x ; 2 - σ_T ; 3 - $\sigma = \sigma_x + \sigma_T$

Fig. 5. Field distribution of voltage components at $T(x=0) = T_1 = 100$ (C).

Now consider the next option.

B. Option-2

Compared to option 1, in this option the value of the set temperature T_1 let's reduce it by three times, i.e. let's accept $T_1 = 50 (C)$. In this case, the nodal temperature values are presented in Table III. The temperature distribution corresponding to the field along the length of the rod under study is shown in Fig. 2. In this case, the highest temperature value will be $T_{278} = 260,034 (C)$. This temperature value corresponds to the section of the rod whose coordinate $x = 13,85 (cm)$. Naturally, this is due to the supplied heat flow of constant intensity and power $q = -1000 (W/cm^2)$ on the side surface areas $12 \leq x \leq 16 (cm)$ rod.

The distribution field of the displacement field is given in Fig. 3. From these data it is clear that all sections of the rod under study move against the direction of the Ox axis. When the section moves the most, the coordinate of which $x = 8,7 (cm)$. This section moves against the direction of the Ox axis by $u_{88} = -0,0148657 (cm)$.

TABLE III. NODAL TEMPERATURE VALUES ($T_1 = 50 (C)$)

Nodal points	$T (C)$	Nodal points	$T (C)$	Nodal points	$T (C)$	Nodal points	$T (C)$
1	50,000	101	75,942	201	188,655	301	252,280

40	60,411	140	104,153	240	237,808	340	212,401
50	62,790	150	115,724	250	248,213	350	201,475
60	65,064	160	129,596	260	255,281	360	190,837
70	67,242	170	144,773	270	259,149	370	180,475
80	69,329	180	159,441	280	259,958	380	170,380
90	71,831	190	173,611	290	257,840	390	160,540
100	75,506	200	187,308	300	252,922	400	150,947

The field-corresponding distribution of these components along the length of the rod in question is shown in Fig. 6.

1 - ϵ_x ; 2 - ϵ_T ; 3 - $\epsilon = \epsilon_x + \epsilon_T$

Fig. 6. Field distribution of strain components at $T(x = 0) = T_1 = 50 (C)$.

From these data it is clear that the behavior of the elastic deformation component in the area $0 \leq x \leq 8,65 (cm)$ the rod will be compressive, and then tensile. In this case, the largest compressive elastic component of deformations ϵ_x falls close to the left clamped end of the test rod of variable cross-section, $\epsilon_x = -0,0032431$. Greatest tensile ϵ_x corresponds to the section with coordinate $x = 14,45 (cm)$. In this section the value ϵ_x will be $\epsilon_x = 0,0019087$. Behavior of the temperature component ϵ_T along the entire length of the rod will be compressive. At the same time, the greatest compressive ϵ_T corresponds to the section with coordinate $x = 13,85 (cm)$. In this section $\epsilon_T = -0,0032504$.

Unlike ϵ_x and ϵ_T field distribution of the thermoelastic component of deformations $\epsilon = \epsilon_x + \epsilon_T$ will be described by a smooth curve. Along the entire length of the rod it has a compressive character. Moreover, its greatest value $\epsilon = -0,0038718$ corresponds closer to the left pinched one, and the smallest $\epsilon = -0,0009826$ closer to the right end.

Nodal values of all three stress components (σ_x, σ_T and $\sigma = \sigma_x + \sigma_T$) their field distributions along the length of the rod of variable cross-section under study are shown in Fig. 7.

1 - σ_x ; 2 - σ_T ; 3 - $\sigma = \sigma_x + \sigma_T$

Fig. 7. Field distribution of stress components at $T(x = 0) = T_1 = 50 (C)$.

From these results it is clear that the values of these stress components are directly proportional to the values of the corresponding strains. In addition, in this case the value of the compressive force will be $R_3 = \sigma_n(x = 0,05) \cdot F_n = -24448,9304 (kG)$. This value is 10.8% less than the compressive force that occurs when $T_1 = 150 (C)$.

C. Option-3

Now consider the fourth option, when $T_1 = 0 (C)$. The corresponding field temperature distribution along the length of the test rod of variable cross-section is given in Fig. 2.

The corresponding displacement distribution fields along the length of the rod under study are shown in Fig. 3. It should be noted here that, except for the pinched ends, all sections of the rod move against the direction of the Ox axis. At the same time, in this direction the section whose coordinate moves more $x = 8,6 (cm)$. The displacement value of this section $u_{87} = -0,0155244 (cm)$.

The corresponding field distribution along the length of the rod under study is shown in Fig. 8.

Fig. 8. Field distribution of strain components at $T(x = 0) = T_1 = 0 (C)$.

From these results it is clear that in the area $0 \leq x \leq 8,55$ (cm) behavior of the rod elastic component of deformation ε_x will be compressive, and then tensile. In this case, the greatest compressive ε_x corresponds near the left pinched end. The highest value of the compressive elastic component of deformation $\varepsilon_x = -0,0036275$, and tensile $\varepsilon_x = 0,0019657$ and it corresponds to the section with coordinate $x = 14,45$ (cm) rod. Behavior of the temperature component of deformation ε_T along the entire length of the rod will be compressive. In this case, its lowest value corresponds near the left pinched end, and its highest value $\varepsilon_T = -0,0032249$ corresponds to the section with coordinate $x = 13,85$ (cm) rod. As can be seen from Fig. 8 field distribution of the thermoelastic component of deformation $\varepsilon = \varepsilon_x + \varepsilon_T$ is described by a smooth monotonically increasing curve. At the same time, behavior along the entire length of the rod under study will be compressive. Its greatest value occurs near the pinched left end of the rod and will be equal to $\varepsilon = -0,0036374$. Its smallest value corresponds closer to the right pinched end of the rod under study.

Fig. 9. Field distribution of voltage components at $T(x = 0) = T_1 = 0 (C)$.

The field distribution of these voltage components is given in Fig. 9. Naturally different behavior matches behavior $\varepsilon_x, \varepsilon_T$ and $\varepsilon = \varepsilon_x + \varepsilon_T$. The values of these stress components will be

proportional to the corresponding strain components. In this case, the compressive force values R_4 will be equal $R_4 = \sigma_n(x = 0,05) \cdot F_n = -22968,6555$ (kG). This is less than R_1 (in the case when $T_1 = 150 (C)$) by 16.2%.

Now let's look at the fifth option.

D. Option-4

In this version we will accept $T_1 = -50 (C)$. The corresponding temperature distribution field along the length of the rod of variable cross-section under study is shown in Fig. 2. In this case, the maximum nodal temperature values $T_{max} = T_{279} = 255,968 (C)$ and it corresponds to the cross section of the rod in question whose coordinate $x = 13,9$ (cm).

The corresponding distribution field on Fig. 3. In this case, all sections of the rod move against the direction of the Ox axis. In this direction the greatest movement of the section of the rod whose coordinate is $x = 8,4$ (cm). The displacement value of this section $u_{max} = u_{85} = -0,0161891$ (cm).

The field-corresponding distributions of these strain components are shown in Fig. 10.

Fig. 10. Field distribution of strain components at $T(x = 0) = T_1 = -50 (C)$.

From these results it is clear that the behavior of the elastic component of deformations ε_x location on $0 \leq x \leq 8,35$ (cm) of the rod under study will be compressive, and then tensile. Highest compressive value $\varepsilon_x = -0,0040118$ and it corresponds near the left pinched end of the rod. In this case, the largest tensile value of the strain component $\varepsilon_x = 0,0020226$ and it corresponds to the section with coordinate $x = 14,45$ (cm) rod. Unlike previous options, the behavior of the temperature component of deformations ε_T will be alternating. Location on $0 \leq x \leq 2,05$ (cm) core behavior ε_T will be tensile, and then it behaves compressively. In this case, the greatest tensile value ε_T observed near the left pinched end and it is equal $\varepsilon_T = 0,0006089$. Location on $2,15 \leq x \leq L = 20$ (cm) rod behavior ε_T will be compressive. Maximum compressive temperature component of deformation ε_T will be equal $\varepsilon_T = -0,0031994$ and it occurs in the section of the rod whose coordinate is $x = 13,95$ (cm). Behavior of the thermoelastic component of deformations $\varepsilon = \varepsilon_x + \varepsilon_T$ along the entire length of the rod will have a compressive character. It should be noted that the values ε starting from the left pinched end, it monotonically decreases along the length of the studied rod of

variable cross-section. The highest value $\varepsilon = -0,0034029$ which corresponds to the left pinched end of the rod. Near the right pinched end of the test rod, the value ε will be the smallest and will be equal $\varepsilon = -0,0008636$.

The distribution of these stress components corresponding to them along the length of the rod of variable cross-section under study is given in Fig. 11.

Fig. 11. Field distribution of voltage components at $T(x = 0) = T_1 = -50 (C)$.

Location on $0 \leq x \leq 8,35$ (cm) behavior of the elastic component of stress of the rod under study σ_x will be compressive. In this case, the highest compressive stress σ_x observed near the left pinched end and will $\sigma_x = -8023,682$ (kG/cm²). On another part of the rod $8,45 \leq x \leq L = 20$ (cm) behavior σ_x will be stretchy. Moreover, its greatest value $\sigma_x = 4045,210$ (kG/cm²) observed near the section whose coordinate $x = 14,45$ (cm). Unlike σ_x behavior of the temperature component of voltage σ_T location on $0 \leq x \leq 2,05$ (cm) the rod under study will be tensile. More over, its greatest value $\sigma_T = 1217,790$ (kG/cm²) observed near the left pinched end. On the rest of the behavior rod σ_T will be compressive. The highest value of compressive stress $\sigma_T = -6398,852$ (kG/cm²) observed in the section whose coordinate $x = 13,95$ (cm). Behavior of the thermoelastic stress component $\sigma = \sigma_x + \sigma_T$ along the entire length of the rod under study will have a compressive character. Its greatest value $\sigma(x = 0,05) = -6805,893$ (kG/cm²) observed at the left pinched end of the rod. As the length of the rod increases its value decreases monotonically and near the right pinched end $\sigma(x = 19,95) = -1727,199$ (kG/cm²), i.e. $\frac{\sigma(x=0,05)}{\sigma(x=19,95)} = 3,94$ times. From the obtained values $\sigma = \sigma_x + \sigma_T$ let's calculate the value of the compressive $R_5 = \sigma_n(x = 0,05) \cdot F_n = -21488,3838$ (kG).

Now consider the next sixth option.

E. Option-5

In this option, we assume that the given value is $T_1 = -100 (C)$. In this case, the field temperature distribution along the length of the considered rod of variable cross-section is shown in Fig. 2. From Fig. 2 it is clear that the highest temperature value, $T_{280} = 253,952 (C)$ and it corresponds to the section of the rod whose coordinate $x = 13,95$ (cm).

The corresponding field of elastic displacement of sections of the rod is shown in Fig. 3. From Fig. 3 it can be seen that all sections of the rod under study move against the direction of the Ox axis. Moreover, in this direction the greatest displacement belongs to the section with the coordinate $x = 8,3$ (cm). The displacement value of this section will be $u_{84} = -0,0168614$ (cm).

Fig. 12. Field distribution of strain components at $T(x = 0) = T_1 = -100 (C)$.

The field-corresponding displacement of these deformation components along the length of the rod under study is shown in Fig. 12. From these tables and the figure it is clear that the behavior of the elastic component of deformations along the length of the rod under study will be alternating in sign. For example, on the site $0 \leq x \leq 8,25$ (cm) rod character ε_x will be compressive, and then it has a tensile character. Maximum compressive elastic deformation $\varepsilon_x = -0,0043962$ observed near the left pinched end where the temperature is set $T_1 = -100 (C)$. In this case, the maximum tensile elastic deformation $\varepsilon_x = 0,0020795$ corresponds to the section $x = 14,45$ (cm). On the contrary, the behavior of the temperature component of deformation ε_T in the initial section of the rod under study will have a tensile character, and then a compressive character. The highest value of the tensile temperature component of deformation $\varepsilon_T = 0,0012277$ corresponds near the left pinched end of the rod under study. At that time, the highest value of the compressive temperature component of deformation ε_T will $\varepsilon_T = -0,0031744$ which belongs to the section whose coordinate $x = 13,95$ (cm) the rod under study. In Fig. 12, it is clear that the behavior of the thermoelastic component of deformations $\varepsilon = \varepsilon_x + \varepsilon_T$ along the entire length of the rod under study will be compressive. In this case, from the left to the right end of the rod it will decrease monotonically. Highest value $\varepsilon = -0,0031685$ corresponds to the section near the left pinched end of the rod.

The distribution of these voltage components corresponding to the field is given in Fig. 13. The behavior of these stress components will correspond to the behavior of similar strain components. In this case, the value of the compressive force $R_6 = \sigma_n(x = 0,05) \cdot F_n = -20008,1089$ (kG).

Fig. 13. Field distribution of voltage components at $T(x = 0) = T_1 = -100 (C)$.

Finally, let's look at the last option.

F. Option-6

In this option the value T_1 let's accept $T_1 = -150 (C)$. Field temperature distribution along the length of the test rod of variable cross-section in the case $T_1 = -150 (C)$ shown in Fig. 2. In this case, the highest temperature value $T_{280} = 251,950 (C)$ corresponds to the section whose coordinate $x = 13,95 (cm)$.

The corresponding displacement field is shown in Fig. 3. From these results it is clear that all sections of the rod except the clamped ones move against the direction of the Ox axis. In this case, the greatest movement $u_{83} = -0,0175417 (cm)$ which corresponds to the section coordinate $x = 8,2 (cm)$.

Fig. 14. Field distribution of strain components at $T(x = 0) = T_1 = -150 (C)$.

The field-corresponding distributions of these strain components are shown in Fig. 14. From Fig. 14 it is clear that the behavior of the elastic component of deformations ϵ_x location on $0 \leq x \leq 8,15 (cm)$ will be compressive, and then tensile. In this case, the greatest value of the compressive force ϵ_x observed near the left pinched end of the rod and will $\epsilon_x = -0,0047805$. The largest value of the tensile component of deformation $\epsilon_x = 0,0021365$ corresponds to the section $x = 14,45 (cm)$. From Fig. 15 it is clear that the behavior of the temperature components of deformations ϵ_T at the initial section $0 \leq x \leq 3,85 (cm)$ the rod will be tensile, and then compressive. In this case, the greatest value is tensile $\epsilon_T =$

$0,0018464$ which is observed near the left pinched end of the rod. The highest compressive value $\epsilon_T = -0,0031494$ which corresponds to the section whose coordinate $x = 13,95 (cm)$. From the results given Fig. 14 it is clear that the behavior of the thermoelastic component of deformations $\epsilon = \epsilon_x + \epsilon_T$ along the entire length of the rod will be compressive. Moreover, as x increases, its value decreases monotonically. Highest value ϵ observed near the left pinched end of the rod and will be equal to $\epsilon = -0,0029341$.

Table IV presents the values of the stress components σ_x , σ_T , $\sigma = \sigma_x + \sigma_T$ in the cross-sections of the studied rod. The field-corresponding distribution of these components along the length of the test rod of variable cross-section is shown in Fig. 15.

Fig. 15. Field distribution of voltage components at $T(x = 0) = T_1 = -150 (C)$.

TABLE IV. NODAL VALUES OF $\sigma_x, \sigma_T, \sigma = \sigma_x + \sigma_T$ AT $T_1 = -150 (^\circ C)$

Nodal points	Nodal points σ_x	Nodal points σ_T	Nodal points $\sigma = \sigma_x + \sigma_T$
1	-9561,083	3692,868	-5868,216
2	-9447,384	3579,169	-5868,216
3	-9219,750	3466,593	-5753,157
...
10	-8136,232	2708,653	-5427,579
50	-3066,817	-757,061	-3823,878
100	1653,829	-4305,735	-2651,906
150	4214,083	-6160,725	-1946,642
200	2283,025	-3772,275	-1489,250

It should be noted here that the behavior of these stress components will be like the corresponding strain components. Naturally, the value of the stress components will be proportional to the values of the corresponding strain components. In this case, the corresponding value of the compressive force $R_7 = \sigma_n(x = 0,05) \cdot F_n = -18527,8372 (kG)$.

By analyzing the seven options considered, you can build a comparative Table I. From this table it can be seen that with

decreasing value T_1 the magnitude of the resulting compressive force R decreases. For large negative values T_1 the magnitude of the compressive force is noticeably reduced. Thus, setting the values T_1 it is possible to control the magnitude of the compressive force R arising from the distribution of the temperature field in such a way that this rod element of the variable cross-section of the structure does not collapse. We will also build Fig. 16, where a curve is given that characterizes the relationship between the resulting compressive force R and the values of the given temperature $T(x = 0)$ on the left pinched end. It should be noted here that the radius of the left end of the rod is two times smaller than the right one.

Fig. 16. Dependency between $T(x = 0)$ and R.

TABLE V. INFLUENCE VALUE $T(x = 0) = T_1$ BY THE MAGNITUDE OF THE RESULTING COMPRESSIVE FORCE R

No. p/p	T_1 (C)	T_{max} (C)	Coord. sections (cm)	u_{max} (cm)	Coord. section (cm)
1	150	264.153	$x = 13,75$	-0.0135704	$x = 8,9$
2	100	262,089	$x = 13,80$	-0.0142153	$x = 8,8$

7	-150	251,950	$x = 13,95$	-0.0175417	$x = 8,2$

IV. CONCLUSION

As a result, the following tasks were completed:

1) Algorithms have been compiled for studying local heat flows and heat transfer problems transmitted in the fields of temperature, displacement, deformation and stress on a variable rod with a cross-sectional area of finite length;

2) Algorithms and methods have been created for determining the thermal field of the side surface of an insulated column under the influence of heat flow and heat transfer.

The scientific and practical significance of the work lies in the possibility of using the developed approach to study the non-stationary thermophysical characteristics of plant elements having the shape of a rod with different cross-sectional configurations. The results also contribute to the development of research areas in mechanical engineering. The use of

developed methods and algorithms for studying non-stationary thermophysical processes in rods with different transverse shapes provides significant savings, as they allow one to select a reliable rod for given operating conditions. This makes it possible to ensure continuous and reliable operation of installations used in mechanical engineering.

In the Republic of Kazakhstan, similar developments and research are practically absent.

The development of the proposed methods and algorithms makes it possible to study in detail complex non-stationary thermophysical processes in rods with different cross-sectional shapes. In addition, they make it possible to theoretically develop an appropriate methodology for studying the thermophysical characteristics of rod structures used in the engineering industry of the Republic of Kazakhstan. The development of such smart products contributes to the development of this industry and strengthens the country's sovereignty.

Abstract—Recently, there's been growing excitement around the innovative capabilities of blockchain technology, especially for enhancing security, privacy, and transparency. Its application in various sectors, like finance and logistics, is intriguing, but its potential in healthcare stands out. Specifically, in the realm of medical data management, blockchain can transform how we protect patient data. Our study unveils a cutting-edge approach to handle digital health records by harnessing the power of Amazon Web Services (AWS). This pioneering, serverless model is not only cost-effective, with charges only for used resources, but also offers heightened security and for blockchain network access. We build a private, permissioned blockchain network with Hyperledger Fabric to control access while ensuring transparency. The paper demonstrates the prowess of this new system is validated through rigorous tests on speed, network prowess, and multi-user handling, complete with a detailed cost analysis for implementation. The paper further demonstrates the use of the Gatling open-source library to design various experiments for performance measurement.

Keywords—Hyperledger; blockchain; healthcare; data management

I. INTRODUCTION

Distributed ledger technology, commonly referred to as blockchain, facilitates the sharing of data between peer-to-peer networks [1]. Its first application was seen in 2008 with the Bitcoin cryptocurrency [2]. The main appeal of blockchain is its low cost, speed, improved security, and direct peer-to-peer transactions without relying on a central third party.

In today's technological age, the increasing reliance on accurate data calls for new methods of storing and analyzing information. Ensuring that data is immutable, secure, and maintains its integrity has become an important part of modern systems. Especially since the implementation of Bitcoin in 2008, blockchain has stood out as an emerging solution [3]. The rapid growth of medical data [2] coupled with the rise of blockchain suggests the need for a new framework. As electronic medical records (EMRs) increase in size and scope [4], modern systems struggle to keep up. Maintaining and securing EMR data is essential, especially given the fragility of patient information and the complexity of sharing such information across locations, and traditional databases often fail to meet these challenges accurately [5]. Moreover, the integration of blockchain technology could offer a robust

solution to these issues, providing a decentralized, secure, and transparent platform for managing and sharing EMR data.

Considering blockchain's inherent properties such as data immutability, decentralized ledger, and strong security, it appears to be a powerful solution for EMR management [6]. The immutable and transparent nature of blockchain ensures that once data is stored, it remains untouched [7]. This could significantly reduce the risks of data tampering and unauthorized access, which are common concerns in traditional EMR systems.

Four key characteristics define blockchain: decentralization, immutability, audibility and traceability, and data integrity. This ensures that any transactions or records on the network remain unchanged [8]. Blockchain operates without a central governing body, instead using consensus mechanisms to support data and network peers. Correlations are verified using a Merkle tree-like structure [9], which supports data integrity.

There are basically three types of blockchain: public, federated, and private. Like Bitcoin and Ethereum, public versions are open source. In contrast, confederation block chains limit access to a particular group, and although they are confined to private blocks, they are managed by a single entity. Given the breadth of blockchain applications, there is rarely a universal definition. Table I provides an in-depth comparison of these three types.

This paper explores a comprehensive review of a cloud-centric approach to securing data management systems through blockchain technology, specifically through AWS. The article begins with an overview that emphasizes the need to address security challenges in EMRs. The paper then describes the proposed system architecture, clarifies external components such as the Hyperledger blockchain grid, and specific AWS applications. Additionally, a diagram of the sequence of reactions is provided. Reinforcing the background, the paper presents an experimental performance measure of the system.

In conclusion, the paper recounts his major publications and contributions. In the final sections, it discusses the development of the system and potential efficiencies, demonstrating a progressive research focus and the ability to continuously refine and modernize the system.

TABLE I. TYPES OF BLOCKCHAINS [2], [9]

Property	Public blockchain	Consortium blockchain	Private blockchain
Consensus determination	All miners	Selected set of nodes	One organization
Read permission	Public	Public or restricted	Public or restricted
Immutability	Nearly impossible	Could be tampered	Could be tampered
Efficiency	Low	High	High
Centralized	No	Partial	Yes
Consensus process	Permissionless	Permissioned	Permissioned

II. RELATED WORK

Asma Khatoun [10] investigated in detail the integration of blockchain-enabled smart contracts in the healthcare industry. His proposal includes a medical system built on smart contracts and blockchain, demonstrating the benefits of decentralization for healthcare services. Key objectives include reducing transaction costs, streamlining administrative tasks, and bypassing intermediaries.

MedChain, a blockchain system designed for the privacy of medical data, was introduced by Daraghmi et al. [11]. Their platform provides patients, healthcare providers and those who value patient privacy with reliable health records. Short-term smart contracts, with sophisticated encryption, are used to manage transactions and promote data security. Additionally, it is recommended that incentives be developed for health professionals to maintain and develop updates.

Through their research, Zhang et al. [12] examined the synergies between blockchain and smart contracts in healthcare, highlighting its effectiveness in solving many healthcare challenges. Furthermore, they shed light on the obstacles faced when integrating blockchain into healthcare.

Kumar and his team [13] examined various applications of blockchain in the healthcare system. They acknowledge the barriers to integration but point to smart contracts as a logical solution in a blockchain-based healthcare system.

Sial and others [14] highlighted the benefits of integrating blockchain with smart contracts to improve healthcare services. They point to blockchain's ability to prevent loss and prevent data manipulation by storing data safely on a ledger. The potential of Hyperledger Fabric for storing medical records was the focus of Daisuke et al. [15], who aimed to transfer medical data from smartphones to the Hyperledger blockchain system.

Aiming to address the obstacles of a permissive and open blockchain system, Rouhani and his team [16] turned to a Hyperledger system to empower patients with suggestive autonomy of their health data to develop a new system developed by Sukhpal Gill [17] to enable cloud maintenance, serverless, Combining quantum computing and blockchain, the management layer covered the IoT devices in a service layer that manages resources and communicates with IoT devices,

while the service side performs computing tasks through Serverless FaaS architecture.

Bhati et al. [18] supported the adoption of blockchain in healthcare, especially in the management of EHRs. Their goal was to increase the accessibility and relevance of EHRs by leveraging blockchain's improved security, with the introduction of streamlined access guidelines. Their design also includes external data storage to address scalability issues, ensuring security, and flexibility.

Finally, Anurag and his team [19] compiled the literature on its role in healthcare and delved into the potential of blockchain to manage healthcare intelligence.

A. Blockchain Technology Limitations

When it comes to storing large amounts of data, blockchain faces two important challenges: scalability and privacy. The data stored on the blockchain is visible to all authorized users, which could be a concern for healthcare organizations that need to store sensitive patient information. Additionally, storing a patient's complete medical history, records, visits, lab results, and other reports in the blockchain can cause significant strain on its storage [20].

Blockchain technology is still not fully understood by many, as it is a relatively new field and is constantly evolving. This lack of knowledge and understanding can complicate the adoption of blockchain in healthcare. Additionally, the transition from traditional EHR systems to blockchain will require significant effort, as hospitals and healthcare organizations need to change their systems to take advantage of this new technology.

As blockchain technology is still relatively new and evolving rapidly, there is no established standard for it. This means that implementation in the healthcare industry requires additional time and effort. To ensure the safe and secure use of blockchain, international authorities should develop standardized guidelines to assist in the standardization of this technology.

III. PROPOSED SOLUTION

A. Implementation

Fig. 1 illustrates the system architecture diagram, illustrating the use of the Hyperledger blockchain network for storing and processing medical records.

Each participant in this network operates through a unique client application, which connects them to the blockchain and allows them to access medical data.

Member A, who is the embodiment of the patient only has the right to view his/her own medical history and other ability to change his/her address information On the other hand, member B which refers to the health reputation has the right to do detailed medical information and edits for individual or multiple patients and may also include patient access instructions Conversely, Member C on behalf of the regulatory agency may request and select records a can be adopted for research purposes.

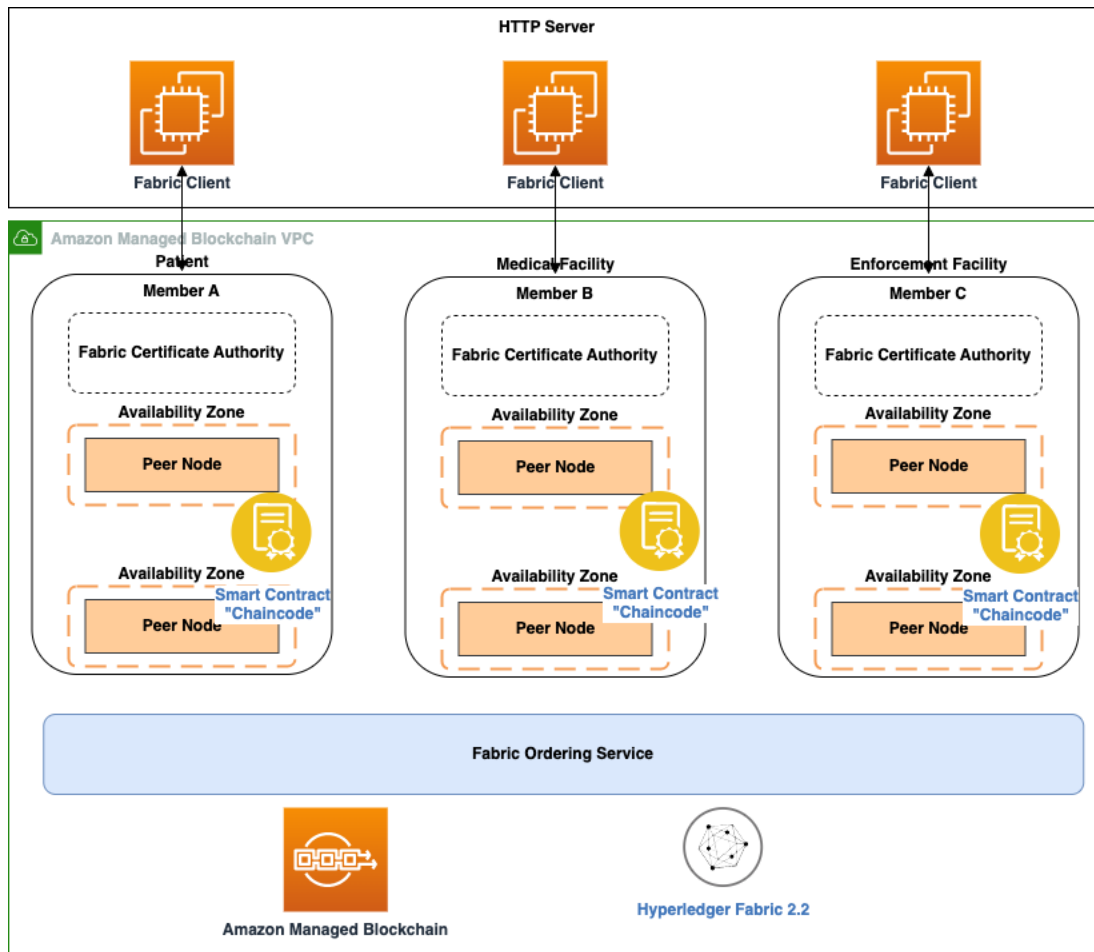

Fig. 1. High level system architecture diagram [21].

Arvind et al. [20] utilized IBM cloud and Kubernetes containers to execute their approach. In contrast, our suggested method employs Amazon Web Services (AWS) and the principle of serverless computing. This strategy allows us to avoid paying for inactive resources and offers the flexibility to adjust our scale according to traffic demands. As we will observe in the results section, this results in substantial performance improvements.

Integrating ownership and authorization protocols is key to maintaining the purity and resilience of the Hyperledger blockchain network. This ensures that only authenticated users can access it, thus protecting the network from inappropriate access or threats. Authentication focuses on supporting the identity of the user or device, while authorization is about defining what activities are allowed for a user or device in the network. Using these safeguards reduces the chance of a there is greater access to unauthorized networks or potential security breaches.

In the described Hyperledger framework, authentication and authorization are seamlessly integrated into the client software. As a result, the specific client applications used by network participants come equipped with built-in mechanisms to authenticate and direct users, enabling secure and regulated transactions with the blockchain.

The infrastructural layer of our Hyperledger network is built on the Amazon Managed Blockchain, essentially following version 2.2 of the framework. Notably, Amazon Web Services (AWS) provides two different versions of the said network: ‘Starter’ and ‘Standard’. Given the budget constraints, our decision wanted to utilize the capabilities of the ‘starter’ version.

TABLE II. MACHINE TYPES SUPPORTED BY AMAZON MANAGED BLOCKCHAIN STARTER EDITION

Machine Type	Member cost	Peer node	Hourly cost	Daily cost
bc.t3.small	\$0.30	\$0.034	\$0.334	\$8.0
bc.t3.medium	\$0.30	\$0.067	\$0.367	\$8.8

Delving into the specifics, “Table II”, enumerates the varies of current compatible device configurations, providing a comparative analysis of their economic implications for general understanding, consider a hypothetical scenario of a network composed of three member groups. The table describes the total cost of this three-member network and breaks down the hourly computation costs for each member next to a peer node. It should be noted that a maximum storage

fee of \$.20 is charged on, and writing work the cost matrix of this amount is directly proportional to the requirement of identical nodes on the monthly cadence.

B. Sequence Diagram and Transaction Flow

Extending the complexity of the transaction process within our blockchain framework, “Fig. 2”, presents a complete sequence of diagrams describing the entire course of a transaction [21]. This diagram carefully describes a

multifaceted level integral to the progress of a transaction. Starting at the point of user interaction, the sequence flows normally, through each level, and finally ends up in the Hyperledger system's integral sequence annotation services once processed in Hyperledger, the feedback reconfigures a route, which reaches the user to the destination. Through this approach, a comprehensive understanding of the complex behavioral journey is gained by emphasizing the interactions between each level within the larger behavioral ecosystem.

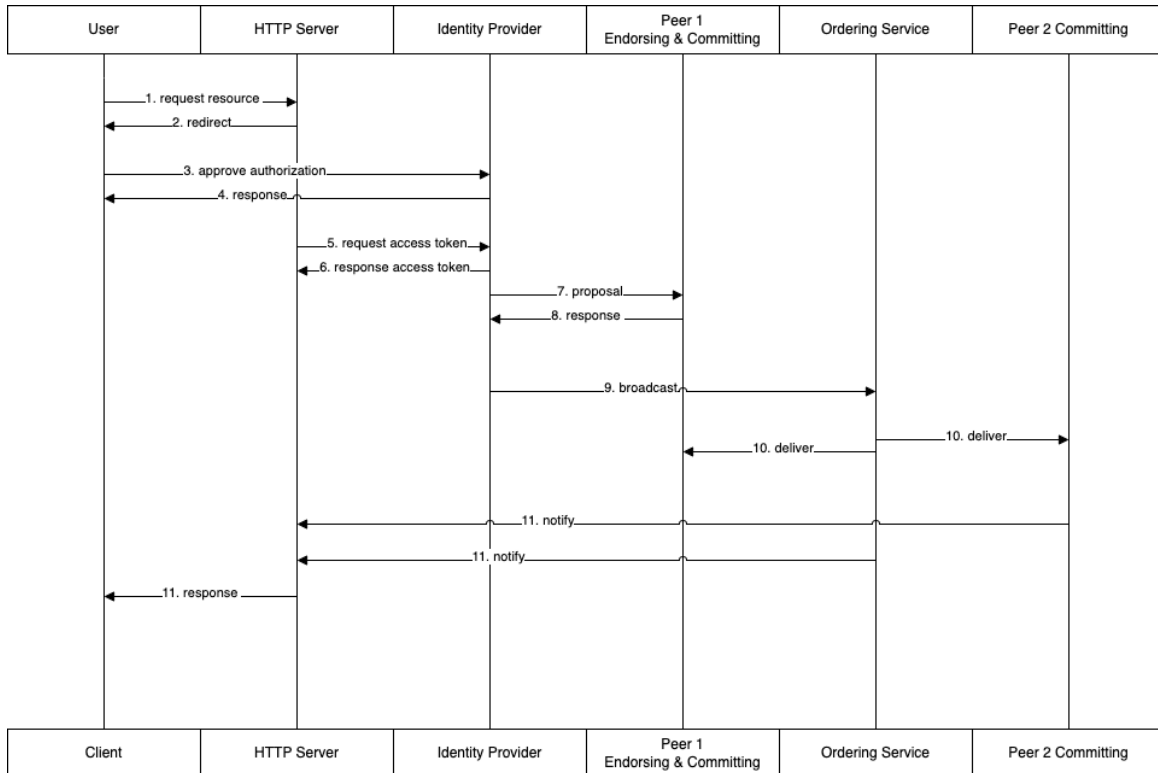

Fig. 2. Transaction flow and sequence diagram.

HTTP and License Phases When a user initiates a request to the server, the server immediately checks the user's license credentials. Based on this authentication, the server grants access or denies the user's request. If the user credentials meet the required criteria and are considered valid, the server proceeds to communicate with the identity provider, requesting a token. After, the token and user request have been successfully received and validated, the server with the installed Fabric SDK carefully builds a transaction offer, ensuring that the appropriate certificate is included for authentication.

Detailed Steps

1. Initiation by the User
 - a. The user sends a request to the server.
 - b. The request is routed to a specific function based on the provided URI and HTTP method.
 - c. The user embeds a valid token within the request header for authentication and authorization.
2. Token Verification

- a. The system verifies the validity of the embedded token.
- b. If the token is invalid or absent, the user is redirected to a login page.
3. Credential Input and Validation
 - a. The user enters their authentication credentials on the login page.
 - b. The credentials are validated.
4. Communication with Identity Provider

A response is generated from the identity provider after validation.
5. Token Request by Server

The server requests a token from the identity provider.
6. Token Receipt

The identity provider issues a valid token for the ongoing request.
7. Transaction Proposal and Invocation

- a. A transaction proposal is created using the Fabric SDK on the server.
- b. The proposal is signed with the correct certificate and sent as an invoke request to the network.

Endorsement Phase

8. Endorser Verification
 - a. The endorsing peer verifies that the client is authorized to invoke the chaincode.
 - b. If authorized, the endorsing peer executes the chaincode and generates a response without changing the world state.
 - c. The endorser signs the proposal with its identity and sends it to the client.
9. Endorsement Collection
 - a. The client collects responses from multiple endorsers.
 - b. The client verifies that the responses satisfy the endorsement policy.

Ordering Phase

10. Transaction Broadcast: The client broadcasts the endorsed transaction to the ordering service.
11. Block Creation
 - a. The ordering service packages the transactions into blocks.
 - b. The ordering service signs the blocks.
12. Block Delivery: The ordering service delivers the blocks to the leading peer nodes.

Validation & Committing Phase

13. Block Dissemination: The leading peers disseminate the blocks to all peers in the same channel and organization.
14. Block Verification: The peers verify the signature of the blocks.
15. Transaction Validation: The peers check all the transactions within the blocks.
16. Ledger Update: If all the transactions are valid, the blocks are appended to the ledger and the world state is updated.

Response Phase

17. Event Notification: The HTTP server is notified via the Channel EventHub listener once the target transaction has been committed to the ledger.
18. Response Formation:
 - a. A registered callback function collects details of the event.
 - b. The callback function forms a response in JSON format using the collected details.
19. Response Delivery: The response is sent back to the user via the client application.

C. Challenges and Limitations

Data migration poses a significant challenge in migrating existing medical records to blockchain-based systems due to format and data type compatibility issues. Careful design with

data washing and validation process various uses are paramount to ensure a smooth and accurate transfer while maintaining data integrity and security Compliance with regulatory frameworks Not a trivial matter. The proposed system should not only leverage the advantages of blockchain technology but also strictly comply with these regulations.

User adoption depends on the active involvement of multiple stakeholders, including health care providers, patients, and regulatory agencies. Getting these organizations to thrive in the new system and ensure they are profitable is a difficult task. In terms of security and scalability, it is important to enforce strict security measures, especially when dealing with medical data. New systems should take full advantage of blockchain's inherent security features and add components when needed. It should also demonstrate adaptability to meet the growing demand for health care. From an economic perspective, setting up and maintaining a blockchain-related system to manage healthcare data can be expensive, considering ongoing infrastructure, development and operational costs. If designed such a wonderful implementation, will require skilled professionals with expertise in blockchain technology, security, and data management.

IV. RESULTS AND DISCUSSIONS

After the text edit has been completed, the paper is ready for the template. Duplicate the template file by using the Save As command, and use the naming convention prescribed by your conference for the name of your paper. In this newly created file, highlight all of the contents and import your prepared text file. You are now ready to style your paper; use the scroll down window on the left of the MS Word Formatting toolbar.

In this section, we examine the results of our experiments and subsequent performance implications. Our test revolved around a sample dataset focused on the patient's medical record. We used the open-source Gatling library to facilitate these tests. This tool allowed us to perform simultaneous tasks, specifically designed to create, retrieve, modify, and purchase patient records. Test automation and quality assurance play an important role in monitoring test results because they reduce human effort and cost and improve the accuracy of results.

For our test parameters, we started with a modest ten users working simultaneously. Gradually we increased this, aiming for 2000 users, all within a short period of 100 seconds. Such a configuration has given us the ability to test our system, so that it serves 20 users at once, each performing one task.

The following images offer insights directly from Gatling. "Fig. 3", describes the sum of responses required to complete each request and the corresponding duration. Remarkably, not a single request experienced a failure, with each task taking just over 1.2 seconds to complete. Turning to "Fig. 4", it shows the flow of active users throughout the test phase, with a noticeable upward trend, rising to 1,706 users in a joint What last, "Fig. 5", provides a granular representation of the response time distribution, which shows how long the server needs to return a response.

Fig. 3. Response time range and number of requests.

Fig. 4. Active users timeline.

Fig. 5. Response time distribution.

The findings showed that the introduced solutions are efficient and mature in handling the requirements in real-world situations. What sets this platform apart is the efficient use of Amazon web services.

V. CONCLUSIONS AND FUTURE WORK

This research presents a cloud-based approach, for storing and retrieving medical records on the Hyperledger blockchain network. We were able to transfer a volume of historical data consisting of approximately five million records and demonstrated that our system can handle daily traffic effectively. By utilizing the edition of Amazon Managed Blockchain, our solution seamlessly integrates with AWS ensuring adaptability for future data analysis. To ensure accuracy and efficiency we implemented testing with Gatling scripts to assess performance. Not does our system provide storage and analysis capabilities but it also paves the way for further advancements such, as integrating emerging technologies and enhancing security measures. This direction emphasizes how our system can adapt to the evolving demands of healthcare data management.

Enhancing Business Intelligence with Hybrid Transformers and Automated Annotation for Arabic Sentiment Analysis

Wael M.S. Yafooz

Computer Science Department, College of Computer Science and Engineering, Taibah University, Medina, 42353, Saudi Arabia

Abstract—Business is a key focus for many individuals, companies, countries and organisations. One effective way to enhance business performance is by analysing customer opinions through sentiment analysis. This technique offers valuable insights, known as business intelligence, which directly benefits business owners by informing their decisions and strategies. Substantial attention has been given to business intelligence through proposed machine learning approaches, deep learning models and approaches utilizing natural language processing methods. However, building a robust model to detect and identify users' opinion and automated text annotation, particularly for the Arabic language, still faces many challenges. Thus, this study aims to propose a hybrid transfer learning model that uses transformers to identify positive and negative user comments that are related to business. This model consists of three pretrained models, namely, AraBERT, ArabicBERT, and XLM-RoBERTa. In addition, this study proposes a hybrid automatic Arabic annotation method based on CAMeLBERT, TextBlob and Farasa to automatically classify user comments. A novel dataset, which is collected from user-generated comments (i.e. reviews on mobile apps), is introduced. This dataset is annotated twice using the proposed method and human-based annotation. Then, several experiments are conducted to evaluate the performance of the proposed model and the proposed annotation method. Experiment results show that the proposed hybrid model outperforms the baseline models, and the proposed annotation method achieves high accuracy, which is close to human-based annotation.

Keywords—Business intelligence; machine learning; sentiment analysis; transformers; BERT; Arabic annotation

I. INTRODUCTION

Business intelligence can be enhanced through Sentiment Analysis (SA), which provides a nuanced understanding of customer opinions, market trends and brand reputation. SA allows businesses to gauge public sentiment accurately by analysing large amounts of text data from sources, such as social media, customer reviews and feedback forms. This insight helps companies identify consumer impressions, pain points and emerging trends, allowing them to tailor their products, services and marketing strategies [1, 2]. In this manner, businesses can stay competitive by responding quickly to changes in consumer behaviour and market conditions by understanding sentiment.

By integrating SA with business intelligence systems, companies can make more informed and strategic decisions based on gained insights into the emotional tone of customer

feedback, which provides context to quantitative data, such as sales figures and retention rates. Social media platforms, such as Facebook, Twitter and Instagram, have billions of active users who regularly share their thoughts, opinions and experiences. By analysing social media posts, comments and reviews, businesses can identify emerging trends, monitor brand sentiment, gather feedback on products and services and identify early potential issues and address them proactively [3,4]. Similarly, mobile app reviews provide businesses with valuable feedback from users regarding their experiences with the app. These reviews often contain rich insights into user preferences, pain points and suggestions for improvement. By analysing app reviews, businesses can identify recurring issues, prioritise feature enhancements and enhance user satisfaction. Today's digital age has created a marketplace where consumer opinion is crucial to maintaining a positive brand image. SA makes it easier for businesses to keep an eye on public perception and respond quickly to changes in public opinion.

Therefore, scholarly efforts have been made to use SA in many domains, such as healthcare [5–7], education [8–10] marketing [11–13], business [14–16] and finance [17, 18] with binary classification or multi classification. The main two challenges that this task suffers from are dataset and building mode [19, 20]. Firstly, in the dataset preparation, the labelling process, which is known as the annotation process, is important because it is related to the model's performance in terms of accuracy [21]. This process is time consuming and requires considerable effort from annotators to classify data to relevant classes. Secondly, a robust model to distinguish between the good and bad comments or words is required. Researchers have attempted to address this issue by using Machine Learning (ML) classifiers, Deep Learning (DL) models and Natural Language Processing (NLP) methods for many languages, such as English, French and Chinese. However, the Arabic language and its dialects lack scholarly attention due to the Arabic language having morphological richness with 22 countries with different dialects. Some researchers introduced methods for Arabic annotations, such as AraSenCorpus [19], Sentialg [22], Arasenti-tweet [23] and ZAEBUC [24]. The majority of SA works in the literature review is based on manual annotation by Arabic native speakers [25–29] or by automatic annotation tools [22, 30–34]. Some of them use Google Translator to translate from Arabic to English, and then they apply automatic annotation tools [24]. In such manner, Google deals with modern standard Arabic, not Arabic dialects. Therefore, this still remains a challenge in the Arabic

language due to its complex morphology, dialectal variation, ambiguity and contextual understanding.

Therefore, the purpose of this study is to propose a robust model to detect the users' sentiment to improve business intelligence and to propose methods for automatic Arabic annotation. The proposed model is a hybrid transfer learning model designed to distinguish between the good and bad user comments; it consists of XLM-RoBERTa, AraBERT Ver2 and Arabic BERT models. These models are all based on Bidirectional Encoder Representations from Transformers (BERT) which are Transformers architectures. In addition, this hybrid model comprises two methods which have been used; the first being the voting mechanism, and the second being the fusion feature. In the automatic Arabic annotation method, three annotator tools, i.e. CAMeLBERT, TextBlob and Farasa, are utilised. This method is called the Artificial Intelligence Annotator (AIA). Additionally, a novel dataset that has been collected from mobile apps, which consists of 223,341 user-generated comments, is introduced to validate the performance of the proposed model and to determine how well the AIA method accurately assigns the user comments to the relevant classes. The same dataset is also annotated by three Arabic native speakers; this process is called Human-based Annotation (HA). Then, several NLP methods, such as data cleaning, preprocessing and data annotation, are applied on the dataset to validate the proposed hybrid transfer learning model and the AIA. Several experiments are conducted using ML classifiers, DL models and transformers. The results of these experiments were in terms of the most common metrics, which are, recall, precision, F1-score, Area Under Curve (AUC)–Receiver Operating Characteristic Curve (ROC) and accuracy. Experiment results show that the proposed model is based on the fusion features and voting mechanism which outperformed all the baselines in terms of accuracy, i.e. 97.24% and 98.11%, respectively. Additionally, the experiment results show the AIA method is closely tied to HA in Arabic corpora annotation.

The contributions of this study are multifaceted and can be summarised as follows:

- Proposed a hybrid model of transformers (transfer learning) to detect business SA based on mobile apps that are related to home delivery and taxi. This model consists of XLM-RoBERTa, AraBERT Ver2 and ArabicBERT. In this model, two methods are used: the voting mechanism and the fusion feature.
- Proposed a hybrid automatic Arabic annotation method for the Arabic corpora, which consists of the CAMeLBERT, TextBlob and Farasa methods.
- Introduced a novel Arabic dataset which consists of 223,341 user-generated comments collected from reviews of mobile apps. It was reduced after annotation process to 63,313 user comments using AIA method and 54,988 using the HA method.
- Compared the model performance in terms of accuracy with various ML classifiers, DL models, transformers for AIA and HA methods.

The remainder of this paper is organized as follows. Section II provides a review of recent studies that focus on sentiment analysis and business intelligence. Section III explains the methods used to achieve the objectives of this study. The results and experiments are presented in Section IV. Discussion is given in Section V. Finally, the paper concludes in Section VI, summarizing the findings and implications of the study.

II. RELATED STUDIES

This section explores the studies that focus on sentiment analysis from a business intelligence perspective and also focuses on the Arabic annotation methods for the Arabic corpora.

In business intelligence and social media, Kurnia & Suharjito [1], developed a business intelligence dashboard to observe the performance of each topic or channel of news posted on social media apps such as Facebook and Twitter. The research tested different ML classifiers like Naive Bayes (NB), Support Vector Machine (SVM), and Decision Tree (DT) to categorize text from social media. The data used was posts from Facebook and Twitter. The research shows that SVM was the most accurate, reaching 78.99% accuracy. Similarly gathering a dataset from twitter, Khan [3]., conducted a case study on the official PlayStation account to illustrate their focus on sentiment analysis from a business intelligence standpoint, notably examining emotions and feelings expressed on Twitter. One thousand tweets from Twitter make up the dataset that was used. User emotions are compared between mentioning the official account and speaking generally as part of the analysis. When people contact their friends and followers instead of merely citing official accounts, the study finds that users are more open about their ideas and discontent. Also revolving on the idea of social media, Sánchez-Núñez et al. [35], provided an approach to model the business intelligence for identifying the users' abnormal emotion from their post through the social media marketing platform. To this end, to detect unusual manifestations in microblogs, the model uses the principles of multivariate Gaussian distribution and joint probability density. Data used in the study was obtained from micro-blogs, aggregated from 100 users over the period of 5 years with a sample size of 10,275. Thus, the accuracy rate that the presented model was achieving was approximately 83%. 87% for identification as an individual user or malicious bot. 84% for monthly identification of the subjects' abnormally endowed emotions.

In business intelligence and sentiment analysis, Swain & Cao [36], focused on utilizing sentiment analysis in order to extract the valuable insights from social media data related to supply chain management. The dataset which was used in the study includes and has over 600 randomly sampled companies from various industries, with data collected from forums, blogs, and microblogs such as Twitter. Tokenization, stemming, and feature selection utilizing filtering strategies such document frequency and mutual information are among the language processing approaches. With F-measures of 0.70 and 0.91 on the test set, respectively, the sentiment analysis approach uses a four-dimension classification algorithm and a positive-negative sentiment classification algorithm. Another

study about sentimental analysis, Aqarwal [37]., aimed to have a better understanding about customer sentiments and goals in order to improve overall business strategy and overall customer satisfaction by applying DL models, namely Recurrent Neural Networks (RNNs) and a Convolutional Neural Networks (CNNs). The study does not specifically disclose the dataset that was utilized for analysis. English was the language used for sentiment analysis. The model uses deep learning techniques, such CNNs and RNNs, to effectively capture the subtleties of customer feedback, resulting in high accuracy rates in sentiment classification. Similarly focusing on customer satisfaction, Prananda & Thalib [38], focused on utilizing sentiment analysis and predictive analytics for business intelligence purposes, specifically in the context of analyzing customer reviews for GO-JEK services. It used predictive analytics and sentiment analysis for business intelligence, particularly when examining customer reviews for GO-JEK services. The dataset is made up of 3,111 tweets from various countries that had keywords associated with GO-JEK that were gathered in January 2019. For sentiment analysis classification, the research uses computer learning techniques like neural networks, SVMs, NB, and DT. The DT method does perform the best, it achieved a score of 0.55 in precision, recall, and f1-score. Almost Identically, Capuano [39], proposed a Hierarchical Attention Networks based approach for sentiment analysis application in customer relationship management. The model was trained on a dataset of more than 30,000 items, 40% of which were collected from an Italian IT company and 60% were collected from public datasets to balance the class distribution. The experimental results show that the proposed approach attains high accuracy rates, with a macro-averaged F1-score of 0.89 for the Italian language and 0.79 for English. The incremental learning mechanism does not affect the overall system performance, improving the model's performance over time.

In the same way, Srinivasan et al. [40], worked on the sentimental analysis of the impact of COVID-19 on social life using ML classifiers. The data which is used for the analysis is gathered from Twitter which contains manual sentiment labels on tweets like "Extremely Positive", "Positive", "Neutral", "Negative" and "Extremely Negative", it also has 41,158 rows of data. The data is collected from Kaggle COVID-19 NLP Text Classification dataset. They worked on the BERT model for the sentimental analysis and check the sentiment of the tweets from various countries and for India. Further focusing on the idea of NLP methods, Sanchez-Nunez et al. [41], concentrated on the opinion mining, sentiment analysis and emotion understanding particularly in the context of advertising. The research draws data from the WoS database and embraces articles published between 2010 and 2019. The study uses NLP and SA methods to analyze latent trends in consumer perceptions of international brands and products. Similarly, Gołębniowska et al. [42], elaborated on cybersecurity aspects in business intelligence analytics via sentiment analysis and big data. It addresses the need for dealing with large volumes of information and the corresponding needs and challenges of latest security demands. The analyzed dataset contains a broad range of information and may originate from different websites, social, scientific, political as well as business topics. The sentiment analysis should help to

investigate user knowledge on information technologies, industry 4.0 and the related dangers and risks.

Similarly utilizing big data, Sreesurya et al. [43], centered on employing big data sentiment analysis with Hypex, an improved Long Short-Term Memory (LSTM) technique for retrieving business intelligence from reviews and comments. The dataset used to train is the 5-core Amazon dataset, which comprises of about 18 million reviews. The language processing method utilized entails converting text into word vectors using the GloVe model that has been trained previously. The model presents a testing accuracy rate as an indication of how the model performs when it comes to predicting the sentiment of the reviews. Hypex is the proposed activation function which surpasses general activation function for providing better accuracy in terms of sentiment classification for business intelligence. Further expanding on the idea of using big data, Niu et al. [44]., presented the Optimized Data Management using Big Data Analytics (ODM-BDA) model as a solution of optimizing organizational decision making by adopting big data technology and cloud computing strategies. It is intended to facilitate the Increase in efficiency in processing data, optimization of profits, and upgrade methods of decision. In this particular study, the improvement facilitated by the proposed ODM-BDA framework is achieved through a simulation analysis using 10 to 100 iterations to compare the enhancement in accuracy and duration.

Alike, Saura et al. [45]., employed a Latent Dirichlet Allocation (LDA) and Sentiment Analysis with SVM algorithm and to analyze the User Generated Content through Twitter for arriving at the critical factors that make a startup successful. The studied data set entails 35,401 tweets that include the #Startups hashtag. The analysis is performed through Python LDA 1. 0. 5 software and MonkeyLearn's Sentiment Analysis algorithm. In our model, the accuracy rate was obtained more than 0. 797 for positive sentiment, and >0. 802 for neutrality and above 0 for positive sentiment analysis. Similarly employing an SVM algorithm, Al-Otaibi et al. [46]., discussed about a system designed to measure customer satisfaction using sentiment analysis on Twitter data. The dataset used consists of 5513 hand-classified tweets, with positive and negative sentiments selected for training. The system employs the SVM classifiers for sentiment classification, achieving an accuracy rate of 87% on a 4000-tweet testing dataset.

In Arabic annotation, Guellil et al. [47], developed "ArAutoSenti" which aims to annotate Arabic text automatically based off its understanding on the sentiment behind the Arabic text. "ArAutoSenti" achieves an F1-score of 88%. It is important to mention that this method was applied for the under-resourced Algerian dialect. While Guelil [22], proposed SentiALG in this study, which is a tool intended for automatic annotation for the Algerian dialect in sentiment analysis. The dataset for it consisted of 8,000 messages. Correspondingly, Jarrar et al. [48], proposed an Arabic corpus called "SALMA", which consists of around 34,000 tokens which are all sense-annotated. It is also worthy to mention that a smart web-based annotation tool was developed to support scoring multiple senses against a given word. In the same way,

Al-Laith et al. [19]., presented a way to annotate large prices of texts in Arabic Corpus called “AraSenCorpus”. A neural network was used to train a set of models on a manually labeled dataset containing 15,000 tweets.

III. METHODS AND MATERIALS

This section describes the methods that were used to carry out this study. There are six phases which were conducted namely; data collection, data cleaning, data annotation, data pre-processing, feature engineering, building models and model evaluation, all are as shown in Fig. 1.

Fig. 1. Phases of the study.

A. Data Collection

In this phase, the data collected by user generated comments from the Play store of Mobile apps was through using the Python programming language. The main criteria are select the user comments and mobile apps are as follows: firstly, the period of collection for the user comments was between Jan 2022 to March 2024. Secondly, the mobile apps that are related to home delivery and transportation in total are eight Mobile apps. Lastly, the text for user comments is related to the Arabic language. All the user comments were downloaded into a separate CSV file for each application, then, all the files were combined together into one CSV file. At the end of this phase the total number of downloaded comments was approximately 223,341.

B. Data Cleaning

This phase had the task of preparing the dataset, in this phase several steps were used to remove duplicates of user comments, remove any user comments that are non-Arabic, remove the spaces from the files if there are any comments which are only empty, remove comments which consisted of special characters due to these types of comments being meaningless in the area of sentiment analysis.

C. Data Annotation

In the data annotation phase, there are two methods which have been utilized, namely; the first being the AIA tools which were used in the annotation process and the second being the HA method. In AIA, three tools have applied which are, TextBlob, Farasa, and CAMELBERT. TextBlob is a python library built on Natural Language Toolkit (NLTK) and has been used for NLP tasks. Particularly “ar-textBlob” using the Stanford API for Arabic tokenizer. In this study it is used for sentiment analysis which indicates whether the user comments

are positive or negative. Farasa at the Qatar Computing Research Institute has been developed for Arabic NLP. The CAMELBERT is a pre-trained model based on the BERT architecture and specifically for Arabic NLP. In this type of annotation which is known as “ensemble techniques” is based on a voting mechanism which the decision is based on the majority. Therefore, if two classifiers indicated that the user comments belong to a specific class (either positive or negative) then the decision will be based on that. Thus, by the output of this method, the first dataset was constructed. Table I shows the description of the first dataset.

TABLE I. FIRST DATASET DESCRIPTION (AIA)

Item(s)	No.comments	Min.Length	Max. Length
Positive	28,465	6	88
Negative	34,848	3	76
Total	63,313		

In the HA method, which has been conducted based on human annotation, three Arabic speakers helped in annotating the downloaded user comments. The user comments have been assigned to a class based on the decision of the majority, that means if two annotators agree about a specific decision on the user comments being assigned to the relevant class (either positive or negative) then the decision will be taken. Thus, the output of this method the second dataset has been constructed. Table II shows the description of the second dataset.

TABLE II. DATASET DESCRIPTION (HA)

Item(s)	No.comments	Min.Length	Max. Length
Positive	25,363	4	85
Negative	29,625	2	76
Total	54,988		

D. Feature Engineering

This phase is before feeding the models; each user comment is converted to numerical representation which is known as word representation. Such numerical representation is used as input to train and test the models. There are two types of word representation used in this study; the first being the Term-Frequency Inverse Document Frequency (TF-IDF) and word embedding’s. The TF-IDF is represent how the words is important in the dataset, it’s calculated as in mathematical Formula (1). While the second type of word embedding discovers the sematic relation between the words in user comments. Each word represented in vector dimension that contains values that measure the closeness of the word syntactic and semantic that happened in the training process.

$$TF - IDF(W, UC) = TF(W, UC) \times IDF(W, UD) \quad (1)$$

Where, W is the word in the User Comment (UC). UD is represented in the dataset for all user comments. The TF is calculated based on the following mathematical Formula (2).

$$TF = \frac{FW,UC}{N_{UC}} \quad (2)$$

Where $F_{W,UC}$, is the number of times the word (W) appears in the UC, and N represents the total number of W in UC.

While IDF is calculated as in the mathematical Formula (3).

$$IDF = \log \frac{N}{1+n_w} \quad (3)$$

where, n_w is the number of UC that W appears in it.

E. Building Models

This subsection demonstrates the models that were used to evaluate the proposed models' performance compared. These models consisted of ML classifiers, DL models and transformers. The most common classifiers in ML were selected, which are NB, Logistics Regression (LR), Random Forest (RF), K-Nearest Neighbors (KNN), DT and SVM [49]. While in DL experiments a LSTM, Bidirectional (BiLSTM), Gated Recurrent Unit (GRU), and CNN-LSTM were utilized, and in transform learning (transformers) [50], RoBERTa, MARBERT, distilbert, CAMELBERT-DA, CAMELBERT-Ca, AraELECTRA, ArabicBERT(Qarib), and AraBERTVer2 were utilized.

The proposed model consists of three transformers, which are built on the concept of transfer learning, as shown in Fig. 2. These models which were used in the proposed model are XLM-RoBERTa, AraBERT Ver2 and Arabic BERT. These models were trained on a large diverse Arabic dataset. These models are called pretrained models which can capture Arabic language patterns.

Fig. 2. Transfer learning.

Additionally, these models are built on the BERT architecture. In this manner, the performance of the model improves. These pretrained models, called 'fine tuning models', can be utilised on a specific dataset. Therefore, these three state-of-the-art models can be utilised to benefit each one to improve the model's performance through SA on Arabic business intelligence. XLM-RoBERTa is a multilingual pretrained model which can be trained on a huge opera, including the Arabic language. It can help in discovering the linguistics between Arabic user comments and SA. By contrast, AraBERT Ver2 is an updated version of AraBERT and is essentially trained on Arabic text from different sources. It can handle and deeply understand the relation of Arabic words in the language's unique morphological characteristics. Arabic BERT is trained on a large dataset from different sources, and it is different from the datasets of AraBERT ver2.

The proposed model comprises of two methods, namely, the voting mechanism and feature fusion. In the voting mechanism, the models predict the class of the input comments, and each model gives its prediction separately. Then, the ensemble methods, i.e. the voting mechanism, are applied. In this manner, the decision is based on majority of the output of the pretrained models, as shown in Fig. 3.

Fig. 3. Voting mechanism method.

The second method is feature fusion, which works by receiving the vectors from three pretrained models. Then, these vectors are combined to a large vector that is subsequently used to feed fully connected layers that are produced in the final prediction of the classes. Fig. 4 illustrates the feature fusion method.

Fig. 4. Feature fusion method.

F. Model Performance Evaluation

In order to validate the proposed method of automatic Arabic annotation and also the proposed model of hybrid transformers models (transfer learning). The models' common measurement matrix has been used which is the precision, recall, F1, Accuracy and AUC-ROC.

Precision is the ratio of correctly predicted positive observations to the total predicted positives. Precision is calculated based on the correctly positive user comments (UCs) predicted to the total number of predicted positive UCs as presented in mathematical Formula (4). In the instance in which the precision is high, that means the model predicted the positive or negative UCs correctly. Recall is the ratio of the True positive UCs predicted to the actual positive UCs as displayed in the mathematical Formula (5). The F1-score or also called the F-measure is the homogenous between the precision and recall. While the accuracy is the total number of correct predicted positive UCs over the total number of UCs in the dataset as portrayed in the mathematical Formula (7).

$$\text{Precision} = \frac{\text{True positive UCs}}{\text{True positive UCs} + \text{false positive UCs}} \quad (4)$$

$$\text{Recall} = \frac{\text{True positive UCs}}{\text{True positive UCs} + \text{false negative UCs}} \quad (5)$$

$$F1 = 2X \frac{\text{Precision} \times \text{Recall}}{\text{Precision} + \text{Recall}} \quad (6)$$

$$\text{Accuracy} = \frac{\text{True positive UCs} + \text{True negative UCs}}{\text{Total number of UCs in dataset}} \quad (7)$$

AUC-ROC is the graphical representation that shows the model performance in distinguishing between the positive user comments and the negative UCs. AUC-ROC is calculated based on the True Positive Rate (TPR) as presented in mathematical Formula (8) and False Positive Rate (FPR) as shown in mathematical Formula (9). The final value is between 0 and 1, the higher the values are, indicates how well the model has performed.

$$\text{TPR} = \frac{\text{True positives UCs for both classes}}{\text{True Positive + False Negative}} \quad (8)$$

$$\text{FPR} = \frac{\text{False positives UCs for both classes}}{\text{False positive + True Negative}} \quad (9)$$

IV. RESULTS AND EXPERIMENTS

This section describes the settings of the experiments for the four types of experiments conducted: ML experiments, DL experiments, transformer experiments and the proposed model experiments. The experiment results are then explained.

A. Experimental Settings

All the experiments are conducted using Google Colab, utilising the GPU and other hardware-related matters. The programming language of choice is Python. In the ML experiment, the scikit-learn package is used to split the dataset and to import and use the ML classifiers. In the DL experiments, the TensorFlow framework is used for building DL models. The transformer package is imported to conduct the transformers experiments, utilising the hugging face platform to access the pretrained models. In all the experiments, the dataset is divided into two parts, 70% for training and 30% for testing the models. Hyperparameters for ML, DL, transformers and the proposed model is presented in Tables III, IV and V respectively.

TABLE III. ML HYPERPARAMETERS

Classifier	Values
DT	Criterion 'gini'
KNN	n_neighbors 5
LR	penalty 'l2'
RF	n_estimators 100
SVM	C 1.0

TABLE IV. DL HYPERPARAMETERS

Parameter	Value
LSTM Units	64
Dropout	0.5
Batch Size	32
Optimizer	Adam
Activation function (Hidden Layers)	ReLU
Activation function (output)	Sigmod

TABLE V. HYPERPARAMETERS TRANSFORMERS

Item(s)	Values
Batch Size	16
Number of Epochs	6
weight_decay	0.01
logging_steps	100
learning_rate	2e-5

B. Experimental Results

In this subsection, the results of the four experiments are analysed. In the ML experiments, several experiments are conducted using the AIA and HA methods. Table VI shows the results based on the most commonly used measurements, i.e. precision, recall, F1-score and accuracy.

TABLE VI. COMPARISON BETWEEN THE FOUR MEASUREMENTS USING THE AIA METHOD

Classifiers	Precision	Recall	F1-Score	Accuracy
DT	81.53%	64.19%	65.64%	78.05%
KNN	73.45%	75.90%	74.28%	77.41%
LR	83.08%	80.27%	81.46%	85.21%
NB	74.91%	77.88%	75.84%	78.59%
RF	81.99%	80.76%	81.33%	84.77%
SVM	82.82%	79.77%	81.04%	84.93%

Table VI presents the performance metrics of various classifiers used for SA in the context of business intelligence, specifically in extracting insights from user comments on mobile apps. LR shows the highest accuracy of 85.21% and an F1-score of 81.46%, indicating its strong ability to classify sentiments from user comments accurately. RF and SVM also perform well, with accuracies of 84.77% and 84.93%, respectively, and F1-scores exceeding 81%. By contrast, the DT classifier has the lowest recall at 64.19% and F1-score at 65.64%, suggesting that it may not be as effective for this application compared with the other models. KNN and NB show moderate performance, with KNN achieving a recall of 75.90% and an F1-score of 74.28%, whereas NB shows a balanced performance with a precision of 74.91% and an F1-score of 75.84%. The confusion matrix is shown in Fig. 5, and the AUC-ROC is presented in Fig. 6. When the HA method is used, the best accuracy is recorded when using the LR classifier and low accuracy is achieved using KNN. Table VII shows the comparison between the four measurements using the HA method for the ML classifiers. The confusion matrix and AUC-ROC are presented in Fig. 7 and Fig. 8, respectively.

Fig. 5. Confusion matrix SVM and KNN using AIA method.

Fig. 6. AUC-ROC- AIA method.

Fig. 7. Confusion matrix SVM and KNN using HA method.

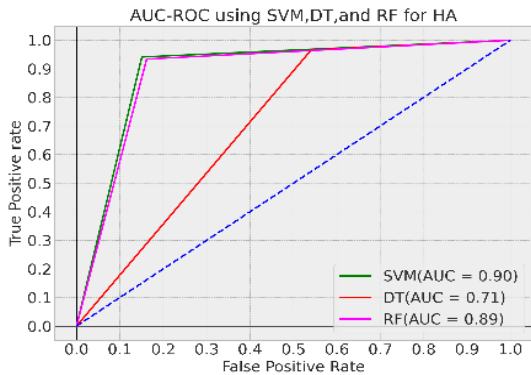

Fig. 8. AUC-ROC –HA method.

TABLE VII. THE COMPARISON BETWEEN THE FOUR MEASUREMENTS USING HA METHOD

Classifiers	Precision	Recall	F1-Score	Accuracy
DT	82.75%	71.25%	73.56%	80.64%
KNN	79.68%	65.93%	67.40%	77.34%
LR	89.96%	89.13%	89.53%	91.06%
NB	83.00%	86.13%	84.07%	85.54%
RF	88.99%	88.61%	88.80%	90.39%
SVM	90.02%	89.52%	89.76%	91.23%

Table VII presents the performance metrics of various classifiers used for SA in the context of business intelligence, focusing on user comments from mobile apps. LR and SVM stand out with the highest performance, achieving accuracy rates of 91.06% and 91.23%, respectively, and F1-scores of 89.53% and 89.76%. R also shows strong performance with an accuracy of 90.39% and an F1-score of 88.80%. NB

demonstrates balanced performance with an accuracy of 85.54% and an F1-score of 84.07%. By contrast, DT and KNN perform less effectively, with DT achieving an accuracy of 80.64% and an F1-score of 73.56%, whilst KNN has the lowest accuracy at 77.34% and an F1-score of 67.40%. Overall, LR, SVM, and RF are the most effective classifiers for extracting sentiment-based insights from user comments, highlighting their suitability for enhancing business intelligence through SA.

In the DL experiments, specifically during the utilisation of the AIA method, GRU demonstrates the highest performance with an accuracy of 90.01% and an F1-score of 87.93%, indicating its effectiveness in accurately classifying sentiments from user comments. The accuracy of training and validation is presented in Fig. 9. fNN-LSTM, whilst still effective, shows a slightly lower performance with an accuracy of 89.37% and an F1-score of 87.34%.

Fig. 9. Accuracy of training and validation using GRU for AIA.

In the HA method, LSTM demonstrates the highest performance with an accuracy of 95.54% and an F1-score of 94.85%, making it the most effective in accurately classifying sentiments from user comments. The accuracy of training and validation is shown in Fig. 10. GRU follows closely with an accuracy of 95.38% and an F1-score of 94.64%, indicating its strong potential as well. CNN-LSTM, whilst showing slightly lower recall, maintains high precision and F1-score with an accuracy of 95.09%. BiLSTM, although slightly behind the others, still performs robustly with an accuracy of 94.94% and consistent precision, recall and F1-score of 94.14%. Fig. 11 shows the precision, recall, F1-score and accuracy using the AIA and HA methods.

Fig. 10. Accuracy of training and validation using LSTM for HA.

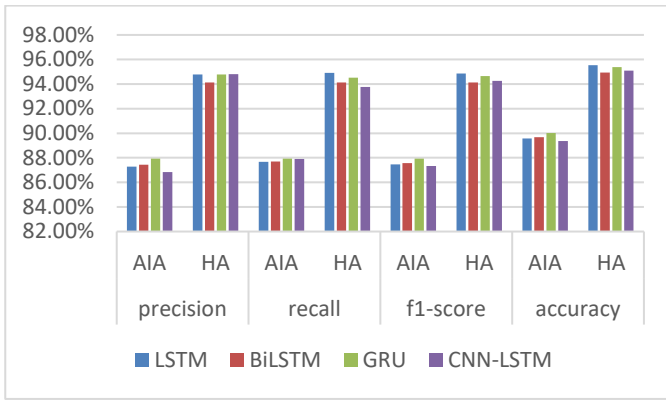

Fig. 11. Model performance between the AIA and HA methods.

In the pretrained models (transformers) and the proposed models, the experiments were conducted using the AIA and HA methods. The experimental results of the AIA and HA methods for the pretrained (transformers) and the proposed models is presented in Table VIII. In the proposed model, two methods, namely, voting mechanism and feature fusion, are used.

Table VIII summarises the performance of the pretrained models (transformers) used for the SA of user comments and reviews on mobile apps for enhancing business intelligence. Each model was evaluated across two approaches: AIA and HA. Amongst the models, ArabBERTVer2 achieved an accuracy of 92.48% in AIA and 97.06% in HA. The proposed Model 1 (feature fusion) demonstrated the highest accuracy with 93.96% AIA and 98.11% HA. These accuracies reflect how effectively each model can classify sentiments expressed in user feedback, providing valuable insights for improving mobile app performance and user satisfaction in business contexts. Additionally, the proposed Model 2 (voting mechanism) achieved an accuracy of 92.65% and 97.24%. The confusion matrix and AUC-ROC for the proposed model using

the feature fusion method is presented in Fig. 12 and Fig. 13, respectively. While Fig. 14 and Fig. 15 shows confusion matrix and AUC-ROC of the proposed model using the voting mechanism respectively.

Fig. 12. Confusion matrix of the proposed model using feature fusion.

Fig. 13. AUC-ROC of the proposed model using feature fusion.

TABLE VIII. COMPARISON BETWEEN THE PRECISION, RECALL, F1-SCORE AND ACCURACY FOR TRANSFORMERS AND THE PROPOSED MODEL

Model(s)	Precision		Recall		F1-score		Accuracy	
	AIA	HA	AIA	HA	AIA	HA	AIA	HA
ArabBERTVer2	93.43%	97.50%	96.13%	98.22%	94.76%	97.86%	92.48%	97.06%
ArabicBERT-Qarib	90.37%	97.01%	95.46%	98.26%	92.84%	97.63%	89.58%	96.74%
AraELECTRA	92.23%	97.34%	96.08%	98.34%	94.12%	97.84%	91.50%	97.03%
CAMeLBERt-DA	94.40%	96.86%	94.99%	97.47%	94.69%	97.17%	92.46%	96.11%
CAMeLBERt-Ca	92.57%	97.05%	95.59%	97.78%	94.06%	97.41%	91.45%	96.44%
distilbert	93.75%	97.57%	96.05%	98.22%	94.89%	97.89%	92.68%	97.11%
MARBERT	94.10%	97.27%	95.39%	97.59%	94.74%	97.43%	92.51%	96.48%
MERTICRobBERt	90.78%	97.33%	97.09%	98.20%	93.83%	97.76%	90.96%	96.92%
Proposed Mode 1	93.94%	98.22%	92.78%	97.94%	93.36%	98.07%	93.96%	98.11%
Proposed Mode 2	92.24%	97.62%	93.12%	96.95%	92.66%	97.28%	92.65%	97.24%

V. DISCUSSION

This study has two findings related to the proposed hybrid transform learning model and the proposed automatic Arabic annotation methods.

Firstly, the experiment results reveal that the performance of the proposed model outperforms the aforementioned experiments, i.e. DL, ML, and transformers experiments. To go into depth of the precise method in which the proposed model achieved the highest results in, is the feature fusion which attained an accuracy score of 98.11%, which proves that it is better equipped for identifying the sentiment behind user comments in the Arabic language on whether the sentiment behind the written comment is positive or negative than the voting mechanism which reached an accuracy if 97.24% respectively. This study demonstrates that utilising transfer learning (pretrained models/transformers) enhances the model's performance in terms of accuracy in identifying and distinguishing positive and negative sentiments in Arabic user comments. The reason is that the pretrained models have been trained on large datasets that help in exploring and discovering the semantic and syntactic relationships between Arabic words.

Secondly, in the proposed Arabic automatic method, AIA saves time and effort in annotating Arabic user comments because it is completely automated as opposed to the HA method, which requires much more effort in annotating Arabic

user comments and at least three native Arabic speakers to perform the voting mechanism. Nevertheless, the HA method achieves a somewhat higher accuracy than the AIA method, whilst the difference between the two methods in performance is approximately 5%. This result is observed in all the conducted experiments.

VI. CONCLUSION

Transformers have been utilised to improve the capabilities in handling natural language processing. Therefore, this study proposes a robust hybrid transfer learning model to enhance business intelligence by accurately detecting users' sentiments. The model combines XLM-RoBERTa, AraBERT Ver2 and Arabic BERT, and the model additionally utilises a voting mechanism and feature fusion to improve the models' performance. Additionally, the study introduces AIA, which integrates CAMeLBER, TextBlob and Farasa. Furthermore, a novel dataset of user-generated comments from mobile apps is introduced. Results demonstrate that the proposed model leveraging feature fusion and the voting mechanism outperforms all baselines with an accuracy of 97.24% and 98.11%, respectively. Furthermore, the AIA method is closely matched with the HA in the Arabic corpora annotation, confirming its reliability and accuracy. In the future work, enhanced Arabic annotation methods are to be through utilising transformers and to build lexical dictionary, expanding the dataset to include more diverse sources and languages that could help generalise the model's applicability across various domains. Apply the automatic annotation to Arabic dialects across the 22 Arabic-speaking countries, each Arabic speaking country with its own unique variations. This approach can significantly enhance the classification process.

A Method by Utilizing Deep Learning to Identify Malware Within Numerous Industrial Sensors on IoTs

Ronghua MA

Zhengzhou Railway Vocational and Technical College, Teacher Work Department of the Party Committee,
Zhengzhou 450052, China

Abstract—The industrial sensors of IoT is an emerging model, which combines Internet and the industrial physical smart objects. These objects belong to the broad domains like the smart homes, the smart cities, the processes of the industrial and the military, the agriculture and the business. Due to the substantial advancement in Industrial Internet of Things (IIoT) technologies, numerous IIoT applications have been developed over the past ten years. Recently, there have been multiple reports of malware-based cyber-attacks targeting IIoT systems. Consequently, this research focuses on creating an effective Artificial Intelligence (AI)-powered system for detecting zero-day malware in IIoT environments. In the current article, a combined framework for the detection of the malware basis on the deep learning (DL) is proposed, that uses the dual-density discrete wavelet transform for the extraction of the feature and a combination from the convolutional neural network (CNN) and the long-term short-term memory (LSTM). The method is utilized for malware detection and classification. It has been assessed using the Maling dataset and the Microsoft BIG 2015 dataset. The results demonstrate that our proposed model can classify malware with remarkable accuracy, surpassing similar methods. When tested on the Microsoft BIG 2015 and Maling datasets, the accuracy achieved is 95.36% and 98.12%, respectively.

Keywords—Malware; malware detection; industrial sensors; Internet of Things (IoT); Deep Learning (DL)

I. INTRODUCTION

The advancement of various technologies such as the sensors, the wireless communication, the embedded computing, the automatic tracking, the widespread access to the Internet and the dispensed services increases the possible of the accretion of the smart sensors in our daily lives via Internet. The convergence of Internet and the smart sensors, which can connect with together, describes IoTs. This novel example has been detected as one from the foremost significant factors on the industries of the data and the communication technology in the coming years [1].

The goal of the IoTs technology is to enable the objects for the connection at any time and any place with anything and anyone, who uses any path or any network as optimally. IoTs is a new evolution from Internet. IoTs is the new technology that pays attention to the pervasive presence of the environment and deals with the diversity of the smart objects with the wireless connections and the wired connections for the communication with together. These objects work together, to create the new applications or the new services and to achieve the common goals. In fact, they are the development challenges for the

creation of a smart big world. A world that is the real, the digital and the virtual and is converging towards the formation of the smart environments. This world creates the smarter environments of the energy, the transportation, the cities health and many others [2].

However, the integration of the smart objects in the real world by Internet can bring the threats of the security in the several of our daily behaviors [3]. According to the wide standards of the communication, the limited power of the computing and the great number of the connected sensors, the common actions of the security against the threats cannot work effectively on IoTs. Therefore, the development of the specific solutions of the security for IoTs is necessary, to enable the organizations users, to detect total weaknesses of a network [4]. Several ongoing projects for evolution of the security in IoTs include the methods that provide the data confidentiality, the authentication of the control of the access on IoTs, the privacy, the trust among the users and the implementation of the security policies. [5]. Nevertheless, even with the methods, IoTs are assailable to the several attacks. The attacks which are done, to interrupt and to disrupt the networks. For this reason, the required method of the defense is the creation of the models for the detection of the attackers. The development of the web-based technologies and the cloud computing will mark the future revolution in the digital technologies. Also, it will lead to the increased health, the productivity, the convenience and a wide range of the useful information for the individuals and the organizations. On the other hand, there will be challenges in the field of the personal privacy, the complexity of the intrusion technology and the creation of a digital gap [6].

The security establishment is perhaps the biggest challenge in the IoTs network. The security in the current Internet is also considered as a big challenge, but in the Internet of Things, this issue takes on the greater dimensions. One of the reasons for this issue is the distribution of the network and the more entry points into the system. Also, the objects that are supposed to be connected to the Internet, usually have a simpler architecture than the computers, and this implementation makes the security tools as the difficult. The IoTs technology is much closer to the real life than the current Internet; In fact, the intrusion into this network will be equivalent to the intrusion into the daily life of the users [4]. Due to the security problems on the real world and in the technology of IoTs, and according to the problems of the intrusion into the networks, it is very necessary to present the optimal method, in order to discover the intrusion and to keep the security on the networks [7].

*Corresponding Author.

Following an extensive review of the literature, it has been noted that current methods face several limitations and security challenges, such as low accuracy, insufficient large datasets, limited scalability, and high prediction times for detecting zero-day malware or unknown malicious activities. Therefore, this work proposes an efficient zero-day malware detection framework utilizing a hybrid deep learning model for IIoT systems. The main contributions of this paper are as follows: i) It introduces a novel AI-powered zero-day malware detection system for IIoT, utilizing an image visualization technique by combining CNN and LSTM models. ii) D3WT is employed for deep feature extraction, breaking down malware images into approximate and detailed coefficients. iii) The proposed hybrid model is tested on three major cross-platform malware datasets and compared with advanced models. The method is applied to detect and to classify the malware. The background of research is provided in Section II. Our method is described in Section III. Section IV shows the experiments and the evaluation of the results. Section V also presents the conclusions and the effective suggestions by using the obtained findings.

II. RELATED WORKS

In the recent decade, the many models based on the theory of the game on scope of the security in the networks have been done, to model the analysis and to optimize the efficiency of IDSs in the related technology to IoTs, such as the mobile contingency networks [8, 9], WSNs [10], the cloud computing [11] and the physical cyber networks [12]. The research in [11] has presented the various intrusions, that affect the availability of the privacy and the integrity in the cloud computing. They have distributed the methods of the used IDSs in the cloud into three categories: the host-based, the network-based and the hypervisor-based. They are also reviewed the advantages and the disadvantages of every protocol and are recognized the problems, to create the cloud computing as a trustworthy architecture for the providing of IoTs. The research in [9] shows that a malware detection model is capable to handle and to control the several protocols of the communication by combining the rules of the signature and the procedures for the detection of the anomaly. The research in [10] has done a wide review on IDSs in WSNs and has provided a comparative evaluation among IDSs for WSNs, according to the architecture of the network and the method of the detection.

The research in study [13] presents a comprehensive analysis of the security from the several protocols of Internet. Specifically, the authors discuss about the security topics in IEEE 802.15.4 against 6LOWPAN, the Routing Protocol of IPv6 for RPL, the protocols of DTLS and CoAP. The research in [8] has investigated IDSs for the mobile contingency networks, by relying on the detection algorithm. A categorization basis on the tree for IDSs has been introduced according to the character of the used method for the processing in detection model. The research in [14] presents an IDS for LOWPAN-RPL6 that is capable to recognize the Sinkhole attack, the Sybille attack and the Selective attack, by using a hybrid approach that combines the different parameters. The research in study [15] has presented an IDS basis on the features with supervisor, by using forward neural network. In this paper, the feature selection is done on the ISCX-IDS 2012 dataset and the Android CIC dataset. In order to do the feature selection

phase, SVM with the incremental learning has been used, which with the ranking of 43 features in the dataset, 20 features with the highest rank have been selected. Then, by using a neural network, the final detection is made with the accuracy equal to 94% and 98.7%.

The research in study [4] has presented an optimal platform, to show the possible application of the practical in the malware propagation suppression for perseverance of the privacy in the smart objects on IoTs, via an IDS by the game theory calculation of Bayesian. The research in study [16] has examined the security of IoTs, the challenges, the solutions and the threats. After checking and evaluating the possible threats and after specifying the security actions in scope of IoTs, they have done the risk analysis of the quantitative and the qualitative that examines the threats of the security on every layer. The research in [7] has investigated a new plan, by using a combination from the classical encryption and the quantum encryption, to improve the security of the Internet network. A research title which is related to the anomaly-based intrusion detection systems [3], by evaluating solutions and the researches and by using role of DL in IDS, discusses the efficiency of the proposed methods, and also, by identifying the challenge from the past researches, it recommends the deep learning-based guidelines.

The research [17], in an article, in addition to the presentation of a model based on the combination from the artificial neural networks for the intrusion detection, it provides an algorithm for extraction of the optimal features on Cup KDD, which is the standard dataset for the testing of the intrusion detection methods in the computer networks. The researches efforts in the field of IDSs for IoTs have begun and speeded up. By taking the research background, it is important to state which the presented approaches have not deeply checked the abilities and the laxities of every detection model and each placement strategy. The many authors have relied on a few kinds of the attacks. Finally, the very easy validation schemes have presented the foundation for the reproduction of the other proposed approaches.

III. THE PRESENTED APPROACH

Here, the details of our proposed approach are provided. This approach is described to detect the zero-day malwares along with its family by the greater accuracy for the industrial sensors of IoT. The presented method is disturbed in *three* main steps: the first includes the data preprocessing and the image resizing, the second includes the feature extraction by using D3WT and the third includes a hybrid model of LSTM-CNN for the automatic detection of the malwares. Fig. 1 displays the framework of our presented method that is created by integrating LSTM-CNN and D3WT. The coefficients of the approximation and the detail are exploited by D3WT. The exploited features are combined as input of LSTM-CNN, to create the fused images. The proposed approach is evaluated by Microsoft BIG 2015 and Malimg, which contain the different types from the malwares. The details of this approach are provided on the below subsections.

A. Data Pre-Processing

The data preprocessing is a necessary part in every method basis on AI, in order to increase its efficiency. In the current

article, the extraction of the feature has been done from the raw dataset of the malware. Then, the obtained features (like the opcodes, the strings and the bytcodes) are converted to the digits of the binary. Next, a collection from 8 bits are converted to the grayscale image. The converted images have the various sizes in terms of the height, nevertheless, the width of the images is the constant. The conversion of this grayscale images by the bytcodes is provided by using the Python tools. In the next step, the image preprocessing (like the image resizing to a specific size equal to 224×224) is performed on this approach. Then, D3WT is used as a method for the extraction of the feature, to extract the coefficients of the approximation and the detail.

B. Extraction of Features

On our approach, D3WT is used to analyze the inputs by using the banks of the filter. It follows an iterative method. This approach includes 2 wavelets (the high pass) and a scale function (the low pass). A wavelet is the offset by another wavelet. The theoretical flow diagram for 2 filter banks of D3WT is displayed on Fig. 2. D3WT is basis on 3-channel theory for the bank of the filter of the complete reconstruction. A matrix with *three* columns is applied for the scaling and the function of the wavelet. The filter of the scaling $\theta(\alpha)$ is placed on first column and 2 high-pass filters, which are denoted by $\varphi_1(\alpha)$ and $\varphi_2(\alpha)$, are placed on second column and the third column. The function of the scaling is denoted by $T_0(-v)$ and 2 high-pass filters are represented $T_1(-v)$ and $T_2(-v)$. The input $J(v)$ passes via the model of the filter, and the analysis operation is done by the bank of the filter for the analysis, that creates 3 sub-bands. The sub-bands are down-sampled by 2. The output of this filter is 3 signals $C(v)$, $D_1(v)$ and $D_2(v)$. These items are the coefficients with the low frequency (the approximation coefficient) and 2 coefficients with the high frequency (the detail coefficient), respectively [18].

The synthesis filter bank is used to inversely transform the extracted low-pass coefficient $T_0(v)$ and 2 high-pass filters $T_1(v)$ and $T_2(v)$, with the high sampling by 2, and then, in order to receive the output signal, $K(v)$ is fused. D3WT performs the iterative operation with the over-sampled filter bank, to ensure the perfect reconstruction conditions. This work leads to the transformation of the shift constants, namely $T_0(v)$, $T_0(v)$ and $T_0(v)$, which $K_{\text{output}}(v) = J_{\text{input}}(v)$. Also, D3WT is applied to convert the samples of the malware in the coefficients of the detail on every level from the decomposition and into the coefficients of the approximation on maximum level. 2 wavelets, namely $\varphi_1(\alpha)$ and $\varphi_2(\alpha)$, are generated to be separated by $1/2$, as shown in the following equation [19]:

$$\varphi_1(\alpha) = \varphi_2 \times (\alpha - 0.5) \quad (1)$$

The following equations are given for a multi-resolution framework, that should satisfy θ and φ_i :

$$\theta(\alpha) = \sqrt{2} \sum_v T_0(v) \theta(2\alpha - v) \quad (2)$$

$$\varphi_i(\alpha) = \sqrt{2} \sum_v T_i(v) \times \theta(2\alpha - v) \text{ where } i = 1, 2 \quad (3)$$

C. Classification of Malware Samples

Regarding CNNs, it should be said that they are used in the classification of the image for the object recognition and the classification work. The prominent amicability of CNN is

according to its ability for the automatic extraction of the important features from the input samples. CNNs are a set from three important layers: convolution, pooling and fully-connected. In the layer of the convolution, the input features are checked, and the input sample is filtered. This layer does the dot product among 2 matrices, for the creation of the weight matrix and the weighted sum in the layer of the kernel. This filter does the operation of the batch among the pixel values of the input. The proper parameters for the filter size layer, the stride and the zero padding, help to increase in results of the convolution kernels. Also, ReLU is applied, to enhance the non-linearity on the map of the feature. ReLU computes the activation with the setting of the input as 0. ReLU has the values of the negative and the positive. The negatives are displayed by 0 and the positives are indicated by the max value. In the layer of the fully-connected on CNN, a classification is performed, to sequentially determine the given input of the layer of the convolutional and the pooling. In the layer of the pooling, the desired operation is applied, to reduce the dimensionality of the features, by selecting the greatest values by the area for the creation of the matrix. The ultimate layer is the fully-connected, which is applied, to flatten total features in the vectors with the single feature. It presents the communication between the neurons of the previous layer and the next layer. This point causes that feature maps from the input to the output. The output of fully-connected is taken to SoftMax, to predict the samples of the malicious [20].

Regarding LSTMs, it should be said that they include a memory unit and *three* interactive gates: the input, the forget and the output. The memory unit is applied, to protect the late state against the prior state. The gate of the input is applied, to restrict the amount of the input data for the training in network, which is stored on the state of the unit in the time " t ". The gate of the forget determines which whether the data of the input should rouse forward or take away, for the entering to the gate of the input in the time " $t - 1$ ". The gate of the output describes the data of the output. This gate is applied, to deal the problems of the vanishing gradient, that appear in the implementation of 3 gates [20].

In this paper, a combined model of LSTM-CNN is applied, to detect the malware. CNN is superior for the processing of the large volume from the great-dimensional datasets and for the automatic extraction of the informational features by the images. It is done by using the techniques of the optimization with the great dimensional. The efficiency of CNNs is influenced by the samples size of the training and the testing. In the dataset with the variable size, CNN requires to be fine-tuned. The goal of the use from the feature extraction is the minimization of the data dimensions and the time of the training for CNN, that leads to the improvement in accuracy of the detection. On our approach, first, D3WT is used, to extract the first level feature. The fused features include the coefficients of the approximation and the detail, which serve as the input of CNN. Then, CNN exploits the necessary informational features by the minimal dimensions. On our combined approach, 4 layers of the convolution, 4 layers of the pooling, 4 layers of the dropout, one layer of the fully-connected (the flatten, the dense and the dropout), one layer of LSTM and SoftMax are applied. The fetched features are taken as the input of LSTM (by max-pooling). Then, they are passed

to a layer of the fully-connected that transforms total features to a vector with the single feature (by SoftMax). CNN extracts the features as efficiently and as automatically. On our combined approach, CNN works as the encoder for the encoding of features (by convolution), and LSTM decodes the encoded data.

Eventually, a layer of the fully-connected is applied, to classify the malware. Thus, the foremost features of 2 networks are integrated, to model an impressive combined network [21].

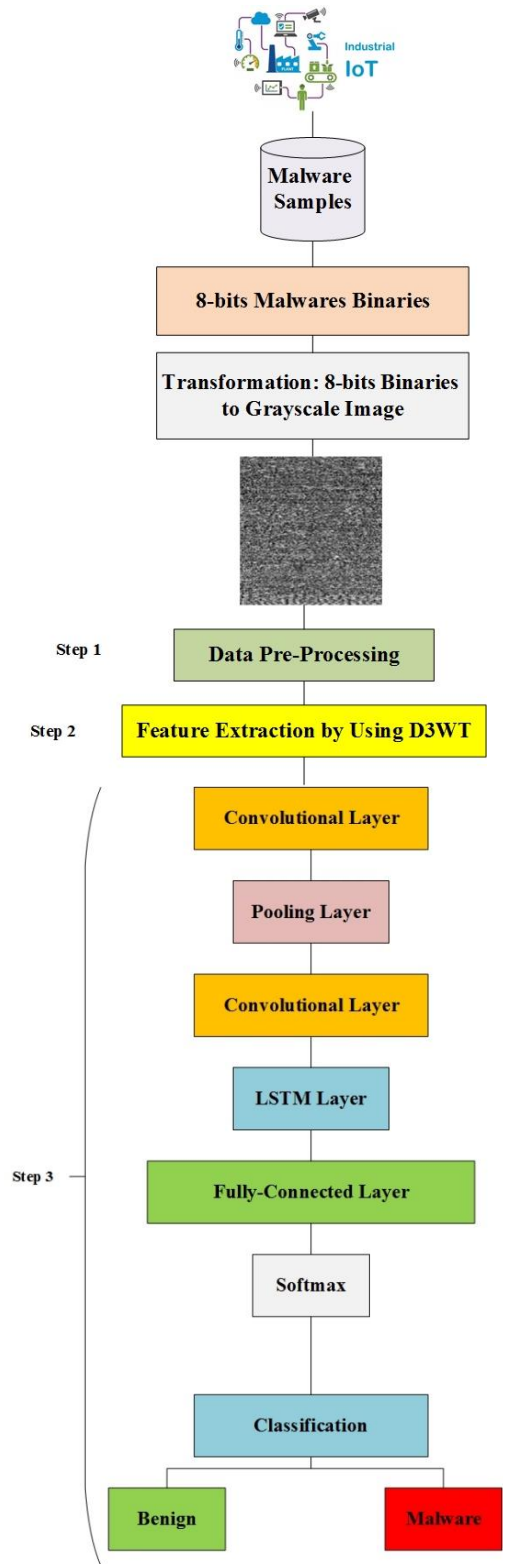

Fig. 1. The general framework of our presented method.

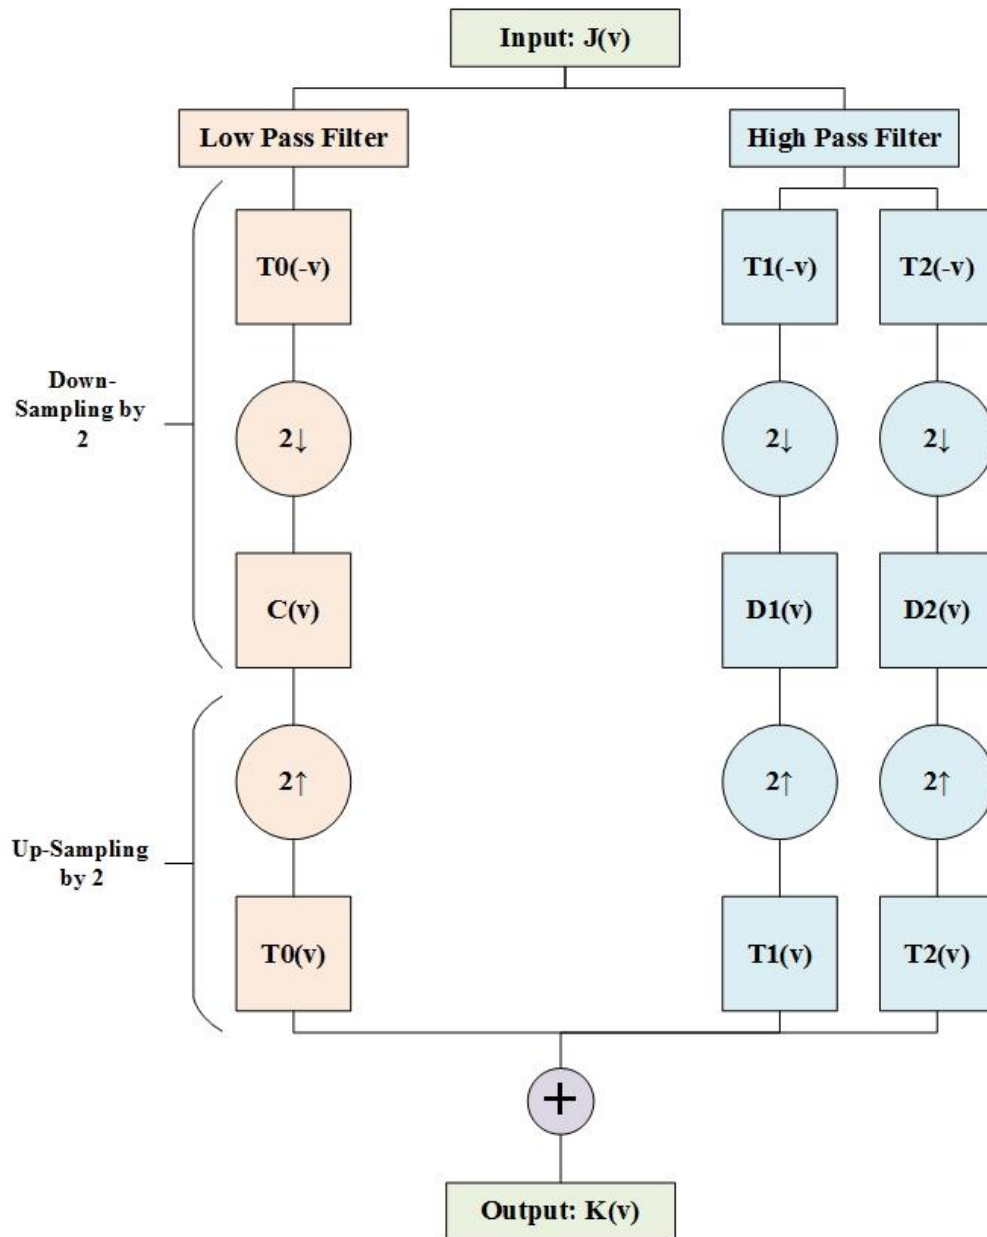

Fig. 2. The D3WT basis on 3-channel filter bank.

IV. EVALUATION AND RESULTS

Here, the details of datasets and tests and results are provided. Python has been applied, to implement these tests. The proposed approach is implemented in the computer with RAM 8G and Intel(R) CPU Core(TM) i7 3.0 GHz. CNN is implemented on GPU and the graphics card is GEFORCE 840M for NVIDIA. The data of training, testing and validation are randomly selected from each dataset, and the evaluation procedures are done as one by one. In the stages of training, validation and testing, the data selection rates are set at 70%, 10%, and 20%, respectively. CNN includes 4 layers of the convolution, 4 layers of the pooling, 4 layers for the normalization of the batch and ReLU with the various sizes of the filter (32, 64 and 128). The sizes of pooling, stride and kernel are equal to 2×2 , 2×2 and 3×3 . After the fourth

layer of the convolution, the features are passed via LSTM and the layer of the fully-connected. The layer of the fully-connected includes the layers of flatten, dense and dropout. Eventually, SoftMax applied, to classify the malware labels.

A. Datasets and Evaluation Criteria

To demonstrate the efficiency of our approach, the several criteria for the evaluation have been applied. These criteria are: sensitivity, accuracy, F1-score and specificity. These criteria are computed as the below:

$$Accuracy = \frac{TN+TP}{TN+FN+TP+FP} \quad (4)$$

$$Sensitivity = \frac{TP}{FN+TP} \quad (5)$$

$$Specificity = \frac{TN}{TN+FP} \quad (6)$$

$$F1 - Score = \frac{2 \times TP}{2 \times TP + FP + FN} \quad (7)$$

TP is the true positive and FP displays the false positive, while TN displays the true negative and FN displays the false negative. The mentioned criteria are the first stage for the interpretation of the efficiency for our approach. The comparison procedures are performed for the proposed combined model with 2 DNNs. These two neural networks are: AlexNet and Resnet-50.

The experiments are performed on two comprehensive datasets: Maling and Microsoft BIG 2015. The dataset of Maling [22] includes 9339 samples from the malwares. Every sample from the malwares on dataset belongs to one of 25 classes. In addition, number of the samples in a class is different. The classes of the malware are: Agent.FYI, Adialer.C, Allaple.L, Allaple.A, Alueron.gen!J, Autorun.K, Benign, C2LOP.P, C2LOP.gen!g, Dialplatform.B, Dontovo. A, Fakerean, Instantaccess, Lolyda.AA1, Lolyda.AA2, Lolyda.AA3, Lolyda.AT, Malex.gen!J, Obfuscator. AD, Rbot!gen, Skintrim.N, Swizzor.gen!E, VB.AT, Yuner.A and Wintrim.BX.

The dataset of Microsoft BIG 2015 [23] includes 21741 samples from the malwares, which are belonging to nine classes, and are: Lollipop, Kelihos_ver1, Ramnit, Vundo, Kelihos_ver3, Tracur, Obfuscator, Gatak, .ACY and Simda. The similar to with Maling, the number of the samples from the malwares in the classes is not uniformly dispensed. Every sample from the malwares is displayed by 2 files: ".asm" and ".byte". In the experiments, ".byte" are only used, to form the malware images.

B. Results

In this section, the outcomes of the performance for our proposed approach and its comparison with the other models are presented. The evaluation criteria define the efficiency of the models. The acute case behind classification is a criterion for the evaluation, which is applied for the understanding of the efficiency of a model [24]. Therefore, the multiple criteria in experimental outcomes and the discussion have been used, to demonstrate the efficiency of our approach. Fig. 3 to Fig. 6 and Fig. 7 to Fig. 10 show the values of the accuracy, the sensitivity, the specificity and the F1-score for AlexNet, Resnet-50 and the presented approach on Microsoft BIG 2015 and Maling,

respectively. According to these results, it can be said which our approach works superior than the DNN architecture. Also, the performance of our approach shows the similar efficiency results on 2 datasets, while the performance of the other DNNs is significantly different on 2 datasets. The above situations show which our approach is stronger, and outperforms than 2 DNNs.

In the next step, the types of the malwares are analyzed along with the confusion matrices. Tables I, II and III show the matrices of the confusion in Microsoft BIG 2015 for nine types of malware by using the proposed approach and AlexNet and ResNet-50. Here, the accuracy rate for each type of the malwares is shown by using the confusion matrices. The matrix of the confusion for the proposed approach shows that it provides the better results for the entire malware classification, with the exception of vundo. In addition, the matrix of the confusion for ResNet-50, which is displayed in Table II, provides the better detection for vundo, in compared to the other approaches. In this situation, total models can quickly detect the malwares of simda and tracur.

Finally, a functional comparison with the advanced results is performed. Tables IV and V display the accuracy in Maling and Microsoft Big 2015 by using our approach and the other models. It should be attended which the efficiency of the presented approach is better than the advanced models, insomuch it creates a greater value for the accuracy.

C. Discussion

The promising results of the proposed framework, which uses an image visualization approach, demonstrate its ability to accurately identify various malware families and new variants. These results indicate that image-based visualization is both effective and efficient for identifying malware samples across different classes. This model has significant potential for detecting advanced malware by analyzing large volumes of input data and classifying them into sub-families. However, the model's performance in training and testing may decline with smaller datasets. Additionally, inaccurate samples of both malware and benign instances can lead to poor malware identification. Despite the effectiveness of our proposed hybrid deep learning architecture in detecting and classifying various malware variants and families, there are still some limitations that need to be addressed.

D. Future Works

The proposed deep learning architecture shows some resistance to obfuscation, as evidenced by satisfactory results on the Microsoft BIG 2015 Dataset, which includes obfuscated malware samples. However, the method has not been tested against adversarial attacks with crafted inputs. Future research aims to evaluate the method's resilience to evasion attacks. Misclassification can occur due to similarities in features among different malware families. The model has only been tested on the Maling and Microsoft BIG 2015 datasets. Future research could involve evaluating the model on additional datasets. The current architecture was implemented with limited computational power and resources. Plans for future work include deploying the model in a cloud computing environment to leverage greater computational power and resources. Additionally, future studies will use fewer hidden layers to reduce model complexity and will focus on extending the model by incorporating explainable AI and the latest feature optimization techniques to enhance real-time malware detection.

V. CONCLUSIONS AND SUGGESTIONS

The IoTs technology deepens the attendance of the connected sensors to the Internet in our daily behaviors, and brings the many benefits in the quality of the life. Also, it has generated the related problems to the security issues. Accordingly, the security solutions for the Internet of Things should be developed. In the current article, a new impressive cross-platform malware detection method based on artificial intelligence is designed for the industrial sensors of IoTs. In the presented approach, D3WT is used for the extraction of the feature. In addition, a combination from CNN and LSTM is used, to detect the malwares. Our approach is evaluated on Maling and Microsoft BIG 2015. First, the proposed approach is compared with every network as separately. The obtained results confirm which our approach can impressively classify the malwares with the great values of the accuracy, the

sensitivity, the specificity and the F1-score. When tested on the Microsoft BIG 2015 and Maling datasets, the accuracy achieved is 95.36% and 98.12%, respectively. Then, the presented approach has been analyzed with the advanced models. The obtained outcomes show the benefit and the superiority of our approach against the similar models.

The model has only been tested on the Maling and Microsoft BIG 2015 datasets. Future research could involve evaluating the model on additional datasets. The current architecture was implemented with limited computational power and resources. Plans for future work include deploying the model in a cloud computing environment to leverage greater computational power and resources. For further study, provision of a detection system that specifically classifies the malwares which uses the obfuscation techniques, can be considered. In addition, the next researches can rely on the deployment of the presented approach, by integrating the model basis on AI by the latest techniques for the optimization of the feature, to enhance the detection of the malware in the real time.

Tongji University, Shanghai, China³

Abstract—This study develops a coverage perception interference model for Wireless Sensor Networks, focusing on the challenges of homogeneous interference within Regions of Interest. Traditional perception models often overlook areas that, while covered, do not meet the required coverage standards for accurate classification. This model addresses both uncovered areas and those inadequately covered, which are susceptible to classification errors. A propositional space for the coverage model is defined to assess the impact of homogeneous interference on sensor nodes, with the aim of quantifying its effects on network coverage quality and stability in complex environments. The study emphasizes the generation of Basic Probability Assignments using Dempster-Shafer theory, a robust framework for managing uncertain information in sensory data. Probability Density Functions derived from historical and real-time data are utilized to facilitate precise BPA calculations by integrating over specific attribute ranges, thereby enhancing the accuracy and reliability of target detection. Algorithms are also developed to calculate the interference effect BPA, which are integrated with perception coverage models to improve the assessment and optimization of coverage quality. The research enhances the methodological understanding of managing interference in WSNs and offers practical strategies for improving sensor network operations in environments affected by significant interference, boosting the reliability and effectiveness of critical surveillance and monitoring applications.

Keywords—Wireless sensor networks; homogeneous interference; basic probability assignment; coverage quality; Dempster-Shafer theory

I. INTRODUCTION

In the current global landscape, security and surveillance of sensitive areas such as borders, critical infrastructures, and urban centers are of paramount importance. The increasing complexity and sophistication of threats, ranging from unauthorized human intrusions to vehicular entries and wildlife disturbances, necessitate advanced technological solutions that can operate under diverse environmental conditions and provide real-time, reliable data. Wireless Sensor Networks (WSNs) have emerged as a pivotal technology [1-9] in this domain, offering the potential to revolutionize the way these areas are monitored. However, despite their significant potential, the deployment of WSNs in security applications faces several critical challenges that hinder their effectiveness.

One of the primary challenges is the high rate of false positives, which can lead to unnecessary alarms and subsequently drain the resources and attention of security personnel. False positives are predominantly caused by the

inability of traditional WSNs to accurately classify the nature of the intrusion [10-14]. For instance, the motion sensors in a network might be triggered by non-threatening entities such as small animals or environmental factors like wind. Such inaccuracies not only undermine the reliability of security protocols but also reduce the trust in these systems.

Moreover, the effectiveness of WSNs is often limited by their capacity for real-time processing and analysis of sensor data. Security applications require immediate responses to detected threats, and any delay in the processing can result in a failure to prevent an intrusion [15-20]. Additionally, the diverse range of intruders and the subtleties in their characteristics necessitate sophisticated algorithms capable of making nuanced distinctions. Current systems predominantly employ simplistic threshold-based algorithms [21-23], which are not only prone to errors but also lack the ability to learn and adapt from past data, thus failing to improve over time.

Current WSN implementations primarily focus on detecting the presence of an intruder rather than classifying the type of intrusion accurately [24-26]. This is a significant limitation, as different types of intrusions require different responses. For instance, the approach to dealing with a human trespasser might differ substantially from that for a wild animal entering a restricted area. Most existing systems utilize basic motion sensors that trigger alarms when interrupted, regardless of the cause. Such systems are unable to distinguish between false alarms caused by non-threatening entities and genuine security breaches, leading to high rates of false positives. This limitation is further exacerbated by the lack of integration of advanced classification algorithms within the sensor networks. While there are robust individual sensor technologies capable of complex data processing [27-30], their integration into network-wide systems that perform real-time analysis and classification is not adequately addressed in existing research.

The integration of advanced computational models, such as those based on Dempster-Shafer theory [31-35], presents a promising solution to these challenges. The Dempster-Shafer theory of evidence allows for the combination of evidence from different sources to arrive at a degree of belief (represented by a belief function) that can handle uncertainty more effectively than traditional probabilistic methods.

Previous studies on Wireless Sensor Networks have primarily concentrated on basic detection algorithms and simplistic models [36-40] that often fail to account for the complexities introduced by homogeneous interference. These studies typically emphasize threshold-based detection

mechanisms, which are inadequate in environments where interference affects multiple sensor nodes uniformly. As a result, these approaches struggle to maintain accurate coverage, leading to increased false positives and unreliable surveillance outcomes. Furthermore, existing research has largely overlooked the integration of advanced probabilistic models to address the uncertainty and ambiguity in sensor data caused by interference.

Given the shortcomings of previous research, there is a clear and pressing need for further investigation into how homogeneous interference impacts the coverage quality of Wireless Sensor Networks. This paper addresses these critical gaps by evaluating the effectiveness of WSNs under the influence of such interference, particularly focusing on interference that uniformly affects multiple sensors. Our study proposes a novel coverage perception interference model that leverages the Dempster-Shafer theory to enhance the robustness and accuracy of WSNs, enabling them to maintain effective coverage even in challenging conditions. Through detailed analysis and modeling, we explore how homogeneous interference compromises the network's ability to sustain reliable coverage and identify vulnerable zones. By incorporating Basic Probability Assignments within the Dempster-Shafer evidence framework, this research provides a nuanced understanding of interference effects, offering practical solutions to improve network reliability. This contribution not only advances the current body of knowledge in WSNs but also establishes a foundation for future research aimed at developing more resilient and adaptive sensor networks capable of operating effectively in complex, interference-prone environments.

This paper is structured as follows: Section II provides a detailed overview of the recognition framework and the mathematical models used in the study, including the implementation of the Dempster-Shafer theory for handling uncertainties in Wireless Sensor Networks (WSNs). Section III introduces the S-I perimeter coverage algorithm, which accounts for homogeneous interference, and discusses its operational rules and algorithmic steps. In Section IV, the simulation results are presented and analyzed, highlighting the impact of interference on coverage quality and the effectiveness of the proposed algorithm. Finally, Section V concludes the paper by summarizing the key findings and suggesting potential directions for future research in improving WSN coverage reliability under interference conditions.

II. PRELIMINARIES

A. Recognition Framework

Wireless Sensor Networks (WSNs), strategically deployed within designated Regions of Interest (ROIs), play a crucial role in enhancing the security and surveillance across vulnerable and sensitive areas by monitoring unauthorized entries from a variety of entities such as humans, animals, and vehicles. These networks are comprised of a coordinated array of sensor nodes, each designated as S_i ($i=1,2,3,\dots, \xi$). These nodes are meticulously programmed and equipped to classify potential intruders into several distinct categories, such as $C_1, C_2,$

C_3, \dots, C_φ , facilitating a targeted response to different types of security breaches.

Each sensor node within the network is outfitted with cutting-edge technology capable of capturing a wide array of detailed attributes from each detected entity. These include visual identifiers like shape and size, infrared signatures that reveal body heat, variations in ambient temperature, and precise measurements of movement speeds. This rich dataset enables a comprehensive and multifaceted analysis of each intrusion, substantially increasing the accuracy of both detection and subsequent classification processes. Beyond mere physical detection, the nodes are also equipped to sense more subtle indicators such as acoustic signals and electromagnetic properties. This capability is essential for distinguishing between organic and mechanical intruders, effectively differentiating between humans, animals, and vehicles. This nuanced approach to intrusion detection is crucial for deploying appropriate security measures and for minimizing false alarms, which are common in less sophisticated systems.

Through the use of advanced data analytics in this article, the information captured by the sensors is analyzed in real-time. This not only ensures timely detection but also enables the network to categorize each object based on its unique attributes and behavior patterns. The adaptability and responsiveness of these networks to a range of environmental stimuli and potential threats are vital, enhancing the overall security protocol of the area.

In our investigation, we explore scenarios involving three primary types of targets, illustrating a methodology and conceptual framework that are universally applicable to scenarios involving the classification of implicit targets into φ ($\varphi > 3$) categories. Utilizing Dempster-Shafer (D-S) theory, we establish a discernment framework denoted as $\Theta = \{C_1, C_2, C_3\}$. The power set of Θ , represented as 2^Θ , encompasses $2^\Theta = \{\emptyset, A_1, A_2, A_3, A_4, A_5, A_6, A_7\}$, where $A_1 = \{C_1\}$, $A_2 = \{C_2\}$, $A_3 = \{C_3\}$, $A_4 = \{C_1, C_2\}$, $A_5 = \{C_1, C_3\}$, $A_6 = \{C_2, C_3\}$, $A_7 = \{C_1, C_2, C_3\}$. Each element within 2^Θ , A_ω ($\omega=1,2,\dots,7$) forms a subset of Θ , symbolizing a specific proposition. Here the propositions $\{C_1\}$, $\{C_2\}$ or $\{C_3\}$ correspond to the sensor classifying the target into categories $\{C_1\}$, $\{C_2\}$ or $\{C_3\}$, respectively. The propositions $\{C_2, C_3\}$, $\{C_1, C_3\}$, $\{C_1, C_2, C_3\}$ indicate ambiguity in the sensing results, suggesting that the target could potentially belong to the combined categories, whereas \emptyset represents the empty set. These propositions are categorized into two types: 1) singleton propositions, where the corresponding subset contains a single element, such as $\{C_1\}$, $\{C_2\}$ and $\{C_3\}$; and 2) multiple subset propositions, where the subset comprises multiple elements, such as $\{C_1, C_2\}$, $\{C_2, C_3\}$, $\{C_1, C_3\}$ and $\{C_1, C_2, C_3\}$.

When a target enters the sensing range of sensor S_i , the sensor perceives each attribute of the target. Based on these attributes, S_i categorizes the target into one of the defined categories, resulting in a classification that is expressed through a basic probability assignment (BPA). The BPA derived from attribute θ by sensor S_i , denoted as m_θ^i , represents a mapping from 2^Θ to the interval $[0,1]$ and adheres to the following conditions:

$$\begin{cases} m_{\theta}^i(\emptyset) = 0 \\ \sum_{A \subseteq \Theta} m_{\theta}^i(A) = 1 \end{cases} \quad (1)$$

The sum of all probability masses assigned across the power set must equal one, ensuring a complete and exhaustive representation of all possible classification outcomes.

The probability of the empty set, \emptyset , is zero, reflecting the premise that every observation can be attributed to at least one category within the framework.

This structured approach not only enhances the precision of target classification within complex environments but also significantly contributes to the development of robust, scalable sensor networks capable of adapting to diverse surveillance and monitoring challenges.

Within the proposition space Θ , A represents any subset, and $m_{\theta}^i(A)$ denotes the mass or credibility allocated to proposition A . For instance, upon detecting the attributes θ of an intruding target, sensor node S_i assigns category probability values as follows: $m_{\theta}^i(C_1) = p_1$, $m_{\theta}^i(C_2) = p_2$, $m_{\theta}^i(C_3) = p_3$, $m_{\theta}^i(\{C_1, C_2\}) = p_4$, $m_{\theta}^i(\{C_1, C_3\}) = p_5$, $m_{\theta}^i(\{C_2, C_3\}) = p_6$, $m_{\theta}^i(\{C_1, C_2, C_3\}) = p_7$, where the sum of p_1 through p_7 equals 1. Given that the invading target A possesses θ attributes, sensor node S_i can measure θ BPA values. For each attribute $i=1,2,\dots,\theta$, sensor S_i combines these θ BPA values using a special fusion rule denoted as \oplus , thereby deriving a new BPA value m^i , which represents the final detection outcome of the target by sensor S_i .

$$m^i = m_1^i \oplus m_2^i \oplus m_3^i \oplus \dots \oplus m_{\theta}^i \quad (2)$$

B. Implicitly Targeted BPA Function Generation

The generation of Basic Probability Assignment (BPA) using the Dempster-Shafer (D-S) theory represents a critical step in applying evidence theory to the accurate characterization and identification of targets within sensor networks. The quality of BPA generation crucially influences the precision of perception results and the accuracy of target classification. Currently, the methodology for generating BPA predominantly relies on classification-based approaches, which can be summarized through the following steps: Derivation of classification criteria from historical data; Collection of attribute data from targets awaiting identification, followed by obtaining initial classification results based on the derived criteria; Transformation of these initial classification results into BPA through specific rules. The initial step, forming classification criteria, is pivotal and broadly categorized into three approaches: Expert Systems and Rule-Based Reasoning; Statistical analysis; Machine learning. While each approach offers distinct advantages, they also present challenges such as the maintenance of rule systems, complexity in parameter setting for fuzzy logic, reliance on prior knowledge in Bayesian inference, and the high cost of data annotation in supervised learning. The chosen approach in this research involves using PDFs to fit the attribute values of category targets, subsequently using these fits to generate BPAs for unclassified targets. This method leverages the Gaussian distribution of attribute values to reflect individual variability and measurement errors.

A novel method for determining BPA has been proposed, involving the division of a dataset into a training and a test set.

Gaussian models for p attributes are established using the training set and then tested using the test set to determine similarities. Attribute weights are adjusted based on the overlap degree among categories to fine-tune the similarity scores and finalize the BPA, as depicted in the methodology section. This approach provides a structured, objective classification by assessing and integrating new information dynamically, which is essential for robust decision-making in sensor networks.

C. Attribute Modeling Approach

In the discernment framework $\Theta = \{C_1, C_2, C_3 \dots C_n\}$, each category φ_i ($i=1,2,3 \dots \tau$) is associated with a Gaussian distribution and is characterized by p_j ($j=1,2,3 \dots P$) attributes. For each category φ_i , the mean and standard deviation for each attribute are derived from the training samples as follows:

The mean value for attribute p , represented as \bar{X}_p is calculated using the formula:

$$\bar{X}_p = \frac{1}{N} \sum_{\tau=1}^N x_{\tau,p} \quad (p = 1,2,3 \dots P) \quad (3)$$

where, $x_{\tau,p}$ is the value of attribute p for the τ -th sample in category φ_i .

The standard deviation for attribute p , denoted as σ_p , is determined by:

$$\sigma_p = \sqrt{\frac{1}{N-1} \sum_{\tau=1}^N (x_{\tau,p} - \bar{X}_{\tau,p})^2} \quad (p = 1,2,3 \dots P) \quad (4)$$

These statistical measures establish the parameters for the Gaussian distribution model of each attribute, which is defined as:

$$\mu_{\alpha}(x) = e^{-\frac{(x-\bar{x}_p)^2}{2\sigma_p^2}} \quad (5)$$

In this model, the Gaussian-type attribute model is considered a singleton proposition where both $\mu_{\alpha}(x)$ and $\mu_{\beta}(x)$ represent individual propositions within the framework. Complex or composite subset propositions are formed by the overlapping regions of these Gaussian membership functions. For example, the composite subset proposition $\{\alpha\beta\}$ is defined by:

$$\mu_{\alpha\beta}(x) = \min\{\mu_{\alpha}(x), \mu_{\beta}(x)\} \quad (6)$$

This expression effectively captures the lowest membership value between the two propositions, representing the degree of certainty that the value x belongs to both categories α and β simultaneously. This formulation allows for a nuanced understanding of the intersections and relationships between different category attributes in a multi-dimensional attribute space, facilitating a more precise and sophisticated approach to category classification in statistical analysis and machine learning applications.

D. Similarity Measurement

In the realm of multi-category classification, the construction of attribute weights plays a pivotal role in achieving unbiased results through a comprehensive evaluation of each attribute. The efficacy of an attribute in distinguishing between categories is inversely proportional to the degree of similarity

among the categories it connects. Specifically, if a given attribute exhibits substantial overlap across multiple category models, its discriminatory power is diminished, increasing the likelihood of misclassification and reducing its reliability. Consequently, the Basic Probability Assignment (BPA) generated from such attributes contributes minimally in a multi-category classification setting.

Conversely, attributes that demonstrate low similarity among categories possess enhanced discriminatory capability, thereby affirming their reliability and increasing their contribution to the BPA in the classification process. It becomes imperative to amplify the role of attributes with substantial contributions while diminishing the influence of those with minimal impacts, to foster more objective classification outcomes.

This section introduces and discusses the concept of attribute weighting, where each attribute's weight is inversely related to its degree of overlap among categories, reflecting its discriminative strength and reliability. Suppose μ_{ij} ($i=1,2,\dots,k; j=1,2,\dots,l$) represents the membership function for the j -th attribute of the i -th category, and μ_{hj}^{Δ} ($h=1,2,\dots,\frac{k^2-k}{2}; j=1,2,\dots,l$) denotes the generalized triangular fuzzy number model for the composite subset proposition $\{AB\}$ for the j -th attribute in the h -th composite category. Let $S(x)$ symbolize the integral or total sum over the defined range of the membership function. The weight ω_j ($j=1,2,\dots,k$) for the j -th attribute can be formulated as:

$$\omega_j = 1 - \frac{\sum_{h=1}^{\frac{k^2-k}{2}} S(\mu_{hj}^{\Delta})}{\sum_{i=1}^k S(\mu_{ij}) - \sum_{h=1}^{\frac{k^2-k}{2}} S(\mu_{hj}^{\Delta})} \quad (7)$$

Here, a higher value of ω_j ($j=1,2,\dots,k$) indicates greater overlap and similarity, thereby assigning a lower weight to the attribute. This weighting approach ensures that attributes contributing significantly to the classification accuracy are emphasized, while those with lesser discriminative power are de-emphasized, optimizing the classification framework for better performance and reliability. This strategy is crucial for enhancing model accuracy and robustness in complex classification landscapes, where the correct identification of category boundaries is vital for effective decision-making and analysis.

In the domain of sensor-based classification, establishing robust Basic Probability Assignments (BPA) for the perception of implicit targets requires a systematic application of Gaussian membership functions. This method takes into account the inherent variability and potential measurement inaccuracies associated with each target attribute, adhering closely to statistical norms found in Gaussian distributions.

For a practical application, consider a category, such as C_1 , which comprises multiple targets each characterized by a series of attributes. The attribute values for these targets are systematically analyzed to formulate a data matrix, with each row representing a target and columns corresponding to attributes. The statistical distribution of each attribute is characterized by calculating the mean and standard deviation

from this ensemble of data points, facilitating the modeling of attribute behaviors within the target population.

The Gaussian membership function for each attribute in category C_1 is defined to encapsulate the likelihood of attribute values deviating within three standard deviations from the mean. Mathematically, this is expressed as:

$$\mu_{\theta}^{C_1}(x) = \begin{cases} e^{-\frac{(x-\bar{X}_{\theta})^2}{2\sigma_{\theta}^2}}, & \text{for } x \text{ within } [\bar{X}_{\theta} - 3\sigma_{\theta}, \bar{X}_{\theta} + 3\sigma_{\theta}] \\ 0, & \text{outside this interval} \end{cases} \quad (8)$$

This formulation precisely quantifies the fit of a given data point x to the modeled attribute distribution, thereby assessing its categorical alignment effectively. It's crucial for ensuring that the classifications are both precise and reflective of the actual attribute distributions, thus reducing misclassifications.

Similarly, this method extends to other categories, such as C_2 and C_3 , where Gaussian membership functions are established for each respective attribute. By analyzing the intersection or overlap of these functions across different categories, one can discern the level of distinctiveness or similarity between categories. Such intersections can range from no overlap, where category functions are distinctly separate, to various degrees of partial overlap, illustrating complex inter-attribute relationships.

In the analysis of Gaussian membership functions for categorical classification, the spatial relationships between the curves can reveal significant insights into the interaction and distinctiveness of category attributes. These relationships can generally be categorized into four distinct scenarios, each representing different levels of overlap and separation among the category-specific functions:

No Intersection: In the first scenario, the Gaussian functions for each category are entirely distinct, with no overlap. This separation indicates clear demarcation between categories, suggesting that each category possesses unique attribute values that are significantly different from the others. This scenario is ideal for classification tasks, as it implies high discriminative power for the attributes in distinguishing between categories.

In an ideal scenario where these Gaussian functions are distinct and do not intersect—as depicted in the hypothetical Fig. 1—selecting a point on each curve allows us to determine the precise probability that a sensor node categorizes a target into C_1, C_2 and C_3 based on a specific value of attribute θ . Such configurations where $\mu_{\theta}^{C_1}(x)$, $\mu_{\theta}^{C_2}(x)$ and $\mu_{\theta}^{C_3}(x)$ are independent, facilitate straightforward predictions with high confidence levels about the category of the detected targets.

Partial Intersection: The second scenario involves two of the Gaussian curves intersecting while the third remains separate. This configuration implies that while two categories share some similarity in attribute distributions, they both remain distinctly different from the third category. Such a setup can be useful in identifying overlapping characteristics between the two intersecting categories and leveraging this information to enhance classification accuracy for more complex scenarios.

Fig. 1. Scenario of independent gaussian curves.

In contrast, as illustrated in Fig. 2, the Gaussian functions $\mu_{\theta}^{C_1}(x)$ and $\mu_{\theta}^{C_2}(x)$ intersect, whereas $\mu_{\theta}^{C_3}(x)$ remains distinct. The intersection point, noted as $(x_{4,\theta}, \mu_{\theta}^{C_1,C_2}(x_{4,\theta}))$, marks the area of ambiguity between C_1 and C_2 . This area is crucial because it represents the values of θ where the distinction between categories C_1 and C_2 becomes unclear. The upper boundary of this region is defined by the composite subset membership function $\mu_{\theta}^{C_1,C_2}(x)$, which is the minimum of $\mu_{\theta}^{C_1,C_2}(x) = \min\{\mu_{\theta}^{C_1}(x), \mu_{\theta}^{C_2}(x)\}$. This function captures the highest degree of overlap and hence, the maximum uncertainty in classification between these two categories.

Fig. 2. Two intersecting and one independent GMF curve.

Single Intersection with Others: In the third type, one Gaussian function intersects with each of the other two, but those other two do not intersect with each other. This pattern suggests a central category that shares attributes with the other two categories, which are otherwise distinct from each other. This scenario can be particularly challenging for classification, as it requires careful analysis to ensure accurate category determination.

In Fig. 3, the Gaussian membership functions for the categories C_1, C_2 and C_3 are depicted with specific interactions. The membership functions for C_1 and C_2 , $\mu_{\theta}^{C_1}(x)$ and $\mu_{\theta}^{C_2}(x)$, intersect at a point defined as $(x_{8,\theta}, \mu_{\theta}^{C_1,C_2}(x_{8,\theta}))$. Simultaneously, the functions for C_2 and C_3 , $\mu_{\theta}^{C_2}(x)$ and

$\mu_{\theta}^{C_3}(x)$, intersect at $(x_{9,\theta}, \mu_{\theta}^{C_2,C_3}(x_{9,\theta}))$. The upper limits of these intersections are defined by the composite subset membership functions $\mu_{\theta}^{C_1,C_2}(x)$ and $\mu_{\theta}^{C_2,C_3}(x)$, calculated as the minimum values between the respective intersecting functions. This represents a complex but realistic scenario where categories C_1 and C_2 share some common attributes as do categories C_2 and C_3 , but C_1 and C_3 remain distinct in this configuration.

Fig. 3. Two intersecting and separately independent GMF curves.

Mutual Intersection: The final scenario depicts each Gaussian curve intersecting with the other two, indicating a high level of attribute overlap among all three categories. This extensive overlap can lead to higher classification ambiguity and may necessitate more sophisticated analytical techniques or additional data to effectively resolve category assignments.

Fig. 4 illustrates a scenario where all three categories intersect pairwise. The Gaussian curves $\mu_{\theta}^{C_1}(x)$, $\mu_{\theta}^{C_2}(x)$ and $\mu_{\theta}^{C_3}(x)$ each intersect with one another, yielding intersection points at $(x_{13,\theta}, \mu_{\theta}^{C_1,C_2}(x_{13,\theta}))$, $(x_{14,\theta}, \mu_{\theta}^{C_2,C_3}(x_{14,\theta}))$ and $(x_{15,\theta}, \mu_{\theta}^{C_1,C_3}(x_{15,\theta}))$. These points delineate the regions where distinguishing between any two categories becomes challenging due to shared attribute values. The corresponding upper bounds are defined by the composite membership functions $\mu_{\theta}^{C_1}(x)$, $\mu_{\theta}^{C_2}(x)$ and $\mu_{\theta}^{C_3}(x)$, each calculated as the minimum of the intersecting Gaussian functions. This scenario is indicative of a highly intertwined attribute space where each category shares significant overlaps with the others, complicating the classification tasks but also providing rich data for analysis.

Fig. 4. Pairwise intersecting GMF curves.

E. Interference Effect BPA Generation

In the context of sensor networks, understanding the influence of interference from various sources on sensor nodes is critical, especially how it affects the perception of specific attributes and the subsequent Basic Probability Assignments (BPA) used for decision-making. Interference does not cause sensor failure but introduces biases in the sensors' measurements of attributes, thereby altering the BPA calculations. Here's how to model and calculate the effect of interference on BPA:

Initial BPA Calculation without Interference: First, a sensor S_i measures an attribute θ of a target without any interference. Using the methodology described earlier, the sensor's BPA for the attribute, denoted as m_θ^i , is calculated, representing the sensor's unaltered perception.

BPA Calculation With Interference: The same sensor S_i then measures attribute θ in the presence of a specific interference source G_g . The interference-altered BPA, $m_{\theta,g}^i$, is calculated using the same method as before but adjusted to reflect the combined effect of the original sensor data and the interference. This is done using a specialized operator \oplus_Z , where $m_{\theta,g}^i = m_\theta^i \oplus_Z u_{\theta,g}$. This operator blends the original perception effect with the interference effect to produce a new, integrated BPA.

Equation Formulation for Combined BPA: With $m_{\theta,g}^i$ and m_θ^i already derived from the previous steps, the combined BPA equation can be constructed using the operator \oplus_Z , finalizing the calculation of the interference-influenced BPA.

Calculating BPA for Other Interference Types: If other interference sources affect sensors designed for different attributes, the above steps (1), (2), and (3) are repeated for each new interference source to calculate its specific impact on BPA.

Fig. 5. Membership with interference.

For instance, consider a scenario depicted in a hypothetical Fig. 5, where the original measurement of attribute θ for target 19 is (x_{19}, θ) . Under interference, this measurement changes to (x_{20}, θ) . Consequently, the BPA generated by the affected sensor node will shift from the original (non-interfered) BPA to a new BPA that is a composite of the original and the interference effects.

In the context of sensor networks, the challenge of accurately interpreting sensor data is compounded when external interference affects the sensor's operation. The concept of Basic Probability Assignment (BPA) is pivotal in quantifying the degree of belief in each possible classification of a target based on sensor data. Consider the scenario where a sensor, without any interference, produces a BPA denoted by m . For example, the probabilities that the target belongs to categories C_1, C_2 and C_3 might be given as $m(C_1) = p_1, m(C_2) = p_2, m(C_3) = p_3, m(\{C_1, C_2\}) = p_4$, respectively, with probabilities for combined categories defined similarly.

However, when an interference source affects the sensor, the perception results are altered, introducing deviations in the measured attribute values. The interference effect is itself modeled as a BPA, denoted by g , with its own set of probabilities such as $g(C_1) = p_8, g(C_2) = p_9, g(C_3) = p_{10}, g(\{C_1, C_2\}) = p_{11}$, and so forth, reflecting the impact of the interference on the sensor's ability to classify targets correctly.

The combined effect of the original sensor data and the interference is then calculated using a specialized operator \oplus_Z , known as the Dempster combination rule. This rule is employed to integrate the original BPA m and the interference BPA g , resulting in a modified BPA m^* . The probabilities in m^* are recalculated to reflect this integration, providing new insights into the likely classifications in the presence of interference. For instance, the revised probability that the target belongs to category C_1 in the presence of interference would be updated to $m^*(C_1) = p_1^*$, and similarly for the other categories and combinations thereof.

In the context of dealing with sensor interference within wireless networks, the probabilities associated with the Basic Probability Assignment (BPA) for both the non-interfered sensor data and the interference-adjusted data can be methodically calculated using Gaussian membership functions. This calculation treats the probabilities $p_1, p_2, p_3 \dots p_7$ associated with the original, undisturbed sensor readings as known quantities. These probabilities reflect the sensor's belief in the target's classification into respective categories without the presence of any distortion.

Similarly, the probabilities $p_1^*, p_2^*, p_3^* \dots p_7^*$ for the interference-affected classifications are derived directly from these Gaussian functions. By applying these well-defined statistical methods, we treat these values as known, calculated based on the sensor's data under the influence of interference.

For the unknown quantities, specifically the interference effect BPA components $p_8, p_9, p_{10} \dots p_{14}$, they are not directly observable but can be computed through an established formula that considers the nature of the interference and its impact on the sensor's perception capabilities, refer to the appendix A for detailed computational procedures. This involves leveraging the relationships defined by the Dempster-Shafer theory of evidence, which provides a systematic approach to combine different pieces of evidence, in this case, the original BPA and the interference-induced alterations.

III. S-I PERIMETER COVERAGE ALGORITHM

A. Operational Rules

Sensor Coverage: If a point on the perimeter of sensor node S_i falls within the sensing range of another sensor node S_j , then that point is considered to be covered by S_j .

Segment Coverage: If an entire segment of S_i 's perimeter is covered by other sensor nodes excluding S_i itself, it is classified based on the number of covering nodes. For instance, a segment covered by k other nodes is denoted as a k -segment perimeter coverage.

Interference Coverage: If the entire perimeter of a sensor node S_i is within the coverage radius of an interference source I_j , which is the sum of the radius of I_j and S_i , it is considered to be under the interference perimeter coverage by I_j .

B. Algorithmic Steps

1. **Identify Covered Segments:** For each sensor node S_j , calculate the segments of other nearby sensor nodes S_i that fall within a double radius distance ($2r$). These segments are represented by angular intervals $[\alpha_i, L, \alpha_i, R]$.

2. **Construct and Sort Points:** For all neighboring nodes within a distance less than $2r$ from S_i , place the points α_i, L and α_i, R on the circular boundary $[0, 2\pi]$. These points are sorted in a list L and marked as either the start or end of a covered segment.

3. **Determine Coverage Frequency:** Traverse the circular boundary $[0, 2\pi]$ using the sorted list L , from left to right, to determine the coverage status of S_j and count the number of times each segment is covered by other sensor nodes, denoted as $N_{S_{seg}}$.

4. **Check Interference Influence:** For each interference source I_j , check if S_j is within the interference coverage. If so, place corresponding points α_i, L and α_i, R on $[0, 2\pi]$.

5. **Calculate Interference Coverage Count:** Using the sorted list L , determine the number of times each segment is covered by interference sources, represented as $N_{I_{seg}}$.

MSR defined by the arbitrary segmentation of the perimeter of a sensing node S_i are referred to as the MSRs associated with node S_i . For instance, as depicted in Fig. 6, the specific associations between nodes and MSRs are as follows:

MSR 2 and MSR 3 are associated with S_1 ; MSR 4 and MSR 5 are associated with S_2 ; MSR 6 and MSR 7, MSR 8 and MSR 9, MSR 10 and MSR 11 are associated with S_3 ; MSR 9 and MSR 10, MSR 8 and MSR 11 are associated with S_4 ; MSR 6 and MSR 9, MSR 7 and MSR 8, MSR 12 and MSR 13 are associated with S_5 ; MSR 14 and MSR 15 are associated with S_6 ; MSR 15 and MSR 16 are associated with S_7 ; MSR 13 and MSR 14 are associated with S_8 .

This structured association allows for a detailed analysis of how each segment of a sensing node's perimeter interacts with the coverage provided by other nodes, facilitating the calculation

of coverage frequencies and the influence of interference sources on the network's overall sensing reliability.

MSR1 and MSR2 are within the sensing range of S_1 , MSR2, MSR3, MSR4, MSR21, and MSR22 are within the sensing range of S_2 , and MSR4, MSR5, MSR6, MSR9, MSR10, MSR19, MSR20, MSR21, MSR23, and MSR26 fall within the sensing range of S_3 . MSR6, MSR7, MSR8, MSR9, MSR25, and MSR26 are covered by S_4 , while MSR8, MSR9, MSR10, MSR11, MSR12, MSR18, and MSR19 are within the sensing range of S_5 . Similarly, MSRs covered by S_6 to S_{10} can be determined based on their sensing ranges.

Fig. 6. Perimeter coverage considering homogeneous interference.

The number of times an MSR MSR_p is covered by other sensing nodes is denoted as Q_s , which can be calculated using the function $MSR_p(N_{S_{seg}})$. Similarly, the number of times MSR_q is covered by interference nodes is denoted as G_i , which can be calculated using the function $MSR_q(N_{I_{seg}})$. The function details are as Appendix B.

C. Model Example

After obtaining the sensing coverage count Q_s and the interference coverage count G_i through these functions, the confidence level of the corresponding MSR can be calculated. If a target T_1 enters MSR r , the BPA of the sensing result for T_1 by the sensing node is m , and the interference effect BPA by the interference source is g . Considering the interference effect, the final sensing result in MSR r for the target T_1 is $M_i = (\oplus m)^{Q_s} \oplus (\oplus g)^{G_i}$, where $(\oplus m)^{Q_s}$ represents the combination of Q_s BPAs, such as $(\oplus m)^5 = m \oplus m \oplus m \oplus m \oplus m$. The belief degree $bel(MSR_i)$ of MSR r can then be obtained. According to the reliability metric formula $D_{C_\xi}^\delta$, we can compute $D_{C_1}^\delta$, $D_{C_2}^\delta$, $D_{C_3}^\delta$, $D_{\{C_1, C_2\}}^\delta$, $D_{\{C_1, C_3\}}^\delta$, $D_{\{C_2, C_3\}}^\delta$ and $D_{\{C_1, C_2, C_3\}}^\delta$.

Based on this analysis, an algorithm to evaluate the reliability of WSN coverage considering the interference is proposed:

For any MSR in the ROI:

Consider the final sensing result $M_i = (\oplus m)^{Q_s} \oplus (\oplus g)^{G_i}$

Compute $D_{C_1}^\delta$, $D_{C_2}^\delta$, $D_{C_3}^\delta$, $D_{\{C_1,C_2\}}^\delta$, $D_{\{C_1,C_3\}}^\delta$, $D_{\{C_2,C_3\}}^\delta$ and $D_{\{C_1,C_2,C_3\}}^\delta$

To further illustrate the process of this algorithm, we take the sensing node S_3 in Fig. 6 as an example. Besides being perimeter-covered by other sensing nodes S_2 , S_4 , S_5 , S_9 , and S_{10} , node S_3 is also influenced by interference sources I_1 , I_2 , and I_4 . The coverage of various segments of node S_3 's perimeter by other sensing nodes is illustrated in Fig. 7.

In a detailed examination of the sensing perimeter associated with sensor node S_3 , we observe that interference sources I_1 , I_2 , and I_4 impact its operational efficacy. As demonstrated in Fig. 7, the sequence list provides insights into the perimeter segments of S_3 that are influenced by these interference sources. Table I (refer to Appendix C) summarizes the count of coverage occurrences for each segment of S_3 's perimeter, reflecting the interplay between sensory and interference coverages.

Fig. 7. Perimeter coverage sorted list of S_3 .

In the detailed examination of the coverage dynamics within a sensor network, specific attention is directed toward Sensor Node S_3 . This node serves as a focal point for evaluating the MSRs related to its periphery, delineated in accordance with the established network protocols and environmental interactions. The process involves a meticulous traversal and assessment of all related MSRs, denoted as MSR_p , to ascertain their sensory coverage status, which is captured in the ensuing coverage information table.

Additionally, the examination extends to the MSRs associated with Sensor Node S_2 , including MSR 1 and MSR 2. These regions, lying outside the sensory radius of S_2 , experience coverage counts of 1 and 2 respectively, reflecting varying levels of sensor influence. Furthermore, an expansive list of MSRs associated with Sensor Node S_5 includes regions from MSR 5 to MSR 28. Among these, MSR 12, located within S_5 's sensory radius, exhibits a coverage count of 2, signifying robust sensor activity, whereas MSR 13, outside this radius, is covered once, indicating lesser sensory influence.

The remaining MSRs, specifically MSR 14 to MSR 17, relate to Sensor Node S_6 . MSR 14, found within the sensory radius, is covered twice, affirming its significant sensory

engagement. In contrast, MSR 15, outside the sensory radius, demonstrates a reduced coverage count of 1. Similar patterns are observed with MSR 16 related to Sensor Node S_8 , covered twice within the sensory radius, and MSR 17, with a coverage count of 1 outside the radius.

Post compilation of sensory coverage counts for all pertinent MSRs, the interference coverage counts, denoted G_i , for these regions are calculated using the function MSR_q . This leads to a nuanced understanding of both the sensory and interference dynamics impacting each MSR.

Upon obtaining the sensory (Q_s) and interference (G_i) coverage counts for the smallest sensing regions, the ultimate sensory results considering interference effects are derived through the formula $M_i = (\oplus m)^{Q_s} \oplus (\oplus g)^{G_i}$. Subsequently, the reliability indices $D_{C_\xi}^\delta$ for various configurations are computed, providing a quantitative measure of the network's coverage reliability across diverse environmental and operational scenarios.

IV. MODEL SIMULATION

In the ongoing research to enhance the comprehension and reliability of belief coverage in sensory networks, the integration of Monte Carlo simulation offers a robust methodology to analyze the impact of varying parameters on system robustness. This advanced approach not only facilitates a detailed assessment across multiple scenarios but also augments the analytical capabilities concerning sensory and interference node deployments within a defined Region of Interest (ROI).

In Fig. 8, thirteen sensory nodes and four interference nodes are randomly positioned within a 100 by 100 ROI. The sensory range, depicted by blue circles, extends a radius of 10 units, while the interference range, illustrated with red dashed circles, extends a radius of 15 units. Using this setup as a basis, we evaluate the reliability metrics $D_{C_1}^\delta$, $D_{C_2}^\delta$, $D_{C_3}^\delta$, $D_{\{C_1,C_2\}}^\delta$, $D_{\{C_1,C_3\}}^\delta$, $D_{\{C_2,C_3\}}^\delta$ and $D_{\{C_1,C_2,C_3\}}^\delta$. These assessments employ a Monte Carlo method to explore how various parameters influence system reliability, increasing the resolution of our point matrix to 500 by 500 to enhance simulation accuracy. The Gaussian Membership Functions (GMFs) for categories C_1 , C_2 , and C_3 are defined with respective means and standard deviations of 7.5 and 2, 12.5 and 2.5, and 15.5 and 2.

Fig. 8. Random deployment of sensor nodes and interference nodes.

These functions are graphically represented in Fig. 9. Notable intersections of these functions occur at (9.71, 0.54) between $\mu^{C_1}(x)$ and $\mu^{C_2}(x)$, and at (11.48, 0.14) between $\mu^{C_1}(x)$ and $\mu^{C_3}(x)$, and at (14.15, 0.8) between $\mu^2(x)$ and $\mu^3(x)$. Fig. 10 and Fig. 11 illustrate the computed reliability indices. Setting the confidence threshold δ at 0 and the interference factor I at 1, where I=1 implies no consideration of interference effects, the comprehensive ROI coverage rate is 0.9739.

Fig. 9. Gaussian membership function simulation.

Assuming classification is based solely on a single attribute that varies from 8.5 to 17.2. For values of x ranging from 0 to 4.85, $D_{C_1}^0$ dominates at 0.9739, with other classifications scoring zero, indicating that targets within the full sensory coverage are classified exclusively as C_1 . At critical values of x such as 9.71 and 14.15, peak values are observed for $D_{\{C_1, C_2\}}^0$ and $D_{\{C_2, C_3\}}^0$, respectively.

Fig. 10. Reliability trend (I=1).

As x increases, the category shifts: from 4.85 to 9.71, the proportion of regions classifying the target as C_1 decreases, while $D_{\{C_1, C_2\}}^0$ grows, indicating ambiguity in classification between C_1 and C_2 . Between 9.71 and 12.5, $D_{C_2}^0$ increases directly with x, peaking at x=12.5. Beyond 14.15, more regions start classifying the target as C_3 , although some areas remain uncertain between C_2 and C_3 , until a definitive classification as C_3 becomes predominant as x approaches 17.2.

Fig. 11. Reliability trend (I=0.7).

In Fig. 11, with δ set at 0 and I at 0.7, significant shifts occur in the reliability metrics compared to when I=1, underscoring how interference significantly impacts sensory coverage reliability. Despite these variations, the overall coverage rate remains 0.9739, affirming robust system performance under varied conditions. As x ranges from 0 to 7.25, most of the ROI classifies targets as C_1 ; between 11.48 and 12.67, C_2 becomes more likely; and from 15.53 to 17.2, the classification increasingly favors C_3 .

Setting the confidence threshold δ to zero allows for a more detailed observation of the reliability metrics for different classifications: $D_{C_1}^\delta$, $D_{C_2}^\delta$, $D_{C_3}^\delta$, $D_{\{C_1, C_2\}}^\delta$, $D_{\{C_1, C_3\}}^\delta$, $D_{\{C_2, C_3\}}^\delta$ and $D_{\{C_1, C_2, C_3\}}^\delta$, with attribute values ranging from 0 to 17.2 and interference factors between 0.7 and 1. The overall trends for these functions are illustrated in Fig. 12 to Fig. 17.

In Fig. 12, within the attribute value range of 9.71 to 17.2, changes in the interference factor do not affect the reliability outcome $D_{C_1}^\delta$. However, for values from 0 to 9.71, as the interference factor decreases, the reliability for category C_1 similarly declines, and the lower the interference factor, the greater the reduction in reliability, indicating that the disruptive effects of interference sources are particularly significant within specific attribute value ranges.

Fig. 12. Overall trend of the function $D_{C_1}^\delta$.

This figure clearly demonstrates the relationship between external intrusion attribute values and the reliability of the sensing coverage system. Across the higher attribute value range of 9.71 to 17.2, regardless of changes in the interference factor,

the system's sensing classification reliability remains stable, indicating that the sensor network's monitoring of attribute values has become stable and robust. When attribute values fall below 9.71, the reliability of the coverage system significantly decreases with increasing interference factor; thus, when designing sensing coverage systems, particular attention needs to be paid to the effects of interference in scenarios with low attribute values, as smaller interference factors mean greater disruption from external interference sources, leading to faster declines in system reliability. This may be due to the low intensity of the target's relevant attributes under these conditions, making them more susceptible to environmental noise and electromagnetic interference, thus reducing the sensing nodes' detection accuracy.

Fig. 13. Overall trend of the function $D_{C_2}^\delta$.

In Fig. 13, for attribute values within the ranges of 0 to 9.71 and 14.15 to 17.2, there are no MSRs that classify the sensing results as category C_2 , indicating that the attribute values of the intrusion targets are either too low to elicit an adequate system response or too high, exceeding the optimal operational range of the sensing coverage system. From 9.71 to 14.15, the reliability results of sensing classification for $D_{C_2}^\delta$ initially increase and then decrease, particularly as the attribute value reaches 12.5, where the characteristics of the intrusion target highly align with the features of category C_2 , resulting in maximum reliability for this classification—a peak symbolizing the sensing coverage system's highest confidence level in assigning targets to category C_2 . Thereafter, the degree of membership for classifying targets as C_2 gradually diminishes until it reaches zero, with the interference factor I and the reliability of classification $D_{C_2}^\delta$ being directly correlated—the larger the interference factor, the higher the classification reliability.

Fig. 14. Overall trend of the function $D_{C_3}^\delta$.

In Fig. 14, within the range of 0 to 14.15, the reliability outcome of sensing classification $D_{C_3}^\delta$ does not fluctuate with changes in the interference factor, but from 14.15 to 17.2, the degree of membership for classifying targets as C_3 , $D_{C_3}^\delta$, steadily increases with rising attribute values. Similarly, $D_{C_3}^\delta$ shows a positive correlation with the interference factor I , with an increase in the factor enhancing the classification result's reliability, which, in turn, results in a decrease in $D_{\{C_2, C_3\}}^\delta$ as shown in Fig. 17.

Fig. 15 illustrates that from 0 to 8.5, the changes in $D_{C_1}^\delta$ and $D_{\{C_1, C_2\}}^\delta$ display a symmetrical trend due to the intensified effect of interference, causing uncertainty in the sensing classification results right from the start ($D_{\{C_1, C_2\}}^\delta \neq 0$). From 8.5 to 9.71, the number of MSRs unable to determine the category of the intrusion target gradually increases, and from 9.71 to 11.48, the reliability of classification results $D_{\{C_1, C_2\}}^\delta$ consistently decreases, due to the attribute values increasing the affiliation of the intrusion targets to category C_2 more frequently.

Fig. 15. Overall trend of the function $D_{\{C_1, C_2\}}^\delta$.

Fig. 16 indicates that within the range of 8.5 to 15, there are portions of the sensing coverage area unable to correctly classify intrusion targets as either C_1 or C_3 , reaching a peak number of problematic MSRs at 11.48, although this has limited impact on the overall reliability of classification results, indirectly showing that these parts of the sensing coverage due to negative effects from interference sources have insufficient detection accuracy.

Fig. 16. Overall trend of the function $D_{\{C_1, C_3\}}^\delta$.

Fig. 17 shows that the interference factor impacts the reliability of sensing coverage $D_{\{C_2, C_3\}}^\delta$ only within the specific attribute value range of 11.48 to 17.2, not significantly in all cases, allowing for an assessment of the dynamic nature and sensitivity of the sensing coverage system to external condition changes. From 11.48 to 14.15, as the interference factor increases, the reliability of coverage $D_{\{C_2, C_3\}}^\delta$ also gradually improves, with the number of MSRs unable to correctly classify targets within the ROI incrementally increasing. From 14.15 to 17.2, the weaker the interference effect, the stronger the reliability of sensing coverage $D_{\{C_2, C_3\}}^\delta$.

Fig. 17. Overall trend of the function $D_{\{C_2, C_3\}}^\delta$.

V. CONCLUSION

The research presented in this study contributes a novel and robust approach to enhancing the security and reliability of Wireless Sensor Networks (WSNs) by addressing the critical issue of false positives and improving intruder classification accuracy. The use of Dempster-Shafer theory for evidence combination is a key innovation, offering a powerful means to manage the uncertainty inherent in sensor data, particularly in environments where interference and overlapping signals are prevalent. This methodology stands out for its ability to integrate multiple sources of evidence, thereby refining the overall decision-making process and enhancing the reliability of intrusion detection systems.

Despite these strengths, there are several areas where the model could be further refined and extended. One significant limitation of the current approach is its static nature. While the model effectively reduces false positives by distinguishing between different types of intruders, it does so based on predefined Gaussian membership functions and belief structures that may not adapt well to rapidly changing conditions. In dynamic environments, where the nature of threats can evolve quickly, this rigidity could lead to reduced effectiveness over time. Therefore, integrating machine learning algorithms into the framework could be a promising direction for future research. Such integration would enable the model to learn from real-time data, adapt its parameters dynamically, and improve its accuracy in response to changing environmental factors and threat landscapes.

Moreover, while the model has been demonstrated to work effectively in the context of high-security areas, its application to larger and more complex WSNs raises questions about scalability. As the network size increases, the computational

demands associated with processing and integrating data from numerous sensors could become significant. This potential bottleneck suggests a need for optimization techniques that can maintain the model's efficiency in larger deployments. For instance, hierarchical or distributed processing methods could be explored to manage the computational load more effectively, ensuring that the system remains responsive and reliable even as the scale of the network grows.

Another important consideration is the model's applicability beyond the immediate context of high-security monitoring. The principles underlying the proposed framework—such as the use of evidence theory and the focus on managing uncertainty—could be valuable in a range of other domains. For example, in wildlife tracking or traffic management, where sensor networks must operate under varying and often unpredictable conditions, the ability to accurately classify and respond to different types of entities is crucial. Expanding the framework to address these broader applications could provide substantial societal benefits, making WSNs more versatile and effective across diverse fields.

In addition to these technical considerations, it is also worth reflecting on the broader implications of this research in the context of WSN development. The growing reliance on sensor networks in critical infrastructure and security applications means that the robustness and reliability of these systems are of paramount importance. By providing a framework that can better manage the inherent uncertainties and complexities of these environments, this research contributes to the advancement of WSN technology as a whole. However, as with any emerging technology, continuous improvement and adaptation are necessary to keep pace with evolving challenges. Future research should not only focus on technical enhancements but also consider the ethical and societal implications of deploying increasingly autonomous and intelligent sensor networks in sensitive areas.

In conclusion, while the current study represents a significant step forward in the development of more reliable and adaptable WSNs, there is ample room for further exploration and refinement. By addressing the limitations of the current model and expanding its applicability, future work can build on this foundation to create even more effective and versatile sensor networks, capable of meeting the demands of a wide range of modern applications.

ACKNOWLEDGMENT

We extend our deepest gratitude to the Shandong Province Social Science Planning Research Project (Grant No. 23CXWJ04), the National Natural Science Foundation of China (Grant No. 61403230), and the Natural Science Foundation of Shandong Province (Grant No. ZR2020MG011) for their generous support. Their contributions were invaluable in the realization of our research. The insights and outcomes presented in this work are a testament to their commitment to advancing knowledge in our field.

APPENDIX B

Algorithm 1: S-I Perimeter Coverage

Initialize:

S = {S₁, S₂, ..., S_i}: Set of sensor nodes

I = {I₁, I₂, ..., I_j}: Set of interference sources

r_s: Sensing radius of sensor nodes

r_i: Interference radius of interference sources

For each sensor node S_i in S do

 Initialize Coverage Status [S_i] to 0

 Covered Segments is initially empty

For each sensor node S_j in S, j ≠ i do

 If distance (S_i, S_j) ≤ 2 * r_s then

 Calculate the segment of S_i covered by S_j

 Add this segment to Covered Segments

 End If

 End For

 Sort the segments in Covered Segments

 Calculate the coverage frequency for S_i based on the sorted segments

End For

For each sensor node S_i in S do

 Interference Segments is initially empty

For each interference source I_j in I do

 If distance (S_i, I_j) ≤ r_s + r_i then

 Calculate the interference segment on S_i due to I_j

 Add this segment to Interference Segments

End If

 End For

 Combine the interference segments with the original covered segments

 Recalculate the final coverage status for S_i considering the interference

 End for

Return:

return the final coverage status of all sensor nodes

Algorithm 2: Calculate MSR_p Coverage Count

Initialize:
 Let S_i be the sensor node under consideration.
 Let MSR_p be a segment related to the boundary of node S_i .
 Compute:
 For each MSR_p associated with node S_i :
 If MSR_p is on the inner side of the boundary:
 $Q_s = N_{S_{seg}} + 1 // N_{S_{seg}}$ is the count of sensor nodes covering the segment S_{seg} .
 Else if MSR_p is on the outer side of the boundary:
 $Q_s = N_{S_{seg}}$.
 End If.
 End For.
 Return:
 $Q_s //$ Return the coverage count for the segment MSR_p .

Algorithm 3: Calculate MSR_q Interference Count

Initialize:
 Let S_i be the sensor node under consideration.
 Let MSR_q be a segment related to the boundary of node S_i .
 Compute:
 For each MSR_q associated with node S_i :
 If MSR_q is on the inner side of the boundary:
 $G_i = N_{I_{seg}} + 1 // N_{I_{seg}}$ is the count of sensor nodes covering the segment I_{seg} .
 Else if MSR_q is on the outer side of the boundary:
 $G_i = N_{I_{seg}}$.
 End If.
 End For.
 Return:
 $G_i //$ Return the coverage count for the segment MSR_p .

Lightweight and Efficient High-Resolution Network for Human Pose Estimation

Jiarui Liu¹, Xiugang Gong^{2*}, Qun Guo³

School of Computer Science and Technology, Shandong University of Technology, Zibo, Shandong, 255000, China

Abstract—To address the challenges of high parameter quantities and elevated computational demands in high-resolution network, which limit their application on devices with constrained computational resources, we propose a lightweight and efficient high-resolution network, LE-HRNet. Firstly, we designs a lightweight module, LEblock, to extract feature information. LEblock leverages the Ghost module to substantially decrease the number of model parameters. Based on this, to effectively recognize human keypoints, we designed a Multi-Scale Coordinate Attention Mechanism (MCAM). MCAM enhances the model's perception of details and contextual information by integrating multi-scale features and coordinate information, improving the detection capability for human keypoints. Additionally, we designs a Cross-Resolution Multi-Scale Feature Fusion Module (CMFFM). By optimizing the upsampling and downsampling processes, CMFFM further reduces the number of model parameters while enhancing the extraction of cross-branch channel features and spatial features to ensure the model's performance. The proposed model's experimental results demonstrate accuracies of 69.3% on the COCO dataset and 88.7% on the MPII dataset, with a parameter count of only 5.4M, substantially decreasing the number of model parameters while preserving its performance.

Keywords—Human pose estimation; model lightweighting; Ghost module; attention mechanism; multi-scale feature fusion

I. INTRODUCTION

Human pose estimation, as a core topic in the field of computer vision, aims to recognize and locate keypoints of the human body from images or videos. The key to this task lies in accurately understanding and analyzing human posture and movement, which is crucial for computer vision to comprehend and process complex scenes. Human pose estimation plays an important role in numerous application areas, such as sports analysis, human-computer interaction, and security monitoring [1] [2].

The research on human pose estimation has evolved from early model-based and traditional learning algorithm-based methods, such as graphical models and handcrafted feature extraction [3], to recent deep learning-based methods. Deep learning methods, particularly Convolutional Neural Network (CNN) [4], have significantly improved the accuracy and robustness of techniques for recognizing and locating keypoints of the body. This heatmap-based approach effectively handles complex scenes and multi-person pose estimation tasks. Since heatmaps can intuitively represent the positional probability of each keypoint, the model can accurately

recognize key points even in cases of partial occlusion or overlap of the human body.

In recent years, numerous classic human pose estimation algorithms have emerged [5][10], achieving significant advancements in recognizing and locating human keypoints in images or videos. Particularly, High-resolution network (HRNet) [11], with their unique network structure and high-resolution feature representation capabilities, can achieve effective human pose estimation while maintaining high accuracy, making them widely applicable in various scenarios. However, due to their complex network structure and large number of parameters and high computational demands, high-resolution networks face difficulties when deployed on resource-constrained devices. Lite-HRNet [12] effectively reduces the model's parameter count by incorporating a Conditional Channel Weighting module. Dite-HRNet [13] introduces dynamic lightweight processing, multi-scale context information extraction, and long-range spatial dependency modeling in high-resolution networks, ensuring model performance with lower parameters. X-HRNet [14] incorporates Spatially Unidimensional Self-Attention (SUSA) for lightweight processing, significantly reducing model parameters without compromising accuracy. These methods have made significant progress in model lightweighting. However, human pose estimation is a task highly sensitive to positional information, and lightweighting high-resolution networks can lead to the loss of critical human keypoint positional information. During multi-scale feature fusion, frequent upsampling and downsampling operations introduce a computational burden. Furthermore, downsampling reduces the spatial detail in feature maps, which is difficult to recover during upsampling.

In response to the issues mentioned above, we propose a lightweight and efficient high-resolution network, LE-HRNet. We utilize the Ghost module to reduce the model's parameter count and introduce a novel attention mechanism in LE-HRNet to enhance the detection of keypoint positional information. This approach ensures model performance while lowering both the parameter count and computational load. Additionally, we optimize the multi-scale feature fusion stage to further decrease computational demands and enhance the extraction of channel and spatial dimensional feature information. The main contributions of this paper are summarized as follows:

- We designed a lightweight module, LEblock, for extracting feature information. We used the Ghost module instead of standard convolution to reduce the model's parameter count, and designed a Multi-Scale Coordinate Attention Mechanism to enhance the

*Corresponding Author.

detection capability of human key points, ensuring the model's performance.

- We optimized the multi-scale feature fusion stage and proposed a Cross-Resolution Multi-Scale Feature Fusion Module. This module optimizes the upsampling and downsampling processes, and by learning cross-branch channel information and spatial features, it ensures the model's performance while further reducing the model's parameter count.
- We conducted experimental validation on the COCO dataset and MPII dataset to demonstrate the effectiveness of the proposed method.

The structure of this paper is organized as follows: Section II introduces the main methods proposed in this paper. Section III conducts experimental verification on the COCO and MPII datasets and analyzes the experimental results. Section E summarize the research results and discuss the future work of LE-HRNet.

II. PROPOSED METHOD

HRNet is widely used for visual tasks that require detailed features, such as human pose estimation and semantic segmentation. Unlike most existing methods that recover high-resolution features from low-resolution features, HRNet connects high-resolution to low-resolution subnets in parallel, maintaining high-resolution feature representation throughout the entire network. It extracts feature information using residual block [15] and achieves multi-scale information exchange through multi-scale feature fusion. This design allows HRNet to effectively retain and utilize high-resolution detailed feature information, enabling more precise capture of image details during the multi-scale feature fusion process. HRNet processes multiple resolution feature maps in parallel within its structure and facilitates information interaction and fusion between feature maps of different resolutions, allowing it to simultaneously acquire local detailed information and high-level semantic information.

Although HRNet has made significant progress in terms of performance, its high parameter count and computational demands make it challenging to apply to devices with constrained computational resources, hindering its practical application value. To address this issue, we propose a lightweight high-resolution network, LE-HRNet, based on HRNet, aimed at human pose estimation. Its structure is shown in Fig. 1.

Fig. 1. LE-HRNet structure diagram.

As shown in Fig. 1, we use LEBlock instead of residual blocks for feature extraction. This block effectively lowers the number of model parameters and computational demands while minimizing performance degradation, ensuring the model's ability to detect keypoints. Between different resolution feature maps, we optimize the sampling process and use CMFFM for multi-scale feature fusion. This process further reduces the parameter count and computational load, and enhances performance by learning cross-resolution channel and spatial information.

A. ELblock

HRNet uses residual block as the feature extraction module. While residual block effectively enhance the model's feature representation capability, they also bring a large number of parameters and computational load. Therefore, this paper proposes a lightweight block, LEBlock, based on the residual block. The structure of LEBlock is shown in Fig. 2. We substitute the conventional 3×3 convolution in the residual block with the Ghost module [16] to reduce the number of model parameters and computational overhead. To minimize performance loss and enhance the detection capability of human keypoints while lightweighting the model, we designed and added a Multi-Scale Coordinate Attention Mechanism, which improves the detection of human keypoints with a smaller computational load.

Fig. 2. The left is the residual block and the right is the ELblock.

B. Ghost Module

In traditional convolution operations, a large number of parameters and computations are generated, many of which are redundant. Ghost module optimizes the convolution process to obtain more image features with fewer parameters, thereby achieving model lightweighting. Ghost module decomposes the standard convolution process into three main steps: first, the number of feature map channels is reduced to generate the initial feature map; second, the initial feature map undergoes linear transformations to generate Ghost feature maps; finally, the initial feature map and the generated Ghost feature maps are concatenated to form the final output feature map. The specific transformation process of the Ghost module is shown in Fig. 3.

Fig. 3. The Ghost module.

Assuming the input feature map size is $C \times H \times W$, the number of output channels is N , and the convolution kernel size is $k \times k$, the number of parameters for standard convolution is:

$$Param_{conv} = k \times k \times C \times N \quad (1)$$

Among them, C and N are usually quite large, which results in a large number of parameters.

To address this, Ghost Convolution compresses the number of channels in the first step, reducing the channels to $m = N / s$. Next, linear transformations are used to generate Ghost feature maps with the number of channels $m \times (s - 1) = N / s$. Finally, the feature maps obtained from the first two steps are concatenated along the channel dimension using an identity operation, resulting in an output feature map with N channels. Assuming $k = d$ and s is much smaller than C , the number of parameters for Ghost module can be calculated as follows:

$$Param_{Ghost} = k \times k \times C \times m + (s - 1) \times d \times d \times m \quad (2)$$

Compared to standard convolution, the parameter compression ratio r_{param} for Ghost Convolution is:

$$r_{param} = \frac{Param_{conv}}{Param_{Ghost}} \approx \frac{s \times C}{s + C - 1} \approx s \quad (3)$$

Through the Ghost module, the number of parameters can be reduced by a factor of s , achieving a significant reduction in parameter count.

C. Multi-Scale Coordinate Attention Mechanism

Although using the Ghost module to replace 3×3 convolution can decrease the parameter count and enhance computational efficiency, it also weakens the model's feature representation capability, leading to performance degradation and affecting the final prediction results. To enhance the detection capability of the model, attention mechanisms are commonly employed. SE (Squeeze-and-Excitation) [17] and ECA (Efficient Channel Attention) [18] enhance feature representation by re-weighting the channels of feature maps. The SE block integrates information between channels through global average pooling and fully connected layers, while the ECA enhances features through local cross-channel interactions. CBAM (Convolutional Block Attention Module) [19] combines channel attention and spatial attention, extracting global feature information through global average pooling and max pooling, capturing inter-channel dependencies and important spatial information, further enhancing feature representation and model performance. Human pose estimation

is a task highly sensitive to positional information, making this information crucial. Coordinate Attention Mechanism[20] encodes spatial information by performing global average pooling in horizontal and vertical directions on the input feature map, and then fuses channel information to generate coordinate attention weights, re-weighting the input feature map. This not only enhances channel feature representation but also captures critical spatial information, thereby improving the model's feature expression capability and overall performance. However, Coordinate Attention Mechanism promotes channel fusion by using channel dimension reduction and expansion, which, although reducing the number of parameters, results in the loss of feature information during the reduction process. Additionally, 1×1 convolution are limited in their ability to extract local feature information and overlook the positional dependencies between different keypoints. Therefore, we propose a Multi-Scale Coordinate Attention Mechanism (MCAM) rove the model's ability to detect human keypoints. The structure of MCAM is shown in Fig. 4.

MCAM enhances the semantic and spatial information of feature maps by using feature grouping, parallel sub-branches, and multi-scale feature learning, producing better pixel-level attention without losing channel dimension information. For the input feature map, to avoid performance loss caused by channel dimension reduction, the input feature map is divided

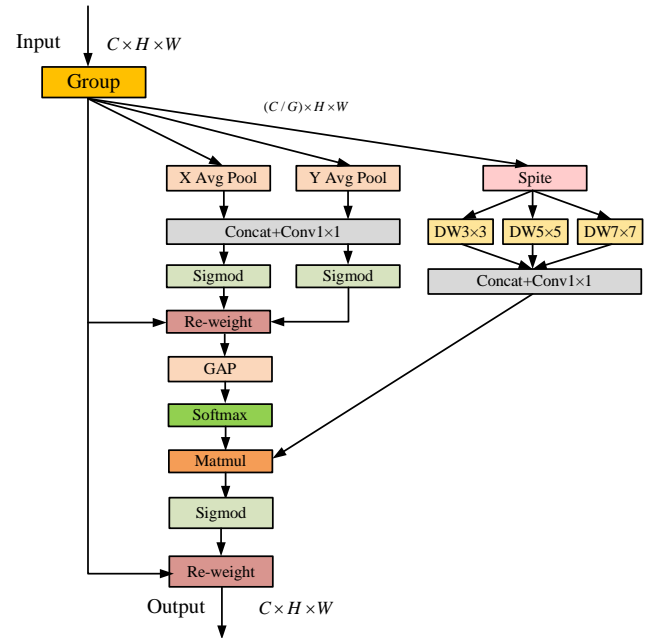

Fig. 4. The structure of multi-scale coordinate attention mechanism.

into multiple sub-feature maps to extract different semantic information. Assuming the input feature map is F_{input} and the output feature map is F_{output} , the generated multiple sub-feature maps are as follows:

$$F_{submap1}, F_{submap2}, \dots, F_{submapg} = Group(F_{input}) \quad (4)$$

For each sub-feature map, three parallel sub-branches are used to extract coordinate position information and multi-scale

feature information. The first two sub-branches use operations similar to the coordinate attention mechanism, performing global average pooling in the vertical and horizontal directions to generate direction-aware attention maps. Then, using concatenation and 1×1 convolution, channel fusion is promoted without channel dimension reduction. Finally, the fused coordinate information feature maps are output through the sigmoid activation function. The formula is as follows:

$$\begin{cases} z_x = f_x^{GAP}(F_{submap_i}) \\ z_y = f_y^{GAP}(F_{submap_i}) \end{cases} \quad (5)$$

$$F_{mid} = f_{conv1 \times 1}([z_x, z_y]) \quad (6)$$

$$\begin{cases} g_x = \sigma(F_{mid}) \\ g_y = \sigma(F_{mid}) \end{cases} \quad (7)$$

$$F_{Coord_i} = F_{submap_i} \times g_x \times g_y \quad (8)$$

In another sub-branch, we split into three branches and apply depthwise convolution with different kernel sizes of 3×3 , 5×5 , and 7×7 . Smaller kernels can extract local feature information, while larger kernels, due to their larger receptive fields, can more easily extract relevant features between different keypoints. By integrating multi-scale feature information from local to global, we can enhance the model's ability to detect human keypoints in complex scenes, further improving the overall performance and robustness of the model. Finally, multi-scale feature maps are generated through concatenation and 1×1 convolution. The formula is as follows:

$$\begin{cases} F_3, F_5, F_7 = f_{split}(F_{submap_i}) \\ F_{multi} = f_{1 \times 1}([f_{DW3 \times 3}(F_3), f_{DW5 \times 5}(F_5), f_{DW7 \times 7}(F_7)]) \end{cases} \quad (9)$$

The feature map with coordinate information is modeled in the channel dimension through GAP and Softmax, and fused with the multi-scale feature map to ultimately output the feature map that integrates multi-scale feature information and positional information. The formula is as follows:

$$\begin{cases} \omega_i = \sigma(f_{GAP}(f_{softmax}(F_{Coord_i})) \otimes F_{multi}) \\ F_{output_i} = \omega_i \times F_{submap_i} \\ F_{output} = [F_{output_1}, F_{output_2}, \dots, F_{output_g}] \end{cases} \quad (10)$$

Compared to existing attention mechanisms, MCAM not only offers higher computational efficiency but also avoids the compression and expansion in the channel dimension, which reduces the loss of feature information. MCAM effectively enhances the detection capabilities for human keypoints by integrating coordinate positional information with multi-scale feature information.

D. Cross-Resolution Multi-Scale Feature Fusion Module

HRNet enhances the network's understanding of feature maps from local to global by integrating multi-scale feature information through a process of multi-scale feature fusion, improving recognition accuracy and adaptability. However, frequent upsampling and downsampling operations increase the computational burden. Additionally, these sampling processes can lead to the loss of spatial feature information, adversely affecting the model's performance.

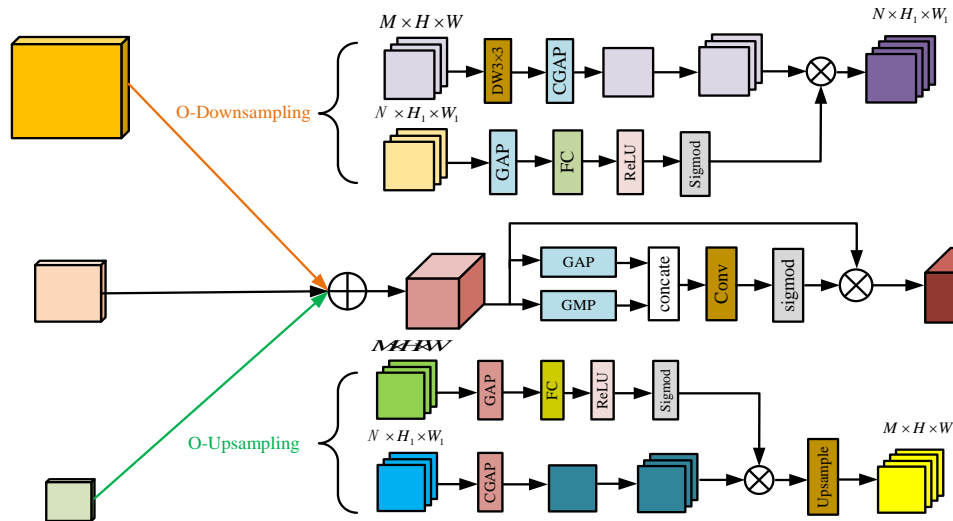

Fig. 5. The structure of cross-resolution multi-scale feature fusion module.

To address this, this paper optimizes the sampling process and proposes a cross-resolution multi-scale feature fusion module, as shown in Fig. 5. Taking the downsampling process as an example, a depthwise convolution with a stride of 2 is applied to the high-resolution branch feature map to reduce its computational load. Global average pooling is then performed along the channel dimension, reducing the number of channels to 1, ensuring that the information of each channel is uniformly

preserved in a single feature map, thereby maintaining the essential information of the channels. The pooled feature map is then duplicated N times, where N is the number of channels of the low-resolution feature map.

For the low-resolution branch feature map, global average pooling is performed along the spatial dimension, and the channel weights are generated through a fully connected layer,

ReLU, and Sigmoid functions. The channel weight information is multiplied with the newly generated low-resolution feature map to achieve fusion, resulting in the optimized downsampled feature map. This process reduces the computational load during downsampling and significantly enhances the response to important feature channels while suppressing the response to unimportant channels by learning cross-resolution channel weight information. The optimized downsampling computation formula is as follows:

$$\begin{cases} \omega = \sigma(\text{ReLU}(f_{FC}(f_{GAP}(F_{low-R})))) \\ F_{down} = \omega \otimes f_{copy}(f_{CGAP}(f_{DW3 \times 3}(F_{high-R}))) \end{cases} \quad (11)$$

Assuming the size of the high-resolution feature map is $M \times H \times W$ and the size of the low-resolution feature map is $N \times H_1 \times W_1$, the compression ratio r_{flops} of the computational load in the downsampling process is:

$$r_{flops} = \frac{Flops_{new}}{Flops_{original}} = \frac{H_1 \times W_1 \times M \times 3 \times 3}{H_1 \times W_1 \times N \times M \times 3 \times 3} = \frac{1}{N} \quad (12)$$

From the formula, it can be seen that this optimization effectively reduces the computational load in the downsampling process. The upsampling process is similar to the downsampling process. The processing flow for upsampling is as follows:

$$\begin{cases} \omega = \sigma(\text{ReLU}(f_{FC}(f_{GAP}(F_{high-R})))) \\ F_{up} = f_{upsamp}(\omega \otimes f_{copy}(f_{CGAP}(F_{low-R}))) \end{cases} \quad (13)$$

We optimize the upsampling and downsampling processes in two main steps. The first step involves channel-wise aggregation compression, where information from different channels is merged into one channel. This representation encapsulates key information from multiple channels, resulting in a comprehensive feature representation. The second step focuses on learning cross-resolution channel weight information and using these weights to model the to-be-sampled feature maps along the channel dimension. This optimizes feature selection and reorganization, enhancing the model's representational ability and processing efficiency. These steps not only effectively reduce the computational load but also enhance the model's adaptability and sensitivity to features of different scales. By adjusting channel weights, we can provide varying degrees of emphasis on features at different levels, thus balancing detail and global information better during the upsampling or downsampling processes.

To retain more spatial information and enhance the ability to extract spatial features, we draw on the ideas of CBAM and use a spatial attention mechanism to extract spatial information. First, global average pooling and global max pooling are used to capture the average feature information and salient features of the feature map, respectively. These pooled features are then combined to form a more comprehensive feature representation. A 7×7 convolution is applied to further extract richer spatial feature information, and a Sigmoid activation function is used to generate spatial weights. These spatial weights are fused with the original feature map to

produce a weighted and enhanced feature map, effectively preserving and highlighting the spatial details in the feature map.

III. EXPERIMENT

A. Datasets and Evaluation Metric

COCO (Common Objects in Context) [21] is a large-scale dataset widely used in computer vision, particularly suitable for human pose estimation, object detection, and image segmentation. This dataset offers rich scene complexity and extensive category coverage, including over 200,000 images and 250,000 human-annotated object in-stances. For human pose estimation, COCO meticulously annotates 17 keypoints covering the major joints and parts of the body, making it an essential resource for re-searching and developing advanced human pose recognition algorithms.

MPII [22] dataset is a large-scale dataset focused on human pose estimation, containing over 25,000 images spanning 410 types of activities. Each image is detailed and annotated with 16 human body keypoints, including the head, neck, shoulders, elbows, hands, hips, knees, and feet. These images are derived from everyday life scenes, encompassing both individual and multi-person interactions, making MPII not only extensively used in academic research but also crucial for developing practical application algorithms in pose recognition.

In the COCO dataset, the performance of human pose estimation is primarily assessed using Object Keypoint Similarity (OKS). OKS is an evaluation metric that compares the similarity between predicted keypoints and true keypoints. The formula for calculating OKS is as follows:

$$OKS = \frac{\sum_i \exp\left[\frac{-d_i^2}{2s^2 k_i^2} \delta(v_i > 0)\right]}{\sum_i \delta(v_i > 0)} \quad (14)$$

Where d_i is the Euclidean distance between the ground truth and predicted keypoint i ; k is the constant for keypoint i ; s is the scale of the ground truth object; v_i is the ground truth visibility flag for keypoint i ; $\delta(v_i > 0)$ is the Dirac-delta function which computes as 1 if the keypoint i is labeled, otherwise 0.

OKS can be understood as a normalized measure of the error between the predicted and true annotations for each keypoint, which takes into account the size of the human body and the specific sensitivity of each keypoint. Based on OKS, the COCO dataset also calculates Average Precision (AP) at multiple thresholds, ranging from OKS=0.50 (looser matching) to OKS=0.95 (very strict matching).

MPII uses PCK (Percentage of Correct Keypoints) as the main metric to evaluate model performance. PCK measures the percentage of predicted keypoints that match the true keypoints within a certain distance threshold. The specific calculation formula is as follows:

$$PCK = \frac{1}{n} \left(\sum_{i=1}^n \delta(\text{dist}(p_i, q_i) \leq \alpha \max(h, w)) \right) \quad (15)$$

Where n is the number of keypoints; p_i is the predicted position of the i -th keypoint; q_i is the actual position of the i -th keypoint; $dist(p_i, q_i)$ is the distance between the predicted keypoint p_i and the actual keypoint q_i ; α is a predefined threshold, and $dist(p_i, q_i) < \alpha$ means the prediction is considered accurate.

B. Experimental Setup

The experimental setup for this paper is as follows: Intel(R) Xeon(R) Silver 4310 CPU @ 2.10GHz, 64GB RAM, two RTX A5000 GPU with 24GB VRAM each, Ubuntu 22.04.3 LTS, Python 3.8. The deep learning framework used is Pytorch 3.9, with CUDA 11.5 for accelerated computing.

When training on the COCO training set, images from the COCO training set are cropped and scaled to a fixed size of 256×192 . Adam is used as the optimizer during network training, with an initial learning rate of 0.001. The learning rate is reduced to 0.0001 at the 170th epoch, and then to 0.00001 at the 210th epoch, with a total of 230 epochs of training. During training, random image rotation and horizontal flipping are also used for data augmentation. When training on the MPII dataset, cropped images are uniformly scaled to a fixed size of 256×256 . Other training details are the same as those for the COCO dataset, using the same parameter settings and experimental environment.

C. Result and Analysis

The performance comparison of LE-HRNet with other human pose estimation algorithms on the COCO validation set, with an input size of 256×192 , is shown in Table I. As seen from the table, compared to HRNet, LE-HRNet reduces the number of parameters and computational load by 81.1% and 78.7% respectively, while the AP only decreases by 4.1%. LE-HRNet achieves a significant reduction in model parameters and computational load with minimal performance loss, maintaining a balance between model performance and parameter size. Compared to Hourglass and CPN, LE-HRNet has lower parameters and higher performance. Compared to SimpleBaseline, LE-HRNet's AP is only 1.1% lower, but its number of parameters is much lower than SimpleBaseline. Compared to lightweight models like MobileNetV2[23] and ShuffleNetV2[24], LE-HRNet's AP is higher by 4.7% and 9.4% respectively, and LE-HRNet also has an advantage in terms of parameters and computational load. Compared to even smaller lightweight models like Lite-HRNet, Dite-HRNet, and X-HRNet, LE-HRNet has more parameters, but its AP is higher by 2.1%, 1.0%, and 1.9% respectively. Unlike these models which aggressively pursue lightweight design, LE-HRNet focuses more on balancing parameter size and performance, ensuring model performance while reducing the number of parameters.

With an input size of 384×288 , the performance comparison on the COCO test set is shown in Fig. 6. LE-HRNet achieved an AP score of 72.1, outperforming other networks while maintaining a balance between performance and computational load.

Fig. 6. Performance comparison of different algorithms on the COCO test set.

Fig. 7. Performance comparison of inference speed of different models.

The comparison of inference speed between some methods and LE-HNet was conducted in this paper. The testing of lightweight models emphasizes performance under limited resources, so the tests in this paper were conducted using only the CPU, specifically an Intel(R) Xeon(R) Silver 4310. The tests were carried out under consistent experimental conditions, and the results are shown in Fig. 7. Compared to other models, LE-HRNet achieves an inference speed of 9.6 FPS while maintaining high performance, making it faster than Lite-HRNet, Dite-HRNet, and X-HRNet. Although other lightweight models, such as ShuffleNetV2, have slightly faster inference speeds, their accuracy is lower and they fail to accurately detect human key points. LE-HRNet offers a better balance, and the verification of its inference speed demonstrates that LE-HRNet is more suitable for edge computing platforms.

TABLE I. PERFORMANCE COMPARISON OF DIFFERENT ALGORITHMS ON THE COCO VALIDATION SET

Model	Params /10 ⁶	GFlop s/G	AP/ %	AP ⁵⁰ / %	AP ⁷⁵ / %	AP ^M / %	AP ^L / %	AR/ %
Hourglass	25.1	14.3	66.9	-	-	-	-	-
CPN	27.0	6.20	68.6	-	-	-	-	-
SimpleBaseline	34.0	8.90	70.4	88.6	78.3	67.1	77.2	76.3
HRNet	28.5	7.10	73.4	89.5	80.7	70.2	80.1	78.9
MobileNetV2	9.6	1.48	64.6	87.4	72.3	61.1	61.1	70.7
ShuffleNetV2	7.6	1.28	59.9	85.4	66.3	56.6	66.2	66.4
Lite-HRNet	1.8	0.31	67.2	88.0	75.0	64.3	73.1	73.3
Dite-HRNet	1.8	0.3	68.3	88.2	76.2	65.5	74.1	74.2
X-HRNet	2.1	0.3	67.4	87.5	75.4	64.5	73.3	73.5
LE-HRNet	5.4	1.51	69.3	88.6	77.2	66.1	74.3	74.6

Table II shows the comparison results with different human pose estimation algorithms on the MPII validation set. Compared to HRNet, LE-HRNet significantly reduces the number of parameters and computational load, with only a

3.6% decrease in accuracy. Compared to MobileNetV2 and ShuffleNetV2, LE-HRNet has lower parameters and an accuracy improvement of 3.0% and 5.6%, respectively. Compared to Lite-HRNet, Dite-HRNet, and X-HRNet, LE-HRNet improves accuracy by 1.7%, 1.1%, and 1.4%, respectively, with a slight increase in parameters and computational load. This demonstrates that LE-HRNet maintains model performance while ensuring low parameter count.

TABLE II. PERFORMANCE COMPARISON OF DIFFERENT ALGORITHMS ON THE MPII VALIDATION SET

Model	Params/10 ⁶	GFLOPs/G	PCKh/%
MobileNetV2	9.6	1.9	85.4
ShuffleNetV2	7.6	1.7	82.8
Lite-HRNet	1.8	0.4	87.0
Dite-HRNet	1.8	0.4	87.6
X-HRNet	2.1	0.4	87.3
HRNet	28.5	7.6	92.3
LE-HRNet	5.4	1.44	88.7

Fig. 8. Performance comparison of different algorithms on the MPII test set. (a) Comparison of different algorithms on GFLOPs and PCK; (b) Recognition accuracy of different algorithms at each keypoint.

Fig. 8 shows the performance comparison of different algorithms on the MPII test set. From the results in the figure, LE-HRNet has higher keypoint recognition accuracy compared to other lightweight algorithms. Particularly for some challenging keypoints such as Wrist, Knee, and Ankle, the accuracy improvement is more significant than for other keypoints. This is mainly due to the MCAM, which

significantly enhances the detection capability for human keypoints.

We randomly selected a set of images from the COCO dataset for visual analysis. This set includes various scenarios such as single-person and multi-person scenes, as shown in Fig. 9. From the figure, it can be seen that LE-HRNet can accurately identify human keypoints in single-person scenarios.

Fig. 9. Visualization results on the COCO dataset.

In multi-person scenes, especially when there is overlap between body parts, LE-HRNet, with its strong feature extraction capabilities, can accurately infer the positions of the occluded keypoints by extracting multi-scale feature information and utilizing other visible keypoints. The visual analysis of different scenarios demonstrates that LE-HRNet maintains excellent detection performance in various complex scenes.

D. Ablation Experiment

To validate the effectiveness of the proposed method, we conducted ablation experiments on the COCO dataset for LEblock and CMFFM. The experimental results are shown in Table III. By replacing the residual block with LEblock, the model's parameter count is reduced by 76.4%, while the AP score only decreases by 4.5%, demonstrating that the lightweight module LEblock can significantly reduce the model's parameter count with minimal performance loss. Building on this, we inserted CMFFM for multi-scale feature fusion. The model's parameter count was further reduced, and the AP increased by 0.4%. This improvement is due to the optimization of the sampling process and the decomposition of the convolution process, which reduced the parameter count. Additionally, learning cross-resolution channel weight information effectively models channel features, and the spatial attention mechanism preserves more spatial detail features.

TABLE III. ABLATION EXPERIMENTS ON LEBLOCK AND CMFFM ON THE COCO DATASET

Model	LEblock	CMFFM	Params	AP/%
HRNet	×	×	28.5M	73.4
LE-HRNet	✓	×	6.7M	68.9
	✓	✓	5.4M	69.3

To further validate the effectiveness of MCAM, we conducted ablation experiments on MCAM, with the results shown in Table IV. With the addition of MCAM, the parameter count increased by only 1.4M, while performance improved by 1.5%, demonstrating that MCAM effectively enhances the model's ability to detect human keypoints.

TABLE IV. ABLATION EXPERIMENTS ON MCAM

Model	Params	AP/%
+ELblock	6.7M	68.9
+ELblock (No MCAM)	5.3M	67.4

E. Discussion

To enable human pose estimation on mobile devices or edge computing devices, we propose a series of methods to streamline the high-resolution network. High-resolution networks are widely used in scenarios such as human pose estimation and semantic segmentation due to their high recognition accuracy. However, the high parameter count and computational complexity of these models make it difficult to deploy them on devices with limited computational resources. To address this, we propose replacing the standard 3×3 convolution with a Ghost module to reduce computational load, and we further optimize the upsampling and downsampling processes to improve computational efficiency. Additionally, to maintain model performance while reducing computation, we introduce a multi-scale coordinate attention mechanism that effectively minimizes performance loss due to lightweighting. Through this series of methods, we have successfully streamlined the high-resolution network and achieved favorable inference speed on low-power devices.

IV. CONCLUSION AND FUTURE WORK

To address the issues of large parameter count and high computational complexity in high-resolution network models, we propose a lightweight and efficient high-resolution network module. We use the Ghost module to replace 3×3 convolution to reduce the parameter count and computational load of the model. Simultaneously, to minimize the loss of feature information during the lightweight process and ensure model performance, we designed a Multi-Scale Coordinate Attention Mechanism. This mechanism effectively enhances the detection of human keypoints by integrating multi-scale feature information and coordinate positional information without compromising performance. Finally, we optimized the multi-scale feature fusion stage, modeling both channel and spatial features while reducing the parameter count, further enhancing the model's performance. Experiments on multiple datasets validated the effectiveness of our proposed method.

In future work, we will deploy LE-HRNet on mobile devices and apply it in physical education, such as high jump, long jump, and swimming. By using LE-HRNet to identify key points of students' movements and calculate similarity with standard actions, we will be able to score students' movements and provide improvements for non-standard actions, which will aid in students' sports training.

Enhanced Resume Screening for Smart Hiring Using Sentence-Bidirectional Encoder Representations from Transformers (S-BERT)

Asmita Deshmukh, Anjali Raut

Hanuman Vyayam Prasarak Mandal's College of Engineering and Technology, Amravati, 444605, Maharashtra, India

Abstract—In a world inundated with resumes, the hiring process is often challenging, particularly for large organizations. HR professionals face the daunting task of manually sifting through numerous applications. This paper presents ‘Enhanced Resume Screening for Smart Hiring using Sentence-Bidirectional Encoder Representations from Transformers (S-BERT)’ to revolutionize this process. For HR professionals dealing with overwhelming numbers of resumes, the manual screening process is time consuming and error-prone. To address this, here the proposed solution is developed for an automated solution leveraging NLP techniques and a cosine distance matrix. Our approach involves pre-processing, embedding generation using S-BERT, cosine similarity calculation, and ranking based on scores. In our evaluation on a dataset of 223 resumes, our automated screening mechanism demonstrated remarkable efficiency with a screening speed of 0.233 seconds per resume. The system's accuracy was 90%, showcasing its ability to effectively identify relevant resumes. This work presents a powerful tool for HR professionals, significantly reducing the manual workload and enhancing the accuracy of identifying suitable candidates. The societal impact lies in streamlining hiring processes, making them more efficient and accessible, ultimately contributing to a more productive and equitable job market.

Keywords—S-BERT; resume; automated screening; job; CV

I. INTRODUCTION

In the contemporary landscape of recruitment, the influx of numerous resumes for a single job opening poses a considerable challenge for Human Resources (HR) professionals [1]. The traditional method of manual resume screening, while (being) essential, is not without its shortcomings [2]. This process, laden with time-consuming intricacies, demands meticulous attention in detail to ensure the identification of the most qualified candidates [3]. However, the reliance on conventional keyword matching methods in automated screening introduces its own set of challenges, often resulting in false positives and negatives [4].

To address these challenges, this research paper introduces a pioneering approach to automated resume screening [5]. Leveraging the capabilities of Sentence-Bidirectional Encoder Representations from Transformers (S-BERT), a cutting-edge natural language processing (NLP) model, our methodology offers a novel perspective to the intricate task of identifying the most suitable candidates for a given role. S-BERT's unique ability to generate contextualized representations of text enables a nuanced understanding of resumes, allowing for the

identification of relevant skills and experiences even when not explicitly articulated.

A. Bert

BERT, or Bidirectional Encoder Representations from Transformers, is a groundbreaking language model developed by Google AI, significantly impacting natural language processing (NLP). Operating on the Transformer architecture, it excels in learning intricate relationships between words and phrases, crucial for understanding textual meaning. BERT demonstrates state-of-the-art performance across NLP tasks, including natural language understanding (NLU), natural language generation (NLG), and natural language inference (NLI). Its functionality involves tokenizing input text, embedding tokens into meaningful vectors, adding positional embeddings, passing tokens through Transformer encoders to understand relationships, and generating final embeddings for the desired NLP task. BERT finds applications in enhancing search engine results, improving machine translation accuracy, developing context-aware chatbots, and generating concise text summaries. As an evolving tool, BERT holds immense potential to transform human-computer interactions.

B. S-Bert

S-BERT, short for Sentence-BERT, is a BERT model adaptation designed for sentence embedding computation. These embeddings, representing sentence meaning, are valuable for tasks like semantic similarity, clustering, and information retrieval. In contrast to BERT, which undergoes masked language modeling and next sentence prediction training, S-BERT trained on natural language inference. This task involves predicting if pairs of sentences entail, contradict, or are neutral. S-BERT utilizes a triplet loss function, minimizing distances for similar sentence pairs and maximizing them for dissimilar ones. During application, S-BERT processes each sentence independently, generating vector outputs for the first token. This single-pass approach is computationally more efficient than BERT's pairwise sentence comparison. S-BERT excels in producing semantically meaningful embeddings due to its emphasis on understanding sentence relationships. Demonstrating superiority over BERT, S-BERT excels in downstream tasks, including semantic textual similarity, paraphrase identification, and clustering.

Fig. 1 shows the process flow of S-BERT (Sentence-BERT), a machine learning algorithm that uses a shared encoder and a distance metric to train a model. The shared encoder is

used to train the model, and the distance metric is used to measure the distance between two points.

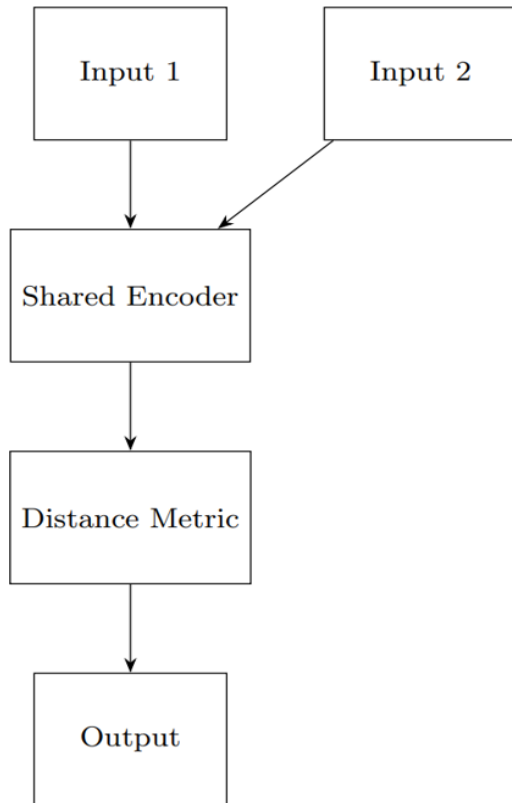

Fig. 1. Process flow diagram of sentence BERT (S-BERT).

Process flow:

Input: S-BERT takes two input sentences as input.

Shared encoder: The shared encoder is a neural network that learns to represent each sentence as a dense vector. The shared encoder is trained using a natural language inference (NLI) task, where the model is given a pair of sentences and must predict their relationship: entailment, contradiction, or neutral. This NLI training enables S-BERT to capture the semantic differences between sentences, leading to more meaningful sentence embeddings. The shared encoder generates embeddings for the two input sentences. The embeddings are dependent on the inputs, meaning that the embedding for a sentence is different depending on the other sentence in the pair.

Distance metric: The embeddings are then fed to a distance metric to calculate the distance between the two sentences. A common distance metric used for S-BERT is the cosine similarity.

Output: Based on the distance, a decision is made about whether the sentences are similar or dissimilar. If the distance is small, then the sentences are considered to be similar. If the distance is large, then the sentences are considered to be dissimilar.

This paper outlines the proposed methodology, which involves generating embedding from both resumes and job

descriptions using S-BERT and subsequently measuring their alignment through cosine similarity. The ranking of resumes based on these scores facilitates an efficient and accurate screening process.

The effectiveness of our approach is validated through a comprehensive evaluation on a dataset of 223 resumes, showing an impressive accuracy of 90%. Beyond these quantitative metrics, our method's resilience to common pitfalls such as keyword stuffing and its efficiency, with a screening speed of 0.233 seconds per resume, mark a significant advancement in the realm of automated resume screening.

As the need for streamlined and unbiased hiring processes intensifies, our research stands as a beacon for HR professionals, offering a solution that not only enhances efficiency but also contributes to the broader goals of diversity, equity, and inclusivity in the workforce. The ensuing sections delve into the intricacies of our proposed methodology, the experimental results, and the potential implications of our work on the future landscape of smart hiring practices.

Fig. 2 illustrates the conceptual framework of the proposed Resume Screening System for Smart Hiring using Sentence-Bidirectional Encoder Representations from Transformers (S-BERT). The model processes 200 resumes in PDF format, initially converting them to Excel format. Subsequently, text normalization techniques such as lemmatization and stemming are applied. Keywords are then extracted, forming sentences for each resume. S-BERT generates embeddings for these sentences. A parallel process is conducted on the job description, creating job description embeddings. Cosine similarity is computed between the sentence and job description embeddings, determining the ranking of resumes based on these similarity scores. While previous studies have made significant strides in automated resume screening, several gaps remain that underscore the urgency of our research. First, many existing systems rely heavily on keyword matching, which can be easily gamed and may miss candidates with relevant skills expressed in different terms. Second, the contextual understanding of resumes has been limited, often failing to capture the nuanced relationships between skills, experiences, and job requirements. Third, there has been insufficient focus on mitigating biases in automated screening processes, potentially perpetuating unfair hiring practices. To address these gaps, our research proposes the use of Sentence-BERT (S-BERT), a state-of-the-art natural language processing model that offers deeper contextual understanding and semantic analysis of resume content. This approach allows for more nuanced matching between resumes and job descriptions, reducing reliance on exact keyword matches. Additionally, by incorporating cosine similarity measures, our method provides a more holistic evaluation of candidate suitability. To tackle bias concerns, proposed solution suggest rigorous testing and continuous refinement of the model with diverse datasets. Our research not only aims to enhance the efficiency of resume screening but also to improve its fairness and accuracy, thus addressing critical shortcomings in existing automated hiring systems.

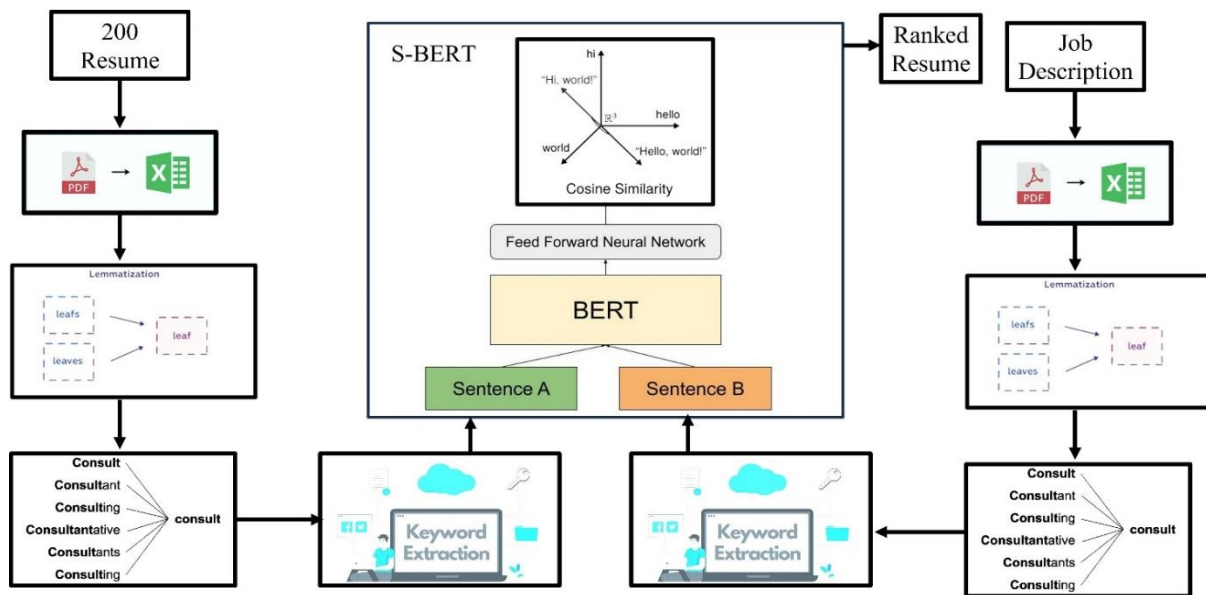

Fig. 2. Concept diagram of the proposed resume screening system for smart hiring using Sentence-Bidirectional Encoder Representations from Transformers (S-BERT).

II. LITERATURE REVIEW

Automated resume screening has evolved as a critical domain within the recruitment process, driven by the need for efficiency, accuracy, and mitigation of biases in hiring [6]. Traditional methods, reliant on manual screening, have proven to be time-consuming, error-prone, and susceptible to human biases [7]. This literature review explores key studies and methodologies in the realm of automated resume screening, culminating in the proposal of an advanced system utilizing Sentence-Bidirectional Encoder Representations from Transformers (S-BERT).

Early endeavors in automated resume screening focused on basic keyword matching and rule-based systems. Kopparapu introduced a system for information extraction from unstructured resumes using natural language processing (NLP) techniques [4]. This marked an initial attempt to streamline the screening process. However, these early systems struggled with nuanced contextual understanding.

Recognizing the limitations of keyword-based approaches, recent years have witnessed a surge in the application of advanced NLP techniques to resume screening. Gundlapalli et al. demonstrated the effective use of NLP tools to screen medical records for evidence of homelessness [8].

Feller et al. [9] explored NLP for predictive modeling of HIV diagnoses, showcasing the potential for contextual understanding beyond explicit mentions [10].

The application of NLP in diverse domains highlights its versatility. Naylor et al. [11] employed NLP for accurate calculation of adenoma detection rates in the context of screening colonoscopies [12]. Trivedi et al. [13] used NLP for large-scale labeling of clinical records, emphasizing the potential for automating data extraction from existing records [14].

The integration of machine learning into resume screening systems has been pivotal. Roy et al. [15] introduced a machine learning approach for automating a resume recommendation system, illustrating the intersection of NLP and machine learning in enhancing screening mechanisms [16]. Recent breakthroughs in NLP, particularly with models like S-BERT, have brought contextualized representations to the forefront. Delimayanti et al. [17] presented a content-based suggestion system using cosine similarity and KNN algorithms [18]. This highlighted the importance of contextual understanding, which is a hallmark of S-BERT. While the literature showcases promising advancements, challenges remain. Ndukwe et al. [19] discussed the need for careful development and evaluation of NLP models to ensure fairness and mitigate biases [20].

Choi et al. [21] emphasized the efficiency of resume screening through NLP but acknowledged the challenges posed by computational expenses. Recent research on automated resume screening and ranking has explored various approaches using natural language processing and deep learning techniques. Several studies have investigated the use of transformer-based models like BERT and its variants for this task. James et al. [22] and Mukherjee employed DistilBERT and XLM [23] for resume shortlisting and ranking. Kinger et al. [24] combined YOLOv5 for resume parsing with DistilBERT for ranking. Sentence-BERT (S-BERT), introduced by Reimers and Gurevych [25], has gained traction for generating semantically meaningful sentence embeddings. Subsequent work has evaluated and refined S-BERT, including TA-SBERT. Seo et al., [26] and Chu et al., [27], these approaches aim to capture nuanced semantic relationships between resume content and job requirements, moving beyond simple keyword matching. Additionally, researchers have explored combining embeddings with other techniques, such as named entity recognition and domain-specific knowledge Vanetik and Kogan, [28]; Yu et al., [29], to further improve matching accuracy [30]. While progress has been made, challenges remain in mitigating biases and ensuring fair evaluation across diverse candidate pools [31].

III. METHODOLOGY

The objective of this study is to develop an automated resume screening mechanism to assist the Human Resources (HR) department in the initial filtering of resumes, ensuring the provision of the most pertinent candidates for further evaluation, such as interviews. The dataset used in this study consisted of 223 resumes in PDF format. These resumes were collected from various job applicants across different fields and experience levels. To facilitate processing, the PDF files were converted to CSV (Comma-Separated Values) format. This conversion preserved the textual content of the resumes while organizing it into a structured tabular format. The CSV structure included columns for different resume sections such as personal information, education, work experience, skills, and additional qualifications. This standardized format allowed for easier extraction of relevant information and application of natural language processing techniques. The conversion from PDF to CSV was performed using a custom Python script that utilized PDF parsing libraries to extract text and organize it into appropriate CSV fields. This structured dataset provided a consistent foundation for the subsequent steps in our automated resume screening process.

The proposed automated screening mechanism leverages Natural Language Processing (NLP) techniques and a cosine distance matrix to evaluate the alignment of resumes with the corresponding job description. The methodology employs Sentence-Bidirectional Encoder Representations from Transformers (S-BERT), a sentence-level model, to extract embeddings that capture the contextual information from the resumes. These embeddings are then compared to those generated from the job description, with the aim of ranking the resumes based on their relevance.

Stop words are common words that do not carry much meaning and can cause noise in text analysis. Removing stop words helps to improve the efficiency and accuracy of the NLP process. Pre-defined list of stop words in English was used to remove stop words from the resumes and job description.

Lemmatization is a NLP technique that groups words with the same meaning together. This is done by reducing words to their root form. For example, the words "cats" and "kittens" would both be lemmatized to the root word "cat". Lemmatization helps to improve the accuracy of the NLP process by ensuring that words with the same meaning are treated similarly.

Stemming is a NLP technique that reduces words to their common stem. This is done by removing suffixes and prefixes. For example, the words "running" and "ran" would both be stemmed to the common stem "run". Stemming when used in combination with lemmatization, produces better results.

The resumes and job description were preprocessed using the following steps:

- Stop words were removed.
- Lemmatization was performed.
- Stemming was performed.

The S-BERT model was employed to generate embeddings from the preprocessed text of both resumes and the job description. Embeddings are numerical representations of words that capture their meaning and context. S-BERT is a sentence-level model that generates embeddings that capture the contextual information from the sentences.

Cosine similarity is a metric used to quantify the similarity between two vectors. In this study, cosine similarity was used to measure the similarity between the embeddings of the resumes and the job description. Resumes with higher cosine similarity scores are considered to be more relevant to the job description.

The resumes were ranked based on their cosine similarity scores. The resumes with the highest cosine similarity scores were ranked at the top of the list.

This methodology aims to reduce the reliance on subjective referral-based hiring by introducing an automated screening process. This approach ensures a more transparent and standardized selection mechanism, promoting fairness in the company's hiring process.

The keywords from each resume are concatenated to form a sentence. S-BERT is then applied to these sentences to generate embeddings of a specific length, e.g., 4x96 bytes.

Cosine similarity is then used to calculate the matching score between the job description embedding and each resume embedding. The matching score is a value between 0 and 1, with 1 being the best match and 0 being no match.

Finally, the cosine scores are ranked in descending order. The resume with the highest cosine score is ranked first.

A step-by-step explanation of the process is as given below:

- Concatenate keywords to form a sentence: The keywords from each resume are concatenated to form a sentence. This sentence captures the essence of the resume and highlights the applicant's key skills and experience.
- Generate S-BERT embeddings: S-BERT is applied to the sentences to generate embeddings of a specific length. Embeddings are vector representations of text that capture the semantic meaning and context of the words.
- Calculate cosine similarity: Cosine similarity is used to calculate the matching score between the job description embedding and each resume embedding. Cosine similarity is a measure of similarity between two vectors. The higher the cosine similarity score, the more similar the two vectors are.
- Rank cosine scores: The cosine scores are ranked in descending order. The resume with the highest cosine score is ranked first.

Fig. 3 illustrates the resume matching mechanism utilizing S-BERT and cosine similarity in our proposed automated screening system. The process begins with extracting key sentences from both the resume and the job description. These sentences are then fed into the S-BERT model, which generates embeddings - dense vector representations of the text with dimensions of 4 x 96 bytes for each input. The embeddings capture the semantic meaning of the sentences, allowing for a

nuanced comparison beyond simple keyword matching. Once the embeddings are generated, a cosine matching algorithm computes the similarity between the resume and job description embeddings. This similarity score quantifies how well the content of the resume aligns with the requirements outlined in the job description. Finally, a ranking algorithm uses these similarity scores to order the resumes, with higher scores indicating better matches for the position. This approach enables a more contextual and meaningful comparison between candidates and job requirements, addressing limitations of traditional keyword-based screening methods.

Fig. 3. Resume matching mechanism using S-BERT and cosine similarity.

The proposed resume matching mechanism has a number of advantages:

- It is able to accurately match resumes to job descriptions, even when the resumes are in different formats.
- It is able to identify resumes that are relevant to the job description, even if the resumes do not contain all of the keywords that are listed in the job description.
- It is able to rank resumes based on how well they match the job description, making it easy for recruiters to identify the most qualified candidates.

IV. RESULTS

The automated resume screening mechanism was rigorously (applied) evaluated on a dataset consisting of 223 resumes in PDF format. The results underscore the efficacy of the proposed methodology in identifying and ranking relevant candidates based on alignment with the job description.

1) *Screening speed*: The screening process demonstrated remarkable efficiency, achieving a speed of 0.233 seconds per resume. This rapid processing speed ensures the practical applicability of the automated mechanism to scenarios involving substantial resume inflow.

2) *Accuracy metrics*: The evaluation metrics utilized for gauging the performance of the screening mechanism encompassed.

3) *Accuracy*: The mechanism exhibited an accuracy rate of 90%, indicating a high precision in identifying resumes that align with job requirements.

4) *Precision*: Precision, representing the percentage of correctly identified relevant resumes out of the total identified as relevant, reached 85%.

5) *Recall*: The recall rate, measuring the percentage of relevant resumes correctly identified out of the total relevant resumes, achieved a commendable 75%.

6) *Ranking consistency*: The ranking mechanism displayed consistent performance, ensuring that resumes were consistently and accurately prioritized based on their alignment with the job description.

7) *Efficiency in large-scale processing*: Experimental outcomes suggested that the proposed solution maintains efficiency even as the dataset scales. This scalability aspect is crucial for handling real-world scenarios involving a substantial volume of incoming resumes.

8) *Impact on workload*: The implementation of the automated screening mechanism resulted in a substantial reduction in the workload of the initial screening team. This points to its potential in enhancing the efficiency of the early stages of the hiring process.

9) *Robustness to updates*: The generated embeddings, once created, demonstrated robustness to updates in resumes. Unless there were significant changes in the content, the same embeddings could be reused for subsequent screenings, contributing to processing efficiency.

Fig. 4 shows the output of an automated resume screening system that uses S-BERT to calculate the similarity between each resume and a job description. The system first extracts words from the resumes and forms sentences from them. The top six rectangular brackets contain words extracted from different resumes and the sentences formed by them in rectangular brackets. Then, it uses S-BERT to calculate the similarity between each sentence and the job description. The second-last line shows the similarity scores between the job description and each of the 30 resumes, and the last line shows the execution time in seconds. The system can be used to quickly identify resumes that are most relevant to a job opening. This can save recruiters time and help them find the best candidates for the job.

The graph illustrates the correlation between the number of resumes and the screening time in an S-BERT-based automated resume screening system. As the number of resumes increases, the screening time also rises, but not in a linear fashion. For instance, screening five resumes takes about 0.3 seconds, while screening 10 resumes takes approximately 0.9 seconds, and screening 30 resumes extends to about 4.9 seconds. This non-linear trend implies that the screening time increases at a varying rate.

Several explanations could account for this phenomenon. One possibility is that the efficiency of the automated screening algorithm improves with experience, allowing it to swiftly identify and discard unsuitable resumes by learning patterns. Conversely, in traditional mechanisms, screeners might experience fatigue with increased resume volume, resulting in slower screening times. In summary, the data indicates that the number of resumes significantly influences screening time. HR managers adopting this solution should consider this relationship when planning their workflow.

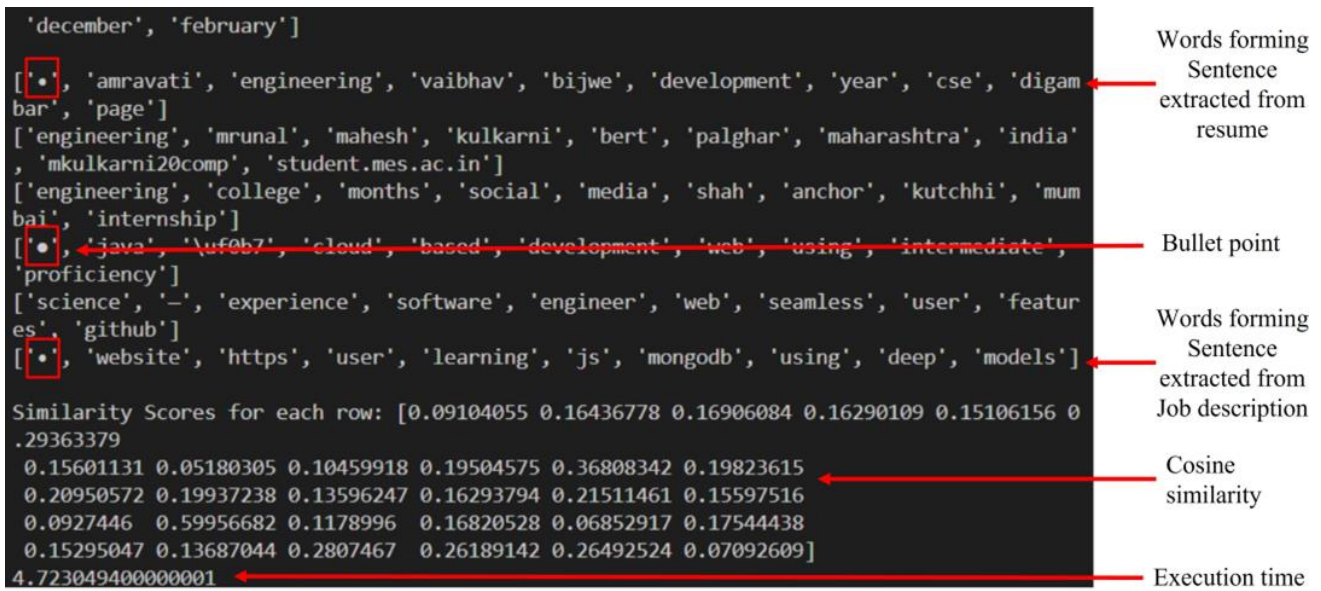

Fig. 4. Output screenshot of the proposed automated resume screening system using S-BERT.

Error computation and calculations were conducted based on feedback from the HR, who serves as the final end user of the developed system. This proposed work curated seven job profiles from the HR manager and selected 10 resumes for each of the seven job descriptions. Some resumes were common, given that candidates had multiple eligibilities. Throughout the system, this approach ranked the top three candidates and asked HR to rank the candidates based on their experience. To assess the system, the proposed work assigned numerical labels (1 to 10) to all resumes in each case, and HR provided rankings that precisely matched our numbering system. Table I presents the results obtained through HR rankings versus the results obtained with the proposed Automated Screening System (AS).

TABLE I. VALIDATION TABLE FOR SEVEN DISTINCT JOB DESCRIPTIONS (JD) COMPARING RANKINGS FROM HR (HUMAN RESOURCES MANAGER) AND AS (AUTOMATED SYSTEM)

Type of Screening	Rank 1	Rank 2	Rank 3
HR (JD1)	5	7	8
AS (JD1)	5	8	7
HR (JD2)	6	7	9
AS (JD2)	6	7	9
HR (JD3)	6	3	2
AS (JD3)	3	6	2
HR (JD4)	5	7	3
AS (JD4)	5	7	8
HR (JD5)	4	3	2
AS (JD5)	4	1	7
HR (JD6)	3	4	9
AS (JD6)	3	4	9
HR (JD7)	3	8	9
AS (JD7)	3	8	4

The error calculations follow the proposed rule base outlined as follows:

If a completely new resume appears on the list, not present in the best three resumes suggested by the HR manager, proposed solution assigns values based on the rank of the resume. If the 1st ranked resume is replaced, a value of -1 is assigned, indicating a 100% error, aligning with our acceptable 3 resumes policy. If a totally new resume appears at the 2nd rank, the error is set to -0.9, where the minus sign indicates an issue, and the value between 0 to 1 indicates the extent of the error in percentage; in this case, 90% unacceptable is denoted by -0.9. For the 3rd rank, the value is reduced to -0.8 as it is the last resume on the list that was missed.

Our primary objective is to prioritize bringing all 3 recommended resumes to the output and ensuring they are in the correct order: 1, 2, and 3.

In another case, when resumes match in the top 3 but are not in the correct order, the proposed solution provides a table to validate this scenario. For Case 1, where rank 1 by HR corresponds to ranks 1, 2, and 3 by AS, the resulting errors are 0, -0.4, and -0.7. This implies that if the rank 1 resume in HR matches the rank 1 in AS, there is no error (0). If the rank 1 HR resume is found at Rank 2 in AS, the error is -0.4, indicating a 40% error. Finally, if the rank 1 HR resume is found at Rank 3 in AS, the error is -0.7.

Similarly, for rank 2 HR, the values are -0.3 (Rank 1 AS), 0 (Rank 2 AS), and -0.3 (Rank 3 AS). The magnitude of error is reduced from 0.4 to 0.3 as the position is lowered to rank 2.

For rank 3 HR, the following errors were computed: -0.4 for Rank 1 AS, -0.2 for Rank 2 AS, and 0 for Rank 3 as this approach is utilized for error computation to validate the effectiveness of the automated screening technique.

The scatter plot in Fig. 5 illustrates the effectiveness of the proposed S-BERT-based automated resume screening system across seven distinct job descriptions: Software Engineer, Data

Scientist, Product Manager, Marketing Manager, Sales Representative, Customer Support Representative, and Human Resources Manager. Accuracy is quantified as the percentage of resumes correctly classified as relevant or not for each job, based on HR evaluations. The proposed mechanism attains an overall accuracy of 90% across all job descriptions, with the Sales Representative role having the lowest accuracy at 43.33%, and the highest accuracy observed for Data Scientist, Product Manager, and Customer Support Representative. The overall error rate of the system is 21.42%, indicating S-BERT's efficacy in automating the resume screening process.

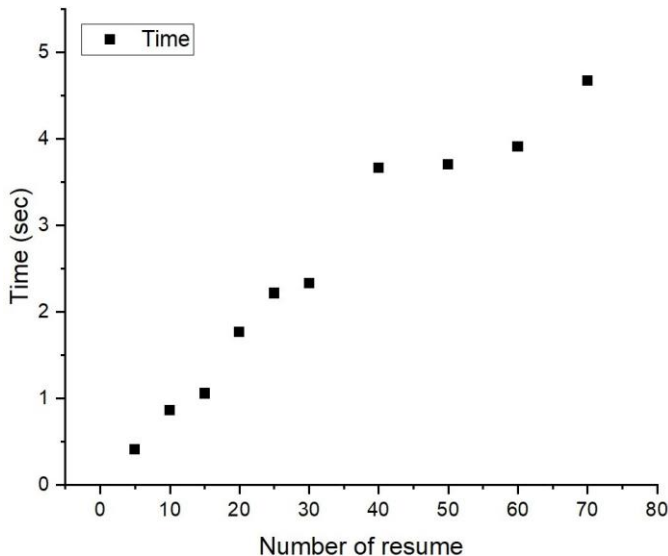

Fig. 5. Plot of number of resumes vs. time required for screening.

This S-BERT-based automated screening tool offers HR managers a means to efficiently handle large volumes of resumes while maintaining high accuracy. This efficiency allows HR managers to redirect their focus toward critical tasks like candidate interviews and hiring decisions. The presented bar graph represents the average accuracy of the system. Future opportunities include testing the mechanism on a larger resume dataset to affirm accuracy and generalizability, extending its application to screen for diverse job types, and developing a user-friendly web or mobile app to enhance accessibility for HR managers.

V. DISCUSSIONS

The proposed automated resume screening mechanism presents a paradigm shift in the recruitment landscape, offering distinct advantages over traditional methods. Firstly, its reliance on Natural Language Processing (NLP) techniques empowers the system to extract nuanced information from resumes, ensuring resilience against tactics like keyword stuffing [10]. This not only enhances the accuracy of candidate evaluation but also reduces the potential for falsification in the initial screening stages [4]. Secondly, the incorporation of a cosine distance matrix for ranking resumes based on alignment with the job description adds a layer of sophistication [22]. By prioritizing relevance over specific keywords, the system ensures that the most suitable candidates rise to the top [18]. This is a crucial departure from conventional keyword-based screening, aligning the system with the broader goal of identifying candidates based

on their actual qualifications and experience [16]. Despite these advantages, it's essential to acknowledge the system's developmental stage and the inherent biases that can be present in NLP models [25]. Rigorous development and evaluation processes are vital to mitigate biases and ensure fairness. Moreover, the system's performance hinges on the quality of training data, emphasizing the need for diverse and comprehensive datasets [8] [13]. Importantly, while the automated screening mechanism streamlines the initial filtering process, it doesn't replace human judgment. HR professionals must review top-ranked resumes for final decisions, emphasizing the collaborative nature of technology and human expertise in the hiring process [2].

The proposed automated resume screening mechanism opens avenues for future research in the realm of human resources. Firstly, it can be a valuable tool for studying factors contributing to resume success [19]. Analyzing top-ranked resumes can provide insights into the skills and experiences highly valued by employers, guiding both candidates and educators in aligning with industry expectations [3]. Secondly, the system acts as a catalyst for developing advanced methods to enhance the accuracy and fairness of automated resume screening. Future research could focus on refining NLP techniques, making them more robust to biases and capable of capturing richer contextual information from resumes [24]. Thirdly, the proposed mechanism sets the stage for the development of new tools and resources for HR professionals. Dashboards visualizing automated screening results could empower HR teams with quick insights, making the hiring process more transparent and efficient [20]. The proposed automated resume screening mechanism not only addresses current challenges in hiring but also paves the way for future innovations and research in the dynamic field of human resources. Future endeavors will likely focus on refining the system's performance, addressing identified limitations, and exploring new frontiers in the evolving intersection of technology and recruitment practices.

VI. CONCLUSIONS

Proposed method offers a transformative solution to the challenges faced in contemporary hiring processes. The conventional method of manual screening, while crucial, is marred by inefficiencies, biases, and the overwhelming influx of resumes. This research introduces an automated screening mechanism leveraging state-of-the-art natural language processing (NLP) techniques, particularly S-BERT, to revolutionize the initial phases of candidate evaluation.

The results of our evaluation on a dataset of 223 resumes reveal the remarkable efficiency of the proposed methodology. With a screening speed of 0.233 seconds per resume, the system showcased practical applicability in scenarios with substantial resume inflow. The accuracy metrics demonstrated a high precision in identifying relevant resumes, with an accuracy of 90%. The ranking mechanism exhibited consistency, ensuring resumes were prioritized accurately based on their alignment with job descriptions.

Beyond quantitative metrics, our automated screening mechanism significantly reduces the workload on initial screening teams, presenting a scalable solution for handling

large volumes of incoming resumes. The robustness of generated embeddings to updates in resumes enhances processing efficiency, allowing for reuse unless there are substantial content changes. This work not only contributes to the efficiency of the hiring process but also aligns with broader societal goals. By automating and streamlining the screening process, this manuscript contribute to making hiring practices more efficient, transparent, and accessible. Moreover, the adoption of advanced NLP techniques like S-BERT helps mitigate biases and promotes diversity and inclusivity in candidate selection.

As one move forward, the implications of this research extend beyond the immediate context. The automated screening mechanism presented here not only serves as a tool for HR professionals but also as a beacon for future developments in smart hiring practices. The integration of cutting-edge NLP models signifies a step toward a future where technology enhances, rather than hinders, the human aspect of hiring.

DECLARATION OF STATEMENTS

Author contribution: The conceptualization was jointly undertaken by Asmita Deshmukh (AD) and Anjali Raut (AR). AD was responsible for data collection, coding, and experimentation. Additionally, AD took the lead in preparing the initial draft of the manuscript, while AR handled corrections. Furthermore, data analysis and graphic design were conducted by AD.

Data and Code availability: Upon a reasonable request, both the data and code utilized in this research will be provided.

Funding: This study is not linked to any funding sources.

Conflict of interest and Competing interests: The authors affirm that they have no conflicts of interest or competing interests to disclose.

Machine Learning Techniques for Protecting Intelligent Vehicles in Intelligent Transport Systems

Yuan Chen

College of Intelligent Transportation, Hunan Communication Polytechnic, Changsha, 410132, China

Abstract—Intelligent transport system (ITS) is the development direction of future transport systems, in which intelligent vehicles are the key components. In order to protect the safety of intelligent vehicles, machine learning techniques are widely used in ITS. For intelligent protection in ITS, the study introduces an improved driving behaviour modelling method based on Bagging Gaussian Process Regression. Meanwhile, to further promote the accuracy of driving behaviour modelling and prediction, Convolutional Neural Network-Long and Short-term Memory Network-Gaussian Process Regression are used for effective feature extraction. The results show that in the straight overtaking scenario, the mean absolute error, root mean square error and maximum absolute error of the improved Bagging Gaussian process regression method are 0.5241, 0.9547 and 10.7705, respectively. In the corner obstacle avoidance scenario, the improved Bagging Gaussian process regression method is only 0.6527, 0.9436 and 14.7531. Besides, the mean absolute error of the Convolutional Neural Network-Long and Short-term Memory Network-Gaussian process regression algorithm is only 0.0387 in the case of the input temporal image frame number of 5. This denoted that the method put forward in the study can provide a more accurate and robust modeling and prediction of driving behaviours in complex traffic environments, and it has a high application potential in the field of safety and protection of intelligent vehicles.

Keywords—Intelligent vehicle protection; machine learning techniques; Gaussian Process Regression; convolutional neural networks; long and short-term memory networks

I. INTRODUCTION

With the rapid development of science and technology, intelligent transport systems have become a hot topic in today's society. In the intelligent transport system, intelligent vehicles play a crucial role [1]. However, with the popularity of intelligent vehicles, their safety problems are becoming more and more prominent. Driving behaviour modelling methods can help intelligent vehicles achieve safer and more efficient driving by predicting and simulating vehicle and driver behaviours. Traditional driving behaviour modelling methods include rule-based methods, probabilistic model-based methods, and so on. However, rule-based methods are difficult to adapt to the complex and changing traffic environment, and the formulation of rules often requires a lot of manual intervention and lacks adaptivity. Meanwhile, probabilistic model-based methods need to learn from a large amount of historical data, and model building requires high computational resources and time costs [2, 3]. Aiming at such problems, the study will explore the machine learning techniques for protecting intelligent vehicles in ITS, and introduce an improved driving behaviour modelling method based on Bagging Gaussian Process Regression

(Bagging GPR), in order to achieve more accurate driving behaviour modelling and prediction. In order to achieve more accurate modelling and prediction of driving behaviour, Convolutional Neural Network-Long Short-Term Memory-Gaussian Process Regression (CNN-LSTM-GPR) is used for effective feature extraction, to achieve good results in the field of intelligent vehicle security protection field to achieve good results. The study is composed of six main sections. The introduction is given in Section I. Section II gives details about the previous research work. Section III introduces the advanced driving behaviour modelling methods, the improved Bagging GPR driving behaviour modelling method is introduced in the first section, and the CNN-LSTM-GPR-based feature extraction method is presented in the second section. Section IV focuses on the experimental validation of the studied proposed method. Section V and Section VI summarize and discuss the experimental results and propose future directions. The contribution of the research is the introduction of advanced driving behaviour modelling methods, which help to improve the accuracy of driving behaviour modelling and prediction. These methods have important application value in the safety protection of intelligent vehicles and can effectively protect the safe driving of intelligent vehicles.

II. LITERATURE REVIEW

GPR is a nonparametric model for regression analysis of data with a Gaussian process prior, which is widely used. Deringer V L et al. put forward the GPR machine learning method to investigate the nature of atoms in chemistry and materials science. The method constructs an interatomic potential or force field using a Gaussian approximation of the potential framework and can be fitted with arbitrary scalars, vectors and tensors. The outcomes denoted that the method can effectively and accurately predict atomic properties [4]. Liu and other scholars developed two related data-driven models for the prediction of the effective capacity of lithium-ion batteries with a systematic understanding of the covariance function in GPR. The results illustrated that the raised models can accurately predict the battery capacity under different cycling modes [5]. Band et al. In order to accurately predict the groundwater level in arid areas, the researchers proposed to use the Support Vector Regression, GPR and its combination with Wavelet Transform for the prediction. The results show that the wavelet transform method combined with GPR has a strong performance advantage in GWL prediction compared to GPR [6]. Hewing L et al. researchers raised a model prediction control method with GPR for modelling and control of nonlinear dynamical systems. The method integrates the nominal system with the additional nonlinear part of the dynamics modelled as GPR. The findings

indicated that the method can effectively assess the residual uncertainty [7]. Zhang Y's team developed a GPR-based predictive model for the optimisation of the magneto-thermal effect and relative cooling power of ferromagnetic lanthanum manganites. The model mainly searches for the correlation between RCP and lattice parameters by statistical learning. The findings denoted that the GPR model can predict RCP values efficiently and cost-effectively [8].

Driver behaviour recognition can detect and correct driver violations in time, reduce the accident rate and play an important role in vehicle protection. Xing and other scholars proposed a deep convolutional neural network-based driver activity recognition system for driver behaviour recognition and safe driving. The system utilizes a Gaussian mixture model to segment the original image to extract the driver's body from the background. The outcomes denoted that the raised system can accurately recognize seven driver activities with an average accuracy of 81.6% [9]. McDonald et al. found that an advanced driver assistance system needs to have a proper understanding of the driver's state, and therefore proposed a method for inference of self-vehicle driver's intention. The results show that the interaction between these modules has a significant impact on the lane change intention inference system [10]. Kabzan et al. researchers put forward a learning-based method to the problem of self-driving racing car control. The method was improved using a simple nominal vehicle model and GPR was used to account for model uncertainty. Test results show that on a full-size AMZ driverless race car, the method can improve the model and cut down the lap time by 10% [11]. Researchers such as Mozaffari have proposed a deep learning-based method for the problem of behavioural prediction of autonomous vehicles, which predicts the future state of a nearby vehicle by observing the surrounding environment. This approach provides better performance in more complex environments than traditional methods [12]. Hoel C J's team introduced a generalised framework that combines planning and learning in order to better address the tactical decision-making challenges of autonomous driving. The approach, based on the AlphaGo Zero algorithm and extended to continuous state spaces, shows better performance than the baseline approach [13].

In summary, numerous researchers and scholars have carried out extensive studies on GPR methods as well as driver behaviour recognition methods, but few scholars have applied improved GPR methods to driver behaviour recognition. Therefore, the study introduces the advanced GPR method for driver behaviour modelling, which is utilised with a view to

achieving intelligent vehicle prediction and avoiding potential hazards.

III. RESULTS

To protect the safety of intelligent vehicles, the study proposes an improved Bagging GPR driving behaviour modelling method, which uses GPR to design the base regressor and Bagging method to improve the whole effectiveness of the algorithm, as well as self-sampling method for the generation of new datasets. In order to achieve more accurate driving behaviour modelling and prediction, the study adopts CNN-LSTM-GPR for effective feature extraction, which mainly uses CNN to extract features from the input time-series image data, and inputs the extracted features into LSTM for processing. Finally, the processed features are used as inputs for model fitting and prediction using GPR.

A. GPR-Based Modelling of Intelligent Vehicle Driving Behaviour

In intelligent transportation systems, to deal with different complex driving environments and promote adaptability and safety, driving behaviour modelling techniques play a key role. Based on this, the study introduces the GPR algorithm, which is a non-parametric Bayesian learning method that can be used for regression problems and is suitable for dealing with problems with uncertainty [14, 15]. In driving behaviour modelling, the perceived state quantities usually include the vehicle's attitude, speed, acceleration and other sensor data, and the GPR algorithm can be used to learn these perceived state quantities to build a model of the driving behaviour and perform real-time prediction and control. Therefore, the GPR algorithm is an effective method for modelling driving behaviour based on perceptual state quantities. However, the basic GPR algorithm has the issue of imitating a large amount of data and uneven distribution, to improve the algorithm's effectiveness, the study further proposes an improved Bagging GPR approach for driving behaviour modelling. The method firstly uses GPR to design the base regressor, and then uses the Bagging method to further improve the algorithm's whole effectiveness. The main process is to first randomly sample the driving behaviour in the training set by self-sampling method with playback, then train N GPR base learners using GPR, and lastly integrate the outputs of each base learner by averaging method to obtain the predicted values [16]. The driving behaviour modelling framework based on Bagging GPR is shown in Fig. 1.

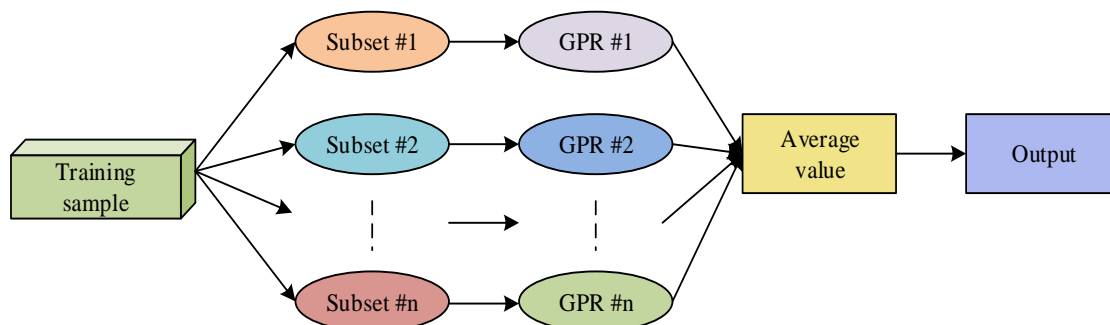

Fig. 1. A driving behaviour modeling framework based on Bagging GPR.

In the Bagging GPR-based driving behaviour modelling method, the self-sampling method is a method to generate a new dataset from an initial dataset. The specific steps of the method are, firstly, given a dataset containing m samples. Then, m random sampling operations are performed. In each sampling, a sample is randomly selected and placed into the new dataset, which is then placed back into the initial dataset. According to the limiting formula for probability estimation of the self-sampling method, it can be deduced that about 36.82% of the samples in the initial dataset never appeared in the new dataset, while about 63.2% of the samples appeared in the new dataset, which is calculated as shown in Eq. (1).

$$\lim_{m \rightarrow \infty} \left(1 - \frac{1}{m}\right)^m = \frac{1}{e} \quad (1)$$

A Gaussian process is a set of random variables, where any finite amount of random variables satisfy the joint Gaussian distribution. GPR mainly uses kernel methods for nonlinear mapping, and is a nonparametric model with good generalisation performance and global mapping ability. Given a training sample set D , where each element is a binary group containing an input vector s_i and an output vector a_i . The GPR model's output is worked out as shown in Eq. (2).

$$a = f(s) + \varepsilon \quad (2)$$

In Eq. (2), ε denotes the error, which satisfies the Gaussian distribution, and its representation is shown in Eq. (3).

$$\varepsilon \sim N(0, \delta_n^2) \quad (3)$$

In Eq. (3), δ_n^2 denotes the variance of the output error. a The prior distribution of is indicated as expressed in Eq. (4).

$$a \sim N(0, \delta_n^2 + K) \quad (4)$$

In Eq. (4), K represents the covariance matrix. Based on the prediction samples as well as the training samples a joint Gaussian prior distribution can be obtained, which is represented as shown in Eq. (5).

$$\begin{bmatrix} a \\ a^* \end{bmatrix} \sim N \left(0, \begin{bmatrix} K(s, s) + \delta_n^2 & K(s, s^*) \\ K(s, s^*)^T & K(s^*, s^*) \end{bmatrix} \right) \quad (5)$$

In Eq. (5), s^* and a^* denote the input vector and output vector of prediction, respectively. $K(s, s^*)$ denotes the prediction and the training samples' the covariance matrix, and $K(s^*, s^*)$ denotes the prediction sample's self-covariance matrix. With the kernel function, the construction of the covariance matrix is mainly carried out. The kernel function chosen for the study is the radial basis function kernel, which is represented as shown in Eq. (6).

$$K(s, s^*) = \alpha^2 \exp\left(-\frac{(s - s^*)^2}{2l^2}\right) \quad (6)$$

In Eq. (6), l is the kernel width of the radial basis function kernel, and α represents the hyperparameters, and the optimal hyperparameters are mainly obtained by the great likelihood method. After obtaining the optimal α , the predicted value a^* 's posteriori probability will be got based on the new s^* , which is calculated as shown in Eq. (7).

$$p(a^* | a) = \frac{p(a, a^*)}{p(a)} \quad (7)$$

In Eq. (8), a^* 's distribution is calculated.

$$a^* \sim N(\hat{y}(s^*), \hat{\delta}(s^*)) \quad (8)$$

In Eq. (8), $\hat{y}(s^*)$ represents the mean value, which is calculated as denoted in Eq. (9).

$$\hat{y}(s^*) = K^T(s^*) \cdot (K + \delta_n^2)^{-1} \cdot a \quad (9)$$

$\hat{\delta}(s^*)$ denotes the variance, which is calculated as shown in Eq. (10).

$$\hat{\delta}(s^*) = K(s^*, s^*) - K^T(s^*) \cdot (K + \delta_n^2)^{-1} \cdot K(s^*) \quad (10)$$

The steps of GPR application are shown in Fig. 2.

Aiming at the characteristics of large volume and uneven distribution of driving behaviour data, the study adopts the Bagging algorithm to promote of GPR algorithm's effectiveness. Bagging is an integrated learning method used to improve the accuracy of learning algorithms, and integrating and combining it can cut down the variance of the output, and promote the accuracy and stability of the algorithm. The Bagging method contains three parts, namely, sampling, training the base learner, and combining the output of three parts, and averaging method is used to obtain the output of the strong regressor, which is calculated as expressed in Eq. (11).

$$\hat{y}(s) = \frac{1}{N} \sum_{k=1}^N GPR_k(s) \quad (11)$$

The study proposes a Bagging GPR driving behaviour modelling method with improved sampling, due to the Bagging GPR algorithm's insensitivity to samples with large learning errors. The method raises the comprehensive effectiveness of the integrated regressor by increasing the sampling probability of samples, increasing the fluctuation of training samples, and increasing the attention of the base learner to samples with large training errors, which further reduces the maximum prediction error of the proposed algorithm [17]. The flow of the improved Bagging GPR approach for driving behaviour modelling is shown in Fig. 3.

Fig. 2. Application steps of the GPR.

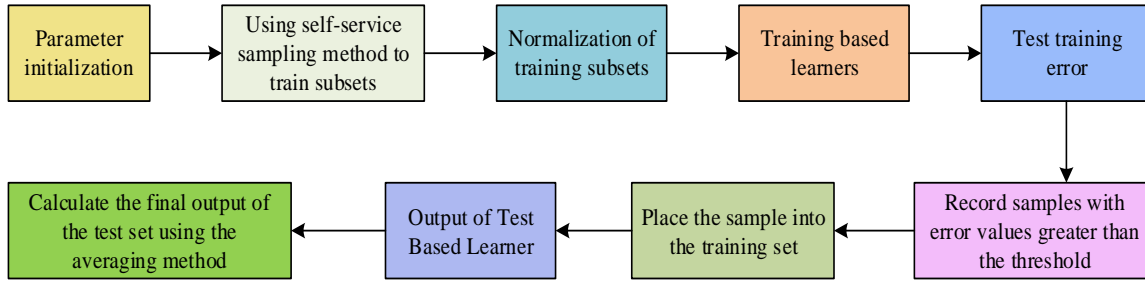

Fig. 3. Flow chart of improved Bagging GPR driving behaviour modelling method.

B. Intelligent Vehicle Feature Extraction Based on CNN-LSTM-GPR

To achieve driving behaviour modelling and prediction, effective feature extraction is required as input. Considering the characteristics of human drivers, driving behaviour learning should focus on the correlation between before and after states and actions. The study focuses on CNN-LSTM for time-series image feature extraction and fusion. Among them, CNN is a dedicated algorithm for image processing. CNN is not only able to efficiently downsize a large amount of image data into a small amount of feature data, but is also able to effectively extract the features related to a specific task through training. Convolutional, pooling, and fully connected layers are composed of CNN networks [18]. The output of the l convolutional layer is calculated as shown in Eq. (12).

$$C^l = \sigma(z^l) \quad (12)$$

In Eq. (12), σ represents the activation function, and z^l denotes the variables of the activation function of the l layer. The output of the pooling layer at l is calculated as shown in Eq. (13).

$$D^l = \text{pool}(C^l) \quad (13)$$

The output of the fully connected layer is calculated as shown in Eq. (14).

$$F^n = \sigma(F^{n-1} * W^n + b^n) \quad (14)$$

In Eq. (14), F^{n-1} , W^n , and b^n denote the output, weight matrix, and bias of the n th fully connected layer, respectively. The LSTM network is mainly applied to deal with the temporal prediction problem, whose input is the features extracted by the CNN at the time t , and the output is the predicted output at the time t . The dimensionality of the output is mainly related to the amount of output nodes of the LSTM network. The LSTM model can be viewed as a stack of cell units, each of which controls the transfer of information through a specially designed "gate" structure. The output of each cell consists of state and implicit layers, while the output of each implicit layer is jointly determined by three gates, including the inputting gate, forgetting gate and outputting gate. Each Cell unit selectively remembers and forgets the information through these three gates, and then passes it to the next Cell unit [19]. The LSTM network's structure is shown in Fig. 4.

Fig. 4. Structure diagram of LSTM.

The CNN-LSTM's error loss function is mainly used to measure the degree of deviation between the labels and the output of the network. This loss function defines a criterion for evaluating the performance of the network and aims to cut down the difference between the actual and the desired output. During the training, the optimisation algorithm continuously adjusts the network parameters to minimise the loss function, thus making the network's prediction more accurate. Its calculation is shown in Eq. (15).

$$E = \frac{1}{N} \sum_{i=1}^N \|y_i - a_i\|_2^2 \quad (15)$$

In Eq. (15), y_i represents the CNN-LSTM network's output, a_i represents the labels of the expert demonstration teaching, and N is the size of the Batch size. The CNN-LSTM method considers the temporal correlation between image sequences while considering the image feature extraction. This method can promote the simulation accuracy of driver behaviour. The neural network's layer is a combination of convolutional and pooling layers. The specific configuration of the convolutional layers is as follows: the first, second, third, fourth, and fifth convolutional layers have a convolutional kernel size of 5×5 , 5×5 , 5×5 , 3×3 , and 3×3 , respectively, and a feature map number of 24, 36, 48, 64 and 64, respectively. The first, second, fourth, and fifth convolutional layers have a

pooling downsampling window size of 2×2 steps with a step size of 2, while the third layer has a pooling downsampling window size of 1×2 steps with a step size of 2. Subsequently these feature maps are fed into the fully-connected layer, which has a node count of 512. The fully connected layer is followed by two LSTM layers. Finally, the output of the LSTM layer is connected to the output layer, which outputs the normalized value of the steering wheel angle [20]. A schematic diagram of the CNN-LSTM feature extraction network structure is shown in Fig. 5.

The research focuses on combining CNN-LSTM with GPR to enhance the understanding of the mapping relationship between temporal features and driving behaviour. The core idea of the method is to utilize GPR to further optimize the features of the CNN-LSTM to promote the fully connected layer's structure. The CNN-LSTM accumulates errors layer-by-layer during the training process, which limits its generalisation ability. Since the fully connected layer is similar to that of CNN, its generalisation ability is limited. By using the GPR method, the perfect temporal feature extraction effect of CNN-LSTM is fully utilized, while the fitting mapping ability between temporal features and driving behaviour is further improved by GPR, to improve the comprehensive performance of the algorithm. The detailed process of the CNN-LSTM-GPR method is denoted in Fig. 6.

Fig. 5. Schematic diagram of CNN-LSTM feature extraction network structure.

Fig. 6. The process of CNN-LSTM-GPR method.

IV. INTELLIGENT VEHICLE PROTECTION ANALYSIS BASED ON GPR METHODOLOGY

This chapter focuses on the experimental analysis of the improved Bagging GPR and the CNN-LSTM-GPR methods proposed by the study. Among them, for the improved Bagging GPR method, the study analyses the effect of driving behaviour modelling and verifies the performance from two scenarios, namely the straight overtaking scenario and the corner obstacle avoidance scenario. The study verifies the effectiveness of each algorithm from different input image frames, and compares the steering wheel corner prediction results of different algorithms to evidence the performance of the raised method.

A. Driving Behaviour Modelling Analysis Based on Improved Bagging GPR Methodology

To verify the effectiveness of the improved Bagging GPR method, firstly, the driving behaviours of the straight overtaking scenario as well as the corner obstacle avoidance scenario are modelled and learned. At the same time, three driver behaviour modelling methods, namely, multi-layer Back Propagation Algorithm (BP), Integrated Regression Tree and GPR, are selected for performance comparison with them. The parameter settings of each method are expressed in Table I.

TABLE I. PARAMETER SETTINGS FOR EACH METHOD

Method	Project	Parameter
Multi-layer BP network	Number of nodes of the two hidden layers	75, 15
Integrated regression tree	Integrated learning cycle	100
	Learner	Regression tree
GPR	Kernel function	Gaussian kernel function
	Nuclear width	1
	Noise parameters	0.1
Improved Bagging GPR	Number of iterations of the Bagging	20
	The size of the Bagging	2000
	Error threshold	3

The steering wheel angle prediction results of different driving modelling methods for different scenarios are indicated in Fig. 7. From Fig. 7, in contrast with the remaining three modelling methods, the driving behaviour modelling method of the improved Bagging GPR has a better fitting performance with the actual steering wheel angle and a higher matching accuracy. Whereas, the multi-layer BP algorithm has the largest deviation from the actual steering wheel angle, representing its worst modelling performance. It indicates that the proposed algorithms in the study have high prediction accuracies in modelling driving behaviours in both straight overtaking scenarios as well as cornering obstacle avoidance scenarios.

The experiments continue to use Mean Square Error (MSE), Root Mean Square Error (RMSE) and Maximum Absolute Error (MAXE) to experimentally validate the different driving behaviour modelling methods. The comparative results of the steering wheel corner prediction performance of each method in different scenarios are expressed in Fig. 8. From Fig. 8, the improved Bagging GPR method outperforms the remaining

three methods for steering wheel angle prediction in the straight overtaking scenario as well as in the corner obstacle avoidance scenario. Among them, in the straight overtaking scenario, the MAE, RMSE, and MAXE of the improved Bagging GPR method are 0.5241, 0.9547, and 10.7705, respectively, whereas those of the multilayer BP algorithm are as high as 1.7763, 3.0334, and 23.0549, respectively. The integrated regression tree is as high as 1.2863, 2.1538, 27.349, and 1.2863, respectively, 2.1538, and 27.3626, respectively. The indexes of GPR are 0.5569, 0.9638, and 10.9934, respectively, which are improved by 0.0328, 0.0091, and 0.2184 compared with the improved Bagging GPR method. At the same time, in the corner obstacle avoidance scenario, the MAE, RMSE, and MAXE of the improved Bagging GPR method are 0.660, 0.660, and 0.660, respectively. MAE, RMSE, and MAXE are 0.6527, 0.9436, and 14.7531, respectively, which are 1.383, 1.8274, and 12.8996 less than the multi-layer BP algorithm, suggesting that the improved Bagging GPR method has better performance and stability when dealing with complex driving behaviour modelling problems.

Fig. 7. Prediction results of steering wheel angles in different scenarios.

Fig. 8. Comparison of steering wheel angle prediction performance of various methods in different scenarios.

B. Feature Extraction Analysis Based on CNN-LSTM-GPR Algorithm

The study first uses a CNN-LSTM network to extract the features of various input sequence images. In terms of training parameter settings, the specific settings are denoted in Table II.

The experiments have been conducted on Apollo dataset using CNN-LSTM network with an input image sequence of 3 and an input image sequence of 5. The variation of the training error loss function is denoted in Fig. 9. The MSE of the training and test set for the case of the input image sequence of 3 is lower than the case of the input image sequence of 5. In particular, the MSE of the test set with an input image sequence of 3 converges to 0.0415 at about 25 iterations, which is 0.014 higher than the case with an input image sequence of 5. This indicates that, for the task of learning driving behaviours, the use of the CNN-LSTM network with longer input image sequences can extract the image features in a better way and help to improve the model's accuracy and generalization ability.

The experiments continued with GPR to fit the features for mapping driving behaviour. The CNN-LSTM-GPR algorithm's parameters were set as below: the kernel function was RBF, the kernel width parameter was 0.5, and the noise parameter was 0.3. The experiments were conducted using 50-dimensional features extracted by the CNN-LSTM on the Apollo dataset for driving behaviour Learning. To ensure the accuracy of the experiments, the study conducted a total of 10 experiments and took the effective average as the final experimental results. Meanwhile, MSE is chosen as the evaluation index of the experiment. The test outcomes of various driving behaviour

learning methods under different input timing image frame numbers are shown in Fig. 10. The CNN-LSTM-GPR algorithm can obtain lower MSE under different input time-series image frame numbers, among which, under the input time-series image frame number of 3, the MSE of the CNN-LSTM-GPR algorithm is only 0.0405, which is 0.010 less than that of the CNN-LSTM algorithm under the input time-series image frame number of 5, the MSE of the CNN-LSTM-GPR algorithm is only 0.0405, which is 0.010 less than that of the CNN-LSTM algorithm. The MSE of the CNN-LSTM-GPR algorithm is 0.0387, which is reduced by 0.0023 in contrast with the CNN-LSTM algorithm. The MSE values of the individual algorithms for the input temporal image frame number of 5 are lower compared to the case where the input temporal image frame number is 3. It shows that the CNN-LSTM-GPR algorithm has higher accuracy in learning to mimic the driving behaviour of the temporal images and the performance of the algorithms is better at a higher number of input temporal image frames.

TABLE II. TRAINING PARAMETER SETTINGS

Project	Parameter
Learning rate	0.0001
Optimizer	Adam
Dropout	0.2
Batch size	20
Number of training samples	5000
Number of training rounds	200
Training time	9h

(a) Change in loss function of input timing image frame number 3

(b) Change in loss function of input timing image frame number 5

Fig. 9. Changes in training error loss function for different input image sequences.

(a) MSE value when the input timing image frame number is 3

(b) MSE value when the input timing image frame number is 5

Fig. 10. MSE values under different input timing image frames.

Fig. 11. Steering wheel angle prediction results of different driving behaviour learning methods based on time series information.

To evidence the function of the CNN-LSTM-GPR algorithm, the study further compares the steering wheel corner prediction outcomes of various driving behaviour learning methods with temporal information on the test set, and the research findings are indicated in Fig. 11. From Fig. 11, the CNN-LSTM-GPR based driving behaviour learning model can simulate human driving behaviour better compared to the CNN-LSTM model. It's learned driving actions are smoother, the coherence between actions is more solid, and the learning error is smaller, which outperforms the CNN-LSTM model. It can also be seen that when five consecutive frames of images are input, the driving behaviours simulated by the CNN-LSTM-GPR-based driving behaviour learning model fluctuate less and the movements are more coherent. This further confirms that introducing more temporal information helps to improve the performance of driving behaviour learning.

Further research was conducted to verify the computational efficiency of the CNN-LSTM-GPR algorithm, using CNN-LSTM algorithm, Extreme Gradient Boosting (XGBoost) algorithm, and Seasonal Autoregressive Integrated Moving Average (SARIMA) model for performance comparison. The calculation time for different algorithms in predicting driving behavior is shown in the table. According to the table, the computation time of the CNN-LSTM-GPR algorithm is only 0.5213 seconds, which is lower compared to the XGBoost and SARIMA algorithms. The computation time of the CNN-LSTM algorithm is slightly lower than that of the CNN-LSTM-GPR algorithm, because the algorithm integrates Gaussian Process Regression to handle uncertainty, thereby increasing computation time. However, overall, the CNN-LSTM-GPR algorithm has better predictive performance.

TABLE III. CALCULATION TIME FOR DIFFERENT ALGORITHMS

Algorithm	Runtime (s)
CNN-LSTM	0.4926
XGBoost	1.6397
SARIMA	15.3969
CNN-LSTM-GPR	0.5213

V. DISCUSSION

An improved Bagging GPR method has been proposed for intelligent protection in intelligent transportation systems. The results showed that in the scenario of overtaking on a straight line, the MAE, RMSE, and MAXE of the improved Bagging GPR method were 0.5241, 0.9547, and 10.7705, respectively. Meanwhile, in the scenario of obstacle avoidance on curves, the MAE, RMSE, and MAXE of the improved Bagging GPR method are 0.6527, 0.9436, and 14.7531, respectively. Compared to the multi-layer BP algorithm, its various indicators have decreased by 1.383, 1.8274, and 12.8996, respectively. ZHONG Q et al. proposed a tool wear prediction method based on maximum information coefficient and improved Bagging GPR. The results show that this method has significant advantages in predictive performance [21]. The Bagging GPR method demonstrates high prediction accuracy in all aspects. The reason is that the improved Bagging GPR method integrates multiple GPR models, each trained with a different subset of data, and then averages or weights their prediction results, thereby reducing the variance of the model. At the same time, this method increases the attention of the base learner to samples with large training errors, further reducing the maximum prediction error and improving the overall performance of the ensemble regressor.

In the effectiveness verification experiment of the CNN-LSTM-GPR algorithm, the driving behavior learning model based on CNN-LSTM-GPR can better simulate human driving behavior compared to the CNN-LSTM model. The driving actions it learns are smoother, with stronger coherence between actions and smaller learning errors, and its performance is better than that of the CNN-LSTM model. When five consecutive frames of images are input, the driving behavior learning model based on CNN-LSTM-GPR simulates less fluctuation and more coherent actions. Chen H and other researchers proposed a CNN-GPR method for driving behavior learning, which addresses the problems of low learning accuracy and poor generalization performance in traditional driving behavior learning methods. They also introduced LSTM and proposed a CNN-LSTM-GPR method for driving behavior learning using time-series images. The results show that the proposed CNN-LSTM-GPR method can fully utilize the temporal information

of the image, resulting in smaller simulation errors [22]. Compared with the CNN-LSTM method, this method can further improve learning accuracy and exhibit better generalization performance. This is similar to the research findings. The reason is that the CNN-LSTM-GPR method can effectively utilize temporal image information. Temporal information includes the temporal sequence of consecutive frame images, which helps capture dynamic changes and coherence in driving behavior. By introducing the GPR (Gaussian Process Regression) model, it is possible to more accurately model the spatiotemporal dynamics of driving behavior, thereby making the learned driving actions smoother and more coherent.

VI. CONCLUSION

Intelligent vehicle safety protection in intelligent transport systems is of great significance. For intelligent protection in intelligent transportation systems, the study successively introduces an improved Bagging GPR-driving behaviour modelling method and a feature extraction method with CNN-LSTM-GPR algorithm. The findings denoted that compared with the remaining three modelling methods, the driving behaviour modelling method of the improved Bagging GPR has better fitting performance with the actual steering wheel angle and higher matching accuracy. Whereas, the multi-layer BP algorithm has the largest deviation from the actual steering wheel angle, which represents its worst modelling performance. Meanwhile, when the input image sequence of the CNN-LSTM network is 3, the MSE of the test set converges to 0.0415 at about 25 iterations, which is an improvement of 0.014 compared to the case when the input image sequence is 5. In addition, compared to the CNN-LSTM model, the driving behaviour learning model with CNN-LSTM-GPR can more accurately simulate human driving behaviour. Its learned driving actions are smoother, the articulation between actions is more natural, and its learning error is relatively smaller, so the whole effect is better than that of the CNN-LSTM model. In addition, when five consecutive frames of images are input, the driving behaviours simulated by the CNN-LSTM-GPR-based driving behaviour learning model show less fluctuation and more coherent movements. It shows that the improved Bagging GPR method and CNN-LSTM-GPR feature extraction method can provide more accurate and smooth driving behaviour modelling and learning schemes for intelligent vehicles in ITS. However, the drawback of this study is that it only focuses on specific scenarios and environments, which may limit the universality and scalability of the proposed technology in a wider range of driving conditions and challenges. Future research needs to expand its scope to cover more diverse scenarios, road conditions, and driving behaviours to ensure the effectiveness and robustness of the developed models in real-world applications.

Abstract—In order to improve the efficiency of automatic book classification, the study uses a crawler to crawl book data from regular websites and perform data cleaning and fusion to build a structured knowledge graph. Meanwhile, the processed data is applied to a pre-trained model to improve it, and migration learning is used to improve the results. Fusion of Multiple Attention Mechanisms, Recurrent Neural Network, and Convolutional Neural Network modules into the classification model and feature fusion is used to enhance feature extraction. In addition, the study designed a pre-trained model architecture to help automatically categorise and manage book resources. The results of this study show a significant improvement in the classification of Chinese books on the Chinese Book L2 Subject Classification, iFlytek, and THUCNews datasets with significant performance improvement. The fusion of long and short-term memory and convolutional network Transformer-based bi-directional encoding models improved the accuracy by 0.19%, 1.54% and 0.42% on the two datasets, respectively, while the weighted average F1 scores improved accordingly. Through wireless technology, the automatic classification efficiency of books is realized and the management ability of the library is improved.

Keywords—Crawler; books; automated; classification; Recurrent Neural Network; Multiple Attention Mechanism; knowledge graphs

I. INTRODUCTION

In the context of the big data era, the huge amount of complex text data makes libraries lack detailed subject classification labels when purchasing books, which leads to the inefficiency of acquiring book resources. Currently, this task mainly relies on library managers, which is costly and time-consuming. The introduction of an intelligent model greatly improves the accuracy of book categorisation, which helps to reduce labour costs and improve work efficiency. The robots not only automatically identify and classify books, but also operate continuously, significantly optimising library resource management and user services [1-2]. Existing studies rarely consider subject-specific library classification work, and the use of the latest natural language processing techniques, including large-scale pre-trained models such as the Bidirectional Encoder Representations from Transformers (BERT) model, can significantly improve the efficiency and accuracy of automatic classification of library resources in subject domains [3]. Such models can effectively reduce the dependence on a large amount of manually labelled data by virtue of their powerful semantic capture and feature extraction

capabilities. Meanwhile, Knowledge Graph, as an intelligent semantic tool, greatly facilitates information sorting and management by interconnecting dispersed data through constructed entities, relationships and attributes [4]. Although the approach limits the application of the system across domains, it tends to show better performance and efficiency within established domains.

Network Centric Quality Management (NCQM) systems often use web-based technologies to collect, analyse and manage quality-related data to improve the efficiency and effectiveness of the overall system or process [5]. In the context of intelligent model book categorisation, NCQM systems can be used to monitor and optimise robot performance, accuracy and efficiency. Therefore, in order to improve the efficiency and accuracy of book management, reduce the dependence on paper records and manual operations, and improve the convenience of users to obtain information, the following work have been made in this study. First of all, the data is collected by efficient crawler technology, and then sorted and cleaned as the basis for the construction of a knowledge map. Based on Neo4j graph database, the book information knowledge graph is quickly constructed according to the pre-defined book knowledge graph Schema. Secondly, the pre-trained data set is divided into training set, verification set and test set, and the transfer learning strategy is used to fine-tune the pre-trained model to achieve the optimal state. By comparing with Text Convolutional Neural Network (Text-CNN) and other baseline models, the proposed model is fully tested on the Chinese book dataset specially constructed for this study. In addition, a feature enhancement method is proposed. This approach combines the multi-head attention mechanism of pre-trained models with the feature extraction and learning advantages of Convolutional Neural Networks (CNN) and Recurrent Neural Network (RNN). The pre-training model of fusion feature extraction technology has an effective effect on the classification of Chinese books. On the basis of using the pre-training model to classify Chinese books, according to the actual needs of university libraries, an automatic classification system of book resources based on the pre-training model is completed.

The study is divided into six sections. Section I discusses the challenges libraries face in the era of big data and proposes the use of intelligent models and natural language processing techniques to improve classification accuracy and efficiency. Section II reviews the research progress of automatic book

*Corresponding Author.

classification, and mentions the application of BERT pre-training model and knowledge graph in information classification. Section III introduces the research methods, including the collection and processing of book data and the construction of a knowledge graph, the collection and storage of data in Neo4j graph database by web crawler technology, and the application of BERT model for transfer learning and feature fusion. Section IV tests the models and compares the classification effects of different models. Section V and Section VI summarize the research results, confirm the effectiveness of the intelligent model in improving classification efficiency and accuracy, and propose future work directions, such as strengthening the subject classification module and improving user experience.

II. RELATED WORK

The application of intelligent model in book categorisation not only improves the efficiency of library management but also provides better reading services to the users. An innovative feature selection optimisation algorithm has been designed by Janani and Vijayarani. To validate the effectiveness of the algorithm, the researchers further proposed a machine learning-based automatic text categorisation algorithm. The results demonstrated the efficiency and accuracy of the algorithm in extracting key features and classifying text documents by content [6]. Zhang designed a classification system based on support vector machines (SVM) for intelligent text classification, which is dedicated to public security information. The results proved the efficiency and practicality of SVM in dealing with specific information classification tasks [7]. For the field of automated text categorisation, Rezaeian and Novikova have compared the efficacy of plain Bayes and support vector machine algorithms, as well as Gaussian kernel function, polynomial kernel function, and Bernoulli's model in plain Bayes in order to enhance the accuracy of Persian textual materials in categorisation. The results of the study showed the better performance of these methods in Persian text classification [8]. Dizaji and other researchers proposed to combine the imperialist competitive algorithm with support vector machines for text classification. After experimental analyses, the results showed that this method showed higher efficiency and accuracy in text classification tasks [9].

The best performing language models for various tasks in the natural language processing direction are pre-trained language models. However, focusing on the topology of knowledge graphs often ignores the potential differences between knowledge graph embeddings and natural language embeddings, which limits the ability to reason effectively using both implicit and explicit knowledge. To address this problem, Cao and Liu designed an innovative model, ReLMKG, which combines pre-trained language models and relevant knowledge graphs. The efficiency and applicability of the model is demonstrated by testing it on the complex WebQuestions and WebQuestionsSP datasets [10]. According to the characteristics of Chinese library classification, Yuhui Z and other scholars used innovative methods to adapt to the problems of extreme multi-label (XMC) and hierarchical text classification (HTC). This paper extracts semantic features by a lightweight deep learning model and combines hierarchical

information and other features with a learning ranking (LTR) framework to improve accuracy and classification depth. This model not only understands deep semantics but also has interpretability, is easy to expand and customize, and is suitable for processing tens of thousands of category labels, providing a solid foundation for comprehensive deep classification [11]. Jiang Y et al. combined domain-specific and general text enhancement strategies, such as category mapping and bilingual theme-based method, to solve the problem of small data volume and unbalanced categories in English books with Chinese picture classification numbers, and added punctuation and conjunction to the English text. Experimental results show that this hybrid strategy can improve the model performance. The visualization of BERT word vectors and the analysis of word information entropy can be applied to the classification and recognition of books [12]. To improve the accuracy of Chinese text Classification, Liu X and other researchers designed Chinese Library Classification based on an adaptive feature selection algorithm and tested a variety of Chinese text types. In this paper, an improved mutual information chi-square algorithm is introduced, which combines word frequency and term adjustment, term frequency-inverse document frequency method, and uses the limit gradient enhancement algorithm to improve the word filtering effect. Experiments show that the proposed algorithm can effectively improve the classification performance of different news texts, but the optimal algorithm selection varies according to the text type [13].

In summary, existing models perform well in specific domains, but are less adaptable across domains. For example, some Chinese book classification models have limited ability to generalize on other languages or topics. Despite the introduction of methods such as Multiple Attention Mechanisms, RNNS, and CNNS, feature extraction and fusion are still inadequate, especially when dealing with long text, which may miss key information or be inefficient. In addition, the lack of a large-scale open-source book knowledge graph limits the model's knowledge reasoning and classification accuracy. Training deep learning models requires a lot of resources and time, which small organizations can't afford. Model tuning and parameter adjustment also require a lot of experiments, and the number of books in different categories is unbalanced, resulting in poor classification performance, especially in small categories. Most methods do not perform well in cross-domain book classification, the model depends on the domain, and the application scope is limited. In order to achieve effective text representation, feature extraction and accurate subject categorisation of book resources.

III. AUTOMATED RESEARCH ON CATEGORISATION OF BOOKS BY INTELLIGENT MODEL BASED ON NCQM SYSTEM

Due to the lack of available open source book knowledge graph and the data requirement of deep learning model, the research first designed an asynchronous anti-anti-crawler based on aiohttp to collect website book information. The collected data was cleaned and used to build the knowledge graph, and the book information knowledge graph was built automatically by using Neo4j. In order to deal with the low efficiency of traditional book classification and the need for professional knowledge, the research adopts the pre-trained model in deep

learning for text representation, and optimizes the model structure through transfer learning. The pre-processed data set was divided into training, verification and test sets, and the model was fine-tuned to compare with the existing baseline models such as TextCNN and TextRNN. RNN module and CNN module are added to the feature extraction layer of the book classification model, and a feature fusion method is proposed to enhance the features of the pre-trained model. To improve the accuracy of Chinese book classification. According to the actual demand of university library, the automatic classification system of book resources based on pre-training model is finally completed.

A. Construction of Knowledge Graph of Book Information

The core advantage of Knowledge Graph is that it can connect related data elements, and its construction is closer to the natural logic of human processing information [14]. Moreover, knowledge graph relies on the use of graphs to store data, which makes it possible to achieve good data visualisation. There are two main methods for storing knowledge graphs, the first is the resource description framework introduced by W3C, and the second is to use of graph databases for data preservation. Graph databases are popular among developers and users because of their intuitive data representation and visualisation features, and they are not inferior to RDF in terms of data query performance. Therefore, the vast majority of developers tend to use graph databases to build knowledge graphs. Fig. 1 shows the construction steps of the book knowledge graph.

In Fig. 1, this construction step first collects data from multiple online resources through web crawling techniques and then pre-processes them to remove redundancies and error messages. Next, the processed data is subjected to knowledge extraction using a predefined schema in the study, i.e., converting the textual information into a structured ternary form. Subsequently, a knowledge fusion step is carried out to solve the problems of word polysemy and textual ambiguity by technical means. Ultimately, using Neo4j, a graph database platform, the collated ternary data is constructed into an exhaustive knowledge graph of book information and its visualisation is achieved to facilitate a more intuitive understanding and analysis of the data. In view of the characteristics of the website where the data comes from, it is necessary to design a crawler programme to obtain the data quickly. In terms of language platform selection, Python language is chosen as the platform for building the crawler programme [15]. After choosing the platform and tools, the design of the crawler programme begins, and the running flow of the crawler programme is shown in Fig. 2.

Fig. 1. Flowchart of the construction of book knowledge map.

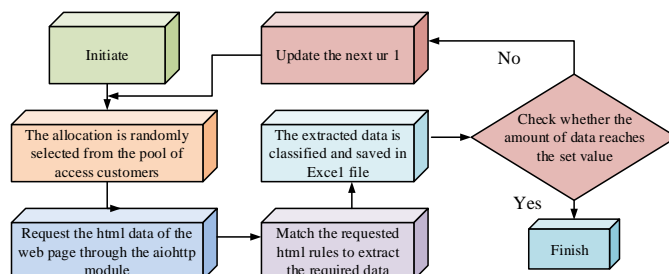

Fig. 2. Crawler operation flow.

According to the flow in Fig. 2, first, the crawler makes use of the asynchronous HTTP web module aiohttp to initiate HTTP requests against the specified book information website URL and obtain the HTML content. The reason for choosing aiohttp as the request tool is that it supports asynchronous processing of HTTP requests, which significantly improves the efficiency of the crawler. Given the large amount of data required to build a knowledge graph of book information, traditional synchronous crawling methods are less efficient, while aiohttp can accelerate the data crawling process. Once the HTML data is successfully retrieved, the program will analyse its content and extract the required textual information. In addition, the study employs the BeautifulSoup tool to crawl the required content from web pages quickly and efficiently. Relying on HTML's Selector for precise positioning, the extraction of target information is achieved. Initially, the acquired data may contain non-targeted components, so it is decided whether to use regular expressions to further remove depending on the situation [16]. Afterwards, it is processed and saved in xlsx format using Python's Xlsxwriter library, a process that converts semi-structured information in HTML into structured data. In constructing the knowledge graph of book information, the study uses Python's py2neo library in combination with the Neo4j graph database. Firstly, pandas are used to extract information from book data in xlsx format, and subsequently entities and relationships are created by py2neo. In order to cope with the polysemy and translation problems in Chinese, translation software is used to translate and staging the foreign language content. When merging entities, if a translated entity is found to have the same primary key as an existing entity, it will be manually reviewed to determine if it should be merged.

B. Automatic Book Classification Method Based on Pre-Trained Model

After initial processing, book title, synopsis and keyword texts are selected for classification. These data were transformed into vectors by a pre-trained model to be adapted for machine processing. The text features are refined through a multi-layer Transformer structured encoder. Subsequently, the learnt text features are fed into the classification system to compute probability values for different classification labels [17]. The final probability distribution is determined by a normalisation method and the label corresponding to the highest probability is assigned as the subject category of the book. The process of Chinese book classification is shown in Fig. 3.

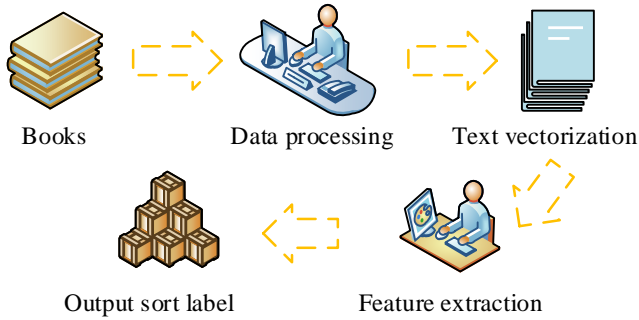

Fig. 3. Process of Chinese book classification.

BERT is a deep learning model based on Transformer, which mainly consists of bi-directional encoders. It is available in two versions, the basic version with 12 layers of encoders and the advanced version with 24 layers [18]. These layers include a multi-head self-attention mechanism and a feed-forward network, as well as residual connectivity and layer normalisation. In pre-training, BERT processes two pieces of text and learns two tasks, next-sentence prediction and masked language modelling. These tasks help BERT to better understand the language structure. Among them, the mask language model is suitable for single or double-paragraph text, while the next sentence prediction is specifically used for two paragraphs. The input representation of BERT consists of the sum of word vectors, block vectors, and position vectors [19]. In order to facilitate the computation, the dimensions of these three vectors are set to e , and the representation of the text is shown in Eq. (1).

$$v = v_t + v_s + v_p \quad (1)$$

In Eq. (1), v_t, v_s, v_p denotes word vector, block vector and position vector respectively, and the length of all three vectors is N . The word vector representation is very similar to the word vector in neural networks, both of which convert a text sequence into a fixed dimensional vector of values. Consider a dictionary with $|\Upsilon|$ words and an e -dimensional word vector space, where the sequence representation x is uniquely encoded into $e' \in \mathbb{R}^{N \times |\Upsilon|}$ and $W' \in \mathbb{R}^{e \times |\Upsilon|}$ represents the learnable word embedding matrix. Then, the word vector formula corresponding to x is given in Eq. (2).

$$v_t = e'W' \quad (2)$$

The role of the block vector is to tell the model which block the current word belongs to. And the role of the position vector allows the model to obtain the absolute position of each word in the sequence, which enhances the memory ability of the model. Applying BERT to the task of single-sentence text classification, the model is mainly composed of an input layer, a BERT feature extraction layer and a classification output layer. For the input text sequence $x_1, x_2, x_3, \dots, x_n$, the specific markers of the BERT model are added to both ends of the sequence to get the original input of the model X as shown in Eq. (3).

$$X = [CLS]x_1x_2x_3 \dots x_n [SEP] \quad (3)$$

Next, the mapping of X is performed according to the above processing of word vectors, block vectors, and position vectors, and let the length of the sentence be n , then the input representation of the model is obtained as v , see Eq. (4).

$$v = \text{InputRepresentation}(X) \quad (4)$$

BERT utilises Transformers encoders with a different number of layers (12 layers for the basic version and 24 layers for the large version) to process the input v and learn the implicit associations between lexical items within the text. Let the implied dimension be d and the textual contextual representation be denoted as $h \in \mathbb{R}^{N \times d}$, corresponding to Eq. (5).

$$h = \text{BERT}(v) \quad (5)$$

The BERT model represents the whole sentence vector for next sentence prediction via [CLS] labelling in the pre-training phase. For task alignment, the implicit layer representation of [CLS] is similarly utilised as the vector representation of the whole sentence for single-sentence classification, denoted as h_0 . To obtain the corresponding categorical labels of the input sentences are simply the [CLS] implicit layer representation h_0 extracted by BERT into the fully connected layer. Setting K as the number of categories, $W^0 \in \mathbb{R}^{d \times K}$ as the weights, and $b^0 \in \mathbb{R}^K$ as the bias, the label probability distribution $p \in \mathbb{R}^K$ is obtained as shown in Eq. (6).

$$p = \text{Soft max}(h_0W^0 + b^0) \quad (6)$$

After obtaining the probability distribution of the classification, it is compared with the real classification labels to calculate the loss, and then backpropagation is performed to update the parameters of the model. Conditional Random Field (CRF) is mainly applied to sequence labelling task to ensure the accuracy of the labelling [20]. The correct sequence is identified by scoring each labelled sequence and calculating the proportion of the total score that a particular labelled sequence scores. The length of the text sequence is l and the length of its true annotation sequence is also l . The total score S_{i, y_i} for position i in the sequence annotation consists of the sum of the current launch score R_{i, y_i} , the total score $S_{i-1, y_{i-1}}$ for the previous position, and the transfer score T_{y_{i-1}, y_i} . The total score of the end point represents the score of the whole sequence, which is calculated in Eq. (7).

$$S(X, y) = \sum_{i=1}^n (T_{y_{i-1}, y_i} + R_{i, y_i}) \quad (7)$$

After obtaining the score of a single sequence annotation, in order to confirm whether a sequence annotation is optimal or

not, it is necessary to calculate the proportion of its score to the sum of the scores of all possible sequences, and the expression of this proportion is shown in Eq. (8).

$$P(y_{now} | X) = \frac{e^{S(X, y_{now})}}{\sum_{y \in Y_x} e^{S(X, y)}} \quad (8)$$

In Eq. (8), the larger P is, the closer the current sequence prediction is to the real value. Therefore, Eq. (8) can be used as the loss calculation of CRF model, and its calculation procedure is shown in Eq. (9).

$$\log(P(y_{now} | X)) = S(X, y_{now}) - \log\left(\sum_{y \in Y_x} e^{S(X, y)}\right) \quad (9)$$

Typically, the CRF uses the Viterbi algorithm to find the optimal solution, labelled as the optimal sequence of X . This formula is shown in Eq. (10).

$$y^* = \arg \max_{y \in Y_x} S(X, y) \quad (10)$$

C. Fine-Grained Book Classification Based on Pre-Trained Model and Feature Fusion

Combining the feature extraction advantages of pre-trained models such as BERT, the newly designed text categorisation model integrates a feed-forward network, using the AdamW optimiser and cyclic unit, convolution and pooling techniques to enhance the feature representation. Based on these techniques, this paper proposes a feature enhancement method of Pre-trained model, PLM-LCN, which combines Long short term memory and Convolution Networks (LCN) and pre-trained language models (PLM). Fig. 4 shows the PLM-LCN model structure.

In Fig. 4, the main flow of the PLM-LCN method model is as follows, firstly, the original input text is encoded into word vectors, block vectors and position vectors, which are combined according to the rules to form the input representation of the Multihead Self-Attention Layer. The text features are extracted after processing in this layer, and the sentence representation with [CLS] characters enters into the convolution and loop unit module. The output features from the convolutional module and the bidirectional long and short term memory network (Bi-LSTM) are combined and spliced to form the ultimate textual representation. These features are used for probabilistic prediction by the classifier and normalised by Softmax, with the highest probability category being the book classification result. The counting formula for the convolution operation is given in Eq. (11).

$$O(i, j) = \sum_{m=0}^{M-1} \sum_{n=0}^{N-1} (I(i+m, j+n) K(m, n)) \quad (11)$$

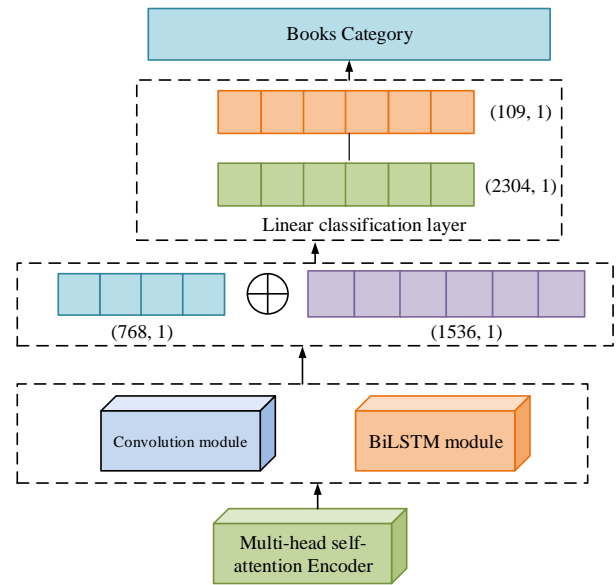

Fig. 4. PLM-LCN model structure.

In Eq. (11), (i, j) represents the output position. I represent the input data into the convolutional layer. K is the convolution kernel and (m, n) denote its size. Attention mechanism, derived from the human characteristic of focusing attention, is introduced into deep learning to highlight key features and downplay secondary information. In this mechanism, Q (Query) locates the target task, while K (Key) and V (Value) form matching pairs. Q It is used to find the corresponding V value in K . The operation of the mechanism and the computation process is shown in Eq. (12).

$$D_v = Attention(Q, K, V) = Soft \max\left(\frac{Q \cdot K^T}{\sqrt{d_k}}\right) V_s = \sum_{s=1}^m \frac{1}{z} \exp\left(\frac{Q_s \cdot K_s^T}{\sqrt{d_k}}\right) V_s \quad (12)$$

Fig. 5. Feature transformation process in self-attention calculation.

In Eq. (12), z represents the normalisation factor. Q_i represents the query value. The feature transformation process in Self-Attention computation is shown in Fig. 5.

Fig. 5 shows the matrix of word vectors X in the input text, representing a complete sentence. X Multiplying different weight matrices produces the Q, K, V matrix in the attention mechanism, where each row corresponds to a vector of words q, k, v . The parameters of these weight matrices W^Q, W^K, W^V are continuously updated during model training. In order to evaluate the model's learning of a -set of parameters, it is necessary to introduce a loss function, whose computational expression is shown in Eq. (13).

$$CE = -\frac{1}{m} \sum_{i=1}^m \sum_{j=1}^c y_j^{(i)} \log \hat{y}_j^{(i)} \tag{13}$$

In Eq. (13), $y_j^{(i)}$ denotes the true output result on the j th class for the i st sample, where only the correct class outputs 1 and the rest of the classes output 0. $\hat{y}_j^{(i)}$ denotes the probability that the model belongs to the j th class for the i th sample. Alternatively, Eq. (13) can be transformed into Eq. (14).

$$CE = -\frac{1}{m} \sum_{i=1}^m \log \hat{y}_t^{(i)} \tag{14}$$

In Eq. (14), $\hat{y}_t^{(i)}$ denotes the model's probability of predicting the first i sample on the correct category t . To realize the book information query and classification function of the automatic book classification robot system, the system is constructed into four levels. The overall framework of the book's automatic sorting robot is shown in Fig. 6.

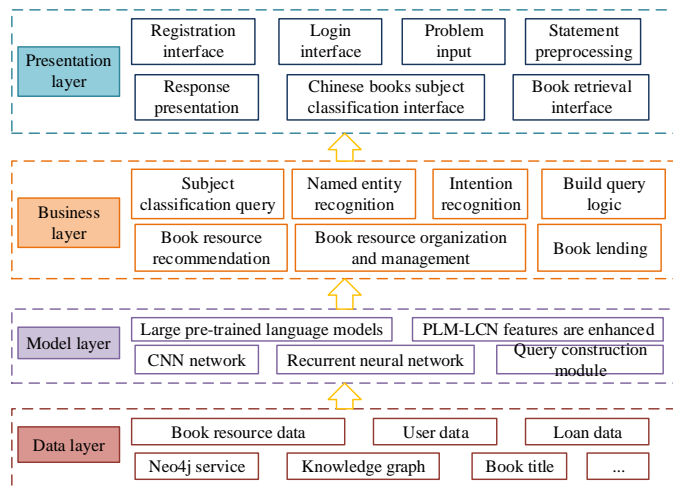

Fig. 6. Overall framework of the book automatic classification robot.

In Fig. 6, the presentation layer mainly realizes the communication between the system and the user. The user enters questions through the visualization window of this layer. The user interaction layer processes the natural language

questions provided by the user to some extent, eliminates certain invalid interference content in the questions, and makes the text to be processed more standardized. The model layer calculates the data based on user commands and pushes the results to the presentation layer. The business layer is the bridge of user interaction scenario, covering various functional modules. The data interaction layer mainly relies on the constructed book information knowledge graph. After obtaining the query statement from the logical layer, the Neo4j server queries the book information knowledge graph. The limited number of candidate answers is returned to the user interaction layer after the candidate answers are sorted. The data interaction layer mainly relies on the book information knowledge graph constructed. After obtaining the query statement from the logical layer, the Neo4j server queries the book information knowledge graph. The limited number of candidate answers is returned to the user interaction layer after the candidate answers are sorted.

IV. ANALYSIS OF EXPERIMENTAL RESULTS

Model training in deep learning research relies on a large number of matrix operations that place high demands on hardware. Graphics Processing Unit (GPU) is significantly more efficient in handling such tasks with its parallel processing capability and fast dedicated memory. The initial input length of all neural network models is set to 128 and the training period is 10 epochs. BERT-Base-Chinese and its improved version with AdamW optimiser and cross-entropy loss function are selected. Pytorch was chosen as the development framework, and its supporting hardware configuration and RSBC model parameter settings are shown in Table I.

TABLE I. EXPERIMENTAL ENVIRONMENT AND MODEL PARAMETER SETTINGS

Experimental Environment	Disposition	Model	Argument
Operating system	Windows 10	RoBERTa version	RoBERTa_zh_L12
CPU	Interl I7-11800H	learning_rate	3e-5
GPUs	NVIDIA GeForce RTX 3060	hidden_dim	768
RAM	16G	dropout_rate	0.5
Hard disk	10G disposable space	batch_size	64

The experiments use seven traditional neural network models as baseline models to participate in the comparison experiments. Accuracy (acc) represents the proportion of correctly classified samples in the total samples, and is a basic index for evaluating classification models. Macro Precision (mc_p) calculates and averages the accuracy of each class separately, reflecting the average accuracy of the model in each class, regardless of class imbalance. Macro Recall (mc_r) also calculates and averages the recall rate for each category separately, and measures the average recall rate of the model across all categories, ignoring the class imbalance problem. Macro F1-Score (mc_f) is the harmonic average of macro average accuracy and macro average recall, taking into account the performance of both accuracy and recall. Weighted

Precision (w_p) takes into account the number of samples in each category and makes a weighted average to reflect the comprehensive accuracy rate of the model in different categories, which is applicable in the case of unbalanced categories. Weighted F1-Score (w_{fl}) is also a harmonic average of weighted accuracy and weighted recall to comprehensively evaluate the model's performance in the case of class imbalance. The experimental results on different neural network models on the secondary subject classification dataset of Chinese books are shown in Fig. 7.

As can be seen from Fig. 6, each benchmark neural network model achieves more than 75% accuracy and average F1 score, indicating that the models show good performance after a number of training cycles. TextRCNN fails to outperform TextRNN. The Fasttext model performs better, with high speed and second only to the TextRNN-Att model. The loss values for the Fasttext model and the TextRNN-Att

model has a loss value of 0.62 and 0.59 respectively, while the TextRNN model with embedded attention mechanism has the best result in all comparisons, which highlights the feature extraction advantage of the attention algorithm, and verifies the feasibility of studying the classification research with the pre-trained model based on the attention mechanism. The LERT model retains the original architecture of the BERT, but optimises the training tasks and methods, which provides a good opportunity to study the BERT series of models. The LERT model retains the original BERT architecture but optimises the training tasks and methods, providing guidance for the study of the BERT series of models. The learning rate is set to $1e-5$, the batch size is 8, and 10 rounds of training are performed, taking the maximum sequence length of the input text as 16, 32, 64, 128, 192, 256, and 512 for the experiments, respectively. The experimental results corresponding to Fig. 8 are obtained.

Fig. 7. Comparison of indicators of each model on the Chinese books' secondary subject classification data set.

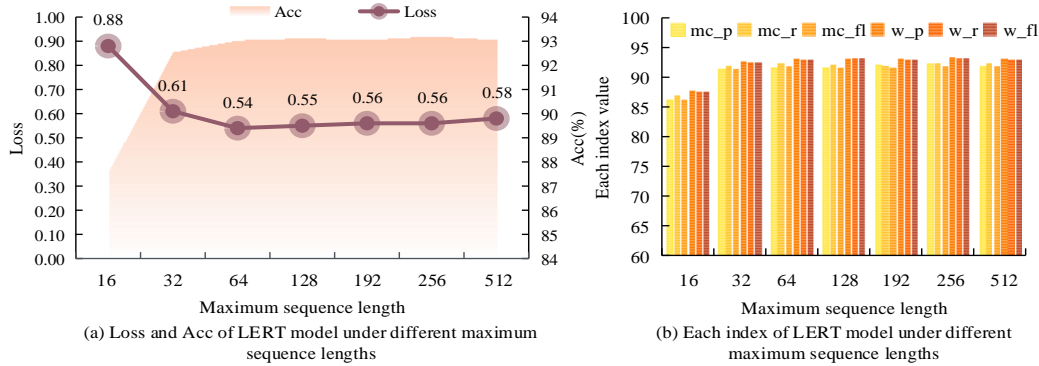

Fig. 8. Experimental results of the LERT model under different maximum sequence lengths.

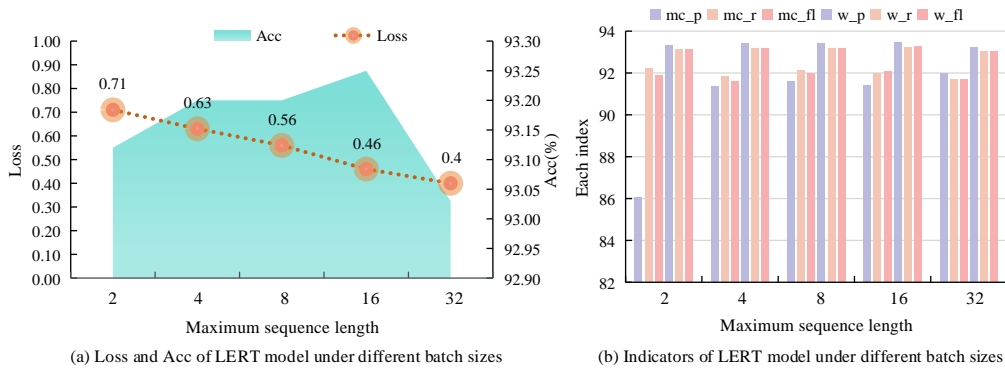

Fig. 9. Experimental results of the LERT model under different batch sizes.

As can be seen in Fig. 7, the performance of the LERT model when dealing with different maximum sequence lengths, where the best performance is achieved when 256 is the sequence length. A sequence that is too short (e.g., 16) will lose more information because the important content is truncated, while setting it too long results in filling too many invalid 0-values, which affects feature extraction and computational efficiency. Therefore, setting 256 as the most suitable text length for the model to handle on the task of secondary subject classification of Chinese books is a significantly preferred solution. Fig. 9 shows the experimental results of the LERT model under different batch sizes.

Fig. 9 shows that the performance of the model typically improves with increasing batch size, although the effect decreases after a certain point. The minimum batch is theoretically good for optimisation, but too low may cause unstable convergence and prolong training time. On the contrary, too large batches tend to trigger memory overruns and impair accuracy. Considering the experimental results and computational efficiency, 16 is chosen as the preferred batch size setting for the BERT pre-training model on the Chinese book secondary subject classification dataset. Fig. 10 shows the experimental results of the LERT model at different learning rates.

As can be seen from Fig. 10, the LERT model performs similarly when the learning rate is set to $1e-5$ and $5e-5$, both

outperforming other higher learning rate settings. A learning rate that is too small may slow down the training speed and cause the model to fall into a local optimum, while a learning rate that is too high may cause oscillations in the loss function and prevent the model from converging. Therefore, based on the trade-off between model performance and training efficiency, $1e-5$ or $5e-5$ is a more appropriate choice of learning rate to promote the model to achieve good training results on the Chinese book secondary subject classification dataset. Experiments are conducted using the Chinese book secondary subject classification dataset, the iFlytek dataset and the THUCNews dataset for ablation experiments on the five models, and the results are shown in Fig. 11.

As can be seen from Fig. 11, the BERT-LCN model exhibits better performance compared to the original BERT when dealing with the Chinese book secondary subject classification, iFlytek and THUCNews datasets. Its accuracy is improved by 0.19%, 1.54% and 0.42%, while the weighted average F1 score achieves an increase of 0.19%, 2.73% and 0.47%, respectively. Meanwhile, due to the original expressive power of the multiple self-attention mechanism, the BERT-LCN model demonstrated significant results on all three different attribute datasets reflecting its highly generalised nature. The ablation experiments were conducted using three datasets on six models and the results are shown in Fig. 12.

Fig. 10. Experimental results of the LERT model under different learning rates.

Fig. 11. Ablation results of the BERT-LCN method model on three datasets.

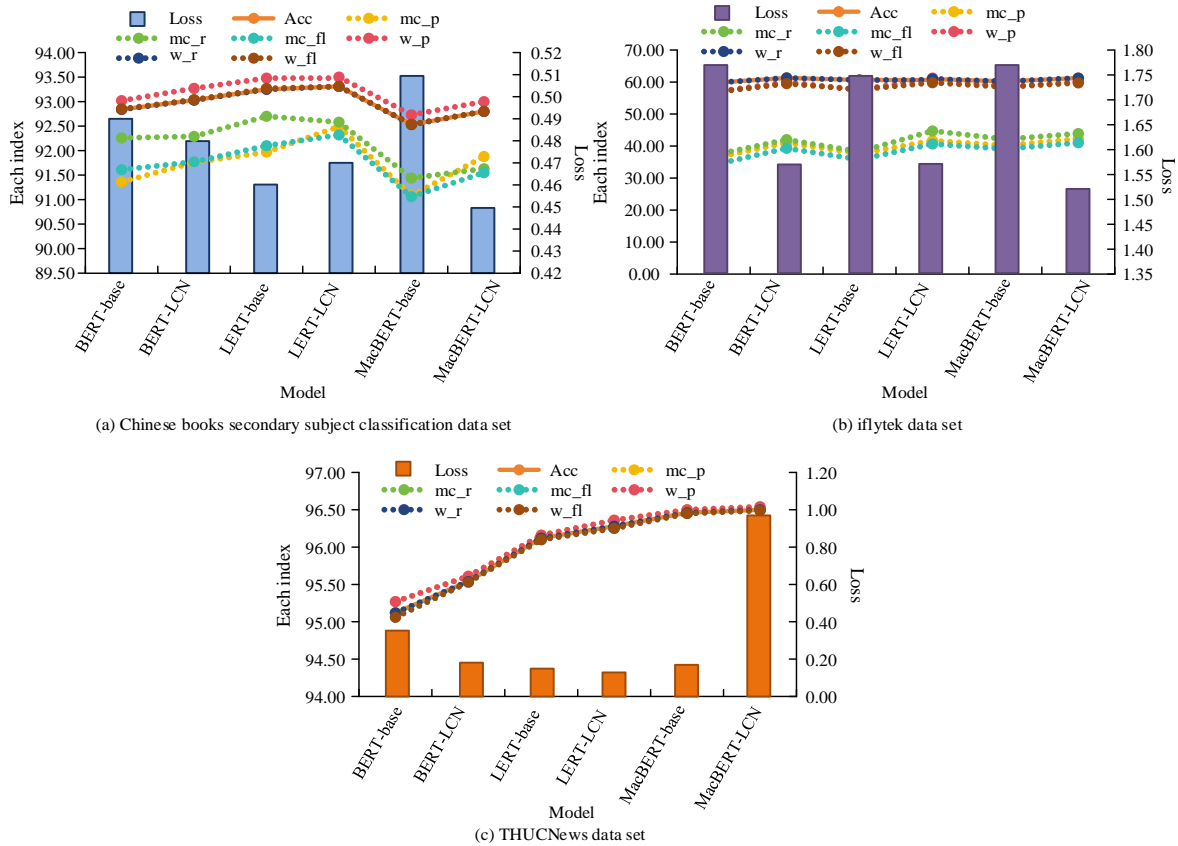

Fig. 12. Experimental results of the PLM-LCN method model on three datasets.

As can be seen from Fig. 12(a), in the BERT-LCN, LERT-LCN and MacBERT-LCN models, the accuracy is increased by 0.18%, 0.07% and 0.28%, the weighted average F1 score is increased by 0.18%, 0.05% and 0.27%, respectively, and the macro-averaged F1 scores are increased compared to the original model. As can be seen from Fig. 12(b), the accuracy of these models increased by 1.55%, 0.32% and 1.04%, with weighted average F1 score enhancements of 2.74%, 2.13% and 1.28%, respectively, and the macro-averaged F1 scores likewise showed significant improvements. As can be seen in Fig. 12(c), these models showed increases in accuracy of 0.43%, 0.17% and 0.04%, and weighted average F1 score boosts of 0.47%, 0.15% and 0.04%, respectively. This difference in effect enhancement may be related to the characteristics of different datasets. In THUCNews and Chinese book subject classification, the baseline model has already achieved a high accuracy of more than 95%, so the room for improvement is relatively small. In contrast, the highest accuracy of the iFlytek baseline model is only 60.64%, so the performance enhancement of the LCN-enhanced model is more significant here.

To further verify the automatic method of book classification based on Network-centric quality management system proposed in this paper, it is compared with existing text classification methods, as shown in Table II.

In Table II, the feature extraction efficiency (96.49±0.74%), flexibility (94.23±0.37%) and accuracy (98.45±0.47%) of this method are superior to other literatures. The corresponding

data in the study [6] were 87.37±0.64%, 88.47±0.68% and 86.46±0.42%. Study [8] were 87.97±0.47%, 87.26±0.59% and 89.68±0.73%. Study [10] were 90.67±0.14%, 90.63±0.62% and 92.67±0.36%. All P values were less than 0.05, indicating that the difference between different methods was statistically significant. In summary, the research method has the best performance in each index.

TABLE II. COMPARATIVE RESULTS OF VARIOUS BOOK CLASSIFICATION METHODS

Method	Feature Extraction Efficiency (%)	Flexibility (%)	Accuracy Rate (%)
Research method	96.49±0.74	94.23±0.37	98.45±0.47
Study [6]	87.37±0.64	88.47±0.68	86.46±0.42
Study [8]	87.97±0.47	87.26±0.59	89.68±0.73
Study [10]	90.67±0.14	90.63±0.62	92.67±0.36
P	<0.05	<0.05	<0.05

V. DISCUSSION

Compared with the feature selection optimization algorithm of Janani and Vijayarani et al. [6], this study can not only obtain a large amount of data quickly, but also ensure the high quality and comprehensiveness of the knowledge graph. In terms of feature fusion technology, the method proposed in this study is more flexible and scalable than the Bayesian algorithm and SVM used by Rezaeian and Novikova et al. [8] in Persian text classification, and is suitable for processing large-scale and

complex data sets. The pre-trained model BERT was also used for optimization in combination with transfer learning. Although Cao and Liu's ReLMKG et al. [10] model combined the pre-trained language model and knowledge graph, this study further integrated RNN and CNN to make the model perform better in the task of Chinese book classification. Overall, this study shows significant advantages in data acquisition, feature extraction and model optimization, especially in the Chinese book classification task showing higher accuracy and efficiency.

VI. CONCLUSION

In the face of the challenge that the Chinese map classification no longer meets the needs of the emerging disciplines, the research proposes to adopt the existing natural language processing technology to solve the problem of classifying Chinese resources in libraries. The research team constructed a Chinese book database, used neural networks and pre-trained models for text analysis, feature extraction and category classification on this dataset, and created an NCQM-based solution to automate the archiving process with the help of an intelligent model. The results show that various benchmark neural network models achieved more than 75% accuracy and average F1 scores on the Chinese book classification dataset, indicating that the dataset is moderately difficult and the model training performs well. Specifically, the single-layer LSTM model outperforms the CNN in text sequence processing, while the TextRCNN does not exceed the performance of the TextRNN. The Fasttext model stands out with its high speed and excellent performance, second only to the TextRNN-Att model with embedded attention mechanism. For models using BERT-LCN, LERT-LCN, and MacBERT-LCN, the results show that they achieved improvements in accuracy and weighted average F1 scores compared to the original models on the Chinese book secondary subject classification, iFlytek, and THUCNews datasets. These enhancements reflect the generalisation ability and feature extraction advantages of the models when dealing with different attribute datasets. In particular, the BERT-LCN model, by combining the CNN and RNN modules, enhances the feature extraction capability and therefore shows significant performance gains on multiple datasets. In addition, there is still room for improvement in the research. In future work, it is planned that the subject classification module will be enhanced to provide diverse model choices and a top ten subject classification display, and the library seat reservation function will be added to improve user experience and convenience.

Abstract—The transportation of fresh agricultural products is not conducted along a sufficiently precise route, resulting in an extended transportation time for vehicles and a consequent deterioration in product freshness. Therefore, the study proposes an agricultural product transportation path optimization model based on an optimized adaptive large neighborhood search algorithm. The Solomon standard test case is used for the experiment, and the algorithm before and after optimization is compared. From the results, the optimized method was effective for the distribution model C201, R201, and CR201 sets after conducting case analysis. The total cost of the R201 transportation set was the lowest, while C101 had the highest total cost. The lowest vehicle cost consumption was R201 at 600, and the highest was C101 at 2220. The C101 algorithm took 145 s to calculate, and R201 took 199 s. All values of CR201 were average, with high fault tolerance. The proposed method was used to address the optimal operator solution. The C201 example took 244 s to calculate 2350 objective function values. The R201 example took 239 s to obtain 657 objective function values. The CR201 example took 233 s to obtain 764 objective function values. This indicates that the designed method has a significant effect on optimizing the distribution path of agricultural products. Compared with the unimproved algorithm, it has more accurate search ability and lower transportation costs. This algorithm provides path optimization ideas for the agricultural product transportation industry.

Keywords—ALNS; agricultural products; path optimization; cold chain transportation; supply chain

I. INTRODUCTION

In a rapidly developing society, the demand for fresh agricultural and related products among urban residents is increasing day by day. In recent years, the e-commerce industry has developed rapidly. Online ordering of fresh agricultural and related products has become one of the main consumption channels that is widely popular among consumers [1]. The distribution task of agricultural products in urban areas is also increasing due to low distribution efficiency, which greatly affects the industrial development. As fresh agricultural and related products themselves have short freshness and shelf life, they are prone to deterioration over time. Once the freshness is too low, they lose their nutritional value and appearance as products for sale. Therefore, how to ensure product freshness during transportation is the main issue that needs to be urgently addressed in the logistics of the entire supply chain. This poses a challenge to the timeliness of logistics transportation and the

cold chain level of transport vehicles [2]. The competition for Fresh Agricultural Products (FAP) to stand out is the entire supply chain. The circulation mode of FAP refers to the transfer mode from the place of origin to the dining table, including various elements involved in the circulation of agricultural products [3]. For the supply chain, it is crucial to increase agricultural product enterprises, production and suppliers of raw materials in the middle and upper reaches, such as vegetables, seedlings and pigs. In addition to being responsible for sowing, picking, breeding, slaughtering and packaging FAP, enterprises must also directly supply raw processed agricultural products to wholesale or retail companies [4, 5]. The supply chain has drawbacks such as high loss, untimely delivery and lack of trust. The reason for this is that certain fresh ingredients that require strict time and storage conditions have increased cold chain transportation pressures and transportation costs.

More and more scholars have noticed that the transformation of agricultural supply chains requires strong technical support. Yu and Rehman proposed an evolutionary game model on the basis of the relationship between agricultural product suppliers and urban residents. This model applied evolutionary game theory to analyze the financing game model. The results indicated that the model could effectively improve the operational capability of agricultural product platforms [6]. Fu et al. introduced contract and trust mechanisms to control the uncertainty. Therefore, a digital system coupling relationship between blockchain and FAP supply chain was proposed. The results indicated that the blockchain-based digital system could help the agricultural supply chain achieve significant industrial transformation [7]. Syofya et al. proposed a value-added approach through transparent methods and supply chain management among commercial actors to address the impact of the Clincy coffee agricultural supply chain on the agricultural economic added value in Chambe Province. The results showed that this method effectively increased the yield of coffee agricultural products [8]. Mukherjee et al. established a decentralized, data-immutable, smart contract supply chain, transparency, and shared database for blockchain technology in complex multi-electronic supply chain. The results indicated that the supply chain provided deep significance for potential practitioners [9]. Luckstead et al. discussed the impact of the pandemic on workers in the food supply chain accepting important job decisions. The study analyzed the attitudes of low-skilled workers towards the processing plant industry during the epidemic. The results showed that gender, current agricultural

workers, and information about COVID-19 and agricultural workers affected respondents' answers [10].

The optimization of supply chain transportation paths cannot be achieved without search algorithms. Prymachenko et al. proposed a method for evaluating multi-modal transportation in transportation enterprises based on the multi-modal transportation route network model. The results indicated that this method could minimize the supply cost [11]. Chang et al. found that there were problems with the route planning of freight buses in urban distribution systems. Therefore, a mixed integer linear programming model was established, and an Adaptive Large Neighborhood Search (ALNS) was developed. The results showed that the correlation of the mathematical model and the model effectiveness was demonstrated through numerical experiments [12]. Hu et al. found that fast online route decisions must be made to fulfill offline retail service commitments. Therefore, a vehicle path optimization method combining an open architecture ALNS algorithm was proposed. The results indicated that this method could achieve offline training of neural network models to generate almost immediate solutions online [13]. Relying on the two levels and multiple centers in the urban logistics joint distribution system, Li et al. analyzed the two-level joint delivery path. An ALNS algorithm was proposed to solve models with multiple deletion and insertion operators. The ALNS algorithm was faster and more effective [14]. Nikzad et al. established a two-stage stochastic mathematical model for asset protection routing under wildfires. This model used the ALNS algorithm to determine routing decisions. The results showed that numerical analysis confirmed the effectiveness [15].

In summary, domestic and foreign researchers have also introduced the ALNS algorithm for the optimization of transportation paths in agricultural supply chains, but few scholars have improved and applied the ALNS algorithm. In response to this issue, a FAP distribution path optimization model is constructed for supply chain decision-making, aiming to improve transportation efficiency. The innovation lies in the ALNS algorithm, which is adapted from the Solomon standard test case for experimental testing. This algorithm fully meets the characteristics of fresh time limit requirements during agricultural product transportation, which benefits to optimize the delivery efficiency of fresh agricultural and sideline product distribution enterprises.

II. METHODS AND MATERIALS

Aiming at optimizing the distribution path of agricultural product supply chain, an improved ALNS is designed. Firstly, the transportation vehicle routing problem is introduced, and the freshness calculation of agricultural products at each stage of transportation is explained. Secondly, the operational framework of the ALSN algorithm and the transportation process and cost of cold chain vehicles are introduced. Finally, an improved ALSN algorithm model framework is proposed.

A. Distribution Cost of Agricultural Product Supply Chain Ground on Improved ALNS Algorithm

The urban transportation stage of the fresh agricultural and sideline product supply chain, which is the transportation stage of delivering goods from the supply location to the consumer's

ordering location [16]. During transportation, agricultural products have the characteristics of high storage difficulty, high distribution cost, freshness requirements, and irreversibility, as well as high timeliness requirements [17]. In accordance with the features of agricultural products, the supply chain distribution path problem is reasonably optimized. Vehicle path refers to the transportation path optimized by the logistics distribution center that meets the delivery requirements under certain dispatching conditions [18]. When planning the vehicle routing problem, it is necessary to cover constraints such as customer needs, location selection of logistics centers, number of transportation vehicles dispatched on different routes, and characteristics of agricultural products. The vehicle routing problem is displayed in Fig. 1.

Fig. 1. Sketch map of vehicle routing problem.

Due to their strict freshness requirements, FAP lose their selling and purchasing value once they exceed the optimal freshness period. However, any fresh or similar product has the freshness loss during transportation, so freshness requirements must be an important constraint in planning and optimizing delivery routes. At present, many transportation enterprises and scholars in related fields have attached great importance to the freshness changes during the transportation of agricultural and sideline products. Various prediction algorithms have been proposed, among which linear decreasing functions can be used to represent the freshness reduction. Combining the decreasing functions, transport vehicles depart at time A , the vehicle arrived at time B , and the freshness at random time $t (A \leq t \leq B)$ is shown in Eq. (1).

$$\theta(t) = 1 - \frac{t - A}{B - A} \quad (1)$$

In Eq. (1), θ signifies the freshness at time t . The maximum freshness time limit T of the product after transportation time $t (0 \leq t \leq T)$ is shown in Eq. (2).

$$\theta(t) = 1 - \frac{t^2}{T^2} \quad (2)$$

In Eq. (2), $1 - \frac{t^2}{T^2}$ represents the freshness factor of a monotonic continuous decreasing function. The freshness changes during the transportation after time t are shown in Eq. (3).

$$\theta(t) = \theta_0 e^{-\mu t} \tag{3}$$

In Eq. (3), θ_0 is the product freshness just picked. μ signifies the decreasing freshness index of FAP. To ensure that agricultural products can exhibit clear changes under the common constraints of time and preservation costs, a three parameter Weil function is used for prediction. The freshness variation of agricultural products constructed by the three parameter Weil function is shown in Eq. (4).

$$\theta(t) = \theta_0^{(\mu - f(r))t} \tag{4}$$

In Eq. (4), μ is the decay rate during transportation calculated by the three parameter Weil function. $f(r)$ represents the cost of preservation investment. FAP is also divided into different categories. To predict the freshness changes of different products, the Arrhenius function is used to construct the freshness changes, as shown in Eq. (5).

$$\theta(t) = \begin{cases} \theta_0 - \mu t & \text{if } \gamma = 0 \\ \theta_0 \cdot \exp(-\mu t) & \text{if } \gamma = 1 \end{cases} \tag{5}$$

In Eq. (5), γ represents the reaction level of FAP. In addition to the inherent freshness characteristics, transportation

efficiency is also affected by the traffic congestion in different regions, the number of residents traveling at different time points, and license plate restrictions. Search models can effectively improve uncertainty factors. ALNS is an algorithm based on large-scale neighborhood search. The solution process of this algorithm is to first calculate the global optimal solution, then move and insert this optimal solution to iteratively calculate and obtain more domain optimal solutions near the optimal solution range [19]. The optimal solution for insertion and removal in this algorithm can represent the planned consumer ordering location in the transportation path. When different transportation routes pass through this location, the nearby better route is searched again and closely associated with the nearest transportation point. The removal and insertion processes of the ALNS algorithm are shown in Fig. 2.

The ALNS algorithm is affected by the weight values of the insertion and removal operators during the iterative calculation process, resulting in the inability to select the optimal path reasonably when there are too many paths to select. Therefore, it is necessary to determine in advance the effectiveness and necessity of the optimal solution calculation for the operators to be removed and inserted, and make adjustments when the optimization conditions are met. The ALNS algorithm must continuously eliminate bad paths and paths with constant distances by adaptively adjusting the adjustable values, which can continuously improve the accuracy of the algorithm's prediction. The ALNS algorithm has been discovered and used by logistics companies for transportation path optimization problems due to its advantages such as wide applicability and large macro search range. The flowchart of the ALNS algorithm is shown in Fig. 3.

Fig. 2. Process diagram of ALNS algorithm's removal and insertion operations.

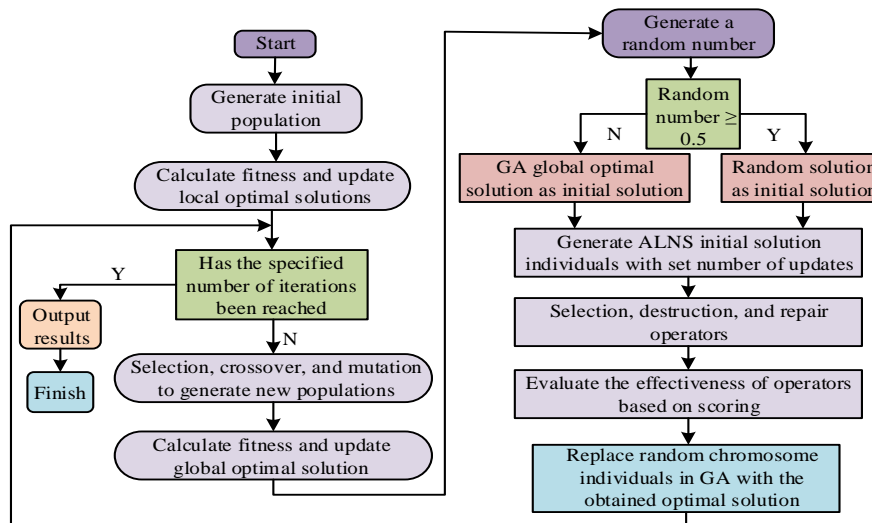

Fig. 3. ALNS algorithm flowchart.

B. Construction of Distribution Route Optimization Model for Agricultural Product Supply Chain Decision Management

The ALNS algorithm optimizes the transportation path, but the transportation mode also has an important impact on the quality of agricultural products. Cold chain transport vehicles can maintain freshness through refrigeration, which is consistent with the principle of refrigeration in refrigerators, ensuring the freshness of agricultural products to the greatest extent possible and reducing the spoilage rate. However, cold chain transportation requires a large amount of energy to cool, resulting in high costs and carbon emissions, which leads to high-cost consumption for logistics enterprises. Therefore, the unit time fuel consumption of the refrigeration unit of the cold chain truck is predicted, as shown in Eq. (6).

$$f_c(g) = R_0 + \frac{R_w - R_0}{Q_{\max}} g \quad (6)$$

In Eq. (6), f_c represents the fuel consumption rate. R_0 is the fuel consumption per unit time when the vehicle is unloaded, and R_w is the fuel consumption at full load. g is the maximum load of the cold chain truck. The fuel consumption of the refrigeration unit generator is displayed in Eq. (7).

$$F(g_{ij}) = \left(R_0 + \frac{R_w - R_0}{Q_{\max}} g_{ij} \right) T_{ijk} \quad (7)$$

In Equation (7), T_{ijk} represents the total time traveled. (i, j) represents the path traveled. $F(g_{ij})$ signifies the fuel consumption of the refrigeration unit generator in the cold chain vehicle. In light of the considerable variation in the loads of different cold chain vehicles and the marked differences in the fuel consumption of refrigeration units at different times of year,

the calculation method of fuel consumption is subjected to rigorous and comprehensive analysis. Numbers 1 to 4 represent prefabricated cold, in delivery, loading and unloading, and returning after completion. Cold chain truck transportation is shown in Fig. 4.

Cold chain vehicles need to be placed in the logistics center's cold storage for full refrigeration before the delivery task departs. It can effectively avoid the aggravation of agricultural product spoilage caused by filling effects [20]. The research assumes that the time required for a single cold chain vehicle to enter the warehouse for refrigeration is T_p . Moreover, the fuel consumption calculation of the unloaded cold chain vehicle refrigeration unit at this time is shown in Eq. (8).

$$F_1 = \sum_{k=1}^K R_0 Z_k T_p \quad (8)$$

In Eq. (8), F_1 is the fuel consumption of the refrigeration unit. After the final stage of service, the delivery unit needs to be shut down to save energy. At this time, the cold chain truck is in an unloaded state. The fuel consumption calculation for the journey back to the logistics center is shown in Eq. (9).

$$F_2 = \sum_{i, j \in N, i \neq j} X_{ijk} f_c(g_{ij}) (T_{ijk} - T_{j0k}) \quad (9)$$

In Eq. (9), F_2 represents the fuel consumption of the cold chain vehicle when the refrigeration unit is turned off and unloaded. Therefore, it can be inferred that the economic cost of refrigeration fuel is calculated, as shown in Eq. (10).

$$C_{21} = P_2 (F_1 + F_2) \quad (10)$$

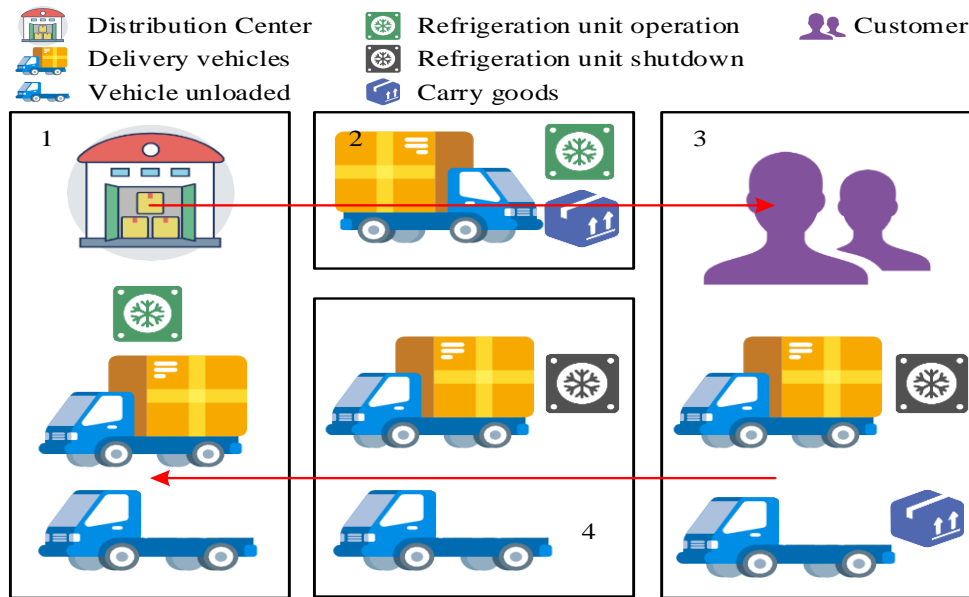

Fig. 4. Cold chain vehicle delivery process diagram.

In Eq. (10), C_{21} represents the economic cost of refrigeration fuel. The fuel consumption and carbon dioxide emissions of delivery vehicles during the delivery process are calculated, as shown in Eq. (11).

$$fuel = \chi \left(\frac{FeNeVe}{v} \frac{d}{v} + \eta\beta d(v)^2 + \eta\alpha d(G_d + G_i) \right) \quad (11)$$

In Eq. (11), $fuel$ represents the fuel consumption of the delivery vehicle. v represents the return speed. d represents the distance between the location of the last delivery task and the logistics center. Fe represents the friction index. Ne represents the engine speed of the cold chain vehicle. Ve represents the carbon emissions of cold chain vehicles. G_d represents the weight of the cold chain vehicle during the return journey. G_i represents the cold chain vehicle load. The research takes into account the distribution costs generated during the distribution process. The final constructed agricultural product distribution path optimization model is shown in Eq. (12).

$$\begin{aligned} \min Z = & c_p \sum_{k \in K} \sum_{j \in V'} x_{0jk} + \\ & c_t \left(\sum_{i \in V'} a_i + \sum_{i \in V'} w_i + \sum_{k \in K} \sum_{(i,j) \in A} x_{ijk} t_{ij} \right) \\ & + c_f \sum_{k \in K} \sum_{(i,j) \in A} x_{ijk} f_{ij} + c_e \sum_{k \in K} \sum_{(i,j) \in A} x_{ijk} e_{ij} \end{aligned} \quad (12)$$

In Eq. (12), c_p represents the cost of dispatching. c_t represents the cost of transportation labor. a_i signifies the time when the delivery vehicle arrives at customer i . w_i signifies the waiting time before the vehicle starts transportation. x_{ijk} represents the transportation vehicle k traveling from node i to customer j . c_f represents the fuel consumption cost. c_e represents the carbon emissions cost. To ensure that the freshness of agricultural products received by consumers exceeds the expected requirements, the calculation is shown in Eq. (13).

$$\theta_i \geq \theta_r, \quad \forall i \in V' \quad (13)$$

In Eq. (13), θ_i represents that the agricultural products are within the freshness expected by consumer i . θ_r represents the minimum freshness that consumers can accept. The waiting time for the delivery vehicle of agricultural products to consumers is shown in Eq. (14).

$$w_i = b_i - a_i, \quad \forall i \in V' \quad (14)$$

In Eq. (14), w_i represents the waiting time before the delivery vehicle starts transportation. b_i represents the time

when consumer i started being served. The time for the consumer to confirm receipt, the delivery vehicle to leave the delivery point, and proceed to the next service point is displayed in Eq. (15).

$$\tau_i = b_i + s_i, \quad \forall i \in V' \quad (15)$$

In Eq. (15), τ_i signifies the time when the delivery vehicle leaves after completing the task. s_i represents the time when consumers accept agricultural products. The calculation results of the model constructed represent the set of distribution paths for cold chain vehicles. Meanwhile, the study enhances the ALNS algorithm by incorporating insertion and removal operators, specifically the ordering consumer. The improved ALNS algorithm is shown in Fig. 5.

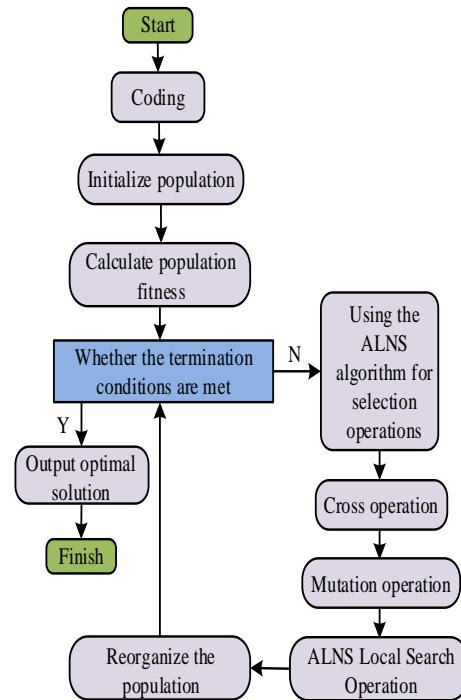

Fig. 5. Optimized ALNS algorithm.

The distribution of agricultural products exhibits regional characteristics, with a greater concentration observed in urban residential areas. The service distance for consumers in close proximity to one another is approximately equivalent [21,22]. The transportation path needs to meet various delivery conditions of the waybill, ensuring smooth driving, less congested road sections, and less freshness loss. Therefore, based on the density of distribution tasks, the supply chain hub is established. The distribution hub combined with the distribution path optimized by ALNS can ensure the freshness of agricultural products reaching consumers. Cold chain vehicles can also minimize consumption. The red dots represent the points at which consumers are required to complete delivery tasks when placing orders. The black five-pointed stars represent the points at which supply chain hubs are constructed. The overview of distribution tasks and hub construction is shown in Fig. 6.

Fig. 6. Overview of distribution tasks and hub construction.

III. RESULTS

To display the effectiveness of the improved ALSN in optimizing the transportation path of agricultural products, a set of case studies were conducted. Firstly, a standard test case was constructed to compare the driving paths of cold chain vehicles. Next, C201, R201, and CR201 were used to conduct case studies to further validate the freshness and total cost of agricultural products. Finally, the path results before and after ALSN algorithm optimization were compared.

A. Effectiveness of Distribution Route Optimization in Agricultural Product Supply Chain Decision Management

Due to the high demand for freshness in agricultural products, a cold chain distribution route model for agricultural products was constructed. Relevant experimental data required for the model was supplemented. The Solomon standard test case was used to conduct numerical experiments on the adapted ALNS algorithm. The experiment adopted Windows 10, 64 bit operating system, and the processor uses Intel® Xeon® Platinum 8124 M, with 64 GB memory. The experiment was conducted using Solomon standard test cases adapted and downloaded from the website neo.lcc.uma.es/vrp/solution-methods/. An example of a set of 100 consumers was analyzed. Class C refers to densely distributed consumption points, Class R refers to dispersed consumption points, and CR refers to consumption points with cross distribution. The experiment mainly focused on C201, R201 and CR201 sets for example analysis. Therefore, the distribution path scheme of the six cold chain vehicles presents two states, as shown in Fig. 7.

From Fig. 7(a), before the optimization of the distribution path, the path was relatively chaotic and cumbersome. Six cold chain vehicles crossed the central hub significantly, resulting in high transportation costs and low efficiency. Fig. 7(b) shows the optimized distribution route. The transportation of each cold chain truck was in an orderly manner. Among them, vehicles 3 and 4 had a wider service range due to their larger capacity, while vehicle 5 had a narrower time window constraint and presented a narrow and short driving path due to its urgent service demand at consumer points. The cost of six vehicles and the freshness delivered to consumers are displayed in Table I.

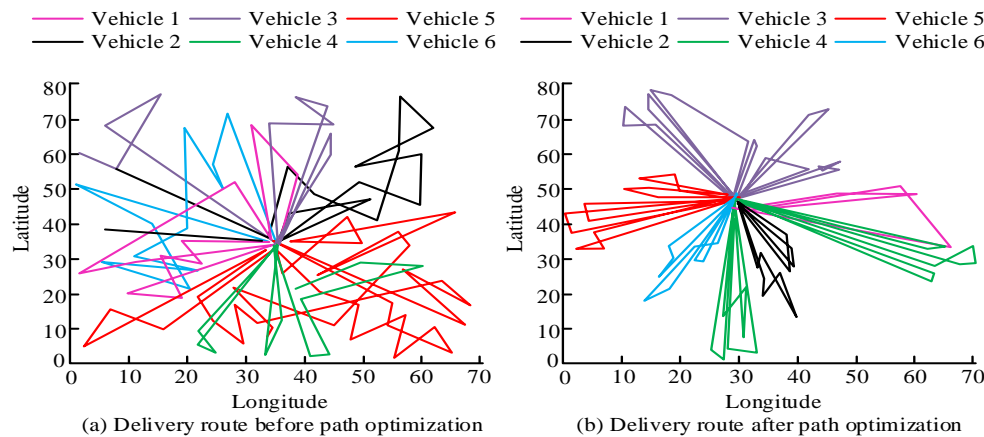

Fig. 7. Delivery path plan for cold chain vehicles.

TABLE I. THE CORRELATION EVALUATION COEFFICIENTS OF THE EXPERIMENT AND THE CALCULATED RESULTS

Example number	Total cost	Vehicle cost	Labor costs	Fuel cost	Low carbon cost	Average freshness	Medium speed driving ratio	Algorithm running time
CR101	1457	1540	23	35	8	90.96%	19.26%	153 s
CR201	764	700	26	31	7	82.86%	21.17%	195 s
R101	1676	1600	25	33	8	92.55%	22.19%	149 s
R201	657	600	24	27	6	80.81%	20.72%	199 s
C101	2533	2220	106	40	9	80.86%	21.66%	145 s
C201	2350	2200	103	39	8	81.17%	19.31%	194 s

From Table I, in order to evaluate more objective and accurate path optimization examples, the agricultural products delivered to consumers were all delivered with average freshness and moderate transportation speed. The lowest total cost for R201 transport set was 657. The highest total cost of C101 was 2533, with the lowest vehicle cost consumption of R201 at 600 and the highest consumption of C101 at 2220. The minimum running time of the algorithm was C101, taking 145 s, and the maximum time was R201, with a total time of 199 s. All values of CR201 were average values, and the optimized delivery path was within this average value, with high fault tolerance, which could meet consumers' requirements for freshness of agricultural products, and the cost was also within a reasonable range. The ALNS algorithm used the following parameters when calculating the substitution example: maximum number of customers removed 15 (N), weight response coefficient 0.9 (ρ), weight score σ_1 (50), weight score σ_2 (20), weight score σ_3 (5), weight score σ_4 (0), and initial annealing temperature 5000 (T_e). The numerical variation of the global optimal solution with specific values is shown in Fig. 8.

In Fig. 8, C201 showed a downward trend before 200 iterations, dropping from 3500 to around 2500. After 200 iterations, the value remained constant at 2400, with small fluctuations. The overall trend of R201 values was roughly consistent with C201, with a decrease from the highest value of 2300 before 250 iterations to 1600. After 250 iterations, the values fluctuated around 1600. CR201 showed significant fluctuations before 450 iterations, with values dropping from 1200 to 700, but the overall change was flat. This indicated that

as the iteration increases, the optimal solution converged, and the weights of the three sets of examples decreased. Operators were quickly stacked in the early stage, which maximized the probability of obtaining the global optimal solution.

B. Analysis of Factors Influencing Delivery Routes based on Improved ALNS Algorithm

In order to further analyze the ALNS algorithm, it was necessary to compare the weights of the insertion and removal operators in the actual optimization effects during solving. The study mainly analyzed the Worst Removal (WOR), Wait-time Related Removal operator (WRR), Regret Insertion operator (REI). The calculation example was validated to obtain the updated weight values and their adaptability as the number of iterations increased. The iteration is shown in Fig. 9.

Fig. 8. Objective function iteration diagram.

Fig. 9. Operator weights and usage iterations graph.

As shown in Fig. 9(a), the WOR operator had a higher iteration weight in example C201, which was much higher than WRR and REI. It had significant changes in the overall curve, with the highest weight value of 33 and the lowest weight value of 11. The WRR operator was in the middle, with a minimum weight value of 6 and a maximum weight value of 24. The weight values of the REI operator were the highest at 17 and the lowest at 7. In Fig. 9(b), the WRR operator had the highest weight of 35 and the lowest weight of 7. The overall curve position and most of the values were higher than the other two operators, which indicated that WRR had the highest proportion of weights. The WOR operator was the median curve, with a maximum weight of 34 and a minimum weight of 8. The maximum weight value of the REI operator curve was 19, and the minimum was 7. In Fig. 9(c), in the CR201 example, the weight values of the WOR operator were relatively stable in the later stage, with a maximum of 26 and a minimum of 9. The overall fluctuation of the WRR operator curve was uniform, with a maximum of 19 and a minimum of 7. The weight value curve of the REI operator had the smallest variation, with a

maximum value of 17 and a minimum value of 6. This demonstrated that the improved algorithm yielded more accurate results. The running results before and after improvement is displayed in Fig. 10.

In Fig. 10, the purple color represented the unimproved ALNS algorithm. Among them, C201 took 194 s to calculate 2495 objective function values, R201 took 199 s to calculate 699 objective function values, and CR201 took 195 s to calculate 768 results. The green color represented the improved ALNS algorithm. Among them, C201 took 244 s to calculate 2350 objective function values, and R201 took 239 s to calculate 657 objective function values. The CR201 example took 233 s to attain 764 objective function values. This indicated that the improved ALNS algorithm had higher efficiency and less time consumption in the same number of iterations. The decay rate also affected the delivery quality of agricultural products. Based on a decay rate of 0.01, the study incorporated the rates of each stage of agricultural products into the improved ALNS algorithm for optimal solution calculation, as shown in Fig. 11.

Fig. 10. Comparison of running results before and after algorithm improvement.

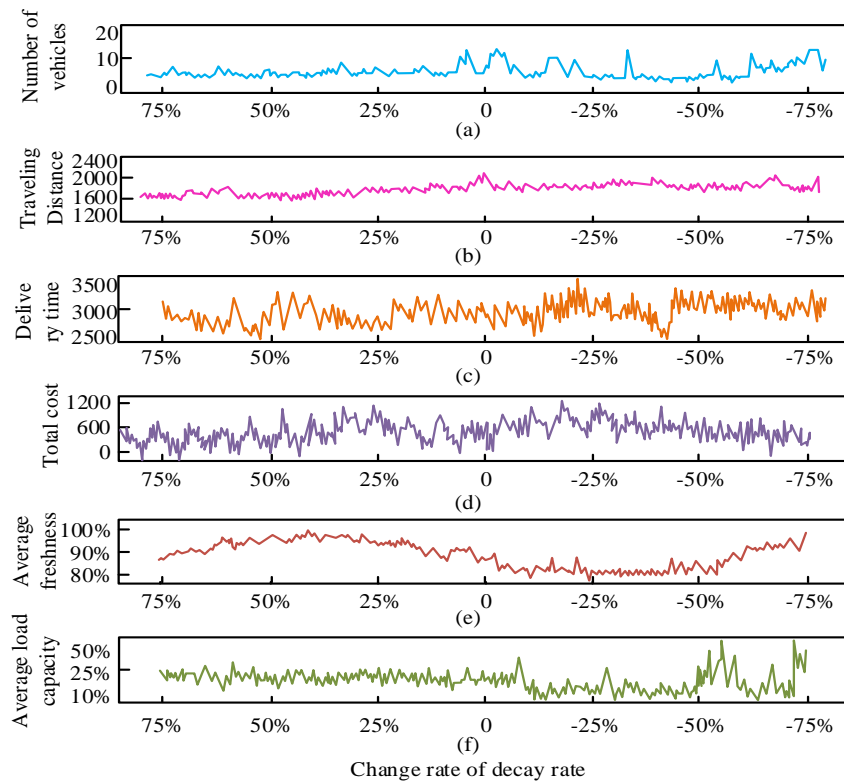

Fig. 11. Analysis of the calculation results of decay rate.

Fig. 11(a) shows the number of transportation vehicles for agricultural products. At a decay rate of 75%, the maximum number of transport vehicles reached 11. In Fig. 11(b), the driving distance was the lowest at a speed of -75%, only 1510 km. In Fig. 11(c), the delivery time was the highest at a 25% decay rate, reaching 3043 minutes, and the lowest at a 50% rate, reaching 2478 minutes. The total cost in Fig. 11(d) was directly proportional to the change in decay rate. In Fig. 11(e), when the decay rate was -75%, the freshness was as high as 91.89%. When the rate was 25%, the freshness remained the lowest at 81.55%. In Fig. 11(f), when the decay rate was -75%, the freshness was as high as 91.89%. When the rate was 25%, the freshness remained the lowest at 81.55%. From this, in practical application, the optimized path for delivering agricultural products was faster and more efficient, with the lowest cost and the best freshness.

IV. DISCUSSION

As the demand for fresh produce delivery increases, consumers have demands for delivery times and product freshness. Therefore, the study proposes an improved ALNS algorithm for optimizing the cold chain distribution path of agricultural products, taking into account product characteristics comprehensively. The results showed that after analyzing the optimized distribution models C201, R201, and CR201, the total cost of the R201 transportation set was the lowest at 657 and the highest at 2533. The lowest vehicle cost consumption was 600 for R201 and 2220 for C101. The minimum runtime of the algorithm was C101, taking 145 s. Moreover, the maximum runtime was R201, with a total runtime of 199 s. All values of CR201 were average, with high fault tolerance. The improved ALNS algorithm was used to solve the operator optimal solution, and the C201 case took 244 s to calculate 2350 objective function values. The R201 example took 239 s to obtain 657 objective function values. The CR201 example took 233 s to obtain 764 objective function values. The study optimized the delivery path by combining the ALNS algorithm to ensure that the average freshness of agricultural products was above 80%. The lowest loss cost was achieved when the spoilage rate was between -25% and -75%. The higher the decay rate, the more cold chain vehicles were used, and the lower the decay rate, the shorter the driving distance. When the delivery time was at a decay rate of 25%, it took the most time, reaching 3043 minutes. Moreover, the lowest consumption was at a rate of 50%, 2478 minutes. The improved ALNS algorithm proposed in the study has significant advantages in optimizing the cold chain distribution path of agricultural products and can provide a reference for path optimization in the agricultural product distribution industry. Nevertheless, research is predominantly grounded in historical empirical data, which limits its practical applicability. In the future, there is the potential for greater use of real-time data in research.

V. CONCLUSION

The research proposes an improved ALNS algorithm for optimizing the cold chain distribution path of agricultural products. By combining the ALNS algorithm to optimize the distribution path, the average freshness of agricultural products was ensured to be above 80%, and the lowest loss cost was achieved when the decay rate was between -25% and -75%. Ni

C et al. also obtained similar data for the verification calculation of the freshness of cold chain vehicles, which proved that the higher the decay rate, the more cold chain vehicles were used, the lower the decay rate, and the shorter the driving distance [23]. When the decay rate was -75%, the freshness reached 91.89%. Moreover, when the rate was 25%, the freshness remained the lowest at 81.55%. Wofuru Nyenke O et al. also obtained similar data on freshness preservation under different decay rates, proving the effectiveness of the research experiment [24]. When the delivery time was at a decay rate of 25%, it took the most time, reaching 3043 minutes. Moreover, the lowest consumption was at a rate of 50%, 2478 minutes. Bao H et al. also obtained similar data in their experiment on the effect of cold chain truck delivery time on the spoilage rate of agricultural products [25]. This indicates that the improved ALNS algorithm proposed in the study has significant advantages in optimizing the cold chain distribution path of agricultural products and can provide a reference for path optimization in the agricultural product distribution industry.

Harnessing Technology to Achieve the Highest Quality in the Academic Program of University Studies

The Quality Based on ABET and NCAAA Accreditations

Rania Aboalela

Information Systems Department, King Abdulaziz University, Jeddah, Saudi Arabia

Abstract—This research aims to utilize information technology to improve education quality, particularly in higher education. A key contribution of this research is the application of generative artificial intelligence, specifically ChatGPT, to validate test questions that meet both international (ABET) and local (NCAAA) academic accreditation standards. The study was conducted within the Information Systems Department's bachelor's program at King Abdulaziz University in the Kingdom of Saudi Arabia, focusing on a website development course. The custom ChatGPT application, named Question Checker, was developed to validate questions generated by instructors. These validation criteria were aligned with the accreditation requirements for technology and computer science programs, ensuring compliance with both ABET and NCAAA standards. The application was tested by validating nine questions related to Student Outcomes, demonstrating its effectiveness in supporting the educational objectives of the program.

Keywords—ChatGPT; academic accreditations; technology programs; computer science; Kingdom of Saudi Arabia; website development; NCAAA; ABET

I. INTRODUCTION

ChatGPT is a Generative Pre-trained Transformer (GPT) language model designed to generate text in response to natural language inputs. It received widespread media coverage following the launch of a free preview by OpenAI in December 2022 [1][2]. The goal of ChatGPT is to mimic human communication not only in language translation systems but also in other applications such as chatbots and virtual assistants. ChatGPT employs highly effective machine learning techniques and has been trained on extensive textual datasets, creating a robust intelligence that enables it to provide nearly flawless responses to user input. It represents a significant advancement capable of revolutionizing the way humans interact with technology, fostering more conversational and intuitive communication. ChatGPT is applied in various domains, including customer service chatbots, language translation tools, and virtual assistants. Research into its potential applications in education aims to enhance student learning and engagement [3].

In this research, we propose a cutting-edge solution to assist faculty in improving the quality of the questions they generate by incorporating ChatGPT into the question-generation process. Additionally, this study focuses on validating the correctness of questions generated by instructors. This modern method allows

teachers to easily request questions relevant to specific academic units while ensuring compliance with rigorous accreditation criteria. It benefits the education system by enabling the creation of questions adaptable to various credits and accreditations, thereby increasing productivity. Our intention is to use Bloom's Taxonomy as a roadmap to methodically construct a robust structure aligned with NCAAA [4] and ABET standards [5]. Establishing the link between Bloom's Taxonomy and the curriculum has received considerable attention and contributes positively to the creation of high-quality questions that assess student understanding [6][7][8].

This study utilized Bloom's Taxonomy to align with various academic accreditations. Subsequently, a novel approach employing ChatGPT was devised to generate questions based on shared criteria. The mapping established correlations between the requirements and contexts of diverse academic accreditations for evaluating students' knowledge through questions. This mapping, which uses Bloom's Taxonomy verbs to gauge different knowledge levels, facilitated the selection of appropriate verbs for questions based on accreditation needs. The integration of this technology streamlines question development, ensuring accurate and swift alignment with academic accreditations, thereby saving instructors' time and aiding examiners in certifying program eligibility. The study also explored faculty members' readiness to adopt this technology for evaluating their questions in terms of compliance with ABET outcomes and NCAAA three-level domain zones. A questionnaire administered to faculty members revealed that 100% of respondents endorsed the technology's role in assisting question development, while 11% refused to accept its role in correcting question composition.

A. The Research Objective

The research aims to leverage generative artificial intelligence (AI), particularly ChatGPT, to improve the quality of test questions in an academic setting, aligning with international ABET and local NCAAA accreditations.

B. Research Questions

Is there a method to use generative artificial intelligence to correct instructors' questions to a high-quality level??

Answer:

Yes, by utilizing customized ChatGPT.

C. Methodology

To This study aims to develop and assess the effectiveness of a customized ChatGPT application designed to enhance the quality of questions in educational assessments. The focus is on ensuring that these questions meet the standards required by international and national accreditation bodies, specifically ABET (Accreditation Board for Engineering and Technology) and NCAAA (National Commission for Academic Accreditation & Assessment).

1) *Selection of course and program:* The study was conducted within the Information Systems bachelor's degree program at King Abdulaziz University, a leading institution in the Kingdom of Saudi Arabia. This program is globally recognized with ABET accreditation and is in the process of obtaining national certification from NCAAA. For this study, a course on Web Design was selected as the testing ground due to its relevance to both computing and information systems education.

2) *Development of the ChatGPT application:* To align the questions with accreditation standards, a customized ChatGPT model was developed. The model was tailored to generate and evaluate questions based on the criteria set by ABET and NCAAA. The customization process involved fine-tuning the ChatGPT application to understand and apply the specific requirements of both accreditation bodies.

3) *Criteria for question evaluation:* The evaluation criteria were derived from the Student Outcomes (SOs) defined by ABET and the domains outlined by NCAAA. The focus was on ensuring that the questions generated by instructors are compatible with these criteria, promoting the development of competencies that are essential for program accreditation.

4) *Application of bloom's taxonomy:* To further enhance the quality of the questions, Bloom's Taxonomy was employed as a framework. Bloom's Taxonomy classifies educational learning objectives into levels of complexity and specificity. By mapping the accreditation criteria of ABET and NCAAA onto Bloom's Taxonomy, the study aimed to establish clear links between these criteria and the cognitive levels required by the taxonomy. This approach ensured that the questions not only met accreditation standards but also targeted appropriate levels of cognitive learning.

5) *Testing and validation:* The customized ChatGPT application was tested on the selected Web Design course. The questions generated were evaluated to ensure they met the dual requirements of ABET and NCAAA accreditation. The validation process involved a detailed comparison of the questions against the established criteria, with a particular focus on the alignment with Bloom's Taxonomy.

6) *Data collection and analysis:* The data collected from the application testing was analyzed to assess the effectiveness of the ChatGPT model in generating questions that satisfy both accreditation standards. The analysis also explored the extent to which the use of Bloom's Taxonomy contributed to the improvement of question quality. The study utilizes the links between the two accreditation criteria to provide material

helping ChatGPT evaluate instructors' questions in terms of compatibility with ABET's Student Outcomes (SOs) and the domains outlined by NCAAA [27].

The remainder of this paper is organized as follows:

Section II discusses related works; Section III illustrates the accreditation NCAAA & ABET; Section IV illustrate the Bloom Taxonomy. Section V covers the six students' outcomes of information Systems bachelor Program. Section VI illustrates the mapping Bloom's Taxonomy with NCAAA and ABET. Section VII discusses the design of the proposed custom ChatGPT. Section VIII covers the test of the proposed custom ChatGPT. Section IX covers a questionnaire to assess the acceptance of academic teachers regarding the use of artificial intelligence (AI) and the efficiency of the proposed application. Sections X and XI present the discussion, conclusions and future work, respectively.

II. LITERATURE REVIEW

A. GPT Technology

Number GPT (Generative Pre-trained Transformer) technology is a kind of AI language model created by OpenAI. The main objective of this model is to generate syntactically correct, human-like prose by predicting the next word in a sentence based on contextual information provided by previous words. GPT utilizes deep neural networks to process extensive text data and learn text patterns, enabling the system to generalize contextual and linguistic phrases. As a result, GPT-3, one of the latest versions of GPT, boasts over 175 billion parameters and was trained on a vast volume of internet text data, making it one of the most powerful natural language models available today [9].

B. GPT Technology in Education

There are several ways in which the GPT language model can be used in education [10]:

- GPT technology can be utilized to develop chatbots and virtual language coaches that serve as practice tools for students as they focus on their language skills.
- GPT can serve as a tool for teachers to assist students in improving the quality of their written work.
- GPT can be exploited for grading essays and other types of written assignments without human intervention, saving time and providing students with instant assessment of their progress.
- GPT technology can be applied for students' personalization of interactive learning activities. By analyzing a student's learning processes and preferences, GPT can provide recommendations concerning the type of learning materials that best suit the user, such as articles, videos, and textbooks.

C. ChatGPT

In recent years, Natural Language Processing (NLP) has undergone tremendous development. Nevertheless, the emergence of ChatGPT (Chat Generative Pre-Trained Transformer) has reignited conversations and optimism

surrounding the technology. Developed by OpenAI, ChatGPT was introduced to the public in November 2022 [11]. It quickly gained popularity, reaching over 1 million users in just five days, a stark contrast to Facebook's 300 days, Twitter's 720 days, and Instagram's 75 days [12].

ChatGPT is a large language model with extraordinary comprehension and generation capabilities, closely resembling human speech. Its unparalleled ability to answer questions, engage in conversations, and provide logical and relevant responses within the context of the conversation marks a revolutionary advancement in the development of conversational AI. The diverse applications of ChatGPT and its capacity to enhance across various sectors has brought about new discussions about this cutting-edge AI technology [13]. However, ChatGPT is merely a complicated chatbot at the early stage of Long Short-Term Memory (LSTM) research [14] and cannot be compared to developments in language processing and cognitive sciences. Nevertheless, it is widely used in many industries, including customer service assistance, e-commerce, healthcare, and education. Machine learning, a subfield of AI, enables computers to automatically learn from data, surpassing human-coded instructions. Deep learning has become a powerful predictive tool due to improvements in hardware processing power, data availability, and algorithmic innovations [15], [16], [17], [18]. Furthermore, ChatGPT needs to be fine-tuned for exam purposes as well [19]. ChatGPT is a large language model with remarkable comprehension and speech production capacities akin to those of humans. Its outstanding performance in comprehending questions, dialogue processing, and delivering contextual and coherent responses represents a significant achievement in conversational AI [14]. The first GPT model, GPT-1, was released in 2018, then a successor called GPT-2 in 2019, and later the GPT-3 model in 2020. The model's size, along with the training data and language test scores, have significantly improved since its first version. On November 30, 2022, Open AI released a free behind-the-scenes look at ChatGPT, their AI-powered chatbot expected to be worth \$29 billion [20]. A chatbot is a software system that employs artificial intelligence techniques to converse with humans, simulating human communication. Users pose questions, and the system responds promptly. Within five days of its release, ChatGPT had garnered 1 million users [21].

D. ChatGPT for Exam Correction

The use of ChatGPT for generating and correcting exam questions was studied by Aboalela et al. [22]. The study found that faculty members accepted the use of ChatGPT for both producing and correcting questions. Also, the study by Weng et al. [23] evaluated ChatGPT for Taiwan's Family Medicine Board exams, which included English and Chinese. Despite its popularity and extensive database, ChatGPT's accuracy was found to be 41.6%, indicating limited performance in the medical domain. Notably, it performed better on negative-phrases, mutually exclusive, and case scenario questions. Challenges such as the exam's difficulty level and the shortage of traditional Chinese language resources probably contributed to its lower accuracy. While ChatGPT may be useful for learning and exam preparation, improvements are needed for specialized exams.

E. Benefit of ChatGPT in Education

According to Cribben and Zeinali [24] the benefits of ChatGPT in education are as follows: ChatGPT can generate course materials for professors and produce assignments, test questions, and solutions across different courses. Professors can also utilize ChatGPT to instruct a chatbot to answer students' inquiries over the internet when they are not available during office hours. As an illustration, students have the option to submit their queries to an internet-based discussion platform like eClass or Blackboard, utilizing ChatGPT.

In the same context [25] ChatGPT is an educational accessibility website that assists people with disabilities and non-English speakers by providing spoken responses, topic summarization, and translation services. It enables homework with tailored explanations and examples and builds academic skills. It supports teachers in lesson planning, test generation, grading, analysis, and resource planning in higher education. In addition, ChatGPT personalizes learning adapting to individual styles and performance and assists in exam preparation by reviewing notes, formulating answers, and identifying strengths and weaknesses.

F. Challenges of Using ChatGPT in Higher Education

The obstacles associated with using ChatGPT in higher education, as identified by EU Business School [26], are as follows: ChatGPT's extensive consumption of internet material may lead to unintentional acquisition of preconceived notions and prejudices, potentially resulting in discrimination against various demographic groups. Both students and teachers should acknowledge its inherent subjectivity of it, thoroughly scrutinizing its output for any prejudice.

III. NCAAA AND THE ABET

Discussed first is the approach that would be most effective in developing a common application to both organizations. These two accrediting authorities have different purposes. The process of NCAAA accreditation process focuses on specialized scientific institutions or academic programs. Certain minimum standards and quality requirements must be met by an institution or program to obtain accreditation from the NCAAA. The reputation of an academic institution or its program depends on whether it is accredited or not, as it provides a global reference point for students. Academic excellence, reflected in both local and global reputation, attracts high caliber researchers and practitioners seeking for assurance of quality education. Accreditation aims to ensure that the outputs of educational institutions and academic programs meet societal needs; it also seeks to foster cooperation between the education system and the professional labor market [28]. This fosters trust and belief in academic programs among the community and helps them attain a stable financial standing.

The NCAAA grants accreditation to the university, as well as to each individual program offered by the institution. The NCAAA accredits both the university as a whole and each individual program it offers. On the other hand, ABET serves as a quality assurance mechanism specifically for programs in applied and natural sciences, computer science, engineering, and engineering technology [5] ABET accreditation is globally recognized for ensuring that college or university programs meet

the quality standards of the profession they prepare graduates for. One distinction between ABET and the NCAAA lies in their accreditation focus: while the NCAAA accredits entire universities, ABET accredits specific programs [29]. Another difference is that ABET prioritizes the attainment of student learning objectives over the instruction of methodologies and course standards. However, both agencies evaluate educational procedures within academic programs and investigate similar topics related to quality assurance, including program objectives, course learning outcomes, and individual student learning outcomes. Program Learning Outcomes (PLOs) are measurable statements that describe the knowledge or skills students acquire upon completing an academic program, while Course Learning Outcomes (CLOs) are specific statements that define the knowledge, skills, and attitudes learners will demonstrate upon completing a particular course. Assessing students' learning outcomes involves formulating questions using action verbs to measure their proficiency and understanding of the subject matter. Subsequently, students' comprehension is evaluated based on the grades they achieve for questions related to specific areas of knowledge or ability. Saudi institutions have the potential to obtain both national and international accreditation for academic programs, allowing them to pursue multiple accreditation approaches. Several research studies have suggested a potential connection between ABET and the NCAAA in the Kingdom of Saudi Arabia, with published evidence supporting these potential outcomes [30] [31].

IV. BLOOM'S TAXONOMY

The importance of Bloom's Taxonomy in assessing knowledge [32] [33] [34] lies in its capacity to correlate specific verbs with the educational outcomes required for both ABET and NCAAA accreditation. This facilitates the use of standardized verbs in questions that meet the criteria of both accrediting bodies. Thus, when employing commonly used question verbs to evaluate the same educational outcomes, alignment with both ABET and NCAAA standards is ensured. The subsequent task involves categorizing the verbs used according to the areas required for NCAAA accreditation measurement. Bloom's Taxonomy functions to classify verbs assessing skills and comprehension into six distinct categories, as depicted in Fig. 1. These six domains of Bloom's Taxonomy have been further delineated to encompass areas specific to NCAAA accreditation. The top five domains, which are the most intricate, include the NCAAA domain of skills, covering processes such as application, assessment, evaluation, and production. The lowest and most intricate domain, understanding, remains a specialized area within the NCAAA domain. Verbs were categorized according to Bloom's Taxonomy, as illustrated in the figure depicting the mapping. Once the correlation between taxonomy verbs and NCAAA measure verbs that evaluate skills is established, they can be identified based on either the prescribed verbs for ABET certification or the NCAAA accreditation criteria.

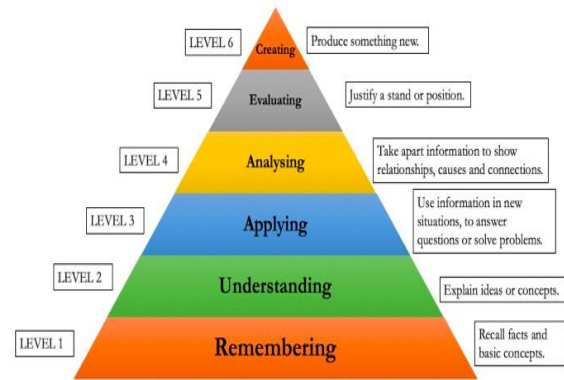

Fig. 1. The Bloom taxonomy verbs [40].

V. ABET SIX STUDENTS' OUTCOMES OF INFORMATION SYSTEM BACHELOR PROGRAM

The mapping of Bloom's Taxonomy to ABET is as follows:

SO 1 corresponds to the third-level verb in Bloom's Taxonomy:

Design, implement, and evaluate a computing-based solution to meet a given set of computing requirements in the context of the program's discipline.

SO 2 corresponds to levels 6, 5 and 4 based on the SO subpoint and the action verb in Bloom's Taxonomy: Communicate effectively in a variety of professional contexts.

SO 3 corresponds to special verb in Bloom's Taxonomy based on the target of the asked question and to the value domain of NCAAA:

Recognize professional responsibilities and make informed judgments in computing practice based on legal and ethical principles.

SO 4 corresponds to a special verb in Bloom's Taxonomy based on the target of the asked question and to the value domain verb in NCAAA:

Function effectively as a member or leader of a team engaged in activities appropriate to the program's discipline.

SO 5 corresponds to a special verb in Bloom's Taxonomy based on the target of the asked question and to the value domain verb in NCAAA (Affective Learning):

Support the delivery, use, and management of information systems within an information systems environment.

SO 6 corresponds to the lower level (Understanding) of Bloom's Taxonomy based on the target of the asked question and to the SKILL domain verb in NCAAA. For each SO, there are special verbs for the one director who must ask the question. To find a method to connect the verbs of each ABET's SO with the NCAAA's domains, the six ABET outcomes were divided into the six Bloom's Taxonomy domains, which were then divided into the three NCAAA domains taxonomy.

VI. MAPPING BLOOM’S TAXONOMY WITH ABET AND NCAAA

Fig. 2 shows the mapping between Bloom’s Taxonomy & NCAAA. Table I summarizes the mapping between the accreditations ABET & NCAAA and Bloom’s Taxonomy.

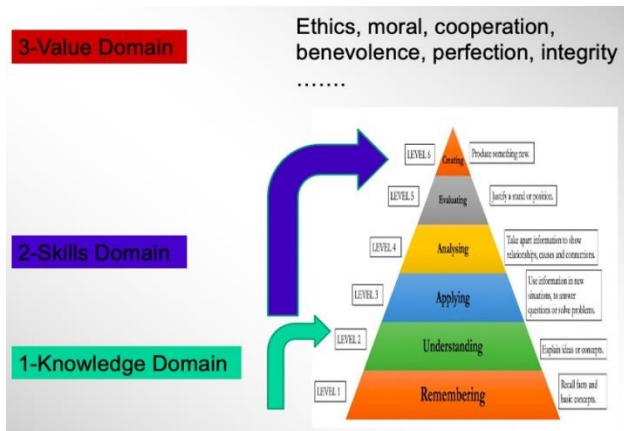

Fig. 2. Mapping Bloom’s taxonomy to NCAAA three domains.

TABLE I. THE MAPPING BETWEEN THE ACCREDITATIONS AND THE BLOOM’S TAXONOMY. [22]

ABET SO	NCAAA Domains	Bloom’s Taxonomy Level
SO1	Skills domain	L3, L5, L6
SO2	Skills domain	L5, L6
SO3	Value domain	L2, L3
SO4	Value domain	L2, L3
SO5	Value domain	L2, L3
SO6	Skills domain	L2, L3

Correlating the Verb Used in a Question to the ABET and Bloom’s Taxonomy. ABET specializes in specific verbs to request information about each subject object. This tool facilitates the creation of questions that align with accreditations. The NCAAA mandates the use of specific verbs. The utilization of these verbs is essential for the automated production and verification of questions utilizing ChatGPT technology. ChatGPT technology is user-friendly when the computer is supplied and educated via generative AI. These identical verbs might be utilized to generate inquiries pertaining to NCAAA. They collectively fulfilling the criteria of both ABET and NCAAA. Therefore, if the academic program receives two distinct accreditations, the questions developed will be suitable for both accreditations. Here are some instances of these verbs. Table II displays the question verb that ABET has designated to assess each Student Outcome (SO). The table also displays the verb mapped to the Bloom's Taxonomy. The question verbs are expected to be the same for both ABET and NCAAA [22].

Whereas the subpoints 1.1, 1.2, 2.1, 2.2, 2.3, 3.1-3.3, 4.1-4.3, 5.1, 5.2-5.3, 6.1, 6.2 and 6.3 are subpoints of the major 6 SO and they measure the following SO.

1.1: An ability to analyze a complex computing problem. (Analyzing).

1.2: An ability to apply principles of computing and other relevant disciplines to identify solutions. (Applying).

2.1 An ability to design a computer-based system, process, component, or program to meet desired needs.

2.2: An ability to implement a computer-based system, process, component, or program to meet desired needs.

2.3: An ability to evaluate a computer-based system, process, component, or program to meet desired needs.

3.1: An ability to conduct an oral presentation using effective communication skills. (Applying).

3.2: An ability to write in a clear, concise, grammatically correct and organized manner. (Applying).

3.3: An ability to develop appropriate illustrations including hand sketches, computer generated drawings/graphs and pictures. (Applying).

TABLE II. QUESTION VERBS MAPPED TO NCAAA AND ABET SO

The question verb	The Bloom’s Taxonomy VERB LEVEL	The ABET SO number
Appraise, assess, evaluate, compare, contrast, criticize, differentiate, discriminate, distinguish, examine, experiment, question, test	[Analyzing]	1.1
Choose, demonstrate, employ, illustrate, interpret, operate, schedule, sketch, draw, solve, use, write.	[Applying]	1.2
An ability to design a computer-based system, process, component, or program to meet desired needs.	[Creating]	2.1
An ability to implement a computer-based system, process, component, or program to meet desired needs.	[Applying]	2.2
An ability to evaluate a computer-based system, process, component, or program to meet desired needs.	[Evaluating]	2.3
Choose, demonstrate, employ, illustrate, interpret, operate, schedule, sketch, draw, solve, use, write.	[Applying]	3.1-3.3
Classify, describe, discuss, explain, identify, locate, recognize, report, select, translate, paraphrase	[Understanding]	4.1-4.3
Choose, demonstrate, employ, illustrate, interpret, operate, schedule, sketch, draw, solve, use, write.	[Applying]	5.1
[Affective Learning] Appreciate, accept, attempt, challenge, defend, dispute, join, judge, justify, question, share, support	Any verb level which should be determined by the SO of the topic.	5.2-5.3
Appraise, assess, evaluate, compare, contrast, criticize, differentiate, discriminate, distinguish, examine, experiment, question, test	[Analyzing]	6.1
Choose, demonstrate, employ, illustrate, interpret, operate, schedule, sketch, draw, solve, use, write.	[Applying]	6.2
Classify, describe, discuss, explain, identify, locate, recognize, report, select, translate, paraphrase.	[Understanding]	6.3

4.1: Understanding of professional responsibilities, ethical theories, legal and social issues. (Understanding).

4.2: Understanding of cyber security threats and corresponding procedures to mitigate these threats. (Understanding).

4.3: Understanding of risk management, security policies and audit procedures. (Understanding).

5.1: An ability to prepare a work schedule for the assigned task and complete it within the appropriate deadlines. (Applying).

5.2: An ability to participate in team meetings with full preparedness for providing useful input. (Affective Learning).

5.3: An ability to share ideas among the team and promote good communication among the team members. (Affective Learning).

6.1 Support the delivery of information systems within an information Systems environments.

6.2 Support the use of information system within an information Systems environments.

6.3 Support the management of Information Systems within an information Systems environments.

Studying the extent to which faculty members accept the use of ChatGPT technology. In order to produce student assessment questions and tests. These subpoints are extracted from ABET official documents from IS department of FCIT of King Abdulaziz University [35].

VII. DESIGN A CUSTOM CHATGPT

Proficiency in programming is essential for developing a customized ChatGPT application. However, beneficiaries may find platforms offering pre-made tools for design applications. Typically, the beneficiary must ascertain three fundamental aspects:

- The application's objective.
- Enumerate the characteristics of it.
- Selecting the platform, whether it is a mobile or web-based chat application.

To integrate GPT, the user must determine the appropriate version of GPT to utilize, such as GPT-3.5, developed by OpenAI. The designer requires an API key, which can be obtained by accessing the OpenAI platform. They can use either the library or the requests module in their chosen programming language, such as Python. In this research paper, the OpenAI platform is employed to correct questions based on accreditation requirements. Two accreditations were examined: ABET and NCAAA. The implementation test focused on the course COIS 492, which is part of the fifth level of the Information Systems Department in the bachelor's degree program at the Faculty of Computing Science & Information Technology, King Abdulaziz University, Rabigh Branch. The course adheres to ABET accreditation requirements for measuring Student Learning Outcomes (SLOs) and aims to fulfill NCAAA requirements, as national NCAAA accreditation is mandated by the Ministry of

Education of Saudi Arabia [36]. The questions in the course assessments must meet ABET standards. In this research, the implementation of the ChatGPT application ensured that both NCAAA and ABET requirements were met before approving a question generated by the application. Several researchers in Saudi Arabia have studied the alignment of ABET [37] and NCAAA [38] [39] accreditation requirements as a unified and mutually satisfactory solution.

In the proposed ChatGPT application, the most crucial condition involves using the correct question verb for a specific Student Outcome within the appropriate domain. The course COIS 492 focuses on SO 2, 4, and 6. Table II illustrates the question verbs mapped to NCAAA and ABET SOs. The content of this table was integrated into the ChatGPT application to ensure the accuracy of the questions. The application's role is to verify the correctness of questions posed by the instructor for a specific SO. If the question is correct, it is approved. ChatGPT was specifically developed to test questions submitted by faculty members, ensuring their adherence to accreditation requirements such as ABET and NCAAA. The application is equipped with two files: an SO file and a relationship table between NCAAA and ABET. The application has been named "QUESTION CHECKER," as depicted in Fig. 3, which illustrates the app interface.

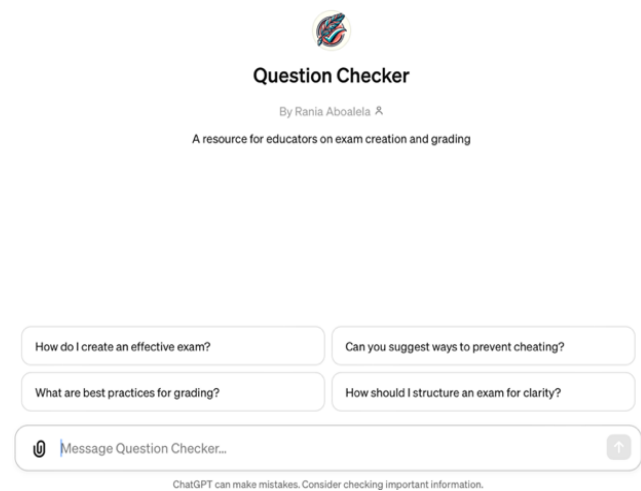

Fig. 3. Question checker application interface.

A. Role and Goal

This GPT serves as an advanced question checker, specifically designed for educators setting short answer and essay questions. It verifies questions for correctness based on the relation between the question's verbs and the intended student outcomes. It also offers suggestions for improving question clarity and alignment with educational goals.

B. Constraints

The checker provides feedback on question grammar, recommends more suitable verbs based on a table of verb relationships and student outcomes, and provides constructive feedback to refine questions. It proactively suggests improvements and awaits explicit queries before offering feedback, aiming to enhance the clarity and educational value of questions.

VIII. THE APPLICATION TEST

The application's ability to correct questions provided by instructors to align with ABET and NCAAA accreditation requirements has been tested. This includes verifying the accuracy of the question's action verb to test the appropriate Student Outcome (SO) and the relevant domain intended for assessment by the question. The application was used to test the accuracy of a diverse set of questions, identifying both incorrect and correct questions. The application was tested for two purposes: assisting in creating accurate questions and correcting erroneous questions while providing comments and suggestions.

A. To Assist in Creating Accurate Questions

After providing the application with the accreditation criteria in terms of verbs and scope, the application explained how to formulate questions as a guide for faculty members. The application provides users with steps to write correct questions as showing in the output of the application which is illustrated in Fig. 4. Fig. 4 shows Question Checker Q. C. explaining how to create appropriate questions that meet NCAAA & ABET criteria. This explanation can be edited by developers.

B. To Validate and Correct the Questions

Faculty members can seek evaluation of their questions using any method they find suitable. A set of questions from various topics and courses was input into the Question Checker App to assess its efficiency. For this paper, a subset of questions was selected from the Web Design & Development course, with each question targeting a specific Student Outcome (SO). The course has three basic ABET Student Outcomes: 1, 2, and 6. The application's responses were as follows:

Questions 1 through 8 were entered into the app to validate test questions targeting Student Outcomes SO: 1.1, SO: 1.2, SO: 2.1, SO: 2.2, SO: 2.3, SO: 6.2, SO: 6.1, and SO: 6.3, respectively. Fig. 5, 6, 7, 8, 9, 10, 11, and 12 show the instructor's questions and the responses of the Question Checker app. These questions were introduced to test the efficiency of the QC application in evaluating the eight student outcomes. The first question was: Q1. "Differentiate among the validators: Range validator and Regular Expression validator in terms of purpose, syntax, and an example."

The QC application validates questions, provides reasons for validation, and offers enhancement suggestions. The question and the app's response are illustrated in Fig. 5. As shown in Fig. 5, the ABET and NCAAA domains were used to evaluate the question. The QC app can either validate or invalidate a question and suggest updates for both cases. For example, consider question Q2: "Use ASP.NET to create a master page including title, dynamic navigation, and copyright." The QC application provided suggestions to improve the question without giving explicit validation responses. Fig. 6(a) shows the instructor's question and the QC application's response with suggestions. The app validated the question but suggested enhancements to clarify it. Fig. 6(b) displays the validation of the revised question.

Question Checker

Crafting questions that align with the National Commission for Academic Accreditation and Assessment (NCAAA) and the Accreditation Board for Engineering and Technology (ABET) standards involves understanding the specified student outcomes and matching them with the appropriate level of cognitive demand as outlined in Bloom's Taxonomy. Here are the steps to follow:

- 1. Understand Student Outcomes (SOs):** Begin by reviewing the specific student outcomes outlined by NCAAA and ABET for your program. These outcomes describe what students should be able to do by the end of the program and are categorized into different domains such as applying knowledge, designing systems, ethical reasoning, communication skills, teamwork, and understanding professional responsibility.
- 2. Review Bloom's Taxonomy Levels:** Familiarize yourself with Bloom's Taxonomy levels— Remembering, Understanding, Applying, Analyzing, Evaluating, and Creating. Each level represents a different type of cognitive demand, from basic recall of information to complex analysis and creative problem-solving.
- 3. Match SOs with Bloom's Levels:** Align each student outcome with the appropriate level(s) of Bloom's Taxonomy. This alignment ensures that the questions you craft will target the cognitive skills necessary to achieve the intended learning outcomes. For example, an outcome related to designing a system may align with the Creating level, while understanding professional responsibility might align with the Understanding level.
- 4. Select Appropriate Verbs:** Use the mapped verbs from the provided tables to guide your question construction. Each Bloom's level is associated with specific action verbs that help in formulating questions. For instance, to assess Analyzing outcomes, you might use verbs like compare, contrast, or evaluate. For Applying outcomes, verbs like demonstrate, solve, or use could be appropriate.
- 5. Craft Questions:** With the outcomes, Bloom's levels, and verbs in mind, start crafting your questions. Ensure that each question is clearly worded, unambiguous, and specifically designed to assess the intended student outcome. For example, to assess the ability to analyze a problem (SO 1.1), a question might start with "Evaluate the following scenario to identify potential computing solutions..."
- 6. Review and Refine:** After drafting your questions, review them to ensure they align with both the student outcomes and the cognitive level intended. Make sure the questions are challenging yet fair, and that they truly measure the students' understanding and skills in relation to the program's learning outcomes.
- 7. Feedback and Iteration:** If possible, seek feedback from colleagues on the clarity and alignment of your questions. Use this feedback to refine your questions further. This iterative process helps in enhancing the quality and effectiveness of your assessment items.
- 8. Integration into Assessments:** Once refined, integrate these questions into your quizzes, exams, or other assessment tools. Ensure that your assessments as a whole cover a broad range of the program's student outcomes and adequately reflect the diverse cognitive skills outlined in Bloom's Taxonomy.

By following these steps, you'll be able to create well-aligned, clear, and effective questions that not only meet NCAAA and ABET standards but also foster deep learning and critical thinking among your students.

Fig. 4. Question checker guideline for creating a correct question.

You

Q2.
Use ASP.NET app to create master page including title, navigation, copyright
Is this valid question to test SO:1.2

Question Checker

Given the objective of SO 1.2, which is to "Apply principles of computing and other relevant disciplines to identify solutions," your question about using an ASP.NET application to create a master page including a title, navigation, and copyright is indeed valid. This task aligns with the action verbs listed under SO 1.2, such as "choose," "demonstrate," "employ," "illustrate," "interpret," "operate," "schedule," "sketch," "draw," "solve," "use," and "write." These verbs emphasize the application of knowledge and skills in practical settings.

The question directs students to apply their knowledge of ASP.NET (a specific computing technology) to create a functional component of a web application (the master page), which is a direct application of computing principles. It requires them to use their skills in a practical task, demonstrating their ability to implement a solution based on specified requirements.

To further align with SO 1.2 and enhance the question, you might consider specifying more details about the functionality or design requirements of the master page, thereby encouraging students to employ a broader range of computing principles and disciplines in their solution. Additionally, asking students to justify their design choices or to describe how their implementation meets the needs of a hypothetical user scenario could deepen their application of computing principles, thus reinforcing the connection to SO 1.2.

Fig. 5. The Validation of question 1 testing SO 1.1.

You
Q2. Update
Use ASP.NET app to create CUSTOM master page including title, dynamic navigation, copyright
Is this valid question to test SO:1.2

Question Checker
The revised question, "Use ASP.NET app to create CUSTOM master page including title, dynamic navigation, copyright," remains a valid and effective way to assess Student Outcome (SO) 1.2. SO 1.2 is focused on the application of computing principles and other relevant disciplines to identify solutions. The task of creating a custom master page with specified features like a title, dynamic navigation, and copyright elements using ASP.NET directly engages students in applying their knowledge of web development practices and principles to solve a practical problem.

The inclusion of "dynamic navigation" in your updated question adds a layer of complexity and practical application that is very suitable for testing SO 1.2. This addition requires students not only to use their knowledge of ASP.NET but also to incorporate principles of user interface design and possibly information architecture, which are essential disciplines within computing.

To further align with the "Applying" level of Bloom's Taxonomy, which underpins SO 1.2, it's crucial that the question prompts students to demonstrate their ability to employ their knowledge in a real-world scenario. Creating a master page with these components requires students to interpret requirements, choose appropriate tools and techniques, and ultimately employ their skills in a practical task—actions that are at the heart of the "Applying" category in Bloom's Taxonomy.

To improve the question further and ensure it effectively measures SO 1.2, you might consider specifying additional requirements or context for the master page creation. For example, indicating the intended use of the master page or the audience can help students understand the practical implications of their design choices, making the task more aligned with real-world application. This specification could also assist in evaluating the students' ability to apply computing principles more comprehensively, as they would need to consider usability, accessibility, and responsiveness in their designs.

In summary, your updated question is well-suited for assessing SO 1.2. It requires the application of computing principles to a practical task, which is directly aligned with the intended learning outcome. Adding further detail or context could enhance its effectiveness by ensuring that students apply their knowledge in a way that mirrors professional practice.

Fig. 6. (a) Suggestion of enhancement question 2 testing SO 1.2. (b) The Validation of revised question 2 to test SO: 1.2.

Another example is question Q4: "Write the correct syntax" for testing SO 2.2. The QC application provided suggestions to improve the question without explicit validation responses. Fig. 8(a) shows the instructor's question and the QC application's response with suggestions. The app validated the question but suggested enhancements for clarity. The instructor implemented the QC suggestions and updated the question. Fig. 8(b) shows the updated question and the app's response.

Question 3 explicitly asked about SO: 2.1. The QC application validated the question and offered suggestions for enhancement. Fig. 7 shows the question and the app's response. Q4 tests the efficiency of the application in validating SO: 2.2. The application suggested adding more information to better target SO: 2.2. Fig. 8(a) shows the question and the QC application's response, while Fig. 8(b) displays the validation of the revised question as per the application's suggestions.

Fig. 9 shows the validation of question Q5, which tests SO: 2.3. As illustrated in Fig. 11, the question targets SO: 6.1, and the QC application directly validated it. Question Q8 tests the target SO: 6.3, and the validation with the application is shown in Fig. 12. Question Q6 was identified as invalid and will be discussed later. A summary of the introduced questions and the application responses is provided in Table III.

You
Q3. Design a web page layout using HTML and CSS that addresses specific user needs or preferences!
User
Is this question valid to ask about SO 2.1

🔊 📄 🔄 🗑️

Question Checker
Yes, the question "Design a web page layout using HTML and CSS that addresses specific user needs or preferences" is valid and well-aligned with Student Outcome (SO) 2.1. SO 2.1 is described as an ability to design a computer-based system, process, component, or program to meet desired needs, and falls under the [Creating] level of Bloom's Taxonomy.

This question effectively targets the [Creating] level by asking students to engage in a design process that requires them to consider user needs and preferences, and then to implement a solution through the creation of a web page layout using HTML and CSS. It encompasses the following aspects that align with SO 2.1:

- **Design Thinking:** Students must conceptualize a web page layout that is not only functional but also tailored to meet specific user needs or preferences, demonstrating an understanding of user-centered design principles.
- **Technical Skills Application:** By using HTML and CSS, students apply technical skills in a practical context, which is essential for the creation of computer-based solutions.
- **Creativity and Innovation:** The requirement to address specific user needs encourages students to think creatively and innovatively to come up with design solutions that are both effective and unique.

To enhance the question further and ensure a comprehensive assessment of SO 2.1, consider specifying certain constraints or requirements for the web page design. This could include considerations for accessibility, responsiveness, or the inclusion of specific elements (like forms or multimedia content) that might be relevant to the user needs or preferences identified. This approach would not only challenge students to apply their technical knowledge in a more targeted way but also to think critically about how design choices impact user experience and system functionality.

🔊 📄 🔄 🗑️

Fig. 7. Validation of question 3 to test SO 2.1.

You
Q4. Write the correct Syntax
is this question valid to test SO:2.2 ?

Question Checker
The question "Write the correct Syntax" in its current form is very broad and lacks specificity, which makes it challenging to directly assess its alignment with Student Outcome (SO) 2.2. As per the documentation, SO 2.2 is about the ability to implement a computer-based system, process, component, or program to meet desired needs, focusing on the application of computing principles in a practical context.

For a question to effectively target SO 2.2, it should encapsulate a scenario or context that requires students to apply their knowledge and skills in implementing a computing solution. The verb "write" falls under the "Applying" category of Bloom's Taxonomy, which is consistent with SO 2.2. However, the term "correct Syntax" is too vague because it does not specify what language or technology students are being asked to use, nor does it describe the problem they need to solve or the context in which their skills are being applied.

To improve the question and make it a valid tool for assessing SO 2.2, consider incorporating the following elements:

1.

Specify the Programming Language or Technology: Clearly indicate whether the syntax pertains to a specific programming language (e.g., JavaScript, Python, C++) or technology (e.g., SQL, HTML/CSS). This specificity is crucial because syntax varies significantly across different languages and technologies.

2.

Provide a Context or Scenario: Offer a scenario or problem that the syntax will address. This could involve asking students to write syntax that accomplishes a particular task (e.g., querying a database, rendering a web page element, or processing user input). The context should reflect a real-world application to demonstrate the practical implementation of computing principles.

3.

Outline Desired Outcomes or Requirements: Clearly define what the implemented solution must achieve. This could include specific functionalities, performance criteria, or user interaction outcomes. These details help students understand the scope of the problem and align their solutions with the defined requirements.

4.

Encourage Problem-Solving and Creativity: Pose the question in a way that encourages students to think critically about how their solution meets the desired needs. This approach assesses not only their technical skills but also their ability to apply those skills creatively and effectively in problem-solving.

In summary, while the intent behind the question "Write the correct Syntax" could be relevant to SO 2.2, its effectiveness as a measure of students' ability to implement computing solutions is limited without further details and context. By specifying the language or technology, providing a clear scenario, and outlining desired outcomes, the question can be refined to more accurately assess students' skills in implementing computer-based systems, thus aligning it more closely with SO 2.2.

(a)

You
Q4 UPDATE
Q4. Write the correct syntax to display the following output in the browser by using JAVA script code
Is this valid question to ask about SO:2.2

Question Checker
The updated question, "Write the correct syntax to display the following output in the browser by using JavaScript code," focuses on the application of JavaScript programming to achieve a specific outcome within a web browser. This question is intended to assess students' ability to apply their knowledge of JavaScript to manipulate or produce content dynamically in a web environment.

Given that SO 2.2 involves the ability to implement a computer-based system, process, component, or program to meet desired needs, this question does align with SO 2.2 under the "Applying" category of Bloom's Taxonomy. Implementing functional JavaScript code to achieve a specified output in a web browser is a practical application of programming skills and directly involves the process of implementing a component of a computer-based system (in this case, a web application or website).

However, to enhance the alignment of this question with SO 2.2 and ensure it effectively assesses the intended outcome, consider the following aspects:

1.

Specify the Output: Clarify what the "following output" refers to. Providing a clear, detailed description of the expected output or behavior in the browser will help students understand the requirements and the context in which their JavaScript code must operate. This detail is crucial for assessing their ability to implement a solution that meets specific needs.

2.

Contextualize the Task: To strengthen the connection to implementing a computer-based system or component, it may be helpful to frame the JavaScript coding task within a broader application context. For example, describe a scenario where the JavaScript functionality plays a crucial role in the user experience or functionality of a web application. This approach emphasizes the relevance of the task to real-world web development and system implementation.

3.

Encourage Problem-Solving: Ensure that the question not only tests students' ability to write syntactically correct JavaScript but also encourages them to think about how their code fits into a larger system or meets user needs. This could involve asking students to consider how their code enhances the functionality or usability of a webpage, aligning with the goal of implementing solutions that meet desired needs.

In summary, your updated question is suitable for assessing SO 2.2, as it requires students to apply JavaScript coding skills in a practical context. To maximize its effectiveness, ensure the task is clearly defined and placed within a broader context that underscores the importance of implementation skills in meeting specific requirements or solving real-world problems. This approach will not only align with the educational goal of SO 2.2 but also prepare students for the practical challenges they will face in their careers.

(b)

Fig. 8. (a) Suggestion of enhancement for question 4 to test SO 2.2. (b) The Validation of Revised question 4 to test SO: 2.

TABLE III. SUMMARY OF THE QC APPLICATION RESPONSES TO VALIDATE THE INTRODUCED QUESTIONS

C. Examples of Question Checker Evaluation to Invalid Questions and Enhancement

Question Q6 was selected to test the application's efficiency in identifying invalid questions. Fig. 10(a) and (b) depict the evaluation of the Question Checker app for questions related to SO 6.2. The original question, Q6, asked for the four methods of a command class, with the instructor seeking validation that it targeted SO 6.2. However, the app's QC deemed the question invalid for testing SO 6.2, providing reasons and suggestions for improvement. Consequently, the question was revised based on the QC's suggestions, resulting in an updated question: Q6: "Explain how the Command class can be used to support information systems within specific environments."

You
Q5. Justify that the ASP.NET supports safe for websites
Is this question valid to ask about SO: 2.3??

 **Question Checker**
The question "Justify that ASP.NET supports safety for websites" is aimed at assessing students' ability to evaluate a computing-based solution, in this case, ASP.NET's safety features for websites. This aligns with the essence of Student Outcome (SO) 2.3, which is focused on the ability to evaluate a computer-based system, process, component, or program to meet desired needs, particularly from the perspective of evaluating for certain qualities such as safety.

SO 2.3 falls under the "Evaluating" category of Bloom's Taxonomy, which involves making judgments based on criteria and standards. The task of justifying the safety features of ASP.NET requires students to critically assess the framework's security mechanisms, how they are implemented, and their effectiveness in ensuring website safety. This requires not only an understanding of ASP.NET's features but also an ability to critically evaluate these features against security needs and standards.

However, to ensure that the question effectively targets SO 2.3, consider the following enhancements:

- 1.

Specify Criteria for Safety: To guide students in their evaluation, it may be beneficial to specify what aspects of safety they should focus on. This could include aspects such as data protection, authentication mechanisms, protection against common vulnerabilities (e.g., SQL injection, cross-site scripting), and so on. Providing criteria will help students understand what aspects of ASP.NET they should be evaluating and what standards or best practices they should use as a basis for their justification.

- 2.

Encourage Use of Evidence and Examples: Prompt students to support their justifications with evidence or examples. This could include referencing specific ASP.NET features, mechanisms, or practices and discussing how these contribute to website safety. Encouraging the use of evidence will make the evaluation more rigorous and grounded in concrete analysis.

- 3.

Ask for a Comparative Analysis: To deepen the evaluation, you might ask students to compare ASP.NET's safety features with those of another web development framework. This comparison can provide a more nuanced understanding of ASP.NET's strengths and weaknesses in terms of safety and encourages students to apply evaluative thinking not just in isolation but in comparison with alternative solutions.

In summary, the question is valid for assessing SO 2.3, as it requires students to evaluate ASP.NET in terms of its ability to support safety for websites. By specifying criteria for evaluation, encouraging the use of evidence, and possibly including a comparative analysis, you can enhance the question's effectiveness in measuring students' evaluative skills in the context of computing solutions.

Fig. 9. The Validation of question 5 to test SO: 2.3

The QC suggested adjusting the question to include how these methods contribute to the support and improvement of information systems, which would make it more valid and relevant for assessing SO 6.2. Fig. 10(b) shows the validation of the revised question.

You
Q6. WRITE FOUR METHODS OF COMMAND CLASS
IS THIS QUESTION VALID TO ASK ABOUT SO 6.2 ?

 **Question Checker**
Student Outcome (SO) 6.2 is centered on supporting the use of information systems within an information systems environment. This outcome emphasizes practical understanding and the application of knowledge to enhance the functionality, efficiency, and user experience of information systems.

The question "Write four methods of the Command class" aims at assessing knowledge related to a specific programming concept, presumably within the context of information systems. The Command pattern is a behavioral design pattern that turns a request into a stand-alone object that contains all information about the request. This separation allows for parameterizing methods with different requests, delaying or queuing a request's execution, and supporting undoable operations.

Considering SO 6.2's focus, this question could be seen as partially aligned because it assesses technical knowledge that could underpin the development or enhancement of information systems, particularly in relation to software design and architecture. Understanding and being able to articulate methods of the Command class might contribute to students' ability to support and improve information system functionalities through software development practices.

However, the direct relevance of this question to SO 6.2 may depend on several factors:

- **Contextual Relevance:** If the curriculum or learning outcomes specifically include software design patterns as a critical component of supporting information systems, this question would be more directly relevant.
- **Application Focus:** SO 6.2 seems to emphasize the practical application and support of information systems. A question that not only asks for methods but also how they are applied can be used to support information systems might align more closely with SO 6.2.
- **Integration with Information Systems:** It would strengthen the question's relevance if it included a prompt for students to explain how these methods support or enhance the use of information systems, tying back directly to the goal of SO 6.2.

In summary, while the question touches on knowledge relevant to software development—a component of information systems—the direct alignment with SO 6.2 would be enhanced by explicitly connecting the technical knowledge assessed (i.e., Command class methods) with the broader goal of supporting the use and functionality of information systems. Adjusting the question to include how these methods contribute to the support and improvement of information systems would make it more valid and relevant for assessing SO 6.2.

Update
Q6. Write how the command class of ASP.NET can be used to support information systems within specific environment.
Is this question valid to test SO:6.2 ?

 **Question Checker**
Yes, the question "Write how the Command class of ASP.NET can be used to support information systems within a specific environment" is a valid approach to assess Student Outcome (SO) 6.2, which concerns the support of the use of information systems within Information Systems environments. This question aligns with the "Applying" category of Bloom's Taxonomy, which is associated with SO 6.2, because it asks students to apply their knowledge and skills to a specific, practical context.

The question targets the application of a technical solution (the Command class in ASP.NET) to support operational aspects of information systems, which is at the core of SO 6.2. The inclusion of "write" as the action verb encourages students to convey their understanding and application skills in written form, which matches the verbs related to SO 6.2 like "choose," "demonstrate," "employ," "illustrate," "interpret," "operate," "schedule," "sketch," "draw," "solve," "use," and "write."

To ensure the question effectively measures students' abilities as intended under SO 6.2, it might be useful to provide additional guidance or context about what "specific environment" refers to. This could include specifying the type of information systems or the operational challenges within those environments that the Command class could address. By doing so, the question not only becomes more precise in its aim but also helps students focus their answers more directly on demonstrating their capability to apply ASP.NET tools in supporting information systems, thereby aligning with the educational goals of SO 6.2.

(b)

Fig. 10. (a) The Suggestion enhancement of Q6 to test SO 6.2. (b) 2- The Validation of Q6 to test SO 6.2 after considering the Question Checker application enhancement suggestion.

You
Q7. Evaluate the use of ASP.NET to manage large websites?
Is this question valid to ask about SO:6.1?

Question Checker
Yes, the question "Evaluate the use of ASP.NET to manage large websites?" is valid for assessing Student Outcome (SO) 6.1, which focuses on supporting the delivery of information systems within an information systems environment. The verb "evaluate" aligns well with the "Analyzing" level of Bloom's taxonomy, appropriate for SO 6.1. This question encourages a critical analysis of ASP.NET's capabilities in managing large websites, directly relevant to the student outcome.

Fig. 11. The Validation of question 7 to test SO: 6.1

You
Is this question valid to ask about SO:6.3?
Q8. Explain the two methods to use CSS cascade style sheet in HTML file .

Question Checker
The question you've presented for SO:6.3 ("Explain the two methods to use CSS cascade style sheet in HTML file") uses the verb "explain," which aligns with Bloom's taxonomy level of "Understanding." Based on the documents, SO:6.3 focuses on supporting the management of Information Systems and requires verbs related to "Understanding" such as "classify," "describe," "discuss," "explain," "identify," "locate," "recognize," "report," "select," and "translate."

Your question's use of "explain" fits well with the verbs associated with SO:6.3. It asks students to discuss the methods of integrating CSS in HTML, which can relate to managing technical aspects of information systems through understanding different integration techniques.

Feedback:

- Alignment:** The verb "explain" aligns with the "Understanding" category necessary for SO:6.3.
- Clarity:** Your question is clear and directly asks for an explanation of methods, which is suitable for understanding and managing aspects of information systems.

Overall, your question is valid and well-suited for assessing SO:6.3 under the provided educational standards.

Fig. 12. The Validation of the explicit question Q8 to test SO 6.3.

D. To Suggest the Right SO

The instructor is free to ask the Question Checker application to evaluate a question using any method. For example, the instructor could request that the app suggest suitable student outcomes rather than inquire about a specific student outcome.

You
Would you find out the following question asks about which SO?
Q9. Write a complete java script code to display in the browser the following text

Question Checker
The question "Write a complete javascript code to display in the browser the following text" primarily utilizes the verb "write," which according to the mapping document of verbs to Student Outcomes (SOs), aligns with the "Applying" Bloom's Taxonomy level. This verb is associated with several specific student outcomes across various sections. Here are the potential SO alignments based on the provided verb:

- SO 1.2:** An ability to apply principles of computing and other relevant disciplines to identify solutions.
- SO 2.2:** An ability to implement a computer-based system, process, component, or program to meet desired needs.
- SO 3.1-3.3:** Various abilities related to communication skills, writing clarity, and development of appropriate illustrations.
- SO 5.1:** An ability to prepare a work schedule for the assigned task and complete it within the appropriate deadlines.
- SO 6.2:** Support the use of information systems within an Information Systems environment.

Based on the nature of the question, which involves writing and implementing a specific solution (in this case, a javascript code to perform a function), the closest match seems to be **SO 2.2**. This outcome focuses on implementing computer-based systems to meet desired needs, which is consistent with writing code to achieve a specific functionality in a software application.

Fig. 13. The Validation of implicitly question 9 to ask about SO 2.2.

Question 9, "Write a complete JavaScript code to display the following text in the browser," is shown in Fig. 13 along with the app's response. As illustrated in Fig. 13, the app validated the question as targeting SO: 2.2 and provided the reason.

The efficiency of the QC application was demonstrated by asking a question that implied a student outcome (SO). The application was used to validate a question aimed at testing an SO implicitly—not by directly asking the app about a specific SO, but by having it identify the correct SO. Fig. 13 shows the question and the app's response with the correct SO. The summary of the tested SO targets is illustrated in Table III.

IX. QUESTIONNAIRE

A survey was conducted to assess academic teachers' acceptance of using artificial intelligence (AI) applications to guide instructors in creating high-quality questions that meet academic accreditation standards and to correct questions submitted by faculty members. The survey was administered in two stages: the first stage occurred before the application was created, and the second stage took place after the application was developed and its efficiency was tested. WhatsApp was utilized to distribute the survey to faculty members across various Saudi universities. In the first stage, the survey received 45 responses, all of which supported using AI tools to guide question creation aligned with accreditation standards. However, 11% of respondents were opposed to allowing the application to correct their questions. Fig. 14 and 15 illustrate the acceptance percentages from the first stage. In the second stage, the survey received 50 responses.

Usability and Effectiveness: Of the 43 responses, 7% did not accept the application's usability. It is possible that those who rejected it are not accustomed to using electronic applications (see Fig. 16 for the usability acceptance rate).

Assistance Rates: The acceptance rate for the application's assistance in correcting questions to meet academic accreditation requirements was 49% (see Fig. 17 for the acceptance rate). However, the acceptance rate for the application's assistance in enhancing assessment effectiveness based on academic accreditation was 33% (see Fig. 18 for the acceptance rate). It is possible that the 17% of respondents who rejected this feature prefer complete independence in question creation and do not want electronic intervention, except by accreditation committees.

X. DISCUSSION

The study most closely related to this research is referenced in [22]. It investigated the alignment between the two accreditations, NCAAA and ABET, and Bloom's Taxonomy,

with the findings presented in Table I. The process of associating question verbs with the levels of Bloom's Taxonomy and ABET Student Outcomes (SO) was accomplished and is shown in Table II. The previous work [22] primarily focused on aligning educational content with the standards of both the NCAAA (National Commission for Academic Accreditation and Assessment) and ABET (Accreditation Board for Engineering and Technology).

In contrast, the proposed research advances this by introducing generative AI tools, specifically ChatGPT, to enhance the quality of test questions, ensuring they meet the rigorous requirements of both accreditations simultaneously. This study involves testing the efficacy of a custom application, named Question Checker, designed to validate and improve questions in alignment with these accreditation standards.

A key innovation of this research is the mapping of question verbs to Student Learning Outcomes (SLOs), which is critical for ensuring accurate measurement through appropriate questions. The Question Checker (QC) application was developed as a custom ChatGPT tool to verify the compatibility of questions with academic accreditation standards. The application's efficiency in validating questions based on ABET and NCAAA's SOs was rigorously tested. Furthermore, the acceptance of using this technology was assessed, with 100% of participants willing to use the technology for guidance, and 88.9% agreeing to allow the application to correct their questions.

The application successfully provided suggestions for any question aligned with a specific educational outcome. It demonstrated its effectiveness in confirming or rejecting questions submitted to it across all three basic educational outcomes of the applied subject, adhering to alignment conditions with both local and international accreditation standards. The application offered suggestions for all submitted questions, explaining the reasons for acceptance or rejection based on alignment with the quality standards of both local and international accreditation.

Additionally, the program was tested in two scenarios to verify its effectiveness:

- The teacher specifies the Student Outcome (SO), and the application either confirms or rejects it.
- The teacher presents the question without specifying the SO, and the application infers the appropriate SO.

In experiments, the program succeeded in both either accepting or rejecting questions based on a predefined SO and in identifying the appropriate SO for questions presented without a specified outcome.

XI. CONCLUSION AND FUTURE WORK

This study introduces a mechanism for using ChatGPT to assist teachers in generating high-quality questions, thereby saving time and providing an effective means of assessing student learning outcomes. The ChatGPT application was successfully developed and thoroughly tested. This research presents a framework for utilizing generative AI applications to enhance educational assessment tools and promote assessment

equity. Specifically, the ChatGPT application for evaluating questions in IS courses was created and tested. The application's efficiency was demonstrated by its ability to assist in creating appropriate questions, provide steps for crafting questions, validate and correct questions, and suggest the correct Student Outcome (SO) for implicit questions. In future work, this study will be extended by testing the application for generating questions across different courses within the same field. Additionally, a comparison of results across various courses or open programs will be conducted to evaluate the application's effectiveness and adaptability in diverse educational contexts.

Enhancing Digital Financial Security with LSTM and Blockchain Technology

Thanyah Aldaham¹, Hedi HAMDI²

Department of Computer Science, Jouf University, Sakka, Saudi Arabia^{1,2}
Manouba University, Manouba, Tunisia²

Abstract—The growing dependence on digital financial and banking transactions has brought about a significant focus on implementing strong security protocols. Blockchain technology has proved itself throughout the years to be a reliable solution upon which transactions can safely take place. This study explores the use of blockchain technology, specifically Ethereum Classic (ETC), to enhance the security of digital financial and banking transactions. The aim is to develop a system using an LSTM model to predict and detect anomalies in transaction data. The proposed LSTM model was trained before being tested and the results prove that the proposed model can effectively enhance the security, especially when compared to other studies in the same domain. The proposed model achieved a prediction accuracy of 99.5%, demonstrating its effectiveness in enhancing security by preventing overfitting and identifying potential threats in network activities. The results suggest significant improvements in digital transaction security, enhancing both the traceability and transparency of blockchain transactions while reducing fraud rates. Future work will extend this model's applicability to larger-scale decentralized finance systems.

Keywords—Digital financing; block chain; ETC; security; anomaly detection; machine learning; LSTM

I. INTRODUCTION

Financial transactions are essential to both the national and global economy. Each day, trillions of dollars are traded in the global financial networks that serve a vast number of individuals. Nakamoto [1] claims that although the financial system still uses an underlying trust-based methodology, it works well enough for the majority of transactions. He said that because financial organizations must arbitrate disputes, irrevocable transactions are not feasible. The banking sector is heavily regulated and conservative, and the revenue model hasn't changed in many years. Financial institutions already deal with a number of problems that impair their effectiveness and performance, including high transaction costs, high fraud rates, centralized control that might be challenged by pirates, and a lack of traceability and transparency [2]. Blockchain technology may boost a company's level of trust and control. Performance is impacted when banking institutions attempt to adapt to new client registration and money transfer procedures. Recently, crypto currencies have attracted the attention of both industry and academia. According to Coinmarketcap [3], the capital market for Bitcoin which is the original cryptocurrency, is expected to reach \$880 billion. Thus, the influence of blockchain technology acceptance on financial transactions and implementation concerns in the banking sector are determined by this research.

ETC which is known today as legitimate and famous decentralized platform for cryptocurrency other than ETH. In particular, as balanced books are maintained and computers do everything very quickly, the system create such a secure digital stamp, just from the blockchain [4].

Digital technology in the form that has already existed in the pre-digital era and has been introduced and popularized can change and acquire new functions such that it can involve completely new tools and services [5]. Cybersecurity is already integrated in many aspects of digital forensics, which poses as a necessary cornerstone to achieving desirable level of security in Internet of Things [6]. Nevertheless, banking industry represents the bunker of all different kinds of money and private conversations and the secrete storage for people's monetary resources. Competitive factors such as efficiency, performance enhancement, and deposit security have significantly propelled the financial sector forward. However, there is a risk that grows in proportion to the increasing number of users for whom the system is designed or as the system becomes more sophisticated. This situation is not a fair play because people started exploring the system's flaws [7].

The identification of errors in blockchain networks is an enormous task because you may find similar issues if you are looking for attacks or fraudulent activities. Anomaly detection plays out as a key element in blockchain security, allowing for deviations to encrypted content or other unexpected events through the monitoring of blockchain data. A quick recognition and response to the anomaly help minimize the possible damage by attackers and safeguard the whole web [8].

Although Blockchain technology has significantly enhanced security in financial transactions, several gaps remain, particularly in detecting sophisticated anomalies such as 51% attacks. Existing machine learning methods have not fully addressed these gaps, often struggling with overfitting and real-time detection issues. This research seeks to bridge this gap by leveraging an Encoder-Decoder LSTM model within the Ethereum Classic blockchain ecosystem to improve anomaly detection and enhance transaction security.

In this paper, the following contributions can be considered:

- Use of Encoder-Decoder LSTM approach for Ethereum Classic Blockchain (ETC) attack detection enhances blockchain security.

- LSTM model's ability to identify sequential dependencies improves accuracy in anomaly detection.
- Encoder-Decoder LSTM model excels in learning from serialized data.
- Application of recurrent neural networks, particularly LSTM, enhances current blockchain security.
- Improved anomaly detection aids in early detection of threats.
- Enhancements contribute to the reliability of blockchain systems.

II. LITERATURE REVIEW

Blockchain technology has been utilized by the majority of today's companies in order to improve the safety of their data. It is one of the newest technologies that is gaining the greatest traction in the field of protecting the digital world. This section explores a variety of approaches, surveys, strategies, and procedures that have been used in blockchain to address concerns around data sharing and security.

Javaid et al. [9], explored the potential applications of blockchain technology for financial service providers seeking to improve risk management, authenticity, and security. In order to create smart contracts, improve efficiency and transparency, and open up new revenue streams, a lot of organizations are aggressively integrating blockchain into trade and finance systems. The adoption of blockchain-enabled IDs is growing widespread in the banking industry, as the unique recordkeeping capabilities of blockchain render traditional clearing and settlement procedures obsolete. In addition to stressing the transfer of asset ownership and the need of keeping accurate financial ledgers, the study highlights the significance of enterprises anticipating upcoming trends in financial blockchain applications. The measurement, communication, and analysis of financial data are the main areas of concentration for accounting experts. The paper focuses on the importance of blockchain technology for financial services by methodically locating and analyzing pertinent papers. It also explores a range of tools, tactics, and featured services. At the end, major applications of blockchain technology in financial services are identified and evaluated, demonstrating the technology's superior security in credit reporting and its potential to open up new markets, cut costs for issuers, and reduce counterparty risk by customizing digital financial instruments. Blockchain provides a single trustworthy source of truth for network users, making it simpler for members of the business network to collaborate, handle data, and reach consensus by utilizing mutualized standards, protocols, and shared procedures.

Trivedi et al. [10], focused in their study on how blockchain technology is used in the financial and e-finance industries. Research questions about the technology's development, acceptance obstacles, and useful applications are examined. After conducting a thorough analysis of 76 scholarly articles, the study narrowed its attention to 59 articles and created a three-dimensional classification framework that encompasses blockchain development, obstacles, and financial sector applications. The results point

to untapped blockchain potential in the finance industry and point to areas in need of technological advancement. The report highlights that the technology is now unregulated, suggesting that it is still in its early stages and that there is ample opportunity for further growth and research in this area.

Hartmann and Hasan [11] drew attention to the abundance of Decentralized Finance (DeFi) Peer-to-Peer (P2P) lending platforms that either demand collateral from users or use conventional credit scoring techniques based on variables like credit history. Some users may find these requirements burdensome, nevertheless. The authors suggest using social media, which has a wealth of publicly accessible personal data and is used by over 55% of the world's population, as an alternative risk mitigator for lending. A user's professional behavior and dependability can be inferred by examining their social media accounts, which results in the creation of a "social score". The study's major contribution is the creation of a fully decentralized lending network that is enabled by the Ethereum blockchain and depends on this social score. With the help of this cutting-edge platform, consumers can obtain a loan even in the event that they don't have enough credit or collateral. The study also explores privacy issues, offering an improved platform that is intended to safeguard the borrower's privacy.

Liao et al. [12] focused on the open banking (OB) adoption trend that financial institutions are currently experiencing for service innovation and integration. Third-party service providers (TSPs) can now access user financial data in an effort to improve user experiences and find the best offers. However, the OB ecosystem's success depends on public confidence in third parties, which raises questions regarding data sharing, privacy protection, and the integration of digital identities. Although there are already decentralized applications (DApps) that address these issues, their integration into a workable three-phase OB method is still lacking, especially in areas like Taiwan. The study presents a blockchain-based identity management and access control (BIMAC) framework and lists the main needs of OB participants. The BIMAC framework creates a trustworthy platform for personal information transaction security control (PITSC) by utilizing smart contracts and a stateless authentication method. This platform provides features like online bank account opening, decentralized third-party login (TPL), integrated payouts, data authorization/revocation, and TSP access monitoring. The evaluation's findings show that the suggested framework's frequently executed functions have less computational overhead than the typical Ethereum transaction cost.

Boughaci et al. [13] introduced, blockchain technology and its fundamental ideas opens the discussion. The paper explores machine learning as a sophisticated instrument for examining large datasets and spotting potentially harmful transactions in untrusted networks. For the purpose of making wise decisions in the fields of banking and finance, the synergy of these clever strategies is highlighted. The suggested method is applied to the Bitcoin system, using the Elliptic dataset available on Kaggle as a standard. Because the dataset is not fully labeled, unlabeled data is divided into two primary clusters using the kmeans technique, and labeled data is

allocated to the appropriate cluster. Four machine learning approaches are then used for a thorough classification of the data. The results show promise, especially when k-means and the random forest classifiers are combined, indicating the potential effectiveness of this integrated approach in boosting security precautions.

Song and Chen [14], conducted research on the security of digital financial transactions using blockchain technology. To begin, the security of sdte is examined, as well as the DoS attacks that each role may launch, the assaults that a single role may send, and the attacks that numerous roles may launch in cooperation. It demonstrates that sdte can withstand various assaults and has robust security. Then, the system test's environment is detailed. Then, performance testing and analysis are performed on the key security transmission, smart contract execution in the trusted environment SGX, and overall running time. The testing findings demonstrate that employing the k-nearest neighbor (KNN) method to process data takes less than 0.45 seconds. At the same time, the system's additional cost is acceptable.

With the advent of post-quantum cryptography, it has become increasingly important to stay informed about the latest developments in cryptographic techniques and systems. Post-quantum cryptography is a branch of cryptography that aims to develop cryptographic systems that are secure against quantum computers. Quantum computers have the potential to break many of the classical cryptographic systems currently in use, such as RSA and ECC, by solving the underlying mathematical problems (like integer factorization and discrete logarithms) much more efficiently. As a result, researchers and organizations are actively working on developing cryptographic algorithms that can withstand attacks from quantum computers. Several relevant papers discussing advances in post-quantum cryptography and related topics, such as low-cost S-box implementations for AES [15], a survey on quantum-resistant algorithms and their applications, and strategies for optimizing cryptographic systems to resist quantum attacks [16]. Additionally, studies on lightweight cryptographic techniques for resource-constrained environments and their relevance in the post-quantum era provide further insights into the field [17]. Jalali [18] offer insights into the development of efficient and secure post-quantum cryptographic algorithms. This work, for example, presents a constant-time software library for the CSIDH (Commutative Supersingular Isogeny Diffie-Hellman) protocol, optimized for 64-bit ARM processors, and discusses its potential in the quantum era, particularly regarding its resistance to timing attacks. Another paper by Kozziel et al. [19] focuses on the optimization of cryptographic algorithms based on Binary Edwards Curves (BEC), which are designed to be both efficient and secure, particularly for resource-constrained environments such as embedded systems and IoT devices.

Side-channel attacks (SCA) pose a significant threat to the security of cryptographic implementations, particularly in lightweight cryptography designed for resource-constrained environments such as IoT devices. Lightweight cryptographic

algorithms such as PRINCE and GIFT-128 offer efficiency in power and memory usage, making them suitable for applications with strict resource limitations. However, their compact designs often expose vulnerabilities to side-channel attacks. For instance, in the work by Xue et al. [20], an SCA was demonstrated against the PRINCE cipher, which utilizes an unrolled architecture optimized for low latency but requires careful handling to prevent leakages during encryption rounds. Similarly, Benjamin et al. [21] explored deep learning-based side-channel attacks on GIFT-128, revealing the effectiveness of neural networks like CNNs in recovering cryptographic keys, even in scenarios involving desynchronized traces. Furthermore, a comprehensive survey by Chao Su and Qingkai Zeng [22] provides an analysis of CPU cache-based side-channel attacks, discussing security models and mitigation strategies, emphasizing the need for resilient designs in modern cryptography. These studies highlight the pressing need for enhanced countermeasures to safeguard lightweight cryptographic algorithms from the growing threat of side-channel attacks.

Table I shows the comparison of the related work mentioned earlier.

TABLE I. COMPARISON OF RELATED WORK

Work	Method	Technologies	Advantages	Limitations
[9]	Integration, smart contracts, revenue	Blockchain technology	Improved risk management, authenticity, security	Privacy concerns, data verification challenges
[10]	Study, examination of development, acceptance, applications	Blockchain technology	Untapped potential, areas for advancement	Lack of regulations, need for further research
[11]	Risk mitigation, social score creation	Ethereum blockchain	Decentralized lending, accessibility for users without credit or collateral	Privacy issues, reliance on social media
[12]	Blockchain-based identity management, access control	Blockchain technology	Improved user experiences, data sharing, privacy protection	Lack of integration, regulatory challenges
[13]	Analysis of large datasets, identification of harmful transactions	Blockchain technology, machine learning	Enhanced decision-making in banking and finance	Limited labeled data, computational overhead
[14]	Analyzing the security of digital financial transactions using blockchain technology, using KNN algorithm to process data for digital financial transaction security.	Blockchain technology, machine learning.	Offering strong security against various attacks and acceptable performance costs.	Lack of extensive studies and established frameworks to build upon.

IV. BACKGROUND

A. Blockchain in Financial and Banking Transactions

Blockchain is a distributed ledger technology that makes it possible for all parties to check and agree on a transaction before it is added to the value chain [23]. The banking industry has tried out new ways to use technology to improve customer flexibility, the speed of transactions and efficiency. Blockchain technology, as part of Industry 4.0, has the potential to transform business operations across a wide range of industries. Blockchain has been widely adopted and used in the banking and finance industries. Many financial institutions are often run by trusted third parties who are in charge of their operations. In the last step of a digital payment, a bank, credit or debit card, or other service provider acts as a trusted central expert and charges a fee to complete the transaction. For this operation to work, it needs an infrastructure that is both expensive and inefficient. The largest financial institutions in the world are now using this technology (see Fig. 1).

Fig. 1. Decentralization [24].

A blockchain can accommodate any new digital asset across multiple nodes. If a node fails, the data remains accessible and can be delivered by the other nodes. Since the blockchain is a public ledger, any sensitive personal information stored on it must be encrypted and can only be viewed by two parties. Data on the blockchain is encrypted using a public key and decrypted using a private key. Due to its consensus mechanism, the blockchain is immutable and cannot be duplicated. A block is added to the chain if there is consensus that the transactions within it are valid [25]. Despite this, blockchain is not yet widely adopted in the investment sector. However, industries are expected to quickly move towards implementing blockchain-integrated infrastructure in business organizations [26].

The primary advantages of blockchain in the banking sector include improved efficiency, enhanced security, immutable records, faster transaction times, and the elimination of third-party involvement, which reduces costs. One of the key benefits of blockchain is its history of unchangeable transactions—once a transaction is made, it cannot be undone, thereby reducing threats to financial institutions. Blockchain utilizes smart contracts, which are sets of rules agreed upon by the contracting parties. These contracts allow digital information to be stored, accessed, or altered only under specific conditions. Blockchain accelerates transaction processing and, due to its decentralized nature, reduces the need for financial intermediaries. This makes

currency conversion cheaper and easier compared to traditional banking methods, while also protecting against scams, money laundering, and trust issues. Financial institutions are expected to adopt blockchain technology very soon, and the banking industry is planning for rapid growth in its use.

B. Ethereum Classic (ETC) Blockchain

Ethereum Classic functions as both a smart contract platform and a cryptocurrency. It's important to note that Ethereum Classic (ETC) should not be mistaken for Ethereum (ETH), despite their shared origins prior to a contentious disagreement that resulted in a split. Below, we delve into the factors that precipitated this divergence.

Ethereum Classic closely resembles Ethereum due to their shared origin. Both are blockchains that facilitate the development of other applications on top of them. These decentralized applications, often referred to as dapps, utilize smart contracts, enabling individuals to exchange money, property, or any other valuable assets without the need for intermediaries. ETC serves as the network's native currency. Additionally, the Ethereum Classic network allows dApps on its platform to create their own tokens, including NFTs [27].

In summary, Ethereum Classic is a decentralized public ledger based on proof-of-work, featuring an embedded Turing-complete programming language that enables the creation of smart contracts and decentralized applications [28][29].

The underlying principles of the Ethereum Classic blockchain closely resemble those of Bitcoin, which stands as the most renowned and prosperous cryptocurrency presently [30]. The consistency of a public ledger in a proof-of-work system is maintained through decentralized mining. Miners continually attempt to solve a complex computational puzzle to find a hash value lower than a specified target. Upon success, miners can generate a block and receive a reward from it.

Fig. 2 represents an example of the general scheme of a blockchain system.

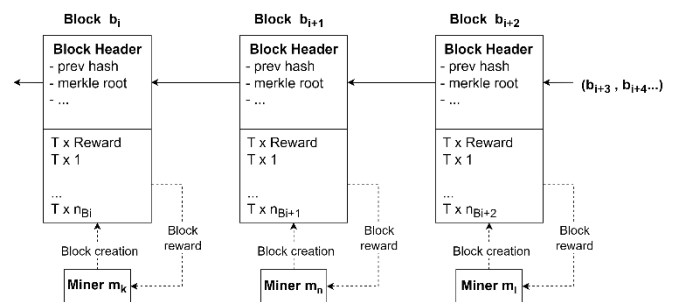

Fig. 2. General scheme of a blockchain system [31].

We won't delve deeply into the technical intricacies of the Ethereum platform here, but notable differences from Bitcoin include the use of accounts instead of UTXO, enhanced internal structures, and Turing-complete scripting languages. Those keen on exploring further can find comprehensive details in the original sources [28]. Instead, we'll focus on a few aspects relevant to the proposed treasury system.

Firstly, it's important to note that the average block time is approximately 14 seconds. This translates to approximately $B_{month} = 1851428$ blocks generated every 30 days.

Top of Form

Another significant distinction lies in the block reward system. Each block incorporates a special reward payment for the miner who mined it. Presently, in Ethereum Classic, this reward amounts to 5 newly created coins per block (uncle blocks excluded). This translates to approximately 9,257,140 coins generated per month $R_{month} = B_{month} \cdot 5 = 9257140$. Miners receive the entirety of these rewards, constituting the sole source of new coins within the system.

In summary, while Ethereum introduces advanced features such as a Turing-complete programming language, enhanced Merkle trees, and a modified GHOST protocol, its foundational principles remain akin to those employed in Bitcoin and other proof-of-work altcoins.

C. Ethereum Classic Security Challenges

In the early days, Ethereum stood alone. A collective known as The DAO (decentralized autonomous organization) utilized Ethereum to establish what essentially functioned as a venture capital fund. Ordinary individuals could invest using ETH, participate in decisions regarding asset allocation, and ideally, reap profits. The venture amassed over \$100 million through token sales. However, a vulnerability in the fund's code was exploited, resulting in millions of dollars' worth of ETH being siphoned out and causing panic among investors. Developers had a 28-day window to devise a solution before the hackers could convert the tokens, representing a substantial portion of Ethereum's market capitalization at that time. The prevailing solution involved implementing a hard fork to nullify the hack and reimburse affected individuals. Although endorsed by Buterin and other prominent figures, this move triggered backlash from purists advocating for the blockchain principle of non-interference with the ledger—arguing that the blockchain should persist with the theft intact. Those advocating for maintaining the status quo remained on the original platform, renaming it Ethereum Classic. Meanwhile, the majority of miners, developers, and users migrated to the forked network, which retained the Ethereum name [27].

Similar to Ethereum, the Ethereum Classic blockchain operates on a "proof of work" mining mechanism, where individuals worldwide utilize hardware and software to validate transactions and maintain network security, earning ETC as a reward. Users can send ETC to each other, akin to Bitcoin or Ethereum transactions with BTC or ETH, respectively. Furthermore, ETC can be used to engage with applications on the Ethereum Classic network, including decentralized exchanges for token swapping. However, it's worth noting that the Ethereum Classic ecosystem isn't as vibrant as Ethereum or other smart contract networks like Solana. As of February 2022, Ethereum Classic exhibited minimal activity in decentralized finance applications, as reported by DeFi Llama. This lower usage rate has raised concerns. Blockchain security hinges on having a diverse group of users actively operating the network; insufficient participation can leave the blockchain susceptible to

vulnerabilities. Between 2019 and 2020, the Ethereum Classic network faced several "51% attacks," allowing a hacker to seize control of the majority of the network's computational power. This enabled them to manipulate the ledger and acquire more ETC. Despite these challenges, Ethereum Classic enthusiasts persist in network maintenance and code updates. In December 2020, core developers enhanced the network to render 51% attacks economically unfeasible. The latest upgrade, the Mystique hard fork, occurred in 2022 [27].

D. Machine Learning in Anomaly Detection of Blockchain Transactions

The merging of both technologies: Machine Learning and Blockchain Technology, has the potential to provide outcomes that are strong and of practical value. This chapter provides an overview of distributed ledger technology and investigates the ways in which machine learning skills may be incorporated into a system that is based on distributed ledgers. In addition to that, it highlighted a number of well-known uses and instances of how this connected method might be used [32].

The capacities for learning that machine learning algorithms possess are very remarkable. These features can be implemented in the blockchain, which will result in the chain becoming wiser than it was in the past. This collaboration could be useful in helping to enhance the safety of the blockchain's shared ledger in some way. Also, the processing power of ML can be used to take advantage of the shorter time it takes to find the best nonce, and ML can also be used to improve how data is exchanged. Additionally, it is able to construct a great many improved models of machine learning by utilizing the decentralized design characteristics that distributed ledger technology offers [33].

The selfish mining assault, often referred to as a transaction holdback attack, is a deliberate effort to compromise the integrity of the decentralized network. Once one member of a mining pool tries to prevent a correctly verified block from being announced to the others in the mining group cluster, this is known only as "selfish miner assault." This selfish operator shows greater proof-of-work than all the other prospectors in the network as a consequence of hiding their correctly extracted block from the community before moving onto the next frame. By doing this, the community as a whole may accept their transaction methods while the self-centred node keeps the block benefits or cash benefits [32].

V. SYSTEM MODEL AND PROBLEM FORMULATION

A. Problem Formulation

In today's world of digital finance and banking, the security and integrity of financial transactions are at risk due to increased reliance on technology and growing cyber risks. For example, consider a business owner who transfers funds between accounts frequently using online banking services. Suddenly he notices unauthorized transactions on his account, which indicates a violation in security. In addition to causing financial loss, this incident also damages people's trust in the banking sector.

The aim of the project is to use blockchain technology to improve the security of online banking services and financial transactions. The paper covers a number of important topics such as cyber risk prevention, protecting data privacy, maximizing business efficiency and assessing the pros and cons of integrating blockchain technology into the financial sector. Given the weaknesses of current digital financial transactions (lack of trust, inefficient data sharing, privacy concerns and immutable data silos) a comprehensive review is needed to build a robust and secure blockchain framework.

B. System Model

A number of processes are involved in the suggested methodology for anomaly detection in the Ethereum Classic Blockchain (ETC), beginning with database analysis, employing the Encoder-Decoder LSTM architecture, and evaluating the outcomes as shown in Fig. 3.

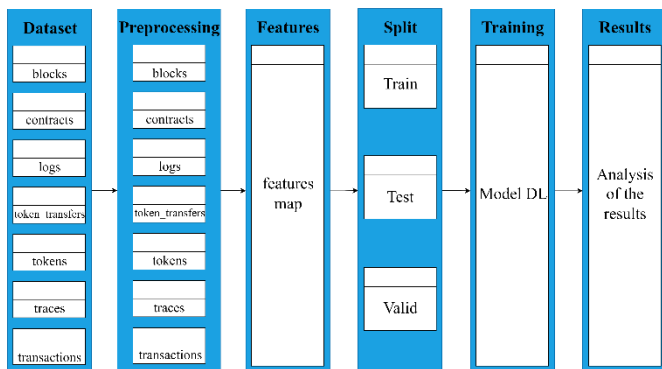

Fig. 3. Methodology used in the research.

VI. PROPOSED SOLUTION

A. Introduction

Ethereum Classic Blockchain has risen to prominence as one of the leading decentralized platforms leveraging the immutable nature of a ledger to undertake safe and transparent transactions. As blockchain technology progresses and is used in more and more industries, the importance of securing and protecting the immutability of blockchain networks grows more important. Given that these systems contain significant monetary transactions and sensitive data, they are prime targets for cybercriminals looking for areas to exploit. Aside from cryptocurrency exchange platforms, another significant challenge that threatens the credibility of blockchain networks is maintaining the safety and security of blockchain networks.

Detecting anomalies is one of the most important challenges to keep blockchain networks trustworthy since these might suggest possible attacks or malicious actions. It is an essential part of proactive measures that help identify any movements or actions that are not consistent with normal blockchain behavior. Early detection and appropriate responses to such anomalies can minimize the consequences of an attack and protect the network.

Deep learning methods have shown impressive results recently in a number of fields, from natural language processing to computer vision. The Encoder-Decoder Long

Short-Term Memory (LSTM) architecture in particular has become well-known due to its capacity to learn and represent intricate sequential patterns. This project focuses on using the Encoder-Decoder LSTM architecture to address the anomaly identification problem on the Ethereum Classic Blockchain by utilizing deep learning.

The Encoder-Decoder LSTM model is a good fit for jobs involving anomaly detection because it can efficiently identify temporal patterns and long-term dependencies in sequential data. The model can be trained on past ETC blockchain data to find patterns in the expected behavior of the network and then spot variations that might point to possible attacks or anomalies. The model effectively captures the subtle patterns that rule-based or statistical approaches may miss because of its capacity to encapsulate the input data and produce insightful representations.

B. Methodology

1) *Database Analysis:* Ethereum Classic is a public, open-source distributed computing platform built on the blockchain. It is notable for having smart contract capabilities, which enable scripts to run on the Ethereum Virtual Machine (EVM), a decentralized Turing-complete virtual machine. An international network of public nodes enables this functionality.

Ethereum Classic is notable for having a native value token called "ether." Ether is a cryptocurrency that may be held in wallets, transferred between users on the network, and used to pay nodes for the processing power they provide to the Ethereum platform.

Over the course of four years, from July 2015 to July 2019, we conducted tests on a section of the ETC blockchain as part of our research. The seven tables in the dataset we used are blocks, transactions, contracts, logs, token transfers, tokens, and traces. It can be accessed on Kaggle. These tables include important details regarding the blocks themselves, the operation of the network, and network use.

Multiple preprocessing stages were carried out in order to get the data ready for additional analysis. First, we carried out feature engineering, which included aggregation, correlation analysis, filtering, and the selection of the most relevant features. In order to rescale values and lessen the possibility of instability impacts during neural modeling, we secondly normalized the data. In addition, the process of normalization attempted to regularize the data by removing trending, cyclic, and seasonal irregularities. Using a shifting quantile ratio, we were able to achieve normalization.

The two parameters that the function first requires are {x}, which stands for the input data, and {window}, which indicates the rolling window's size (the default value is 20). Next, we make an object that rolls windows.

Next, we compute the first quartile. The value that divides the lowest 25% of the data from the remaining 75% is determined by passing the argument {0.25}. Furthermore, we set {interpolation='midpoint'} to ascertain the quartile value estimation technique.

In addition, we compute the third quartile. This time, the parameter {0.75} is passed in order to determine the value that divides the bottom 75% of the data from the top 25%. Lastly, we use the formula:

$$S = \{(x - q2) / (1.5 * (q3 - q1))\}$$

The original data is denoted by {df}, the median by {q2}, the first quartile by {q1}, and the third quartile by {q3}. Taking into consideration the interquartile range, the algorithm scales each value in the DataFrame according to how far it is from the median.

In a similar manner, we get the median by using the rolling window object's `median ()` function. The center figure that divides the data's upper and lower halves is known as the median.

2) *Model architecture:* The model's architecture is made up of multiple layers and hyperparameters that are specifically engineered to handle and evaluate data sequences as represented in Fig. 4. First, the training set is used to extract the length of the sequence and the number of features. One kind of recurrent neural network is the LSTM layer, which has 64 cells or neurons in its configuration. Additionally, the model has attention mechanisms with four attention heads, each with 64 dimensions. In addition, a convolutional neural network (CNN) layer with 64 filters and a kernel size of three is included in the architecture. Regularization methods like L1 and L2 regularization are used with lambda values of 0.2 to avoid overfitting.

Sequence support is defined for the input layer. Masking is applied to the input layer to manage sequences of varying lengths. To lessen overfitting, the model then incorporates numerous CNN layers with L2 regularization, dropout layers, and ReLU activation functions. To extract significant features and downsample the output, max pooling layers are used. The ReLU activation function and the designated number of cells are integrated into the LSTM layer. Furthermore, a multi-head attention layer is added to capture sequence relationships. Next come further CNN layers, dropout layers, and max pooling layers, then another LSTM layer.

To create the output sequence, a time-distributed dense layer is added last. The mean squared error loss function and Adam optimizer are used to construct the model. The model's summary is printed, together with information on its layers and parameter count. A predetermined path is used to save the trained model, and checkpoints are made to save the optimal model in accordance with validation loss. Additionally, a CSV logger is used to monitor the training progress.

The model has a batch size of 100, a validation split of 0.3, and is trained for 50 epochs on the training data. The model checkpoint and CSV logger are two of the callbacks that are used in the training process.

The architecture we've adopted to predict data, whether it's an attack or normal data. In our model, the green blocks represent the inputs and outputs. Then, there's the masking block, which allows us to handle data of different sizes. When we preprocess the data, we take a fixed-size sliding window.

However, at the end of each time sequence, we have a set of data whose size is smaller than the window's size. So, instead of discarding this data, we add it to the model. Thus, the data won't have a fixed size altogether, and there won't be data of different sizes. Therefore, we have to deal with this data, and that's where we use the masking block.

Moving on, the blue block represents the convolutional layer, and the yellow block represents the dropout layer. Here, we'll use two sets, each consisting of two convolutional layers followed by a dropout layer. In the first set, the dropout will be 0.5, and in the second set, it will be 0.8. After finishing the second set, we'll transition to the LSTM layer. Then, after the LSTM layer, we'll apply a multi-head attention layer. At the end of the architecture, in the last group, we have two LSTM layers, and in between, there's a multi-head attention layer. After the LSTM layer, we'll enter two more sets, each comprising two convolutional layers and a dropout layer. The dropout rate will be reversed here, with the first set at 0.8 and the second at 0.5. The transition between them will be done through max pooling, and finally, we'll have the output layer.

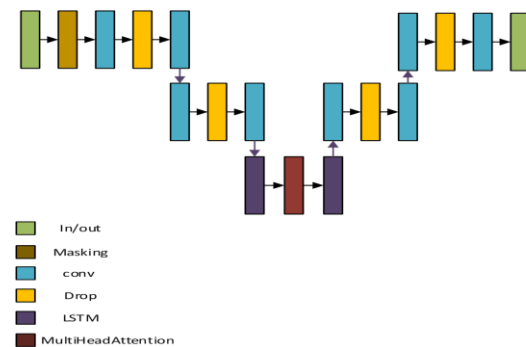

Fig. 4. Architecture of the proposed model.

a) *LSTM layer:* One kind of recurrent neural network (RNN) layer that is frequently utilized for sequence modeling is the Long Short-Term Memory (LSTM) layer [34]. The LSTM layer in this architecture is set up with 64 cells, or neurons. By preserving a memory state, LSTM cells are made to detect long-term dependencies in sequential input. Rectified Linear Unit (ReLU), the activation function utilized in this layer, gives the output non-linearity.

The LSTM (Long Short-Term Memory) layer employs a gating mechanism to regulate the memorization process. Through gates that open and close, you can store, write, or read information within LSTMs. An LSTM layer comprises the following components as can be seen in Fig. 5:

Forget gate: Responsible for deciding what information to retain and what to discard.

Input gate: Updates the cell state by incorporating information from the current input state (x) and the previous hidden state (h).

Cell state: Stores information based on the previous cell state (c) and new layer state. The current cell state is denoted as g.

Output gate: Determines the value of the next hidden state (h).

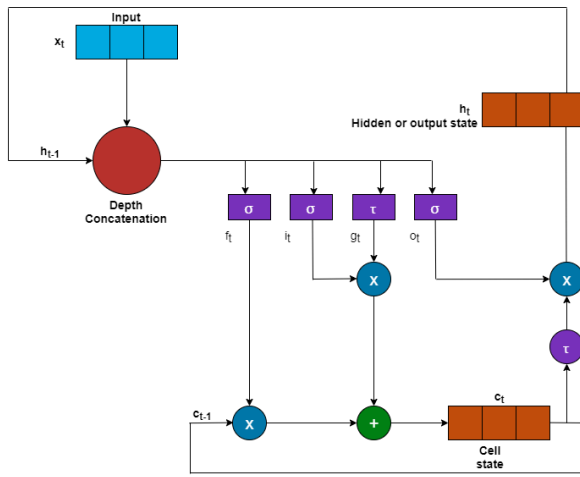

Fig. 5. The components of an LSTM layer [34].

$$W_o \begin{bmatrix} h_1 \\ \vdots \\ h_h \end{bmatrix} \mathbb{R}^{p_o}$$

According to this structure, each head has the ability to focus on distinct segments of the input, which allows for the expression of more complex functions beyond simple weighted averages.

The components of a Multi-Head Attention layer are shown in Fig. 6.

Fig. 6. The components of a Multi-Head Attention layer [36].

b) *Multi-Head attention layer:* For the purpose of identifying linkages within the sequence, the Multi-Head Attention layer [35] is essential. It makes use of an attention mechanism with several attention heads, each of which focuses on a distinct segment of the input sequence. This enables the model to extract useful features by concentrating on pertinent data. With four attention heads and a key dimension of 64, the Multi-Head Attention layer in this design is applied to the LSTM layer's output.

At their core, they consist of keys (k) and values (v). We can create queries (q) to interact with these (k,v) pairs in a way that remains valid regardless of the size of the database.

The same query can yield varied responses depending on the database's contents. Let $D = \{(k_1, v_1), \dots, (k_m, v_m)\}$ represent a database of key-value pairs, and denote a query. We can define attention over D as:

$$Attention(q, D) = \sum_{i=1}^m \alpha(q, k_i) v_i$$

Where $\alpha(q, k_i) \in \mathbb{R} (i = 1, \dots, m)$ represents scalar attention weights, with the operation commonly known as attention pooling. The term "attention" stems from the focus placed on terms with significant weights α , implying larger values. Consequently, attention over D produces a linear combination of database values. Notably, this encompasses the earlier example as a special case where all weights except one are zero.

Given a query $q \in \mathbb{R}^{p_q}$, a key $k \in \mathbb{R}^{p_k}$, and a value $v \in \mathbb{R}^{p_v}$, each attention head $h_i (i = 1, \dots, h)$ is computed as:

$$h_i = f(W_i^q q, W_i^k k, W_i^v v) \in \mathbb{R}^{p_v}$$

Where $W_i^q \in \mathbb{R}^{p_q \times d_q}$, $W_i^k \in \mathbb{R}^{p_k \times d_k}$, $W_i^v \in \mathbb{R}^{p_v \times d_v}$ are learnable parameters and is attention pooling, such as additive attention and scaled dot product attention. The multi-head attention output is another linear transformation via learnable parameters $W_o \in \mathbb{R}^{p_o \times h p_v}$ of the concatenation of heads:

c) *Convolutional Neural Network (CNN) layers:* When attempting to extract geographical and temporal information from data, CNN layers are frequently employed. CNN layers are used in this model to examine the sequence data. Multiple CNN layers with the same configuration are part of the architecture. A predetermined number of filters make up each CNN layer, and these filters are in charge of identifying various patterns and features in the input. When a kernel size of three is employed, the CNN layer scans the input sequence using a three-size window. ReLU is the activation function used in these layers, which gives the output non-linearity. Furthermore, padding is set to'same' to guarantee that the length of the output and the input sequence match.

d) *Dropout layers:* A regularization method called dropout layers is employed to stop overfitting. During training, they arbitrarily deactivate a set of the neurons, which compels the model to (2) be more resilient and comprehensive representations. Dropout layers with a dropout rate of 0.5 or 0.8 are placed after specific CNN layers in this architecture. Dropout layers are strategically placed to improve the model's generalization ability and lessen its sensitivity to noise.

e) *Max pooling layers:* The most notable aspects of the data are captured by downsampling the output using max pooling layers. They remove less significant data by dividing the input into non-overlapping parts and keeping just the largest value within each zone. By keeping the most important attributes, this downsampling aids in lowering the dimensionality of the data. In order to help with relevant information extraction and efficient feature representation, this design uses many max pooling layers after certain CNN layers.

f) *Time-Distributed dense layer:* The output sequence is produced at the end of the architecture using the Time-Distributed Dense layer. It separately applies a dense (completely linked) layer to every time step. As a result, the temporal relationships in the data are captured by the model,

which can now generate predictions for every element in the sequence. Since the aim in this scenario is to predict a single value for each element in the sequence, a dense layer with a single unit is used.

VII. RESULTS

The results that were obtained in this study are divided into three categories, the first of which is the output of the Preprocessing stage, where the data scanning process was applied. The second category, which is model training, is summarized using the loss function. Finally, the third stage is predicting attack data.

There are seven parameters in the database, the result of the Preprocessing for each variable will be presented separately. Regarding the attack data, it will be identified the same for all the data, so that it is possible to see at what timestamp it was determined to be attack data. To show the experimental results, initially the results of data processing are displayed after being pre-processed such that the horizontal axis represents the timestamps, and the vertical axis represents the different variables. Fig. 7 plots the normalized average gas provided along the time window to show the effect of the preprocessing processes. The red lines within the graphs indicate the attack-prone periods.

Fig. 7. Relationship of provided gas average with timestamp after normalization.

Similarly, Fig. 8 shows the timestamps represented on the horizontal axis, while the normalized transaction number is represented on the vertical axis. The red lines also represent attack data at these timestamps.

Fig. 8. Relationship of Transactions Number with Timestamp after normalization.

Fig. 9 shows the relationship between Block Difficult Average and Timestamp after normalization, where the horizontal axis represents the timestamps, while the vertical axis represents the normalized Block difficult average.

Fig. 9. Relationship of Block Difficult Average with Timestamp after normalization.

Another figure, Fig. 10 illustrates the relationship between block size average and timestamp after normalization, where timestamps are represented on the horizontal axis, whereas the block size average is represented on the vertical axis.

Fig. 10. Relationship of Block Size Average with Timestamp after normalization.

Fig. 11 shows the relationship between the gas used sum and the timestamps, where the latter is plotted on the horizontal axis, whereas the sum of used gas is plotted on the vertical axis.

Fig. 11. Relationship of Gas Used Sum with Timestamp after normalization.

Fig. 12 and Fig. 13 show the relationship between the timestamps and the transaction average per plot, and the gas average per transaction respectively.

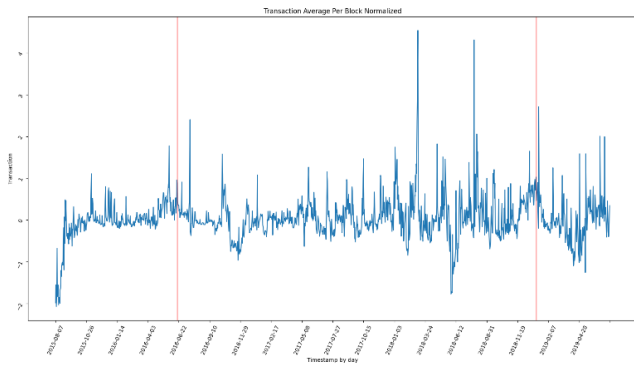

Fig. 12. Relationship of Transaction Average per Block with Timestamp after normalization.

Fig. 13. Relationship of Gas Average Per Transaction Per Block with Timestamp after normalization.

The second part of the results involves the model training process. Fig. 14 shows the training loss for both training (orange) and testing (blue), where it is noticed that the presented model completely handles overfitting as a result of the L2 regularization with a value of 0.02 and the two dropout layers. A dropout rate of 0.8 is considered high enough to address overfitting, so the overfitting ratio was nearly zero from the beginning to the end of the training. However, this will affect the model's accuracy, making it lower than usual or expected, which is also compensated for by data scanning and pre-processing. Therefore, the model with almost have no overfitting and achieve high accuracy.

Fig. 14. Training and Validation Loss.

Fig. 15 shows the results of testing the proposed model on the test data, which includes attack data consistent with the reference study 1 [37]. This data includes a set of natural data over a period of time. Within these time periods, there will be attack data. This model output shows that the data marked by the red lines are attack data, while the rest of the data is natural. The test results show that the pre-processing and the proposed model give good performance for detecting logger anomalies on the network. Within the test data, it is worth noting that the test accuracy of the proposed model is 0.995.

Fig. 15. Results obtained by the proposed model.

VIII. DISCUSSION

Fig. 16 and Fig. 17 represent a comparison between the results obtained in this study and the results found in study 1 [37] and study 2 [38]. The red line represents attack data, while the other data points represent normal data. In both our model and the reference study, the horizontal axis represents the timestamp, while the vertical axis represents a parameter from the database, such as average gas. As we can see, there is a difference because we applied preprocessing to our data, while the reference study used a different preprocessing method. Therefore, there is a slight difference in the data representation. However, both studies practically cover the same time period. We also observed that both models identify attack data during the same time periods. The difference lies in the fact that our model achieved higher accuracy in testing, i.e. in classifying this data as either attack or natural.

Fig. 16. Comparison of Results with reference Study 1 [37].

The anomaly detection results of the proposed model and results of Study 2 are shown in Fig. 17.

Fig. 17. Comparison of results with reference study 2 [38].

As a result, the proposed model shows the ability to predict the detection of anomalies for activities recorded on the network. It also efficiently addresses the challenge of overfitting during model training. It also achieves a prediction accuracy rate of 0.995 for the model on test data. Compared with reference studies, we find that the proposed model has the ability to capture dependencies. It is time efficient and has the ability to detect attacks on the network. For further development, we recommend using more general training data, as well as testing transformers on this type of challenges.

IX. OPEN ISSUES AND RESEARCH CHALLENGES

Open issues and research challenges in the field of enhancing the security of digital financial and banking transactions through blockchain-enabled approaches, particularly the implementation of a Long Short-Term Memory (LSTM) model, remain to be addressed. One of the key challenges is the need to develop more sophisticated anomaly detection techniques to effectively identify and mitigate potential threats in network-recorded activities. Additionally, there is a requirement for further exploration of the scalability and performance implications of using blockchain technology in large-scale financial systems, as well as the development of robust security systems to withstand evolving cyberattacks. Furthermore, the integration of

blockchain technology with existing regulatory frameworks and compliance standards poses legal and regulatory challenges that need to be addressed for widespread adoption. These open issues call for continued research and collaboration among academia, industry, and regulatory bodies to ensure the successful implementation and utilization of blockchain-enabled security solutions in the realm of digital financial and banking transactions.

X. CONCLUSION

Blockchain has shown to be a revolutionary technology, but its widespread adoption has been hampered by a number of restrictions. Our project focused on enhancing the security of digital financial and banking transactions using blockchain technology. It addresses the challenges faced by the banking industry, such as inefficiency, high fraud rates, and lack of transparency, and proposes a solution through the implementation of blockchain. The research aims to develop an analytical model capable of detecting attacks and anomalies on the Ethereum Classic (ETC) blockchain by employing an Encoder-Decoder LSTM architecture. The study emphasizes the importance of cybersecurity in the banking sector and the potential of blockchain technology to revolutionize the industry by providing a secure, efficient, and transparent platform for financial transactions. The thesis outlines the methodology used, the results obtained, and the contributions made to the field of blockchain security. It concludes with suggestions for future research directions, highlighting the ongoing need for innovation in the realm of digital financial security.

The project's findings revealed that adding machine learning and blockchain technology may significantly improve and refine numerous security sectors. However, this study is simply the beginning of a broader and more extensive inquiry into this type of integration, underlining the need for more research that looks into numerous authentication elements across diverse datasets to balance security and usability.

Future work will focus on addressing the scalability of the proposed LSTM model within larger decentralized financial ecosystems, particularly those operating on multiple blockchain platforms. Additionally, further research will explore the integration of reinforcement learning techniques to enhance real-time anomaly detection. Another promising avenue is the application of this model to emerging blockchain networks to determine its effectiveness in varied contexts. Extending the study to multi-blockchain scenarios could also provide insights into cross-network security enhancements.

ACKNOWLEDGMENT

Abstract—Towards malicious activity monitoring in organizations, there exist several techniques and suffer with poor accuracy. To handle this issue, an efficient Sketch and Size orient malicious activity monitoring (SSMAM) is presented in this article. The model captures the video frames and performs segmentation to extract the features of frames as shapes and size. The video frames are enhanced for its quality by applying High Level Intensity Analysis algorithm. The quality improved image has been segmented with Color Quantization Segmentation. Using the segmented image, the feature are extracted and applied with scaling and rotation for different number of size and angle. Such features extracted have been trained with convolution neural network. The CNN model is designed to perform convolution on two levels and pooling as well. At the test phase, the method extract the same set of features and performs convolution to obtain same set of feature lengths and the neurons are designed computes the value of Sketch Support Measure (SSM) towards various class of activity. According the value of SSM, the method classifies the user activity towards efficient video surveillance. The proposed approach improves the performance in activity monitoring and video surveillance.

Keywords—Video surveillance; deep learning; activity monitoring; malicious activity; SSMAM; SSM

I. INTRODUCTION

Growth of information and communication technology has been adapted to various scientific, medical and security problems. Industrial security is the most concern in recent days and they tends to enforce the human monitoring in the units of organization. Video surveillance is the process of monitoring the human activity in various locations and units of any organization. In this way, they can monitor the activity of human, worker towards enforcing security and maintaining the human resource [5, 6]. By monitoring the human activity, the malicious event happening within or outside the organization can be tracked and used towards enforcing security.

The video frames captured through set of video devices and cameras are the key input for the video surveillance system of any organization. By using the images of video, the human object can be tracked in successive frames and their activity can be classified. Image processing plays vital role in identifying the human texture and can be used to extract the features from the frame to support the classification of activity. In order to perform event or activity classification, the system has to maintain number of frames and objects of humans about

different activities. By maintaining such set of frames and objects, the input frame can be classified for its activity [7].

To perform video surveillance there are numbers of machine learning algorithms described in literature. For example, support vector machine (SVM), Decision Tree, Bayesian Classifier, Neural Network are used in earlier articles [11]. The methods capture the video frame and perform background subtraction which is learned from the different previous frames. With the subtracted image, the method would identify the human object to extract the object and train the model. The issue with the machine learning algorithms is the dimensionality and missing features. In order to achieve higher performance in video surveillance, it is necessary to maintain the set of human objects under different activities. With the trace, the method can identify the class of any video frame for its activity. The machine learning algorithms are little uncomfortable to maintain and handling such huge volume of frames. This is where the deep learning algorithms come to play.

The deep learning algorithms are capable of converting the huge volume of features into small set without the loss of feature and data. For example, Convolution neural network is more popular on handling such higher volume data. It would convert the features of video frames into tiny feature set and used to perform classification. With all these consideration, this article presents a novel Sketch and Size Orient Malicious Activity Monitoring (SSMAM) model. The model concentrates on extracting the human features and sketch features. By extracting the sketch and size features, the model has been trained with number of features at each class with convolution neural network. The SSMAM-CNN model is capable of handling various class of activities and support the detection of malicious activity in the premises. By adapting SSMAM-CNN model the human activity can be greatly monitored.

A. Problem Statement

The methods discussed in literature uses variety of features from object, graph, edge, etc. towards human activity monitoring. But still they suffer to achieve higher accuracy towards malicious activity monitoring. The accuracy of video surveillance and activity monitoring is greatly depending on the kind of feature considered. The human sketch is the most effective one which can be used in activity monitoring to detect any malicious activity happening in the venue.

B. Contributions

- The problem of activity monitoring is approached with sketch and size features along with other features.
- CNN model is designed for training and classification.
- Sketch Support Measure (SSM) is estimated to perform classification.

The article is structured to provide general introduction about the problem in Section I. Section II briefs the literature review around the problem and Section III presents the detailed working of the model. Section IV is dedicated to present the experimental result and Section V discuss the conclusion.

II. RELATED WORK

Different methods are analyzed around video surveillance and activity monitoring. Set of methods around the problem is discussed here.

A Gaussian Mixture Model with Universal attribute model is presented in [1], which monitor the violent activities by computing super action vector. A Growing self-organizing map (GSOM) is presented in [2], which uses traditional deep learning and multistream learning to use unlabeled data to handle the over fitting problem to identify malicious activity.

An Efficient Marine Organism Detector (EMOD) is discussed in [3], which uses attention relation to detect malicious activity. A deep learning based video surveillance model is presented in [4], which classify the objects under different categories and identify the region in the frame to perform supervised learning. A human action recognition (HAR) model is presented to monitor the activity in aircraft surveillance. The method uses temporal features and use LSTM to perform classification.

A visual surveillance framework is presented in [6], to monitor the human fall which uses deep CNN and uses aggregated heuristic visual features in detecting the occurrence of falls. An audio video based activity recognition model is presented in [7], towards video surveillance.

A human activity recognition model is sketched in [8], which uses data enhancement techniques to collect discriminative features from various activities. The features captured are transformed with existing model to perform recognition. A hybrid visual geometry group based bidirectional short term memory model is presented in [9], towards monitoring the moments of animals and produces alarm according to the activity of the animals. A transformer network based LSTM model is presented in [10], towards recognizing the activity of the human.

A multipedestrian multicamera tracking (IMPACT) model is presented in [11], which uses spatial and temporal features towards monitoring the pedestrian monitoring. An Interactive video surveillance as an edge service (I-ViSE) model is presented in [12], which works according to the feature queries. The method adapts features of human body, color and cloths in activity monitoring. An LSTM based baby activity recognition model is presented in [13], which uses pose features of baby towards recognition.

A Class-privacy Preserved Collaborative Representation (CPPCR) based multi-modal human action recognition model is presented in [14], which uses temporal structure in recognizing the activity. An LSTM with 3DCNN model is presented in [15], towards detecting illegal activity in the environment.

A realtime surveillance model is presented in [16], towards detecting malicious behavior using deep transfer learning. A posture recognition system is presented in [17], which uses mobilenetV2 towards estimating the human posture and LSTM is used to extract the features. Machine learning algorithm is used for classification. A secure surveillance scheme is presented in [18], to support healthcare system with enabled internet of Things. A deep learning multi layered CNN with LSTM is presented in [19], to capture the physical activities of persons and performs activity classification.

A machine learning based harmful weapon detection model is presented in [20], which uses different pistol classes and objects. The method uses sliding window classification model to perform classification. Lightweight Deep Neural Network (LDNN) with Convolution Long Short Term Memory (ConvLSTM) model is presented in [21], towards detecting abnormal activity in the environment. A Graph Convolution Network with 3DCNN is presented in [22], towards detecting abnormal behavior. 3DNN is used to extract the features and GCN has been used to perform classification. An audio and visual based activity detection model is sketched in [23], which uses both audio and video data in detecting abnormal activity in video frames. The method uses PSO and social force model towards feature extraction and classification. A Faster Region-Based Convolutional Neural Networks (Faster RCNN) is presented in [24], to detect the firearms in organization. The model uses ensemble learning to detect the human face and guns using Weighted Box Fusion techniques.

A spatio temporal attention fusion slowfast network based model is presented in [25], which uses spatial and temporal features to perform classification. A 2D and 3D feature based HAR is presented in [26], which extract the geometric features using deep and machine learning algorithms like CNN to classify the activity of human using LSTM and SoftMax classifier. A multi perspective abnormal posture recognition model is presented in [27], which works according to multi view cross information and posture features towards detecting illegal activity.

All the above discussed approaches suffer to achieve higher performance in activity monitoring and video surveillance.

Research Gap: According to the literature, the existing works does not consider the sketch and size features with the combination of other object features. This affects the performance of activity monitoring.

III. SKETCH AND SIZE ORIENT MALICIOUS ACTIVITY MONITORING WITH CNN (SSMAM-CNN)

The model captures the video frames and performs segmentation to extract the features of frames as shapes and size. The video frames are enhanced for its quality by applying High Level Intensity Analysis algorithm. The quality improved image has been segmented with Color Quantization

Segmentation. Using the segmented image, the feature are extracted and applied with scaling and rotation for different number of size and angle. Such features extracted have been trained with convolution neural network. The CNN model is designed to perform convolution on two levels and pooling as well. At the test phase, the method extract the same set of features and performs convolution to obtain same set of feature lengths and the neurons are designed computes the value of Sketch Support Measure (SSM) towards various class of activity. According the value of SSM, the method classifies the user activity towards efficient video surveillance.

The functional architecture of SSMAM-CNN model has been presented in Fig. 1 and the functions of the model are briefed in this section.

A. High Level Intensity Analysis Preprocessing

The high level intensity analysis algorithm enhances the quality of video frame given. To perform this, the method fetch the image and extract the RGB layers. Among the three layers, the method use the red layer features to enhance the image quality. The method initializes a window size and crops the features from the red layer. Among the window feature, the method computes the max intensity value (MIV) and least intensity value (LIV). Using these two, the method traverse through each pixel and computes the Max Intensity Distance and Least Intensity Distance. Based on the value of distances, the method identifies the closest intensity sector and computes the Intensity Normalization Value. Based on that, the pixel has been adjusted for its intensity. The quality enhanced image has been used to perform segmentation and activity monitoring.

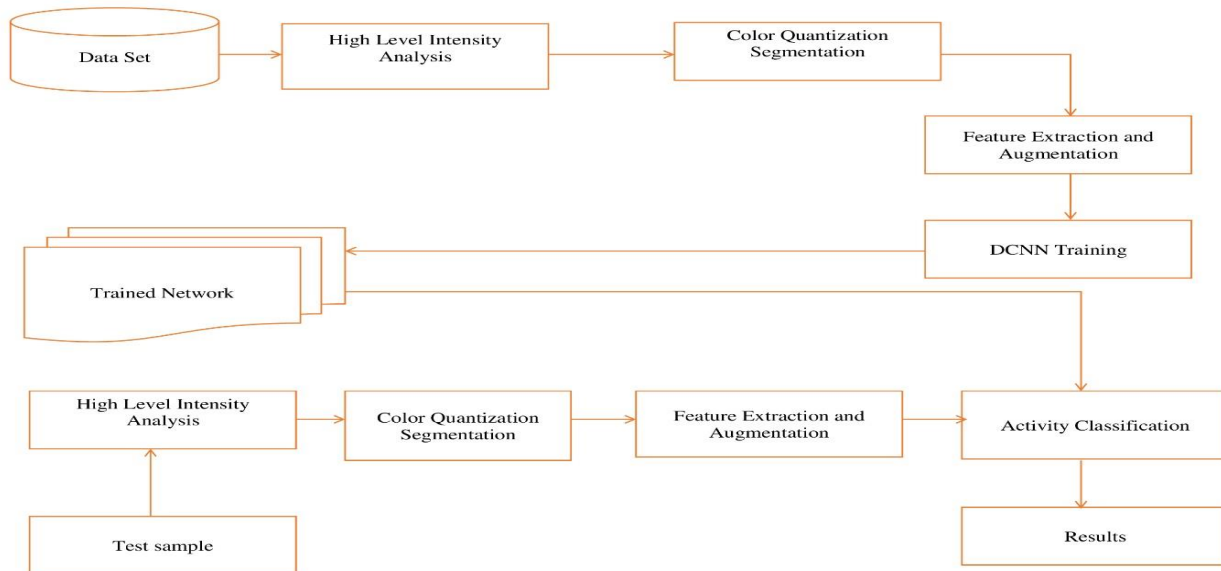

Fig. 1. Architecture SSMAM-CNN model.

Algorithm:

Given: Video Frame Vf
Obtain: Enhanced Video Frame Evf.
Start
 Read Vf.
 [RGB]= Extract RGB Layers (Vf)
 Initialize window size $W_s = 5$
 For each window w
 Compute Max Intensity Value $Miv = \frac{Size(w)}{Max(W(R(i)))}$
 Compute least intensity value $LIV = \frac{Size(w)}{Min(W(R(i)))}$
 For each pixel p
 Compute Max intensity Distance $Mid = Dist(p(R), Miv)$
 Compute Least intensity Distance $Lid = Dist(P(R), LIV)$
 if $Mid < Lid$ then
 Compute intensity normalization value $Inv =$

$\frac{p(R)+Mid/3}{Evf(W(p(R)))} = Inv$
 End
End
Stop

The high level intensity normalization algorithm computes the INV value for different pixels of red layers of the frame to adjust the quality of the frame. The enhanced image has been used towards segmentation and activity monitoring.

B. Colour Quantization Segmentation

The colour quantization algorithm segments the image according to the colour features. The quantization is performed based on the RGB values obtained from the frame given. To perform this, the method reads the red green black layer features and for each layer feature, the method computes the Quantization Measure (QM) which is measured based on the overall feature value and identifies the non-dominant value. To obtain this, the method generates the histogram for each layer

TABLE I. EVALUATION DETAILS

Parameter	Value
Number of Activities	20
Total Images	10000
Tool	MATLAB
No of users	700

TABLE II. ANALYSIS OF MALICIOUS ACTIVITY DETECTION ACCURACY

Malicious Activity Detection Accuracy % vs No of Activities			
	5 Activities	10 Activities	20 Activities
DMPMAM	82	88	95
DFI_SVQA	72	75	79
MuIVIS	76	81	85
SSOcT	71	77	82
SSMAM_CNN	85	91	97

The accuracy of methods in detecting malicious activity has been counted and analyzed in Table II, where the SSMAM_CNN scheme stimulates higher accuracy than other techniques.

The accuracy in detecting malicious activity is measured and compared in Fig. 2. The SSMAM_CNN model improves the performance at the increasing number of activity classes and videos.

Fig. 2. Malicious activity detection accuracy.

The ratio of false detection is measured and compared in Table III, where the SSMAM_CNN approach has produced fewer ratios than other techniques.

TABLE III. FALSE RATIO IN MALICIOUS ACTIVITY DETECTION

False Ratio % vs No of Activities			
	5 Activities	10 Activities	20 Activities
DMPMAM	18	12	5
DFI_SVQA	18	25	21
MuIVIS	24	19	15
SSOcT	29	23	18
SSMAM_CNN	15	9	3

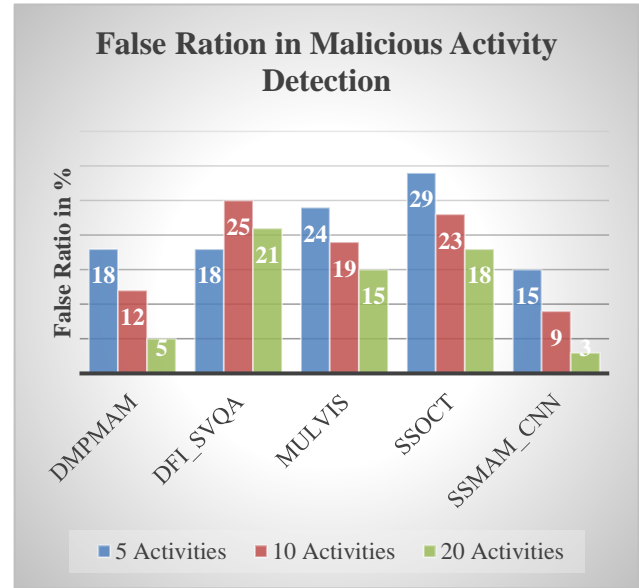

Fig. 3. False ratio in malicious activity detection.

The false classification ratio introduced by various approaches in malicious activity detection is measured & compared in Fig. 3. The SSMAM_CNN models introduces negligible false detection ratio compare to others in all the cases.

TABLE IV. TIME COMPLEXITY IN MALICIOUS ACTIVITY DETECTION

Time Complexity in Malicious Activity Detection % vs No of Activities			
	5 Activities	10 Activities	20 Activities
DFI_SVQA	67	77	88
DMPMAM	21	32	45
MuIVIS	58	73	83
SSOcT	48	62	77
SSMAM_CNN	18	26	37

The time complexity in Millie seconds produced by various methods in detecting the malicious activity is measured and compared in Table IV, where the SSMAM_CNN approach produced less time complexity compare to other approaches.

The time complexity produced by various approaches in malicious activity detection is measured and compared in Fig. 4. The SSMAM_CNN model has produces less time complexity in all the test cases.

Fig. 4. Analysis time complexity in malicious activity detection.

VI. CONCLUSION

To maximize the accuracy of malicious activity detection, this article presented a novel sketch and size based malicious activity detection model with CNN (SSMAM_CNN). Apart from using object and shape features towards the problem, this approach uses the sketch and size features of the person to classify the activity. By adapting sketch and size features with the problem, the accuracy has been greatly improved. The model applies high level intensity analysis to enhance the quality of the image. Further, the method applies color quantization segmentation to segment the image. Next, the features are extracted and augmented data has been produced to train the convolution neural network. At the test phase, the method computes the sketch support measure (SSM) towards various class of activity features. According to the value of SSM, the class with maximum SSM value has been selected to perform the classification. The proposed model improves the performance of malicious activity detection accuracy up to 97%.

Further, the research can be extended by adapting invariant position features to stimulate the performance.

VII. FUNDING STATEMENT

The authors received no specific funding for this study.

CONFLICTS OF INTEREST

The authors declare they have no conflicts of interest to report regarding the present study.

Enhancing Arabic Phishing Email Detection: A Hybrid Machine Learning Based on Genetic Algorithm Feature Selection

Amjad A. Alsuwaylimi

Department of Information Technology-Faculty of Computing and Information Technology,
Northern Border University, Rafha 91911, Saudi Arabia

Abstract—Recently, owing to widespread Internet use and technological breakthroughs, cyber-attacks have increased. One of the most common types of attacks is phishing, which is executed through email and is a leading cause of the recent surge in cyber-attacks. These attacks maliciously demand sensitive or private information from individuals and companies. Various methods have been employed to address this issue by classifying emails, such as feature-based classification and manual verification. However, these methods face significant challenges regarding computational efficiency and classification precision. This work presents a novel hybrid approach that combines machine learning and deep learning techniques to improve the identification of phishing emails containing Arabic content. A genetic algorithm is employed to optimize feature selection, thereby enhancing the performance of the model by effectively identifying the most relevant features. The novel dataset comprises 1,173 records categorized into two classes: phishing and legitimate. A number of empirical investigations were carried out to assess and contrast the performance outcomes of the proposed model. The findings reveal that the proposed hybrid model outperforms other machine learning classifiers and standalone deep learning models.

Keywords—Machine learning; phishing email; BiLSTM; Arabic content-based

I. INTRODUCTION

Phishing emails are powerful instruments for scammers who want to make money by taking advantage of their feelings and trust. Attackers can achieve this by pretending to be trustworthy organizations such as banks or government authorities, and creating a sense of urgency or panic in their victims [1-3]. Phishing attacks offer scammers the possibility of high returns on investment because they are inexpensive and easy to perform. These assaults exploit human susceptibilities, such as the need for self-preservation and curiosity, while avoiding security systems through emotional manipulation. Therefore, one must learn how phishing emails operate if they are to protect themselves from falling victims to these dishonest campaigns. Phishing emails come in all shapes and sizes but share the same end, outsmarting the target to perform their bidding. One type of phishing email is scam email, which disguises itself as a legitimate organization, often a bank or another well-known business, requesting the target to click on links or share personal information [4,5]. The other type is spear-phishing, which uses intimate and personal information about the recipient to appear more authentic and trustworthy.

Furthermore, another type exists, which is called the clone phishing email, which copies a real email the victim has already received, and then sends it back directly with a malicious attachment or URL. Furthermore, cybercriminals imitate high-ranking officers through CEO fraud emails to deceive employees and send urgent payments or sensitive data to them. Meanwhile, phishing emails direct their victims to fake websites, where they attempt to acquire their financial details or log-in credentials. These kinds of deceitful electronic mail play on either trust, urgency, or curiosity to make unsuspecting individuals compromise their own safety.

Researchers have been investigating various techniques, such as Natural Language Processing (NLP) [6-8], Machine Learning (ML) [9-16] and Deep Learning (DL) [17-21] to deal with the significant challenge posed by phishing emails in the field of cybersecurity. NLP methods are used for analyzing the text of emails and detecting linguistic indications or patterns indicative of phishing attempts. ML algorithms can be trained with large datasets containing examples of phishing emails to identify the commonalities between them and subsequently automate the recognition and classification of new ones into predefined categories based on these observed regularities. DL, specifically Convolutional Neural Networks (CNNs) alongside Recurrent Neural Networks (RNNs), makes it possible to detect phishing emails more precisely by learning complex features from both email content and its metadata.

Despite these efforts, achieving time efficiency and accuracy with these techniques remains a significant challenge in the field. The processing of extensive features necessitates substantial memory and computational time, further complicating the development of effective email classification techniques. Furthermore, the proliferation of big data presents also significant challenges for these techniques, mainly due to increased training durations from the heightened computational demands of processing large datasets. Both the larger sample size and greater dimensionality of the data contribute to this issue. High dimensionality particularly affects inference times due to the added computational burden of feature extraction. In real-time phishing detection models, these factors can negatively impact user experience and compromise the effectiveness of deployed techniques. Consequently, optimizing these techniques to balance accuracy and computational efficiency is an ongoing area of research. To address these challenges, researchers and practitioners often use feature reduction or feature selection techniques. By

strategically selecting a subset of features, these methods reduce computational costs [22].

The existing literature describes several feature selection algorithms that are commonly used, such as tree-based methods [23], selectKBest [24], Recursive Feature Elimination [25], LASSO [26], Principal Component Analysis [27], and Evolutionary Algorithms [28]. Evolutionary algorithms utilize a population of candidate solutions that progressively adapt over time via number of operators: selection, mutation, and recombination mechanisms to identify optimal solutions. Their robustness, flexibility, ability address complex, non-differentiable, and non-linear problems with versatility and resilience, parallelization capabilities, and multi-objective optimization potential make them particularly advantageous for various optimization tasks, including feature selection.

Genetic Algorithms (GAs), a subset of EAs, emulate natural selection to solve optimization problems. GAs have demonstrated significant success in addressing diverse optimization challenges, including feature selection. GAs have been employed in feature selection tasks, whereby the features are represented as chromosomes, and various genetic operators, including selection, mutation, and crossover are applied to evolve candidate solutions. The efficacy of each proposed solution is evaluated using a predefined objective function, and the optimization procedure continues iteratively until a satisfactory feature subset is obtained.

In the context of our research, the primary aim is to enhance detection accuracy and recall while simultaneously reducing processing time by minimizing the feature set. This work introduces a new hybrid approach for email classification. Specifically, we propose a method that integrates machine learning (ML) and deep learning (DL) methodologies to detect and categorize content-based phishing emails in the Arabic language, utilizing a GA to identify and select the best features. Our research significantly advances the current state of knowledge in this domain through several key contributions. First, we develop a hybrid model combining Random Forest (RF) and Bidirectional Long Short-Term Memory (BiLSTM) techniques, enhancing the detection of Arabic-based phishing emails. Additionally, we create and introduce a novel dataset comprising 1,173 Arabic content-based emails, providing a valuable resource for future research in Arabic phishing email detection. Furthermore, we innovatively apply a genetic algorithm to optimize feature selection and reduce feature dimensionality, thereby improving the efficiency and accuracy of the model. Finally, we conduct a comprehensive evaluation of the impact of genetic algorithms on model performance, demonstrating their effectiveness in enhancing accuracy relative to ML classifiers and DL models.

The remainder of this paper is organized as follows: Section II reviews related studies on phishing detection techniques, emphasizing recent advancements and the integration of machine learning (ML) and deep learning (DL) methodologies. Section III provides a detailed formulation of the problem addressed in this research. Section IV outlines the methodology and materials used, describing the dataset, preprocessing techniques, and the proposed hybrid model combining Random Forest and BiLSTM with Genetic

Algorithm Feature Selection. Section V presents the experimental results and discussion, comparing the performance of the proposed model with baseline machine learning classifiers and deep learning models. Finally, Section VI concludes the paper by summarizing the key findings and suggesting directions for future research in the field of phishing email detection.

II. RELATED STUDIES

A. Phishing Email Detection Approaches

The ongoing evolution and increasing prevalence of phishing attacks necessitate continued research in detection methodologies. As these threats become more diverse, studies examining detection methods are concurrently updated and enhanced to address emerging challenges. The advent of ML and DL techniques, having proven their effectiveness in various problem domains, has led to their adoption in phishing detection research [16]. Researchers in this field have increasingly employed these advanced computational methods due to their competence in detecting complex patterns and addressing emerging attack strategies. Current studies primarily concentrate on identifying phishing emails and websites, utilizing ML and DL methods to enhance detection accuracy and minimize false positives. This transition to more advanced analytical approaches reflects the field's adaptation to the growing sophistication of phishing attacks and highlights the need for ongoing innovation in cybersecurity defences.

The authors of [1] explored the effectiveness of a transformer model named Bidirectional Encoder Representations from Transformers (BERT) and word embeddings for spam email classification. The findings were compared with those of Deep Neural Network (B-DDN) model, which includes Naive Bayes classifiers, k-nearest Neighbors, the BiLSTM layer. The model was tested and trained using two public datasets. The BERT transformer model with English Wikipedia and BookCorpus was used as the training data, with F1-score of 98.66% and an accuracy of 98.67%. This work investigated spam email detection using contextual word embeddings, attention layers, and deep learning techniques.

The study by [11] explored the use of ML-based spam detection models. Various ML methods were employed to categorize SMS messages as legitimate or spam, including Naive Bayes (NB), Decision Trees (DT), Support Vector Machines (SVM), Convolutional Neural Networks (CNN), Random Forest (RF), and Artificial Neural Networks (ANN). The research utilized several datasets, such as the Spam SMS Dataset and UCI SMS database, along with a custom-crawled dataset. For real-world data, both English and Indonesian languages were considered. Application of these models to the datasets yielded promising accuracy rates: SVM achieved 97.4% precision, CNN demonstrated 99.19% accuracy, and Weka SVM exhibited 99.3% accuracy for spam classification. Preprocessing techniques, including tokenization, removal of stop words, and feature extraction, were identified as methods to enhance accuracy. Similarly, focusing on SMS spam detection, the authors in [17] introduced a Hybrid Convolutional Neural Network-Long Short-Term Memory (CNN-LSTM) approach for the detection of spam within SMS

messages in Arabic and English languages. This approach was compared to conventional machine learning algorithms, including K-Nearest Neighbors (KNN), Support Vector Machine (SVM) and DL models such as LSTM and CNN individually. The study utilized two datasets: the SMS Spam data collection obtained from the UCI Machine Learning Repository containing a collection of Arabic messages and English messages sourced from local mobile phones. This hybrid model was designed to handle mixed linguistic content in Arabic and English communications. The proposed approach achieved a notable accuracy of 98.37% in categorizing SMS messages as spam or legitimate, outperforming all other machine learning algorithms tested in the study.

The study of [12] introduced two novel algorithms, FMMPED and FMPEd, specifically designed to enhance phishing email detection capabilities. These algorithms were developed utilizing undersampling techniques and ensemble learning methodologies. To simulate real-world email environments, the researchers employed a dataset with a 10:1 ratio of malicious to legitimate emails. The study, published in a highly technical journal focused on machine learning and cybersecurity, employs sophisticated terminology commensurate with its computer science orientation. The proposed algorithms demonstrated superior performance compared to traditional machine learning and deep learning approaches, accomplishing accuracy and an impressive F1-score of 0.9945. The authors of [16] employed 13 machine learning classifiers to differentiate between spam and non-spam emails, including Bayesian methods, Decision Trees, Random Forest, Support Vector Machines, Decision Tables, and Bagging. The evaluation methodology incorporated two datasets: Spam Corpus and Spambase. The Random Forest classifier demonstrated superior performance on the Spam Corpus dataset, surpassing all other classifiers implemented using the Python programming language, with an accuracy rate of 99.91%.

The study of [15] investigated the implementation of diverse machine learning approaches for spam email classification. The study utilized traditional spam detection methods, which include Support Vector Machine, Naïve Bayes, Random Forest, and K-Nearest Neighbour models. The research incorporated a comprehensive collection of email datasets and real-life scenarios of varying sizes and formats from multiple sources, such as Kaggle and Sklearn. The study emphasized document pre-processing, encompassing cleaning, integration, transformation, and reduction. Additionally, tokenization and stop word removal were considered. The problem statement effectively elucidated the significance of this research.

In the study by [29], they utilized email samples as the dataset and employed federated learning approaches with THEMIS and BERT models for phishing email detection. Due to architectural constraints, the BERT model focused specifically on the email body. Both training and evaluation of the models were conducted in English. THEMIS achieved a test accuracy of 97.9% for federated learning with five clients at epoch 45, while BERT attained a test accuracy of 96.1% for federated learning with five clients at epoch 15. It is

noteworthy that accuracy rates varied depending on the client. The authors in [18] introduced a new Intelligent Cybersecurity Phishing Email Detection and Classification (ICSOA-DLPEC) model that leverages n-gram feature extraction, a Gated Recurrent Unit (GRU) model, and a Compressive Sensing (CS) algorithm for optimal parameter tuning. They evaluated its performance using a standard dataset, achieving impressive accuracy rates between 98.46% and 99.72% across different training and testing data volumes. This study also discusses online safety terms and deep learning concepts. When compared to other models such as LSTM, CNN, and THEMIS, the ICSOA-DLPEC model demonstrated superior performance in being correct, precise, able to recall, and in its F-score.

Tong et al. 2021 [30], proposed a capsule network model with long-short attention for Chinese spam detection. The authors used the Trec06c dataset and received an accuracy of 98.72% on an unbalanced dataset and a 99.30% accuracy on a balanced dataset. Similarly, Li et al. [31], introduced an LSTM based phishing email detection method and tested it on a dataset of 29,942,735 emails from an enterprise mail server with both Chinese and English content. The model got nearly 100% accuracy in classifying phishing emails. Wu et al. [32], evaluated ChatGPT's spam detection against baseline models like SVM, LR, NB and BERT on the English Email Spam Detection (ESD) dataset and the low-resourced Chinese Spam Dataset (CSD) and the results were achieved in accuracy was 83% and 86% accuracy on two different experiments.

B. Feature Selection Methods

The process of feature selection is a critical component in the fields of ML and data analytics. It involves identifying and extracting the most salient subset of attributes from the complete set of features present within a given dataset. The primary goals of feature selection are to reduce dimensionality, improve model performance, enhance generalization, and provide better interpretability of results [33]. In the context of phishing email detection, the feature selection process involves the identification and selection of the most informative characteristics of emails that effectively differentiate between legitimate and phishing messages. This process is essential for developing accurate and efficient phishing detection systems that can adapt to evolving threats. The selected features must be relevant to phishing indicators, adaptable to new techniques, and effective across different languages and cultural contexts, especially in multilingual environments [34-36].

Common types of features in phishing email detection include linguistic features, such as writing style and urgency indicators; structural features, like email header information and HTML content; contextual features, including sender reputation and domain age; and behavioral features, such as user interaction patterns and email sending times [37-40]. The selection process must strike a balance between content-based and metadata-based features to create a comprehensive and robust feature set.

Various methods are employed for feature selection in phishing detection. These include filter methods, which use statistical approaches to select features according to their relationship with the target variable; wrapper methods, which evaluate feature subsets using specific machine learning

models; embedded methods, which integrate feature selection into the model training process; and evolutionary algorithms, such as Genetic Algorithms, which optimize feature subsets based on multiple objectives [41,42].

Recent advancements in deep learning introduced methods that have the ability to automatically derive pertinent features directly from raw email data, sometimes mitigating the requirement for manual feature selection [43]. However, in many applications, especially those dealing with multilingual content or requiring model interpretability, careful feature selection remains a critical step in developing effective phishing detection systems. By focusing on the most discriminative features, researchers and cybersecurity professionals can develop more accurate, efficient, and adaptable phishing detection models. This approach not only enhances overall email security but also helps protect users from increasingly sophisticated phishing attacks. The ongoing challenge in this field is to continuously refine feature selection methods to keep pace with evolving phishing techniques and maintain robust detection capabilities across diverse linguistic and cultural contexts.

C. Genetic Algorithm-Based Feature Selection Approaches for Phishing Email Detection

Genetic Algorithms (GAs) are evolutionary optimization techniques that draw inspiration from the mechanisms of natural selection and genetics. GAs have become powerful tools for solving complex optimization problems across various domains [44]. In the context of ML and DL, GAs have shown remarkable efficacy in feature selection tasks, offering a robust approach to identifying optimal subsets of features from large and complex datasets [45]. The core premise of genetic algorithms (GAs) is their capacity to iteratively refine a population of candidate solutions over successive generations. Each solution, or "chromosome" denotes a possible subset of features. The algorithm evaluates these chromosomes based on a fitness function, which typically measures the performance of a machine learning model using the selected features. Through processes mimicking genetic inheritance – selection, crossover, and mutation – GAs iteratively refine the population, converging towards an optimal or near-optimal feature subset [46].

In the domain of phishing email detection, the application of GAs for feature selection presents a promising approach to enhancing detection accuracy while optimizing computational efficiency. Phishing emails often contain subtle and evolving characteristics, making the selection of relevant features a critical and challenging task. Given these challenges, GAs can effectively navigate this complex feature space, considering various combinations of linguistic, structural, and behavioral email attributes to identify the most discriminative feature set [47]. The use of GAs in phishing email detection typically involves encoding email features as binary strings, where each element indicates the presence or absence of a specific feature. Moreover, the fitness function may incorporate multiple objectives, such as maximizing detection accuracy, minimizing false positives, and reducing the overall number of features

used. Consequently, this multi-objective optimization approach allows for a balanced solution that meets the often-conflicting goals of high accuracy and computational efficiency [48].

Several studies have demonstrated the effectiveness of GA-based feature selection in phishing detection systems. For instance, the authors in [49] employed a GA to optimize feature selection for their email classification system, resulting in improved accuracy and reduced computational complexity. Similarly, the study in [50] utilized a GA-based approach to identify the most pertinent features for their phishing website detection model, achieving high accuracy rates with a compact feature set.

The adaptability of GAs makes them particularly suitable for the dynamic nature of phishing attacks. As cybercriminals continually evolve their techniques, GA-based feature selection can be periodically re-run on updated datasets, ensuring that the selected features remain relevant and effective against new phishing strategies [51]. This adaptability is crucial in maintaining the long-term effectiveness of phishing detection systems. Moreover, the interpretability of GA-selected feature subsets can provide valuable insights into the most significant indicators of phishing attempts. This transparency can aid security professionals in understanding evolving phishing tactics and developing more targeted prevention strategies [52]. Therefore, the application of Genetic Algorithms to feature selection in phishing email detection offers a powerful means of enhancing detection accuracy, improving computational efficiency, and adapting to evolving threats. As phishing attacks continue to grow in sophistication, the role of advanced feature selection techniques like GAs becomes increasingly critical in developing robust and effective defence mechanisms.

III. PROBLEM FORMULATION

This study involves a problem-formation process for binary text classification. The problem can be framed as classifying emails into two distinct classes: phishing emails and legitimate emails. Let $\{D\}$ be a collection of emails $\{E\}$, known as a dataset. Let $\{D\}$ consist of E_{phishing} and $E_{\text{legitimate}}$. Feature matrices to be used as inputs for the models are derived from D , where rows represent emails (content-based) and columns represent features. Let X be the input feature and Y be the target variable, which can be represented as $D = \{X_1, Y_1, X_2, Y_2, X_3, Y_3, \dots, X_n, Y_n\}$, where n denotes the total number of words in V , X_1 is the feature vector (V), and Y_1 is the label.

The D model is divided into two parts, D_{training} and D_{testing} . The D_{training} is used for training the model, whereas the D_{testing} is used to assess and test it. In both cases, the learn a function $F(X)$, which makes the decision in to detect emails whether the input E is legitimate or phishing, as shown in the mathematical formula (1).

$$F(X) = f(X, Pa) \quad (1)$$

where X is the input features and the Pa is the parameter of the model.

IV. METHODOLOGY AND MATERIALS

This section details the five-phase methodological framework employed in this study. Each phase contributes to the development and evaluation of the machine learning model for email classification. A visual representation of these stages is provided in Fig. 1.

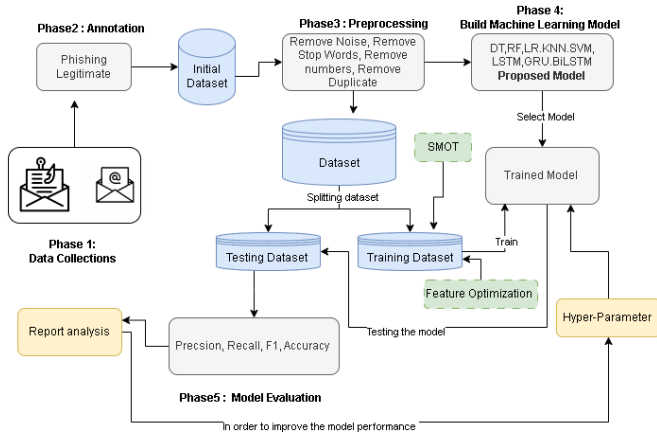

Fig. 1. Methods and Phases of this study.

A. Phase 1: Data Collection

Due to the scarcity of Arabic datasets for phishing emails, this study employed an initial method to construct the study's dataset. Data was gathered from a variety of personal email collections, ensuring a diverse range of sources. To further enrich the dataset, phishing emails were generated using ChatGPT, complemented by additional emails crafted manually. This compilation process ensured a diverse and representative dataset. Upon finalizing the collection, all emails were organized and stored in a CSV file, which was subsequently sent to annotators for detailed processing.

B. Phase 2: Annotation Process

In the annotation process, three native Arabic speakers assisted in the annotation process by classifying the emails into two categories: phishing and legitimate. In addition, Cohen's Kappa was utilized in order to measure the degree of agreement between the annotators [53,54] based on the mathematical formula (2).

$$K = \frac{P_o - P_e}{1 - P_e} \quad (2)$$

P_o is the proportion agreement between judges, while P_e is the expected agreement proportion by chance. Thus, the K is 81% which indicates perfect agreement between the judges (raters). In the end, Table I provides information on the size of the final dataset.

TABLE I. DATASET DESCRIPTION

Factors	No. of Emails	Maximum Words	Minimum Words
Phishing	861	166	23
Legitimate	312	178	46
Total	1,173		

C. Phase 3: Pre-Processing Steps

Pre-processing phase were performed on the Arabic dataset before it was used in the models. These steps included the removal of stop words from the Arabic language, noise such as HTML tags, and duplicate messages or emails.

All Arabic-specific stop words were systematically eliminated to enhance the efficacy of subsequent text analysis procedures. Stop words, defined as high-frequency lexical items that typically carry minimal semantic content, are routinely excluded to optimize the quality and relevance of the dataset. Table II presents a representative sample of common Arabic-specific stop words. Additionally, for noise removal, all irrelevant text, including HTML tags, was removed from the emails. This step ensured that only meaningful textual information was retained, making the data more suitable for analysis. Furthermore, duplicates were identified and removed to ensure that each email in the dataset was unique, thereby preventing redundancy and improving the accuracy of the analysis.

TABLE II. COMMON EXAMPLES OF ARABIC-SPECIFIC STOP WORDS

Arabic-specific stop words	Meaning in English
و	and
في	in
من	from
على	on
إلى	to
أو	Or

D. Phase 4: Build Machine Learning Model

Prior to detailing the process of this phase, we provide a brief overview of the ML classifiers and DL models and GA-based feature selection employed in this investigation to assess the efficacy of our proposed approach.

1) *Machine learning classifiers*: Support Vector Machine (SVM): SVM is a supervised learning algorithm that analyze data to perform regression and classification tasks. The algorithm operates by identifying the optimal hyperplane that best separates the given dataset into distinct classes. SVMs are particularly adept in high-dimensional feature spaces and have been widely employed in text categorization tasks including sentiment analysis and spam detection [55,56].

a) *Decision Tree (DT)*: DT is a non-parametric supervised learning algorithm used for regression and classification. DT works by splitting the data into a number of subsets according to the most significant differentiators in the input features. Decision Trees are highly interpretable and easily understood, making them indispensable tools in decision-making processes [57].

b) *Logistic Regression (LR)*: LR is a statistical technique that employs a logistic function to analyze a binary dependent variable in a model. LR is a widely adopted technique for binary classification problems, including applications such as email spam detection and medical diagnosis [58-60].

c) *Random Forest (RF)*: RF is a widely utilized machine learning algorithm that generates numerous decision trees during the training process and predicts the class that is the statistical mode of the classes output by the individual trees. RF helps overcome the tendency of individual decision trees to overfit to the training data, resulting in a robust and accurate model [61,62].

2) *Deep learning models*:

a) *Long Short-Term Memory (LSTM)*: LSTM is a specialized form of Recurrent Neural Network (RNN) that can effectively model and capture long-term temporal dependencies within sequential data. It addresses the vanishing gradient issue that conventional RNNs face by leveraging memory cells to retain information over extended durations. LSTMs have demonstrated effectiveness in tasks involving sequential data, including time-series forecasting and natural language processing [63].

b) *Gated Recurrent Units (GRU)*: GRU is another variety of RNN which is similar to LSTM but with a simplified architecture. GRU integrates the forget and input gates into a single update gate, resulting in improved computational efficiency without compromising its overall performance. GRUs are used in various applications requiring sequence modeling [64].

c) *Bidirectional Long Short-Term Memory (BiLSTM)*: BiLSTM is a bidirectional variant of the LSTM architecture, which enhances performance by analyzing input sequences in both the backward and forward temporal directions. BiLSTM enables the model to have access to future and past context information, making it particularly useful in tasks like machine translation and text generation [65,66].

3) *Genetic algorithm for feature selection*: Feature selection tasks for content-based email message analysis have proven to be highly effective when using GAs [67, 68], which are optimization techniques. As part of detecting phishing emails, feature selection involves recognizing the most relevant attributes present within the email content, including textual patterns, keywords, and structural characteristics. A genetic algorithm then generates a population of potential solutions and iteratively evolves them through processes such as selection, crossover, and mutation.

The GA efficiently narrows down the feature set to those features that contribute most significantly to distinguishing phishing emails from legitimate ones, by evaluating the fitness of each solution. This process enhances the efficiency of the model by reducing dimensionality and eliminating irrelevant or redundant features, leading to improved accuracy and faster computation. In the proposed model, the GA for feature selection played an important role in optimizing the input features, thus enhancing the overall performance and robustness of the Random Forest and BiLSTM hybrid approach.

To start the GA for detecting normal and phishing emails, a dataset containing both types of emails is loaded, and relevant features are extracted. An initial population of candidate individuals is generated, with each individual denoting a set of

features. The classification accuracy is evaluated based on the fitness of these chromosomes. The algorithm selects parents, performs mutations and crossovers to create offspring, and evaluates their fitness, replacing the old population with new offspring until a satisfactory fitness level is achieved or a specified number of generations is reached. Ultimately, the GA outputs the highest-performing chromosome, representing the optimal feature set for email classification, as depicted in Fig. 2.

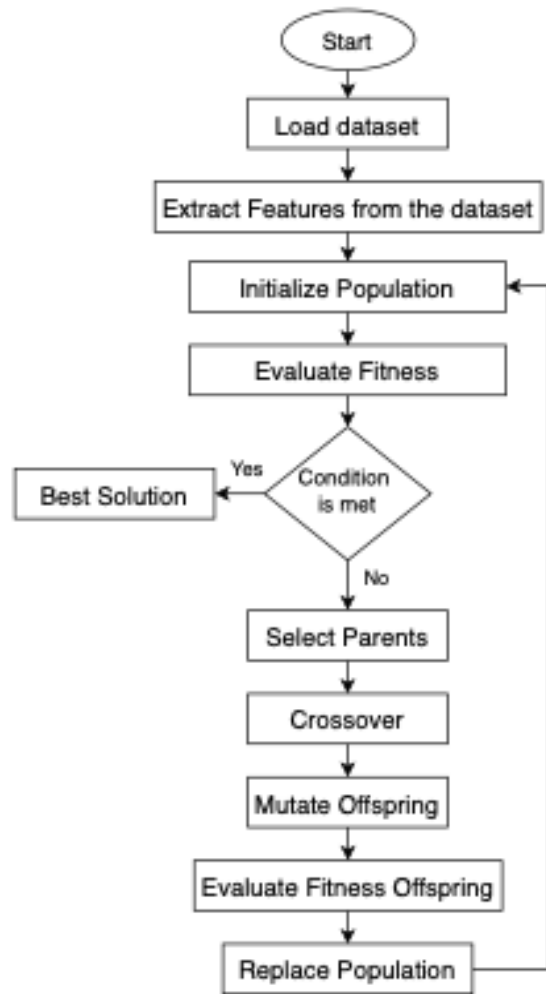

Fig. 2. Genetic algorithm flowchart.

4) *The process of phase 4*: In phase 4, the proposed model for Arabic detecting phishing emails is designed with a multi-stage process, leveraging both machine learning and deep learning techniques optimized through feature selection using a genetic algorithm, as shown in Fig. 3. The proposed hybrid approach provides a number of significant benefits. It integrates RF and BiLSTM with a GA for feature optimization. The model takes advantage of the advantages of both methods by combining the outputs of RF and BiLSTM, improving prediction performance by capturing a variety of data features. Sequential data is best captured by BiLSTM, unlike RF's ensemble approach reduces variance and minimizes overfitting to produce robust predictions. By

choosing the most pertinent features, the addition of GA for feature optimization further improves the model's efficiency and reduces its dimensionality, resulting in quicker training durations. By combining the advantages of both sequential pattern expertise from BiLSTM and structured data handling from RF, this hybrid technique also enhances generalization. The model performs well against noise, and is suitable for various data types. Its scalability and ability to handle large datasets make it a valuable tool in machine learning.

Fig. 3. Flowchart of the proposed model.

Initially, the process begins with the input of email content, which serves as the raw data for analysis. This content undergoes transformation into a word representation format, capturing the essential textual features needed for further processing. In the feature selection stage, a GA is employed to optimize the features derived from the word representation. This optimization step is crucial as it enhances the model's capacity to recognize relevant features that are indicative of phishing attempts.

The process begins with the input of email content, which is transformed into numerical vectors through word representation. This transformation allows the textual data to be processed effectively by subsequent machine learning algorithms. In the next stage, feature selection is carried out using a genetic algorithm. This step is crucial as it identifies and selects the most relevant features from the word representations, enhancing the model's capability to distinguish between phishing and legitimate emails.

Following feature optimization, the refined features are fed into two different machine learning models: BiLSTM and RF. The RF model brings robustness and the capability to handle a large number of features effectively, while the BiLSTM model leverages its capacity to capture sequential dependencies within the email content, making it well-suited for analyzing the context and order of words [69].

The outputs from both the RF and BiLSTM models are then integrated in a fusion layer. This layer combines the strengths of both models, creating a more comprehensive understanding of the email content. The combined data is subsequently processed through an activation function, which refines the decision-making mechanisms employed by the model.

Finally, the model produces its output by classifying the email as either phishing or legitimate. This classification is the culmination of the entire process, providing a clear and actionable result based on the sophisticated analysis of the email content. Through this structured approach, the model effectively identifies phishing emails, ensuring robust detection by integrating feature optimization, machine learning, and deep learning methodologies.

E. Model Evaluation

This section introduces the most widely-used metrics to evaluate the performance of the proposed model. The metrics employed include Precision, Recall, F1-score, Accuracy, and Area Under the Receiver Operating Characteristic (AUC-ROC) curve.

Precision evaluates the accuracy of positive classifications, specifically the proportion of emails categorized as phishing that were correctly identified. This metric is crucial for evaluating the model's capacity to minimize the occurrence of false positive results. Mathematically, Precision is defined in the mathematical formula (3):

$$Precision = \frac{\text{Correct emails retrieved}}{\text{All retrieved emails}} \quad (3)$$

In this formula, "Correct emails retrieved" represents the number of emails accurately identified as phishing, and "All retrieved emails" represents the total number of emails classified as phishing by the model. The model's high level of precision is evidenced by a diminished rate of false positive outcomes, thus ensuring that most of the emails flagged as phishing are indeed malicious.

Recall metric assesses the model's capability to detect all pertinent instances of phishing emails. It represents the proportion of correctly identified phishing emails relative to the total number of actual phishing emails. A high recall value indicates that the model effectively identifies most phishing emails, thereby minimizing the occurrence of false negatives. The mathematical formula (4) is for calculating Recall:

$$Recall = \frac{\text{Correct emails retrieved}}{\text{All relevant emails}} \quad (4)$$

The F1-score is a composite metric that synthesizes the trade-off between precision and recall. It represents the harmonic mean of these two measures, offering a holistic evaluation that is particularly valuable in the context of unbalanced datasets. A high F1-score indicates that the model effectively balances the identification of phishing emails while minimizing both false negative and false positive classifications. The mathematical formula (5) calculates the F1-score:

$$F1 - Score = 2 \times \frac{\text{Recall} \times \text{Precision}}{\text{Recall} + \text{Precision}} \quad (5)$$

This metric is highly useful for comprehensively evaluating the model's performance in scenarios where both incorrectly identifying positive cases and failing to detect true positive cases are crucial considerations.

Accuracy metric evaluates the overall correctness of the model by quantifying the ratio of correctly classified emails (both phishing and legitimate) to the total number of emails. Accuracy is calculated by the mathematical formula (6):

$$Accuracy = \frac{\text{Number of correct emails}}{\text{Total number of predictions}} \quad (6)$$

In this context, "Number of correct emails" includes both correctly identified phishing and legitimate emails, while "Total number of predictions" is the total number of emails that have been classified by the model. High accuracy denotes

that the model performs well in classifying both phishing and legitimate emails correctly.

In addition to the above metrics, the Area Under the Receiver Operating Characteristic (AUC-ROC) is employed to measure the model performance. The AUC-ROC provides a single value that represents the capability of the model to differentiate between classes across various threshold settings. The ROC curve graphically depicts the balance between the true positive rate and the false positive rate across varying decision criteria. A higher AUC value signifies improved model performance, with an AUC of 1.0 denoting a model with perfect classification performance.

V. RESULTS AND DISCUSSION

This section details the experimental settings, findings, and analysis. The proposed model is evaluated in comparison to the baseline ML classifiers and DL models to distinguish between phishing and authentic emails for future identification.

A. Experimental Settings

The experiments were conducted using Google Colaboratory, which has been utilized for all the experiments on ML classifiers, DL models, and the proposed model. We used three Python libraries to conduct the experiments: Matplotlib, Scikit-learn (sklearn), and DEAP. Using Matplotlib, we created plots and charts to visualize the data and results. Sklearn was used for ML classifiers, pre-processing steps, and splitting the dataset. Finally, DEAP was used for the genetic algorithm. The hyperparameters for the machine learning (ML) classification algorithm are enumerated in Table III, while Table IV delineates the architectural and training parameters employed in the deep learning (DL) model.

TABLE III. HYPER-PARAMETER OF ML MODELS

Model	Hyper-parameter	Default Value
Random Forest	n_estimators	100
	criterion	"gini"
	max_depth	None
	min_samples_split	2
	min_samples_leaf	1
Decision Tree	criterion	"gini"
	splitter	"best"
	max_depth	None
	min_samples_split	2
	min_samples_leaf	1
SVM	C	1.0
	kernel	"rbf"
	gamma	"scale"
Naive Bayes	priors	None
Logistic Regression	solver	"lbfgs"
	max_iter	100

TABLE IV. HYPER-PARAMETER OF DL MODELS

Hyper-parameter	Value
Embedding Dimension	32
GR/LSTM Units	32
Batch Size	32
Sequence Length	100
Optimizer	"Adam"
Loss Function	"binary_crossentropy"
Metrics	["accuracy"]
Number of Epochs	30

B. Experimental Results

Numerous experiments have been conducted using ML, DL, and the proposed model. In these experiments, genetic algorithms are used to select the best features. Tables V and VI present a comparison of precision, recall, F1-score, and accuracy, respectively. Table V presents a comparative analysis of the experimental results of the ML classifiers without using genetic algorithms. The performance of various ML classifiers is used to detect phishing and legitimate emails with a focus on their accuracy. Among the classifiers evaluated, the Naive Bayes (NB) model demonstrated the most robust performance, attaining the highest accuracy rate of 90.91%, which underscores its substantial reliability and effectiveness. RF also performed exceptionally well, with an accuracy of 90.06%, making it a strong contender for detecting phishing emails. DT, LR, and SVM showed moderate accuracy, with values of 85.51%, 83.81%, and 84.38%, respectively, indicating that they are fairly accurate, but not as high-performing as NB and RF. In contrast, KNN showed the lowest accuracy among the classifiers, with an accuracy of 67.90%, indicating that it is less effective for this detection task. In summary, NB and RF are the top-performing models, whereas KNN has the lowest accuracy.

TABLE V. EXPERIMENTAL RESULTS OF ML CLASSIFIERS

Classifier	Precision	Recall	F1-score	Accuracy
DT	91.83%	71.98%	76.08%	85.51%
KNN	65.35%	69.76%	64.76%	67.90%
LR	88.61%	69.40%	72.95%	83.81%
SVM	88.04%	70.85%	74.51%	84.38%
RF	92.68%	81.48%	85.25%	90.06%
NB	87.23%	90.65%	88.69%	90.91%

Fig. 4 shows the AUC-ROC and confusion matrix for the NB classifier, which achieved the highest accuracy. The figure illustrates the performance of a Naive Bayes classifier in detecting phishing emails based on content, consisting of a confusion matrix and an AUC-ROC curve. The AUC-ROC curve (a) shows the classifier's true positive rate (y-axis) against the false positive rate (x-axis), with the Naive Bayes model (orange dashed line) performing significantly better than random guessing (blue dashed line), indicating high sensitivity and specificity. The confusion matrix heatmap (b) highlights

classification results, with 82 AI-generated and 238 human-written emails correctly identified, while 9 AI-generated and 23 human-written emails were misclassified. The color intensity reflects the number of instances, demonstrating the classifier's overall accuracy and effectiveness.

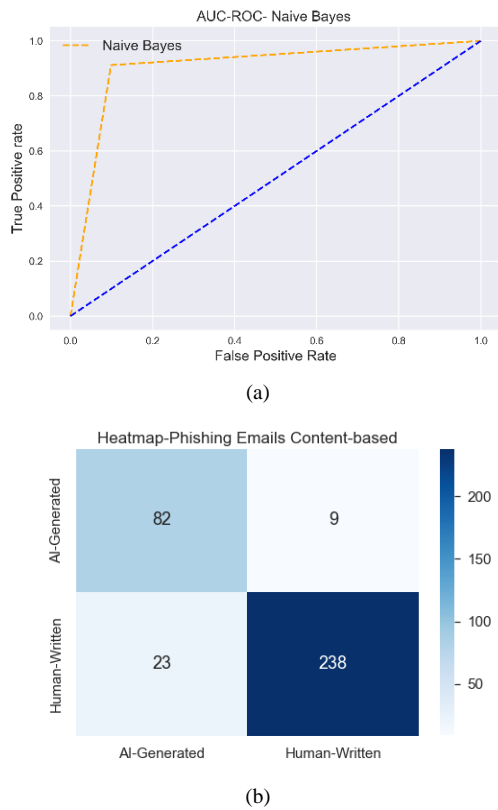

Fig. 4. AUC-ROC and confusion matrix of naive bayes. (a) AUC-ROC curve. (b) Confusion matrix showing correct (82 AI, 238 human) and incorrect (9 AI, 23 human) classifications.

Table VI summarizes the performance metrics for various classifiers used to detect phishing and legitimate emails, this time utilizing genetic algorithms for optimization. Notably, NB emerged as the top performer, with an accuracy of 97.87%, significantly improving from its previous accuracy of 90.91%. LR also saw a substantial increase in performance, achieving an accuracy of 94.47% compared to its earlier 83.81%. RF recorded an improved accuracy of 92.77%, up from 90.06%, thus maintaining its position as a strong classifier. DT demonstrated a marked improvement, with its accuracy increasing from 85.51% to 90.64%, indicating that genetic algorithms significantly enhanced its performance. In contrast, SVM showed a marginal improvement, with its accuracy slightly increasing from 84.38% to 85.53%. KNN improved its accuracy from 67.90% to 74.89%, achieving perfect recall; however, it remained less effective overall compared to other classifiers. In summary, the application of genetic algorithms for optimization led to performance improvements across most classifiers, particularly boosting the accuracy of NB and LR. Despite these enhancements, NB remains the top-performing model, while KNN still lags behind the others.

TABLE VI. EXPERIMENTAL RESULTS OF ML CLASSIFIERS USING GENETIC ALGORITHM

Classifier	Precision	Recall	F1-score	Accuracy
DT	87.55%	87.55%	87.55%	90.64%
KNN	74.89%	100.00%	85.64%	74.89%
LR	96.56%	88.98%	92.03%	94.47%
SVM	91.90%	71.19%	75.36%	85.53%
RF	94.68%	86.16%	89.43%	92.77%
NB	97.99%	96.33%	97.12%	97.87%

Fig. 5 shows the AUC-ROC for the best ML classifier and worst ML classifiers NB and KNN. The figure compares the ROC curves for two classifiers: NB and KNN. In subplot (a), the ROC curve for NB shows a high area under the curve (AUC) of 0.96, demonstrating outstanding performance with a high rate of correctly identified positives and a low rate of incorrectly identified positives. In contrast, subplot (b) displays the ROC curve for KNN, which has an AUC of 0.50, signifying performance equivalent to random guessing, as indicated by the diagonal line. This comparison highlights the superior effectiveness of the Naive Bayes classifier over the KNN classifier in this context.

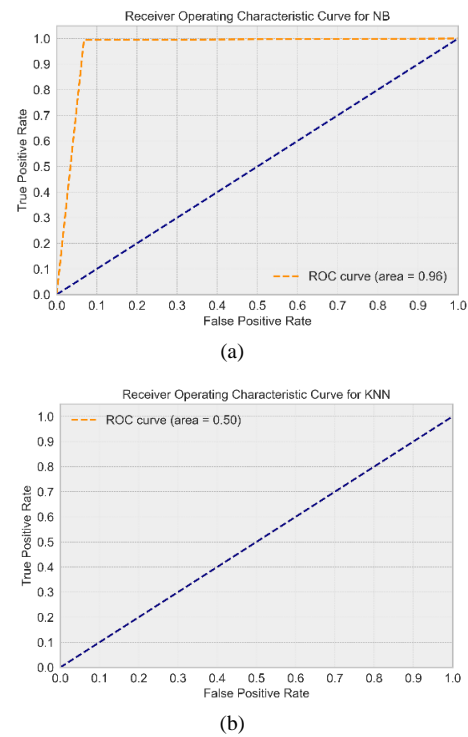

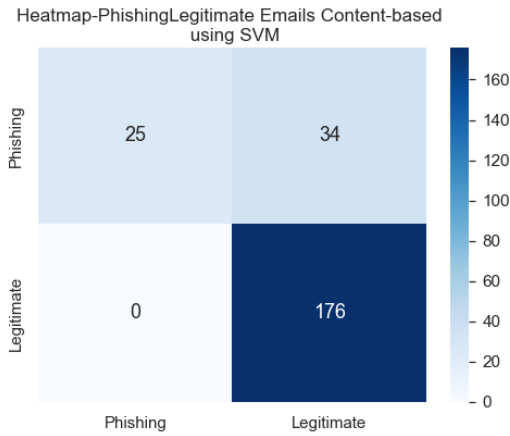

Fig. 5. AUC-ROC Curves for naive bayes and k-nearest neighbors; (a) Naive bayes (b) K-nearest neighbors.

Fig. 6 illustrates the confusion matrices for two machine learning classifiers, SVM and DT, applied to the classification of phishing and legitimate emails. Panel (a) shows the performance of the SVM classifier, which correctly identified 25 phishing emails and 176 legitimate emails. However, it misclassified 34 legitimate emails as phishing, with no false negatives (phishing emails classified as legitimate). Panel (b)

displays the results for the DT classifier, which correctly identified 48 phishing emails and 165 legitimate emails, with 11 false positives (legitimate emails classified as phishing) and 11 false negatives. The color intensity in both matrices represents the number of instances, providing a visual comparison of the classification accuracy and error distribution between the SVM and DT models. This analysis highlights the strengths and weaknesses of each classifier in distinguishing between phishing and legitimate emails.

(a)

(b)

Fig. 6. Confusion matrices (a) SVM, (b) DT.

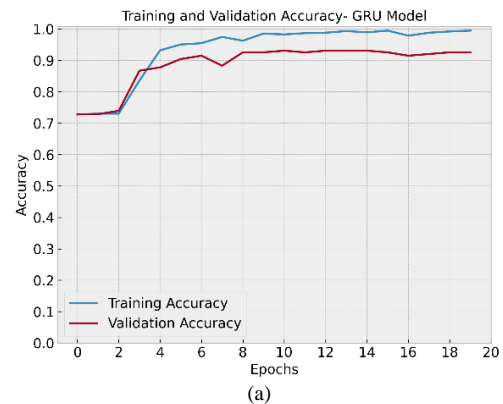

In the DL experiments, various models were evaluated based on precision, recall, F1-score, and accuracy in detecting phishing and legitimate emails. The models tested included LSTM, BiLSTM, GRU, and the proposed model utilizing Genetic Algorithm Feature Selection, as detailed in Table VII. The LSTM model achieved a precision of 94.97%, recall of 96.59%, F1-score of 95.77%, and accuracy of 93.62%. The BiLSTM model recorded a precision of 93.76%, recall of 88.98%, F1-score of 91.04%, and accuracy of 93.62%. The GRU model demonstrated an accuracy of 95.12%, with a precision of 95.28%, recall of 95.32%, and F1-score of 95.28%.

TABLE VII. EXPERIMENTAL RESULTS FOR THE DL MODELS AND PROPOSED MODEL

Classifier	Precision	Recall	F1-score	Accuracy
LSTM	94.97%	96.59%	95.77%	93.62%
BiLSTM	93.76%	88.98%	91.04%	93.62%
GRU	95.28%	95.32%	95.28%	95.12%
Proposed Model	96.77%	100.00%	98.36%	97.90%

In comparison, the proposed model outperformed the ML classifiers and DL models in terms of the common matrix and achieved a precision of 96.77%, recall of 100.00%, F1-score of 98.36%, and accuracy of 97.90% using Genetic Algorithm Feature Selection. Thus, the proposed model can select the most relevant features, thereby increasing its efficiency and accuracy. By combining RF with BiLSTM, we leveraged the strengths of both algorithms: RF's ability to handle high-dimensional data and reduce overfitting through ensemble learning, and BiLSTM's ability to capture sequential dependencies. This combination results in a robust model that can accurately detect phishing emails. In addition to the superior performance of the proposed model, it has also been demonstrated that when RF and BiLSTM are combined with Genetic Algorithm Feature Selection in order to enhance email security, this combination results in a superior performance that is reflected in all metrics evaluated.

Fig. 7 and 8 present the training and validation accuracy and loss functions for the GRU, BiLSTM, and proposed BiLSTM-RF models with Genetic Algorithm Feature Selection over 20 epochs. Fig. 7(a) and 7(c) show that both the GRU and BiLSTM models achieve high training and validation accuracy, with the GRU showing steady improvement and the BiLSTM demonstrating rapid early gains. Fig. 7(b) and 7(d) illustrate the loss functions for these models, indicating good generalization with minimal divergence between training and validation losses. In comparison, Fig. 8 highlights the proposed BiLSTM-RF model's performance, showing superior results: Fig. 8(a) demonstrates that it quickly reaches near-perfect accuracy for both training and validation, while Fig. 8(b) shows a sharp decline and stabilization in loss values, indicating efficient learning and minimal overfitting. Overall, the proposed model outperforms the GRU and BiLSTM models in accuracy and robustness, making it the most effective in detecting phishing and legitimate emails.

(a)

Fig. 7. Training accuracy, validation, and loss function of GRU and BiLSTM.

In terms of precision, recall, and F1-score, the LSTM model achieved 94.97% precision, 96.59% recall, and 93.77% accuracy. A precision of 93.76%, recall of 88.98%, F1-score of 91.04%, and accuracy of 93.62% were recorded by the BiLSTM model. The GRU model demonstrated an accuracy of 95.12%, precision of 95.28 percent, recall of 95.32%, and F1-score of 95.28 percent.

The proposed model outperformed the ML classifiers and DL models in terms of the common matrix and achieved a precision of 96.77%, recall of 100.00%, F1-score of 98.36%, and accuracy of 97.90% using Genetic Algorithm Feature Selection. Thus, the proposed model can select the most relevant features, thereby increasing its efficiency and accuracy. By combining RF with BiLSTM, we leveraged the strengths of both algorithms: RF's ability to handle high-

dimensional data and reduce overfitting through ensemble learning, and BiLSTM's ability to capture sequential dependencies. This combination results in a robust model that can accurately detect phishing emails. In addition to the superior performance of the proposed model, it has also been demonstrated that when RF and BiLSTM are combined with Genetic Algorithm Feature Selection in order to enhance email security, this combination results in a superior performance that is reflected in all metrics evaluated. Fig. 7 shows the training accuracy, validation, and loss function of the proposed model.

Fig. 8. Training accuracy, validation, and loss function of proposed model.

C. Discussions

The experiment findings demonstrate the effectiveness of feature optimization with a GA in identifying Arabic phishing emails. The classifiers performed differently in the first experiments conducted without GA. Certain models outperformed others in terms of precision, recall, and total accuracy, while others had difficulty reaching high effectiveness.

However, in the second set of experiments, all classifiers showed notable gains when the Genetic Algorithm was used for feature optimization. By picking the most pertinent features, the GA improved the models and improved their prediction power. This resulted in increased scores on all metrics overall. The significance of the GA in machine learning workflows, especially for intricate jobs like phishing

email detection, is highlighted by its efficacy in improving features. In addition to improving each classifier's performance, the GA also helped create detection systems that are more dependable and resilient by cutting down on noise and concentrating on the most important data points.

The proposed model has several advantages over conventional deep learning models like LSTM, BiLSTM, and GRU. It combines RF and BiLSTM with GA for feature optimization. This hybrid technique achieves improved precision, recall, F1-score, and accuracy in phishing email detection, demonstrating superior performance. A balanced and thorough feature representation is produced by combining the power of BiLSTM to capture sequential patterns with the capabilities of RF to evaluate feature relevance. By streamlining the feature set, lowering noise, and boosting overall effectiveness, the addition of GA improves the model even more. This results in a detection system that is more precise, dependable, and flexible and can adjust to the changing strategies used by phishing attempts. The proposed model's outstanding performance metrics underscore its effectiveness as a robust tool for enhancing cybersecurity.

VI. CONCLUSION

In this study, we proposed a hybrid model for phishing email detection, combining Random Forest (RF) and Bidirectional Long Short-Term Memory (BiLSTM) networks, augmented with Genetic Algorithm Feature Selection. The experimental results demonstrated that the proposed model significantly outperformed conventional approaches, including traditional machine learning classifiers, LSTM, BiLSTM, and Gated Recurrent Unit (GRU) models, across multiple performance metrics: Precision, Recall, F1 Score, and Accuracy. Specifically, the proposed model achieved an accuracy of 97.90%, recall of 100.00%, F1 score of 98.36%, and precision of 96.77%, illustrating its exceptional capability in correctly classifying phishing emails. The integration of RF and BiLSTM leveraged RF's proficiency in handling high-dimensional data and BiLSTM's capacity to capture sequential relationships, while the Genetic Algorithm Feature Selection ensured optimal feature subset identification.

Future research directions include expanding the dataset to encompass a broader range of phishing and legitimate emails, incorporating diverse linguistic and cultural variations. Additionally, we plan to explore advanced feature selection techniques such as Particle Swarm Optimization or Ant Colony Optimization. Furthermore, to capture more complex patterns in the data, we intend to investigate the integration of additional deep learning architectures, such as Transformers.

ACKNOWLEDGMENT

The authors extend their appreciation to the Deanship of Scientific Research at Northern Border University, Arar, KSA for funding this research work through the project number NBU-FFR-2024-1197-05.

A Feature Interaction Based Neural Network Approach: Predicting Job Turnover in Early Career Graduates in South Korea

Haewon Byeon

Department of AI-Software, Inje Medical Big Data Research Center, Inje University, Gimhae 50834, South Korea

Abstract—Predicting job turnover among early career university graduates is crucial for both employees and employers. This study introduced a Feature Interaction based Neural Network model designed to predict job turnover among university graduates in their 20s and 30s in South Korea within the first five years of employment. The FINN model leveraged the Graduates Occupational Mobility Survey dataset, which included detailed information on approximately 26,544 graduates. This rich dataset encompassed a wide range of variables, including personal attributes, employment characteristics, job satisfaction, and job preparation activities. The model combined an embedding layer to convert sparse features into dense vectors with a neural network component to capture high-order feature interactions. We compared the FINN model's performance against eight baseline models: Logistic Regression, Factorization Machines, Field-aware Factorization Machines, Support Vector Machine, Random Forest, Product-based Neural Networks, Wide & Deep, and DeepFM. Evaluation metrics used were Area Under the ROC Curve (AUC) and Log Loss. The results demonstrated that the FINN model outperformed all baseline models, achieving an AUC of 0.830 and a Log Loss of 0.370. The FINN model represents a significant advancement in predictive modeling for job turnover, providing valuable insights that can inform both individual career planning and organizational human resource practices. This research underscores the potential of advanced neural network architectures in employment data analysis and predictive modeling.

Keywords—Job turnover prediction; feature interaction based neural network; employment data analysis; predictive modeling; university graduates

I. INTRODUCTION

The advent of big data has revolutionized various sectors, including the labor market, where the analysis of employment data plays a crucial role in understanding workforce dynamics and predicting future trends [1,2]. This study focuses on the early career trajectories of university graduates in their 20s and 30s in South Korea, particularly their likelihood of job turnover within the first five years of employment. The accurate prediction of job turnover is paramount for both employees and employers [3-5]. Employees benefit by understanding potential career pitfalls, while employers can devise better retention strategies, thereby reducing recruitment and training costs [3,4].

Employees stand to gain significantly from insights into job turnover predictors. By identifying the factors that contribute to early job departure, graduates can better prepare themselves to

meet the challenges of their initial employment experiences [6,7]. This knowledge empowers them to seek roles and environments that align more closely with their career aspirations and stability [8,9]. For employers, the implications of job turnover are substantial. High turnover rates can lead to increased recruitment costs, loss of organizational knowledge, and diminished productivity. By accurately predicting which employees are at risk of leaving, employers can implement targeted interventions to improve job satisfaction and engagement [10-12]. This proactive approach not only enhances employee retention but also fosters a more stable and committed workforce. The dual benefits of predicting job turnover—enhancing employee career stability and optimizing employer retention strategies—underscore the importance of this research. By leveraging advanced predictive models, this study seeks to provide valuable insights that can inform both individual career planning and organizational human resource practices.

Historically, regression analysis has been a popular method for studying job turnover. Regression models, such as logistic regression, have been widely used to identify factors influencing employee turnover by modeling the relationship between dependent and independent variables [13-16]. For instance, logistic regression can help in estimating the probability of an event (like job turnover) occurring, given a set of predictor variables (such as age, education level, job satisfaction, etc.) [13-16]. However, while regression analysis has its merits, it also has significant methodological limitations when applied to complex, high-dimensional datasets typical in employment studies [7]. One of the primary limitations of traditional regression analysis is its inability to effectively capture complex interactions between features [7]. In employment data, factors influencing job turnover are often interdependent. For example, the interaction between job satisfaction and work-life balance might significantly affect turnover rates, but such interactions can be challenging to model accurately using simple regression techniques. Regression models assume a linear or specific non-linear relationship between the independent and dependent variables, which may not hold true in real-world scenarios where relationships can be highly non-linear and intricate.

Moreover, regression models often require extensive feature engineering to improve their predictive accuracy [16]. Feature engineering involves the manual creation of new features from raw data to better represent the underlying patterns [17]. This process can be labor-intensive and requires

domain expertise to identify meaningful interactions and transformations [18]. Despite these efforts, the performance of regression models may still be limited due to their inherent inability to model complex, higher-order interactions between features [19].

To address these limitations, there has been a growing interest in leveraging advanced machine learning techniques, particularly deep learning models, which can automatically learn feature interactions from raw data without extensive manual intervention. Among these, Feature Interaction based Neural Networks (FINNs) have shown great promise [20]. FINNs enhance the capabilities of traditional deep neural networks (DNNs) by explicitly modeling feature interactions, thereby improving predictive accuracy in complex datasets [21].

Deep neural networks have achieved remarkable success in various fields, such as image classification, natural language processing (NLP), and speech recognition, due to their ability to learn hierarchical feature representations [22]. In the context of employment data, DNNs can be particularly useful as they can capture complex, non-linear relationships between features. However, one of the challenges in applying DNNs to employment data is the sparsity and high-dimensionality of the data. Employment datasets often contain categorical variables, such as job title, industry, and education level, which are typically converted into high-dimensional sparse features using techniques like one-hot encoding. These sparse features need to be transformed into dense representations before being fed into the neural network.

FINNs address this challenge by employing a feature embedding layer that converts sparse categorical features into dense vectors [20]. These embeddings are then used to model pairwise interactions between features, capturing the complex dependencies that influence job turnover [20]. By incorporating a feature interaction layer, FINNs can learn both low-order and high-order interactions, providing a more comprehensive understanding of the factors driving employee turnover.

The need for FINNs is underscored by the limitations of traditional methods. For example, factorization machines (FMs) have been proposed to model feature interactions via the inner product of feature embeddings, but they primarily capture only second-order interactions [21]. While FMs have been successful in some applications, they may not fully exploit the higher-order interactions present in employment data. In contrast, FINNs can model both second-order and higher-order interactions, providing a more robust framework for predicting job turnover [21]. Furthermore, the integration of deep learning components in FINNs allows for the modeling of non-linear interactions and complex feature hierarchies, which are often present in employment data. This capability is particularly important for understanding the multifaceted nature of job turnover, where factors such as job satisfaction, career development opportunities, and organizational culture interplay in intricate ways.

FINNs work by first employing an embedding layer to transform high-dimensional sparse features into dense vectors [20,21]. This transformation is crucial for handling the sparsity

issue inherent in employment data. Once the features are embedded, FINNs apply a feature interaction layer that captures pairwise interactions between the dense vectors. This layer can utilize operations such as inner product or element-wise product to model the interactions. By doing so, FINNs can effectively represent the complex relationships between features, which traditional regression models might miss. Moreover, FINNs extend the capability of simple interaction models by incorporating deep neural network components that can capture higher-order interactions [21]. This means that after modeling the basic pairwise interactions, the network can further process these interactions through multiple layers to extract more complex patterns. This deep architecture allows FINNs to model non-linear relationships and hierarchies among features, enhancing their predictive power. The novelty of FINNs lies in their ability to combine the strengths of traditional interaction models and deep learning. Unlike traditional models that require extensive manual feature engineering to capture interactions, FINNs can automatically learn these interactions from data. This reduces the need for domain expertise and manual intervention, making the modeling process more efficient and scalable.

While traditional regression methods have provided valuable insights into employee turnover, their limitations necessitate the adoption of more advanced techniques like Feature Interaction based Neural Networks. FINNs offer a powerful alternative by automatically learning complex feature interactions from high-dimensional data, thereby enhancing predictive accuracy and providing deeper insights into the factors influencing job turnover. This study aims to leverage FINNs to analyze the early career trajectories of university graduates in South Korea, with the goal of identifying key predictors of job turnover and informing strategies to improve employee retention. The remainder of this paper is organized as follows: Section II reviews related works. Section III describes the details of the proposed model. Section IV presents the experimental analysis. Finally, Section V concludes the paper.

II. RELATED WORK

Logistic Regression (LR) is a fundamental technique widely used in classification tasks, including click-through rate prediction. It is a linear model that solves an unconstrained convex optimization problem, ensuring efficient convergence to a globally optimal solution via gradient descent [23]. The primary advantage of LR is its interpretability; by examining the weights assigned to each feature, one can understand the significance and impact of these features on the prediction outcome [23]. This transparency makes LR particularly valuable in fields where interpretability is crucial, such as field of employment. However, the linear nature of LR limits its ability to capture complex relationships between features [24]. To overcome this, extensive feature engineering is often required, including polynomial features and interaction terms, to improve the model's expressiveness.

Another shallow method worth mentioning is Polynomial Regression, which extends linear regression by considering polynomial terms of the features [25]. By including polynomial terms, the model can capture non-linear relationships between

the features and the target variable. Polynomial regression can be particularly useful when the relationship between the features and the outcome is known to be non-linear. However, as the degree of the polynomial increases, the model becomes more complex and prone to overfitting, especially with limited data [25].

Decision Trees are another fundamental shallow method used for classification and regression tasks. A decision tree splits the data into subsets based on feature values, creating a tree-like model of decisions [26]. Each node represents a feature, each branch represents a decision rule, and each leaf node represents an outcome. Decision trees are easy to interpret and visualize, making them useful for understanding the decision-making process. However, they can be prone to overfitting, especially with deep trees [27]. Techniques such as pruning, bagging, and boosting are often used to mitigate overfitting and improve performance.

Ensemble methods, such as Random Forests and Gradient Boosting Machines (GBM), build on the strengths of decision trees while addressing their limitations [28]. Random Forests create multiple decision trees using different subsets of the data and features, and then aggregate their predictions [29,30]. This approach reduces overfitting and improves generalization. GBM, on the other hand, builds trees sequentially, with each tree attempting to correct the errors of the previous ones [31]. This method is highly effective for both classification and regression tasks but can be computationally intensive.

Field-aware Factorization Machines (FFM) extend the capabilities of FM by introducing the concept of fields [32-34]. In FM, a feature interacts with other features using the same vector, whereas in FFM, a feature uses different vectors to interact with features from different fields [33]. This distinction allows FFM to model interactions more precisely, enhancing the model's expressiveness [34]. For instance, in a recommendation system, user-related features and item-related features can interact differently depending on their respective fields. However, the enhanced expressiveness of FFM comes at the cost of increased memory requirements, which can be a significant limitation when dealing with very large datasets [32].

In summary, shallow methods like Logistic Regression, Factorization Machines, and Decision Trees provide foundational techniques for modeling interactions and making predictions. While they offer interpretability and simplicity, their expressiveness is often limited, necessitating extensive feature engineering or the use of ensemble techniques to capture complex relationships. The ongoing development of these methods continues to enhance their applicability across various domains, from recommendation systems to employment analytics.

III. PROPOSED METHOD

Our main objective in this study is to model the feature interaction representation more effectively to predict job turnover among early career university graduates in South Korea. To achieve this, we propose a Feature Interaction based Neural Network (FINN) tailored for employment data analysis.

A. Sparse Input and Embedding Layer

Unlike image classification or speech recognition tasks, the input data in employment prediction tasks are usually non-contiguous and categorical. These raw input features are typically converted into high-dimensional sparse features via one-hot encoding. One-hot encoding is a process that transforms categorical variables into a binary vector representation, where only one element is "hot" (i.e., set to 1) and all other elements are "cold" (i.e., set to 0). For instance, consider the following categorical variables:

User ID = 001, 002, ...

Job Type = Engineer, Teacher, ...

Gender = Male, Female

Using one-hot encoding, an input instance can be transformed as follows:

User ID = 001 \rightarrow [1, 0, 0, ...]

Job Type = Engineer \rightarrow [1, 0, 0, ...]

Gender = Female \rightarrow [0, 1]

The dimension of these features, particularly the user ID and job type, becomes large after encoding. For instance, if there are 550 job types, the dimension of the job type feature increases to 550, with only one of these values being effective. This results in extremely sparse feature vectors, where the majority of the elements are zero. The sparsity of the coded feature suggests that deep neural networks (DNNs) are not directly applicable because DNNs typically require dense input vectors to perform effectively.

Therefore, these sparse features are embedded into a continuous, dense, real-value vector space with lower dimensions. The embedding layer transforms these high-dimensional sparse vectors into dense vectors. This transformation is achieved by mapping each categorical value to a dense vector of fixed size. The embedding layer can be represented as:

$$[E = [e_1, e_2, \dots, e_1, \dots, e_m]]$$

where (m) denotes the number of fields, $(e_i \text{ in } \mathbb{R}^k)$ denotes the embedding vector of the (i) -th field, and (k) is the dimension of the embedding vector. The embedding process can be visualized as follows:

Each unique value in a categorical feature is assigned a unique dense vector.

These dense vectors are learned during the training process, allowing the model to capture semantic similarities between different categorical values.

The resulting embedded vectors are then concatenated to form a dense representation of the original sparse input.

For example, consider a feature vector with three categorical variables: user ID, job type, and gender. After one-hot encoding and embedding, the resulting dense vector might look like this:

$$[\{\text{User ID embedding}\} = [0.1, 0.3, 0.5]]$$

$$[\text{Job Type embedding}] = [0.2, 0.4, 0.6]$$

$$[\text{Gender embedding}] = [0.3, 0.7]$$

These embeddings are then concatenated to form a single dense vector:

$$[E = [0.1, 0.3, 0.5, 0.2, 0.4, 0.6, 0.3, 0.7]]$$

The dimension of the dense vector is much smaller than the original sparse vector, making it more suitable for input into a deep neural network. The embedding layer not only reduces the dimensionality of the input features but also captures latent relationships between different categorical values, which can be crucial for accurate prediction.

B. Feature-Interaction Layer

To improve prediction accuracy, it is crucial to model feature interactions after the embedding layer. The feature-interaction layer aims to model second-order feature relationships. Intuitively, we can represent the interaction of the (i)-th feature and the (j)-th feature using a vector (p_{ij}). However, due to data sparsity, training (p_{ij}) directly is impractical.

Instead, we use embedding vectors to calculate interaction vectors through methods like inner product and element-wise product. These methods are defined as:

$$f_{\text{inner}}(x) = \sum_{\{i,j \in X\}} (\mathbf{v}_i \cdot \mathbf{v}_j) x_i x_j$$

$$f_{\text{element-wise}}(x) = \sum_{\{i,j \in X\}} (\mathbf{v}_i \circ \mathbf{v}_j) x_i x_j$$

where (X) is the set of features, (\mathbf{v}_i) and (\mathbf{v}_j) are the embedding vectors, and (\circ) denotes the element-wise product. These methods can be too simple to effectively calculate feature interactions, so we propose a more sophisticated method:

$$\mathbf{p}_{ij} = [p_{ij}^1, p_{ij}^2, \dots, p_{ij}^k]$$

$$p_{ij}^u = \mathbf{v}_i^T \mathbf{W}^u \mathbf{v}_j$$

where (\mathbf{W}) in $\mathbb{R}^{k \times k \times 1}$ is a three-dimensional tensor. Each slice (\mathbf{W}^u) represents a relation matrix.

C. Combination Layer and Deep Network

The interaction vectors (\mathbf{p}) are concatenated and fed into a deep neural network (DNN). The combination layer merges the outputs of the feature-interaction layer:

$$[\mathbf{c}] = [c_1, c_2, \dots, c_k]$$

The deep network captures higher-order interactions between features. The fully connected layers are defined as:

$$[\mathbf{h}^{(l)}] = \sigma(\mathbf{W}^{(l)} \mathbf{h}^{(l-1)} + \mathbf{b}^{(l)})$$

where (σ) is the activation function, ($\mathbf{W}^{(l)}$) and ($\mathbf{b}^{(l)}$) are the weight matrix and bias vector of the (l)-th layer. The DNN captures high-order feature interactions through non-linear activation functions like ReLU, sigmoid, or tanh.

Finally, the output vector of the last neural network layer is used to calculate the prediction score:

$$[y_d = \sigma(\mathbf{W}^{(L+1)} \mathbf{h}^{(L)} + \mathbf{b}^{(L+1)})]$$

D. Output Layer and Learning

The overall formulation of the FINN model output is:

$$[y = \sigma(w_0 + \sum_{i=1}^n w_i x_i + y_d)]$$

where (y) is the predicted probability of job turnover, (σ) is the sigmoid function, (n) is the number of features, and (w_i) are the weights of the sparse features. The loss function we aim to minimize is the binary cross-entropy loss:

$$\text{loss} = -\sum_{x \in X} [y_i(x) \log(y_i(x)) + (1 - y_i(x)) \log(1 - y_i(x))]$$

where ($y_{i(x)}$) is the ground truth, ($\hat{y}_{i(x)}$) is the predicted value, and (X) is the set of training instances.

To optimize the model, we use Mini-Batch Gradient Descent with the Adam optimizer. Adam combines RMSProp and momentum methods, adjusting the learning rate adaptively:

$$[\mathbf{m}]_t = \beta_1 [\mathbf{m}]_{t-1} + (1 - \beta_1) \mathbf{g}_t$$

$$[\mathbf{v}]_t = \beta_2 [\mathbf{v}]_{t-1} + (1 - \beta_2) \mathbf{g}_t^2$$

$$[\hat{\mathbf{m}}]_t = \frac{[\mathbf{m}]_t}{1 - \beta_1^t}$$

$$[\hat{\mathbf{v}}]_t = \frac{[\mathbf{v}]_t}{1 - \beta_2^t}$$

$$\left[\theta_t = \theta_{t-1} - \alpha \frac{\hat{\mathbf{m}}_t}{\sqrt{\hat{\mathbf{v}}_t + \epsilon}} \right]$$

where (β_1) and (β_2) are decay rates, (α) is the learning rate, (ϵ) is \mathbf{g}_t is the gradient.

We also apply dropout and batch normalization to prevent overfitting and stabilize training. Dropout randomly drops neurons during training with a probability (p), and batch normalization normalizes intermediate layer outputs.

IV. EXPERIMENTS

A. Dataset and Participants

This study utilizes data from the Graduates Occupational Mobility Survey (GOMS) conducted by the Korea Employment Information Service. The dataset includes approximately 5% of the 500,000 students who graduated from two-year and four-year colleges between August 2014 and February 2015, resulting in a sample size of 28,549 individuals. The survey was conducted in September and October 2016. The GOMS dataset is comprehensive, encompassing a wide range of variables that influence labor market entry and retention. These variables include academic background, current economic activity, job characteristics, job search activities, and individual demographics. The dataset's richness allows for a detailed analysis of the factors influencing job turnover among recent graduates. Participants were selected based on the following criteria: (1) they must have graduated after January 2014 and have secured their first job post-graduation. (2) Furthermore, only those employed in regular, full-time positions without fixed-term contracts were included in the study. This selection criterion ensures that the analysis focuses on stable employment scenarios, eliminating the variability introduced by temporary or part-time positions.

The GOMS survey provides detailed information on various aspects of the participants' careers and educational backgrounds. It includes data on the type of institution they graduated from, their graduation date, current employment status, details about their current job, and information about their first job. Additionally, the survey collects data on job search activities, vocational training experiences, language training, and certifications obtained. This comprehensive dataset allows for a nuanced analysis of the factors that influence job turnover among recent graduates. Table I is a summary of the dataset statistics and Table II is the variables measured in the study.

TABLE I. SUMMARY OF THE DATASET

Dataset	Instances	Categories	Fields	Positive Ratio
GOMS	28,549	50+	20+	0.27

TABLE II. VARIABLES MEASURED

Variable Category	Variable Name	Description
Personal Attributes	Gender	Male, Female
	Age	Age at the time of turnover
Employment Characteristics	Industry	Industry sector of the job
	Job Type	Specific job role
	Company Size	Number of employees
Working Conditions	Weekly Working Hours	Total hours worked per week
	Monthly Salary	Average monthly income
	Union Membership	Whether the employee is a union member
Job Satisfaction	Satisfaction Level	11 items on a 5-point Likert scale

Variable Category	Variable Name	Description
	Job Fit	4 items measuring the alignment of job with skills and interests
Benefits	Social Insurance	Dummy variable indicating social insurance coverage
	Welfare Benefits	Dummy variable indicating availability of welfare benefits
Job Preparation	Work Experience	Employment experience during school
	Job Search Experience	Experience in job searching
	Vocational Training	Participation in vocational training
	Certification	Whether the individual holds any professional certifications
Academic Performance	GPA	Grade point average on a 5-point scale

B. Baseline Methods

We compare FINN with eight baseline models in our experiments (Table III), all implemented with TensorFlow and trained using the Adam optimization algorithm.

TABLE III. THE EIGHT BASELINE MODELS OF STUDY

Model	Description
Logistic Regression (LR)	A classical model in classification tasks that predicts the probability of positive samples. It is a linear model that uses the logistic function to model a binary dependent variable.
Factorization Machines (FM)	Models feature interactions by learning a feature vector for each feature and using the inner product of two feature vectors. FM is effective in capturing second-order interactions.
Field-aware Factorization Machines (FFM)	An extension of FM that considers the field information of each feature, allowing for more precise interaction modeling.
Support Vector Machine (SVM)	A supervised learning model used for classification tasks. SVM constructs a hyperplane or set of hyperplanes in a high-dimensional space to separate different classes. It is effective in high-dimensional spaces and for cases where the number of dimensions exceeds the number of samples.
Random Forest	An ensemble learning method that constructs multiple decision trees during training and outputs the mode of the classes (classification) or mean prediction (regression) of the individual trees. It reduces overfitting by averaging multiple trees.
Product-based Neural Networks (PNN)	Uses product operations to perform pairwise interactions between features to capture interaction information. This model enhances the representation power by explicitly modeling feature interactions.
Wide & Deep	A hybrid model consisting of a single layer wide part and a multilayer deep part. The wide part captures memorization of feature interactions, while the deep part captures generalization.
DeepFM	Improves the Wide & Deep model by replacing the wide part with a factorization machine. DeepFM combines the strengths of FM and deep neural networks to capture both low-order and high-order feature interactions.

C. Evaluation Metrics

We use two primary evaluation metrics to assess model performance: Area Under the ROC Curve (AUC) and Log Loss.

- **AUC:** A widely used metric in binary classification that measures the ability of the model to distinguish between

positive and negative samples. A higher AUC indicates better performance.

- **Log Loss:** Measures the distance between the predicted probabilities and the actual labels. Lower log loss values indicate better performance.

D. Data Processing and Experimental Setup

For data preprocessing, categorical features are converted into one-hot encoded vectors. Numerical features are discretized by equal-size buckets. We also apply negative down-sampling to address the issue of class imbalance, ensuring that the positive sample ratio is approximately 0.5.

We implement all models using TensorFlow and train them using the Adam optimization algorithm with a mini-batch size of 1000. The learning rate is set to 0.0001. For deep models, the depth of layers is set to 5, with ReLU activation functions. The number of neurons per layer is set to 700. We initialize the DNN hidden layers using Xavier initialization and the embedding vectors from uniform distributions. The experiments are conducted on two GTX 4060 Ti GPUs.

E. Performance Comparison and Analysis

We compare the performance of the FINN model with baseline models using the GOMS dataset. The results are summarized in Table IV.

TABLE IV. PERFORMANCE COMPARISON OF DIFFERENT MODELS

Method	AUC	Log Loss
LR	0.751	0.449
FM	0.783	0.417
FFM	0.792	0.408
SVM	0.770	0.430
Random Forest	0.765	0.435
PNN	0.801	0.399
Wide & Deep	0.813	0.387
DeepFM	0.820	0.380
FINN	0.830	0.370

F. Analysis of Results

The experimental results show that our proposed FINN model outperforms all baseline models in terms of both AUC and Log Loss. The superior performance of FINN can be attributed to its ability to effectively capture complex feature interactions through its feature interaction layer. Traditional models like Logistic Regression and Factorization Machines are limited in their ability to model higher-order interactions, which are crucial for accurate predictions in employment data.

Neural network-based models such as FFM, PNN, and DeepFM show better performance compared to traditional models, highlighting the importance of modeling feature interactions. Among these, DeepFM performs well due to its ability to capture both low-order and high-order interactions. However, FINN surpasses DeepFM by employing a more sophisticated feature interaction mechanism that extends beyond simple inner product or element-wise product operations.

To further analyze the effectiveness of FINN, we conduct additional experiments varying the size of the embedding vectors and the number of hidden layers in the DNN. The results, illustrated in Fig. 1 and 2 indicate that FINN consistently outperforms other models across different configurations, demonstrating its robustness and generalizability.

G. Parameter Study

In this subsection, we conduct hyper-parameter investigations for our model, focusing on the embedding part, the DNN part, and the feature interaction part. Specifically, we change the following hyper-parameters: (1) the dimension of embeddings, (2) the depth of DNN, and (3) the dimension of the feature interaction vector.

1) *Embedding part:* We change the embedding sizes from 10 to 50 and summarize the experimental results in Fig. 1 and Table V. As the dimension expands from 10 to 50, our model shows substantial improvement. We find that an embedding size of 30 yields the best performance on the GOMS dataset. Enlarging the embedding size increases the number of parameters in the embedding layer and the DNN part. The optimal embedding size balances model complexity and performance.

2) *DNN part:* We investigate the impact of different DNN depths by varying the number of hidden layers. Increasing the number of layers initially improves model performance; however, performance degrades if the number of layers continues to increase due to overfitting. Fig. 2 and Table VI shows that a depth of 5 layers provides the best balance between model complexity and performance.

3) *Feature interaction part:* We change the feature interaction vector sizes from 10 to 40. Fig. 3 and Table VII shows that a vector size of 10 provides the best performance on the GOMS dataset. The performance remains stable as we increase the vector size, indicating that the model is robust to this hyper-parameter.

TABLE V. EMBEDDING SIZE OF STUDY

Embedding Size	AUC (GOMS)	Log Loss (GOMS)
10	0.815	0.380
20	0.825	0.375
30	0.830	0.370
40	0.832	0.368
50	0.831	0.369

TABLE VI. DNN LAYERS OF STUDY

Number of Layers	AUC (GOMS)	Log Loss (GOMS)
3	0.828	0.373
5	0.830	0.370
7	0.831	0.369
9	0.830	0.371

TABLE VII. FEATURE INTERACTION VECTOR SIZE OF STUDY

Interaction Vector Size	AUC (GOMS)	Log Loss (GOMS)
10	0.830	0.370
20	0.828	0.372
30	0.829	0.371
40	0.829	0.371

H. Variable Importance Analysis

To identify the most important variables influencing job turnover, we use the feature importance scores from the FINN model. The top four variables are Monthly Salary, Job Satisfaction, Company Size, and Weekly Working Hours.

The importance scores indicate the relative impact of each variable on the prediction of job turnover. Table VIII and Fig. 4 illustrates the importance scores of these variables.

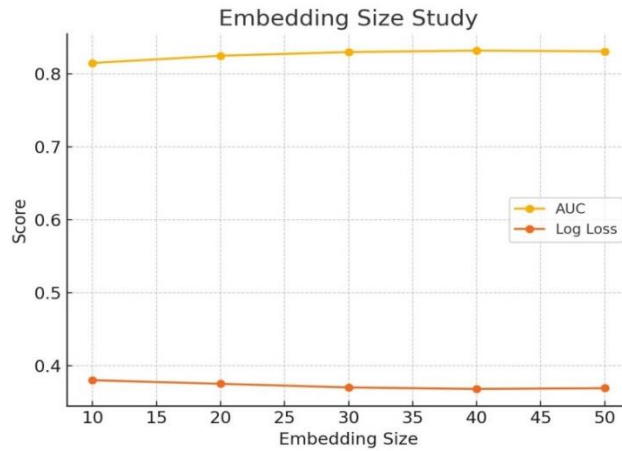

Fig. 1. Embedding size study.

Fig. 2. DNN layers study.

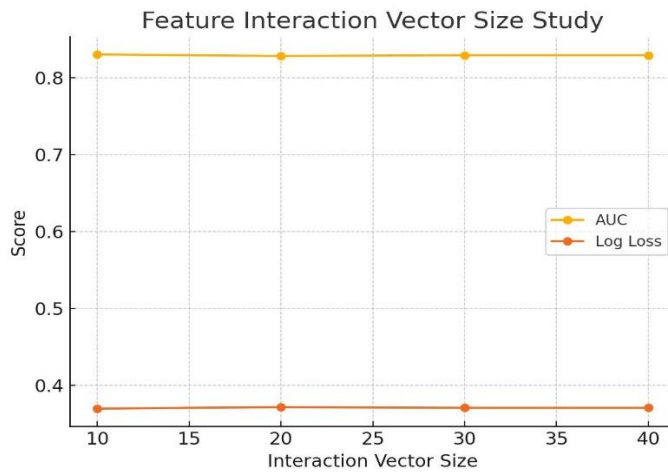

Fig. 3. Feature interaction vector size study.

TABLE VIII. VARIABLE IMPORTANCE OF STUDY

Variable	Importance Score
Monthly Salary	0.25
Job Satisfaction	0.22
Company Size	0.18
Weekly Working Hours	0.15

V. DISCUSSION

The prediction of job turnover among early career university graduates is a crucial task for both employees and employers. Accurate predictions can help employees navigate their career paths more effectively and assist employers in developing strategies to enhance employee retention, thereby

reducing the costs associated with recruitment and training. This study proposes a Feature Interaction based Neural Network (FINN) model designed to address the complexities inherent in employment data and improve the accuracy of job turnover predictions.

In this paper, the results demonstrated that the FINN model outperforms all baseline models in terms of both AUC and Log Loss. Specifically, the FINN model achieved an AUC of 0.830 and a Log Loss of 0.370, indicating its superior ability to distinguish between employees who are likely to leave their jobs and those who are not. This performance can be attributed to the model's ability to effectively capture complex feature interactions through its feature interaction layer, which traditional models and even some advanced neural network models struggle to do [20, 21].

Fig. 4. Variable importance of study.

The study conducted an extensive parameter study to identify the optimal settings for the FINN model. This included varying the embedding sizes, the depth of the DNN, and the size of the feature interaction vector. The results provide valuable insights into the impact of these hyper-parameters on model performance [35,36]. Additionally, the analysis identified key variables that significantly influence job turnover, such as monthly salary, job satisfaction, company size, and weekly working hours. These findings can inform both policy and practice by highlighting areas where interventions might be most effective in reducing turnover rates. This study makes several significant contributions to the field of employment data analysis and predictive modeling. The primary contribution is the development and validation of the FINN model. This model enhances the predictive accuracy of job turnover by effectively modeling complex interactions between features. By leveraging the rich GOMS dataset, the study provides a detailed analysis of various factors influencing job turnover among early career graduates. This comprehensive dataset allows for a nuanced understanding of the predictors of job turnover. These findings have several practical implications. Employers can use the insights from the

FINN model to develop targeted retention strategies. For instance, improving job satisfaction and offering competitive salaries could be effective measures to reduce turnover rates among early career employees. Career counselors and advisors can use the model's predictions to provide personalized guidance to graduates, helping them make informed decisions about their career paths and job choices. Policymakers can leverage the findings to design programs and policies aimed at improving job stability among young graduates. This could include initiatives to enhance job satisfaction and provide better working conditions.

While the FINN model has demonstrated significant improvements in predictive accuracy, there are several avenues for future research. First, future research could explore the integration of additional advanced techniques, such as attention mechanisms and sequence modeling, to further enhance the model's ability to capture complex feature interactions. Second, testing the FINN model on different datasets from various regions and industries could validate its generalizability and robustness across different contexts. Third, conducting longitudinal studies to track job turnover over a more extended

period could provide deeper insights into the long-term predictors of job stability and career success. Fourth, experimenting with different intervention strategies based on the model's predictions could help in identifying the most effective measures for reducing job turnover.

VI. CONCLUSION

In this paper, we have demonstrated that the FINN model represents a significant advancement in the field of predictive modeling for job turnover among early career graduates. By effectively capturing complex feature interactions and leveraging a rich dataset, the FINN model provides superior predictive performance compared to both traditional and contemporary models. The insights gained from this study have the potential to inform strategies and policies aimed at improving job retention and career outcomes for young professionals. As employment data analysis continues to advance, the FINN model is expected to provide a strong foundation for both future research and practical applications, enabling more precise and actionable predictions in the labor market.

A Systematic Review of Virtual Commerce Solutions for the Metaverse

Ghazala Bilquise¹, Khaled Shaalan², Manar Alkhatib³

Computer Information Science, Higher Colleges of Technology, Dubai, UAE¹
Computer Science Department, The British University in Dubai, Dubai, UAE^{2,3}

Abstract—The metaverse, a rapidly evolving field, promises to transform online shopping through immersive technologies. This systematic review aims to explore and analyze the key design features of Virtual Commerce (v-commerce) solutions within this digital environment. By examining 24 studies that have developed immersive v-commerce applications, this review seeks to compile a taxonomy of essential design attributes necessary for creating effective and engaging v-commerce experiences. The review classifies these attributes into three primary dimensions: Product, Intelligent Services, and Functionality. The findings indicate that within the Augmented Reality (AR) category, product visualization and natural interaction were the most studied attributes. In the Virtual Reality (VR) category, intuitive affordances emerged as the most frequently investigated features. Meanwhile, Mixed Reality (MR) studies commonly focused on information quality, intuitive affordances, and shopping assistants. The insights from this review provide valuable guidance for researchers, developers, and practitioners aiming to enhance consumer engagement and satisfaction in the metaverse through well-designed v-commerce applications. By synthesizing the results of various studies, this review offers a comprehensive overview of the current state of v-commerce research, identifies existing gaps, and proposes potential directions for future development in the field.

Keywords—Metaverse; v-commerce; immersive technologies; design attributes

I. INTRODUCTION

Over the past two decades, the online retail market has seen a significant increase, primarily driven by the rise of electronic commerce (e-commerce). The COVID-19 pandemic further accelerated this growth, leading to unprecedented levels of global e-commerce sales, which reached \$5.7 trillion in 2022, representing a rise in market share from 18.8% to 19.7% [1]. Analysts predict that by 2026, the online segment will grow to \$8.1 trillion, nearly a quarter of the total retail market share [2], [3], indicating a lasting shift in consumer behavior towards online shopping [4]. This shift is fueled by advancements in mobile and internet technologies, necessitating businesses to continuously adapt to stay competitive and enhance consumer shopping experiences.

The advent of the metaverse promises to transform online shopping into a more immersive, engaging, and seamless experience. Unlike traditional e-commerce, the metaverse allows users to interact through digital avatars in virtual storefronts, offering an enriched user experience powered by technologies like Augmented Reality (AR), Virtual Reality (VR), and Mixed Reality (MR) [5]. These immersive

technologies, along with Artificial Intelligence (AI) powered chatbots and Internet of Things (IoT), enable personalized shopping experiences and provide retailers with valuable data analytics to tailor offerings to customer preferences [6]. For organizations to fully exploit these capabilities, it is crucial to select optimal v-commerce solutions that integrate the real and virtual worlds, enhance consumer engagement, and support business success. Furthermore, v-commerce attributes can also be used to assess, evaluate and compare multiple v-commerce solutions against each other to select the most optimal one.

To leverage the potential of the metaverse, organizations need to adopt v-commerce solutions that meet their specific needs and enhance consumer engagement and trust. However, there is no consensus among researchers on the effective design elements of these solutions [7]. Studies in Information Systems (IS) have explored factors influencing consumer behavior in immersive shopping environments [7], [8], [9], [10]. However, these studies often focus on behavioral intentions using self-reported data, which can be biased and require validation through more robust methodologies.

To effectively identify the essential design elements of metaverse v-commerce solutions, an investigation of Design Science (DS) research is recommended [11]. DS approach emphasizes the creation and evaluation of innovative IT artefacts and can provide a more rigorous foundation for understanding the impact of design attributes on consumer behavior [12], [13]. To the best of our knowledge, no study has comprehensively combined and presented design attributes for v-commerce solutions.

Several systematic reviews on v-commerce exist in literature [7], [9], [14]. However, the current systematic review diverges from the previous studies in several key aspects. First, the previous reviews focus on IS studies in v-commerce reporting behavioral constructs for the adoption of v-commerce solutions, and the theories applied to predict consumer purchase intentions. The aim is to inform practitioners about the essential factors needed for a v-commerce system to achieve its intended purpose. Second, previous reviews focus on a single immersive technology such as VR [7], or AR [9], [14]. This study seeks to investigate DS research to present the v-commerce attributes for all immersive environments focusing all the immersive technologies (AR, VR and MR). Furthermore, this review aims to identify the design elements for developing and evaluating v-commerce solutions.

This study employs a systematic approach to review and synthesize an analysis based on empirical studies that have

implemented v-commerce solutions. The study aims to categorize literature based on immersive technologies to reveal a taxonomy of the design attributes implemented in v-commerce solutions for consumer engagement. Additionally, it aims to outline future directions and research opportunities in this field.

The rest of the study is organized as follows. Section II provides background information on the metaverse and v-commerce. Section III presents the methodology of the systematic review, while Section IV presents the results and discussion of the review. Section V presents the conclusion of the study along with the research limitations and future work.

II. BACKGROUND INFORMATION

A. Metaverse

The metaverse, initially coined in Neal Stephenson's 1992 science fiction novel "Snow Crash," is a collective virtual shared space created by the convergence of physical and virtual reality [15]. Over the past three decades, technological advancements have laid the foundation for a more tangible metaverse experience [16]. While still in its infancy, ongoing research and development are shaping its potential as the successor to the Internet.

The realization of the metaverse is made possible by various technologies, including immersive technologies, 3D computing, 5G and edge computing, AI, blockchain, and IoT [6], [17], [18]. These advancements offer high-speed, low-latency connectivity, personalized user experiences, secure digital identities, and seamless interactions within the metaverse. AI enhances user experiences by personalizing content and enabling intelligent interactions, while blockchain ensures secure transactions and digital ownership verification [6], [17], [18]. IoT bridges the physical and virtual worlds, mirroring real-world information within the metaverse [17], [19].

At the core of the metaverse experience are immersive technologies such as VR, AR and MR, collectively known as Extended Reality (XR). These technologies create a sense of presence in digital environments, allowing users to interact with and navigate the metaverse seamlessly. Low-immersion environments offer limited sensory stimulation, while high-immersion environments provide a rich, multi-sensory experience, enhancing the realism and interactivity of virtual objects and environments. The immersion spectrum of AR and VR technology is depicted in Fig. 1.

Fig. 1. Immersion spectrum of XR technologies.

Central to this immersive engagement are avatars, digital representations of users that facilitate social interactions within the metaverse [20]. Avatars range from simple 2D icons to

complex 3D models and can perform various functions beyond visual representation, such as gestures and expressions. They enable users to communicate and collaborate in real-time, simulating real-world interactions [15]. The metaverse holds the potential to revolutionize socialization and interaction across various domains, including tourism [21], education, and retail [5], by providing immersive, interactive, and engaging experiences that integrate the physical and virtual worlds seamlessly. Designing v-commerce solutions in the metaverse requires addressing the challenge of creating unique, integrated experiences that enhance consumer engagement and business growth.

B. Virtual Commerce

The evolution of online shopping is rapidly transforming with the advent of new technologies that are quickly gaining traction among consumers. In this expansive digital landscape, v-commerce has emerged as a dynamic and transformative force, offering new opportunities and challenges for businesses and consumers alike. V-commerce is becoming a prominent feature of e-commerce, leveraging immersive XR technologies alongside AI to deliver captivating, three-dimensional shopping experiences [22]. These advanced digital technologies provide highly engaging and interactive experiences, immersing users in unique shopping environments [23].

V-commerce technologies allow consumers to explore virtual stores and examine products in a way that closely replicates the experience of shopping in person. This paradigm shift promises to revolutionize shopping practices by offering enhanced convenience and customer satisfaction [24]. Unlike traditional e-commerce, v-commerce provides immersive experiences that engage consumers through various sensory dimensions, including visual, auditory, kinetic, and tactile stimuli. This approach opens numerous opportunities for increased customer engagement, streamlined purchasing processes, stronger connections, and enhanced profitability.

The evolution of e-commerce towards virtual realms and encounters is evident as several stores facilitate immersive experiences for consumers. For instance, Ikea has developed a virtual reality app that allows customers to visualize furniture in their own rooms before purchasing [25]. Fashion retailer Zara introduced an AR shopping assistant app that displays clothing worn by models when customers point their cameras at the store. Additionally, brands like Sephora and L'Oreal use immersive technologies to let consumers digitally try on makeup products [26].

The convergence of v-commerce and the metaverse, which includes virtual environments where users can interact with various digital assets, offers countless possibilities for creating distinctive and immersive shopping experiences, such as virtual product explorations, virtual social interactions, virtual try-ons, and even virtual malls. In conclusion, v-commerce is poised to transform the online shopping landscape through rich, interactive, and immersive experiences.

III. METHODOLOGY

This paper uses a systematic approach to examine empirical research studies that have implemented v-commerce solutions.

For this purpose, the study adopts the systematic review framework established by [27]. This framework was selected over other frameworks, such as [28], since it provides guidelines specifically for conducting reviews in the technical field. Employing a rigorous theoretical framework is crucial for guiding the comprehensive data collection and analysis methods required for ensuring the reliability of the results. The systematic literature review guidelines by [27] offer a thorough approach to collecting, analyzing, and documenting findings from secondary data sources. By following this methodology, we aim to perform a thorough analysis of the included articles in the review and uncover the v-commerce design attributes to guide practitioners and researchers and further the study in this field.

The review process is segmented into five distinct phases: identifying the data sources, establishing the search strategy with the inclusion/exclusion criteria, selection of the articles using the PRISMA framework, performing the meta-analysis and finally reporting the results. The next subsections explain each phase and the outcomes of the phase. Results of the review are presented in Section IV.

A. Data Sources

Choosing the appropriate data sources is a crucial step in an Systematic Literature Review (SLR) process. To this end, three multidisciplinary databases were utilized as sources for collecting relevant articles – Web of Science (WoS), Scopus and ScienceDirect. The suitability and relevance of these databases has been acknowledged in numerous SLR articles published in well-regarded journals and in scientific research articles, demonstrating their resilience and scholarly evaluation [29]. All the selected databases encompass multiple publications across diverse scientific research domains and from various academic disciplines. Both Scopus and WoS are multidisciplinary databases encompassing peer-reviewed literature in science, medicine, social science, technology, arts and humanities, making them valuable for accessing a broad spectrum of research. ScienceDirect is a comprehensive resource for articles in the scientific, technical and medical fields.

B. Search Process

The search was conducted in two iterative rounds, the first in December 2023 and second in Jan 2024, to ensure that the latest articles are not left out. Additional studies were also sourced using a snowballing technique. The keywords representing immersive technologies such as ‘virtual reality’, ‘augmented reality’, ‘mixed reality’, ‘virtual world’ and ‘virtual environment’ were combined with the keywords ‘virtual commerce’, ‘virtual shopping’, ‘virtual store’ using Boolean operators to limit the search to the respective domain. Moreover, the search encompassed the title, abstract, and keywords to broaden the search space and ensure the inclusion of relevant studies. The formulated keywords search string is given below:

("virtual commerce" or "virtual shop*" or "virtual store") AND ((virtual AND (reality OR environment OR world)) OR ((mixed OR augmented) AND reality)).

A set of inclusion exclusion criteria, presented in Table I, was established to outline the crucial characteristics of the studies incorporated in the research.

TABLE I. INCLUSION / EXCLUSION CRITERIA

Inclusion Criteria	Exclusion Criteria
Must be an empirical study focused on the development of v-commerce applications.	Studies that are qualitative or unrelated to v-commerce application development
Must detail characteristics or design features of the developed application	Studies that do not describe or include any attribute of v-commerce application
Must be published in a peer-reviewed journal or conference proceedings	Publications such as books, book chapters, reviews, or articles not yet published
Must be written in English	Papers written in languages other than English
Must have been published between 2011 and 2024	Papers published before 2011

This study delves into the trends of research by analyzing keywords present in literature, particularly focusing on v-commerce solutions utilizing immersive technologies. After conducting the initial search, which yielded 525 results, the key terms from these findings were visualized using VOSviewer to identify prominent themes in the literature. VOSviewer is an advanced software tool designed for visualizing and analyzing scientific literature [30]. By examining the external characteristics of the data, it enables statistical and mathematical analysis to uncover trends and features within specific disciplines. Fig. 2 illustrates the visualization results. The diagram highlights the significance and interconnections among frequently occurring terms extracted from the abstracts, titles, and keywords of the search results. The size and label of each term indicate its importance, while the color represents clusters in the visualization. Each cluster comprises terms related to one another within the group, and the distance between clusters signifies their relatedness.

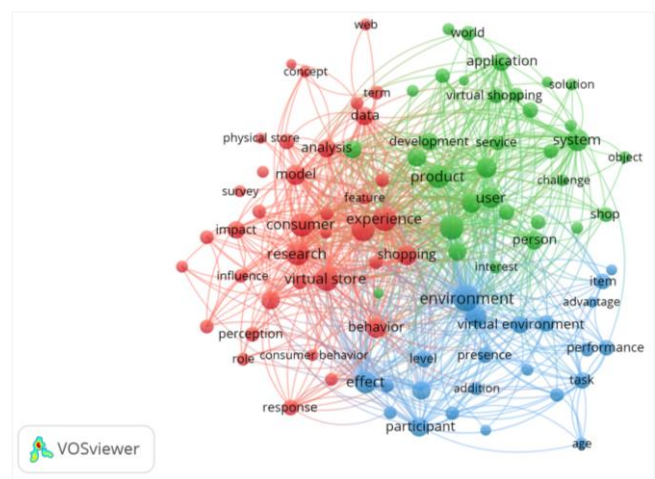

Fig. 2. Visualization of key terms in search results.

The visualization of key terms present in the titles and abstracts reveal three primary clusters, which clearly indicates the divide in the extant literature between IS and DS research. The red cluster encompasses keywords like consumer behavior, purchase intention, perception, influence,

relationship, and model, indicating a research focus on behavioral outcomes concerning v-commerce and purchase intentions arising from IS studies. The green cluster, on the other hand, features terms such as product, solution, service, application, technology, interaction, and development, showcasing a trend towards DS research for v-commerce solution development. Lastly, the blue cluster includes terms like performance, time, advantage, reflecting the evaluation of both IS and DS studies. This differentiation between IS and DS research underscores the need for mapping findings between the two domains.

C. Study Selection

The selection of articles for the systematic review was processed using the PRISMA framework [31] depicted in Fig. 3. This framework offers comprehensive guidelines and an organized method for reviewing documents. It consists of four main phases after performing the keyword search. The first phase is the identification phase in which the articles are retrieved from the identified databases and the duplicate articles are removed. Second is the initial screening phase, in which the inclusion/exclusion criteria are utilized to screen the articles based on the abstracts. Third is the eligibility phase in which a thorough full-text screening is performed to assess the relevance of the articles and to ensure that the article meets the requirements of the SLR. Finally, the last phase involves performing a quality assessment of the articles to ensure reliability of the findings. The application of each of the four phases using the PRISMA model is discussed next.

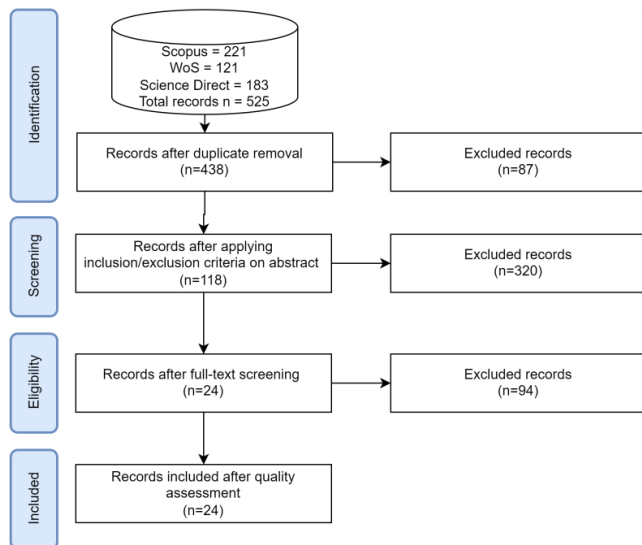

Fig. 3. PRISMA framework.

First, the search yielded 525 results across all databases. The removal of duplicate articles reduced the number of studies to $n=438$. Next, the abstract screening process was used to screen irrelevant articles which further reduced the number of studies to $n=118$. During the abstract screening process, numerous studies were excluded as they did not contribute to the context of this research such as the studies which were not empirical research in the field of v-commerce solutions development. In the eligibility phase a full-text screening of the articles led to the removal of all irrelevant studies that did not

meet the inclusion criteria requirement thereby reducing the number of articles to $n=24$. A thorough screening of the articles revealed that several studies were irrelevant due to multiple reasons such as review articles, articles not in English, unavailability of full-text, articles not related to v-commerce application or solution development.

Finally, a quality assessment was conducted to ensure the reliability and validity of the included articles. It is important to note that the purpose of the quality assessment is to evaluate the relevance of the selected articles to this study's objectives, rather than to critique individual studies or their findings. Ensuring the validity of results and minimizing bias are crucial aspects of systematic reviews, highlighting the importance of quality assessment [32]. Additionally, quality assessment helps refine inclusion and exclusion criteria and contributes to the overall rigor of the review process [27]. The quality assessment checklist, was adapted from an extant SLR study [29]. It comprises of criteria that are crucial for the encoding process such as detailed description of the design elements and evaluation of the application design. The quality assessment also considers the credibility of the source and relevance of the publication to the research community. Each reviewed article was assessed using a quality checklist by assigning a score of 1 when the criteria is met, 0.5 if it is partially met or 0 if it is not met. The total score was converted to a percentage value. Only studies scoring 75% and above are considered for the review. Notably, all the studies passed the quality assessment check and were included in the meta-analysis.

D. Data Analysis and Coding

The objective of this phase is to thoroughly document the systematic review findings by gathering meta-data from the primary studies included in the review, with a focus on the research questions. A thorough data analysis of the relevant features identified during the planning phase is conducted to achieve this objective. The meta-data analysis encompasses various characteristics crucial for achieving the objective of the study such as identifying the design attribute implemented in the study and categorizing the attribute to its respective dimension.

E. Reporting the Review

In the concluding phase of the systematic review, the study results are unveiled. Section IV presents a comprehensive analysis of the meta-data extracted from the full-text review, with the aim of revealing the v-commerce design attribute implemented in the studies. This analysis presents and discusses the insights from the collected data, providing a thorough understanding of the findings and their implications within the context of the objectives of the study.

IV. RESULTS AND DISCUSSION

The scope of the SLR included a qualitative analysis of 24 studies. The studies were categorized based on the immersive technologies utilized in the experimental design. Out of the 24 studies, nine studies developed AR solutions; nine studies developed VR solutions while six studies developed MR solutions. The meta-analysis aimed to uncover the design features in v-commerce applications implemented for respective immersive technologies. This section presents the

design attributes extracted from all the reviewed studies and presents a critical review of the implementation leading to a taxonomy of v-commerce design attributes.

A. V-Commerce Design Attributes

The results of the analysis revealed a total of 13 design attributes that were used to enhance shopping experience in v-commerce solutions. The design attributes were further categorized into three main dimensions: Product, Intelligent Services and Functionality. The definition of each attribute within each dimension is summarized below.

1) *Product attributes*: Product attributes encompass the richness and presentation of product information within an immersive environment. These design features are crucial for users to access detailed product information and interact effectively, enabling informed decisions. Through the literature review product attributes were categorized into four sub-attributes namely information quality (IQ), product visualization (PV), intuitive affordance (IA), and realistic modeling (RM). Each sub-attribute is described below.

a) *Information Quality (IQ)*: Refers to the richness and presentation of the product information in the application. Information quality in a 3D environment may be defined as the quality of product information provided as direct information as well as indirect information revealed through interactions [33]. The richness and abundance of product information empowers consumers to make well-informed purchasing decisions. Utilizing 3D environments, simulations, or augmented reality can optimize the depth of information provided and elevate brand interaction and purchasing intent by improving perceived information accuracy and fostering positive brand perceptions [34]. Interaction with the product can also assist the consumer to gather more information while in an immersive environment.

b) *Product Visualization (PV)*: PV, often implemented as Virtual try-on feature, in an immersive environment fosters customer involvement and provides an opportunity to test the items in order to make an informed purchase decision by reducing product ambiguity [35]. Several studies use algorithms to track the position of the surroundings or the human body to accurately display virtual accessories such as eyeglasses and clothing.

c) *Intuitive Affordance (IA)*: IA refers to designing user interfaces that facilitate natural interactions with virtual objects, including actions like gaze, pinch, touch, grab, and hand gesture recognition, among others [36]. An immersive environment engages multiple human senses. To fully engage users in an immersive environment, the application must cater to their natural expectations for varied sensory experiences [37]. Therefore, virtual interactions that aligned with human perceptions of physical interactions create a more natural interaction.

d) *Realistic Modelling (RM)*: Methods to render a product and/or the virtual environment in such a way that it is perceived to be realistic by users. Realistic modelling

enhances perceived presence in the immersive environment [38], [39] and enhances the level of satisfaction [39].

2) *Intelligent services*: Intelligent Services within v-commerce applications leverage AI, machine learning, and data analytics to enhance the shopping experience. These services encompass the integration of agents that aid users in navigating the online environment, recommend products, and simulate the assistance provided by in-store human assistants. Additionally, AI technologies like computer vision and geolocation features can be integrated to offer a more intuitive and seamless interactive experience within the environment. Five sub-attributes were identified in this category, which include Natural Interaction (NI), Navigation Agent (NA), Recommendation Agent (RA), Shopping Assistant (SA) and Personalization (PS). Each sub-attribute is described below.

a) *Natural Interaction (NI)*: NI involves utilizing technologies that enable users to engage with the application in intuitive and expected ways, for example using computer vision for face or body detection instead of using markers or silhouettes in AR [40], facial expression detection, natural language conversations, gesture recognition in a VR environment [41].

b) *Navigation Agent (NA)*: A smart digital assistant that aids users in navigating a virtual space by providing guidance and directing them on how to interact with objects [42]. Navigation agents may take the shape of an embodied agent with an avatar or a virtual tour.

c) *Shopping Assistant (SA)*: A virtual agent that provides information about the products or services in the virtual environment. The goal of the shopping assistant is to provide a new digital dimension to shopping mimicking the in-store assistants by answering basic FAQs, providing information on deals, coupons, and subscriptions [43].

d) *Recommendation Agent (RA)*: RA utilize AI technologies to suggest products based on user preferences and behaviors. [44]. Product recommendations offer an efficient search option for end users and thereby enhance the brand attitude, user satisfaction and attitude towards technology [45].

e) *Personalization (PS)*: Providing customized information to users based on characteristics, or preferences. Studies reveal that tailoring content to an individual's needs and interests is associated has a greater appeal and convincing impact on the consumer [46]. Moreover, increased personalization enhances brand attitude and user satisfaction [46].

3) *Functionality design*: Functionality attributes in v-commerce applications refer to the design features that aim to enhance interactivity, engagement, and control in an immersive environment. Interactive features are known to positively influence consumer satisfaction [47], [48] and provide an enjoyable shopping experience [38], [49], [50]. Four design attributes were identified in this category, namely Customization (CS), Navigability (NV), Seller Reputation

(SR) and Social Commerce (SC). Each sub-attribute is described below.

a) *Customization (CS)*: CS is a feature of immersive technology that allows the user to manipulate and customize the product and/or the virtual environment. Incorporating VR technology for product customization is expected to improve task-related factors and enhance the perceived value of the user experience [51]. Moreover, these systems may enable users to personalize a 3D layout and adjust specific properties of virtual objects.

b) *Navigability (NV)*: NV refers to the design of functions to enable user navigation or movement through the immersive environment [11]. It enhances the system's ease of use and is essential for creating a sense of physical presence within the immersive environment [52], [53], [54].

c) *Seller Reputation (SR)*: SR is a technique for objectively measuring a seller's credibility based on customer feedback and personal ratings. A mechanism to rate seller's

reputation promotes transparency and enhances repurchase intentions in an online environment [55].

d) *Social Commerce (SC)*: Enabling social presence by adding features of collaborative shopping and social activities such as sharing reviews, voting, likes and more [56]. Social commerce uses technologies to blend shopping with social activities to develop a sense of connection with the e-retailer and thereby enhancing the degree of social presences in a digital environment.

B. Critical Review of V-Commerce Attribute Implementation

This section presents a summary of the design attribute implementation within the respective immersive technology (AR, VR, MR) and develops a taxonomy of the design attributes. Out of the 24 reviewed studies, nine studies belonged to the AR category, nine to the VR category and six to the MR category. Fig. 4 presents the taxonomy, which illustrates the mapping of the design attributes implemented in the reviewed studies.

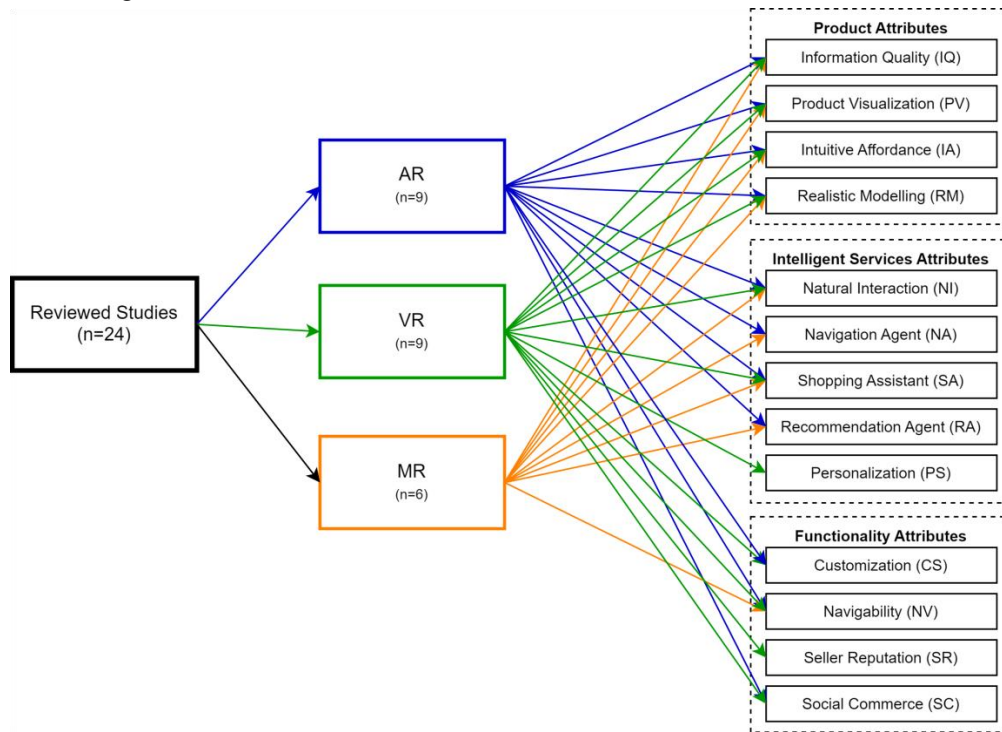

Fig. 4. Taxonomy of v-commerce design attributes.

1) *AR studies*: AR technologies superimpose digital information onto the real physical environment creating a new, combined experience that can be interactive and dynamic [57]. AR uses various devices such as smartphones, tablets, or specialized glasses to display computer-generated images, videos, or other virtual content in real time [14]. AR has the potential to offer new and innovative ways of engaging users in the shopping experience through product visualization, virtual try-ons and more [38], thereby providing consumers with a more immersive, engaging, and interactive shopping experience, leading to increased customer satisfaction and sales.

An analysis of the reviewed studies under the AR category revealed that numerous researchers focused on multiple design features of AR applications to enhance the consumer's shopping experience. Under the product dimension, product visualization and virtual try-ons (PV) were the most investigated design attributes by multiple researchers in the form of trying on clothes, glasses and visualizing furniture and toys [35], [40], [58], [59], [60]. Several studies enhanced the Information Quality (IQ) of the products by providing detailed product information [58], [61], information placement, and provision of additional relevant information [61], [62], while [63] enhanced Information quality by using explainable recommendations, and product comparisons. Intuitive Affordance (IA) was a focus of four out of nine studies in AR.

The research in [62] and [60] implemented intuitive affordance features by adding product rotating, zooming capabilities. The research in [58] implemented a direct selection feature that allows consumers to pick and try on glasses published by other users. While [63] added intuitive visual elements to ease navigation and discovery. Only two studies [62], [64] focused on enhancing the 3D quality and Realistic Modelling (RM) of the product.

In the Intelligent Services dimension, Natural Interaction (NI) was among the highly researched design areas, and the focus of six out of nine studies. Computer vision used to naturally detect users' body [40], facial data [35], [58], or perform a product search [60]. On the other hand, [62] used deep learning to detect users' current in-store location. The research in [60] also focused on other intelligent services such as a Navigation Agent (NA), shopping assistant (SA). Both [60] and [63] added product recommendations using Recommendation Agents (RA) to enhance the user's shopping experience.

In the functionality dimension three studies [40], [59], [62] added Customization (CS) features on the AR shopping app such as by allowing users to customize the product size, color, type or more. Four out of nine studies focused on navigability (NV) by providing easy search features and filter features for products [58], [59], [60] or easy in-store navigation [62]. The research in [40], [58] and [59] enhanced the social presence in the AR shopping app by adding the feature allowing users to share their try-ons with others, thus promoting Social Commerce (SC).

Overall, in the AR category, NA and PV were among the most investigated design attributes with 67% (n=6) and 56% (n=5) studies experimenting with these features respectively. The IQ, IA attributes were studied by 44% (n=4) studies, while the PS and SR attribute were not investigated by any study.

2) *VR studies*: VR technologies simulate realistic and immersive experience in a three-dimensional environment. VR allows consumers to see and interact with a product in a virtual environment, providing a more immersive and realistic experience than traditional 2D images or videos. With VR, businesses can create virtual storefronts and showrooms, allowing customers to browse and providing a multisensory purchase experience [10].

Among the reviewed studies in the VR category, several researchers focused on multiple VR design attributes to applications to enrich the consumer's shopping experience. In the product dimension, Intuitive Affordance (IA) and information quality (IQ) were the most investigated criteria. Three studies, [65], [66] and [67] focused on product presentation and information to enhance the information quality of the user experience. In addition, [67] also provided detailed product information with price comparisons to enhance the quality of information. Intuitive affordance was investigated by four studies by incorporating features such as grabbing, picking, rotating and adding items to the cart [65], [66], [67], [68]. Two studies focused on Realistic Modelling (RM) of the products [66], [68], while only one study

incorporated the product visualization (PV) feature as virtual try on for clothes [67].

In the intelligent services dimension, natural interaction (NI) in a shopping environment was investigated by five researchers in the form of using speech, eye and gaze interaction and virtual touch features [65], [66], [68], [69]. Moreover, [67], [70] also included the feature of an intelligent shopping assistant (SA) in the virtual environment. The research in [71] incorporated the feature of a personalization (PS) based on users' shopping profile. Navigation agents (NA) and recommendation agents (RA) were not studied in a virtual shopping environment by any of the studies.

Navigability (NV) was the most investigated criteria in the functionality dimension. Navigability was implemented with the use of controllers to ease navigation [67], simple and easy environment with clear signs [68], 3D navigation for ease of movement and turns [65], [66]. The research in [72] investigated the feature of customizing (CS) the virtual store. Fang et al. (2014) implemented the seller reputation (SR) feature by using a five senses reputation mechanism to assess the reputation of the seller in the virtual environment. The research in [67] added a social commerce feature by providing users a sense of shopping with other users by showing their online presence.

In the VR category, the NI design attribute is one of the highest investigated design features investigated in 44% (n=4) studies. In addition, IA and navigability NV were also investigated by 44% (n=4) studies. The IQ feature was investigated by 33% (n=3) studies. Furthermore, in the VR studies category the NA and RA attributes were not investigated by any study.

3) *MR studies*: MR is an emerging technology that integrates both virtual and augmented reality elements to create a blended, hybrid environment which includes both real and virtual objects [74]. Unlike AR, MR enables virtual objects to interact with the physical world. MR offers all the benefits of AR with an addition of interaction. Consumers can not just visualize or try the product before purchase, but also interact with it in real-time. Thus, MR allows for a more natural and intuitive interaction between the consumers and the digital products, leading to a more immersive experience.

From the reviewed studies in the MR category, four studies investigated the online shopping experience using MR technology. The research in [75] implemented a total of six design attributes. The study included three product attributes in the form of virtual try-ons (PV), intuitive affordance (IA) using with a full hand manipulation feature and enhanced product information. Furthermore, [75] also added intelligent services with natural interaction (NI) using computer vision for a smart product detection feature and recommendation engine (RA). Navigability (NV) was enhanced by incorporating ease of searching.

The research in [76] applied eight design attributes to an immersive shopping environment. In the product category, all the attributes were implemented (information quality (IQ), virtual try on (PV), intuitive affordance (IA), realistic

modelling (RM)). The research in [76] also applied intelligent services to the shopping application in the form of a navigation agent (NA) that provides a tour of the application, a shopping assistant (SA) that answers users queries and a product recommendation (RA) system that suggests products based on user’s traits. Finally, navigability (NV) of the system was enhanced by an avatar-based guidance system and providing a 360 view of shopping center with free walking and movement.

The research in [77] on the other hand implemented three design attributes (product visualization (PV), natural interaction (NI) and a voice-based shopping assistant (SA)) for a fashion store. The research in [78] implemented two design attributes, intuitive affordance (IA) using a feature to interact with a virtual hand, and realistic modelling (RM) by incorporating a sense of agency on the virtual hand to make it appear realistic. The research in [79] developed an MR shopping assistant using Microsoft HoloLens, which offers product information, reviews, and recommendations to the

shopper. In a later study [80] enhanced the shopping assistant application to include more features. Their prototype incorporated features such as providing product information using textual and video-based formats to enhance the Information Quality (IQ), product reviews from other consumers (SC), recommendations (RA). The study also Intuitive Affordance (IA) using gesture-based interactions such as air tap, touch, drag and hand menu. Moreover, natural interaction (NI) was employed using computer vision technology to recognize images in the user’s field of vision.

In the MR category, IQ, IA and SA were the most investigated design attributes by 67% (n=4) of the studies, while the attribute of PV was implemented by 50% (n=3) of the studies. The attributes of CS and SR were not investigated in any of the MR application design studies. Table II summarizes the design attributes implemented in the reviewed studies.

TABLE II. SUMMARY OF IMPLEMENTED V-COMMERCE ATTRIBUTES

	Reviewed Studies	Product				Intelligent Services					Functionality			
		<i>IQ</i>	<i>PV</i>	<i>IA</i>	<i>RM</i>	<i>NI</i>	<i>NA</i>	<i>SA</i>	<i>RA</i>	<i>PS</i>	<i>CS</i>	<i>NV</i>	<i>SR</i>	<i>SC</i>

V. CONCLUSION

This systematic review has identified and synthesized the essential design attributes of v-commerce solutions within the metaverse. The study reviewed twenty-four empirical studies

which have implemented v-commerce solutions and categorized them based on the three immersive technologies – AR, VR, and MR. The meta-analysis of the reviewed studies revealed thirteen v-commerce design attributes. The attributes were further classified into these attributes into three main

dimensions: Product, Intelligent Services, and Functionality. Each dimension encompasses specific design features that collectively enhance consumer engagement, satisfaction, and overall shopping experience in immersive environments. Results of the systematic review revealed that In AR category, the most investigated attributes were PV and NI. In the VR category, IA and NI were the most frequently investigated features. Lastly, in the MR studies, IQ, IA, and SA were the most common.

This comprehensive taxonomy of design attributes not only provides valuable insights for researchers and practitioners but also sets the stage for future innovations in v-commerce. By leveraging these attributes, businesses can create more engaging and effective v-commerce solutions that meet the evolving needs of consumers in the metaverse.

A. Limitations and Future Directions

Despite the comprehensive nature of this review, several limitations must be acknowledged. First, the scope of the review was limited to empirical studies published between 2011 and 2024, which may exclude relevant research outside this timeframe. Second, the reliance on peer-reviewed journal articles and conference proceedings may have omitted valuable insights from industry reports, white papers, and other non-academic sources. Third, the review primarily focused on studies written in English, potentially overlooking significant contributions in other languages. Additionally, the variability in methodologies and contexts of the included studies may affect the generalizability of the findings.

Future research should address these limitations by expanding the scope to include a broader range of sources and languages. Further research could focus on developing and testing comprehensive frameworks that combine design science and information systems research can provide more robust insights into the effective design and implementation of v-commerce solutions in the metaverse. Finally, incorporating the design attributes in decision-making processes can help businesses create more engaging and effective v-commerce solutions. Researchers can apply decision making methods to evaluate v-commerce solutions using the identified attributes as evaluation criteria. By addressing these future directions, researchers and practitioners can build on the foundation laid by this review, advancing v-commerce and shaping the future of online shopping through immersive and interactive experiences.

DIAUTIS III: A Fuzzy and Affective Platform for Obtaining Autism Mental Models and Learning Aids

Mohamed El Alami¹, Sara El khabbazi², Fernando de Arriaga³

National School of Applied Sciences of Tangier, Abdelmalek Essaadi University, Tangier, Morocco^{1,2}

School of Telecommunication Engineering, Universidad Politécnica de Madrid, Madrid, Spain³

Abstract—Autism spectrum disorders (ASD) are conditions characterized by social interaction and communication difficulties, atypical patterns of activities, and unusual reactions to sensations. Characteristics of autism may be detected in early childhood, but diagnosis is often delayed. The diagnosis of autistic children typically aligns with medical and psychological recommendations, but it does not evaluate all the problems, intensity, or changes in symptoms over time. It also does not identify the affective states associated with these deficiencies, making aid less effective. The mental model of autistic children contains their deficits, tasks, and intensities, beyond diagnostics. That why we enhance DIAUTIS platform for achieve our objectives related to helping children with ASD. DIAUTIS I is a platform that aim to diagnosing autism and identifying its severity using cognitive, fuzzy, and affective computing. It presents tests, evaluates results, and presents a final model. Then, we implemented DIAUTIS II by adding KASP methodology, a new methodology of designing serious games, based on knowledge, affect, sensory, and pedagogy, this tool allows to DIAUTIS II agents to designing over 80 games, considering a child's background. In this paper, we will present a new tool of formalization of the autism mental model based on fuzzy and affective computing. DIAUTIS III is the extension of DIAUTIS II platform aim to represent a cognitive fuzzy mental model with using the metrics of category theory. So far, no mental model has been developed for autism. Our mental model, can be obtained anytime as a fuzzy cognitive map or fuzzy graph and the use of affective computing. In addition, the mathematical theory of categories represent this mental model of an autistic child from a fuzzy graph, and it allows for operations like CONS and TRA to evaluate the difference between two mental models. Fuzzy cognitive mental model can be used to develop new techniques for improving the learning and integration of autistic children into social life, which is the focus of our immediate future.

Keywords—Fuzzy computing; affective computing; mental models; learning aids; autism; category theory

I. INTRODUCTION

Autism, also known as Autism Spectrum Disorder (ASD), is a condition characterized by difficulties in social skills, repetitive behaviors, speech, and nonverbal communication [1].

Autism spectrum disorder (ASD) is a neurological and developmental disorder that affects social interactions, communication, learning, and behavior. Symptoms typically appear in the first two years of life, making it a "developmental disorder." The Diagnostic and Statistical Manual of Mental Disorders (DSM-5), used by healthcare providers, identifies ASD symptoms as

difficulty with communication, restricted interests, repetitive behaviors, and affecting functioning in school, work, and other areas of life [2].

Autism is a spectrum disorder with varying symptoms across genders, races, ethnicities, and economic backgrounds. It can be lifelong, but treatments can improve symptoms and daily functioning. The American Academy of Pediatrics recommends all children receive autism screening, and caregivers should consult their child's healthcare provider about screening or evaluation [2].

Mental models are an analogical representation of knowledge, involving a direct correspondence between the entities and relations in the representation structure and the entities and relations of the real network. They represent a functional form of prior conceptions in relation to a specific and momentary goal, consisting of elements and their relationships that represent the state of things. Each model is predisposed in a way consistent with its intended use.

A mental model is a cognitive simulation of how things work and are related, built over time through learning and understanding. It helps people make sense of the world, make decisions, solve problems, and predict outcomes, enhancing their decision-making abilities.

So far, according to our knowledge, no mental model of autism has been developed, although we have studied the development of other non-mental models.

Our mental model emphasizes the importance of emotional aspects in children, as affective states can trigger learning problems and improve them. It includes all developed affective relationships and uses affective computing to determine and improve these states. This elaborate model can be classified as fuzzy and affective, as it can be used to treat autistic children and improve their emotional well-being. Affective computing began with the works of Rosalind Pickard, followed by a large number of articles and collaborations of different authors [3-4].

Category theory is a mathematical branch that formalizes mathematical structure and has powerful applications in mathematics and programming languages. Concepts like categorical semantics, monads, functors, and proof assistants are deeply connected to category theory, making them essential in various fields throughout one's career.

Category theory is a generalization of algebra that focuses on understanding mathematical objects through structure-preserving transformations called morphisms. It does not embed a

single group into a category, but studies groups through the category of all groups Grp, where objects are groups and morphisms are group homomorphism. Instead, we learn about group's relationships through morphisms rather than the elements that make them up.

In this perspective, the article first presents an overview of Autism Spectrum Disorder (ASD), its symptoms, and diagnosis. Moreover, it describe the main features and functionalities of DIAUTIS I and DIAUTIS II. Next, it introduces DIAUTIS III, which will use the mathematics of category theory for formalization of fuzzy cognitive mental model of autism and compare the differences between two mental models for helping autistic children to enhance their learning and exceed their learning disabilities.

II. AUTISM SPECTRUM DISORDER

American Psychiatric Association define the Autism Spectrum Disorder (ASD) as a set of permanent neuro-developmental described by troubles with social interactivity and restricting and repeating behaviors [5], usually beginning in early childhood, Children with Autism Spectrum Disorder may learn, move, or pay attention with different styles.

Autistic children often have problems with: Keeping eye contact, not responding to their name (9 months of age), Ignoring other children and avoiding play with them (36 months of age), etc. Moreover, they may behave in ways that may seem unfamiliar. as: Repeat voices, words or phrases, Have obsessive hobbies, Flap hands, Spinning in circles, Locked body, Have unusual reactions to some of sounds, odors, flavors, or feels. In addition, there are other characteristics that autistic children may have which include hyperactive, unusual eating and sleeping patterns, anxiety, stress, Not getting scared or getting scared more than expected [6].

A. Diagnosis

Over the past few decades, the symptoms of autism spectrum disorders (ASD) have multiplied, leading to increasing recognition of this developmental disorder [7]. For a diagnosis of ASD to be made, children must exhibit characteristics related to both social communication difficulties and restricted, repetitive, and/or sensory behaviors from an early age. The diagnostic criteria for ASDs have evolved considerably over the years. Currently, diagnosis is mainly made using observational tracking tools that measure the child's social, behavioral and cognitive abilities [8]. There are many diagnostic tools, but the two principle ones used in the diagnosis of ASD are DSM-V and M-CHAT.

American Psychiatric Association is publishing a book titled "The Diagnostic and Statistical Manual of Mental Disorder" for presenting a classification of mental patterns with associated criteria, this association classifies autism, Asperger's syndrome and developmental disabilities as Pervasive Developmental Disorders (PDD). It has been recommended that the term "PDD" should turn into "DSM-V" with "Autism Spectrum Disorder". Autism is described by a range of signs, including the existence of permanent deficiencies in social communication, deficiencies in social interaction in a different situations, and restricted and repetitive patterns of behavior in DSM-IV-TR. It was combined

into two categories in DSM-V: 1) fusing troubles in social communication and interaction; 2) restricted and repetitive behaviors [9]. The DSM-V is a tool that can be used by wide clinical professionals to help in the diagnosis of mental illness and developmental disabilities. This manual (DSM-5) is used by psychiatrists, psychologists, social employees, doctors and nurses for people with mental illness.

B. Mental Models: Autism Mental Model

The Mental model theory proposes a theory of inference that aims to explain different types of thinking according to how the mental model represents. A mental model is a powerful cognitive entity that organizes people's interpretation of their world and their actions in response to it [10]. We view the concept of mental models, described as the ideas people form about the world and the activities they undertake [11].

A Mental Model (MM) is a simulation of the reality that we are producing, with conscience or unintentionally, in our minds [12]. It plays a crucial role in various fields of our life, which a main aim of a MM is to help the model's user to choose the right action of a target system (Johnson-Laird; Norman, 1983) for making sense of, solving problems, making decisions, making plans, or learning/education...etc. A mental model is created, updated and stored through a three-phase process: observation, learning and experience [12].

The purpose of education is to provide access to knowledge. In order to assess the evolution of a learner's knowledge, we believe it is useful to understand the process of learning which has been a principal subject in the field of education [13]. Hence, mental models are a very important part in this process, which play a crucial role in understanding the development of knowledge and the actions of learners. A learner's knowledge passes by three successive stages; these are the Novice, Learner and Expert stages. One of the important contributions of cognitive psychology to learning is the notion of mental models. This notion will allow us to better differentiate between these three stages of learner development [14, 15].

Presenting a mental model visually and formally requires at least three phases: extraction, analysis and formalizing. Finding ways of modeling a mental model presents a challenge to any discipline using this concept as a tool to better understand individuals' internal representations of their environment.

Our mental models of autistic children contain all the imperfections and activities they do not know how to perform, or which they perform clumsily. This is why their mental models are so important, because they show all their limitations, which can be quite different. These can then serve to identify techniques or strategies for enhancing their learning.

C. Learning Aids

Teaching and learning process needs three essential components, identifying the input elements (students, teachers, teaching and learning materials), the procedure, and the output elements (graduation, orientation, skills, diplomats ...). The quality of teaching and learning can be compromised by unfavorable general conditions. It is crucial to provide a sophisticated environment in which to teach and learn effective skills. Using of

learning aids help students to hear, see, or perform with efficiency during the learning process that become more enjoyable and less tedious thanks to learning aids [16].

Previous research has repeatedly demonstrated that the use of learning aids can greatly enhance learning from multimedia materials. For example, Renkl (2002) studied learning from examples worked in a computerized learning environment on probability calculations. He found that students learned better not only when they explained themselves, but also when they took advantage of pedagogical explanations offered through an online help system [17].

In this twenty-first century, the technological revolution plays a vital role in the learning process. The development of smart phones and other ICT devices has become increasingly popular in the field of communication, literacy and entertainment. These technologies can contribute to the diverse educational development areas of the autism community [18].

Children with autism cannot learn new things easily and cannot actively receive new information, but they can benefit from various types of learning aids specially designed for autistic children and other children with learning disabilities. There are many different types of beneficial learning aids available today, including sensory and auditory learning aids, as well as motor development aids. These tools enable autistic children to catch on quickly and increase their chances of leading a normal life. [19].

III. DIAUTIS I: A MULTI-AGENT PLATFORM FOR THE DIAGNOSIS OF AUTISM

M. El Alami, N. Tahiri and F. de Arriaga have proposed an approach based on agents, fuzzy logic and affective computing to build an automatic and autonomous autism diagnosis platform [20]. This platform will offer to clinical teams, doctors, parents, guardians and schools a set of tests that help them to get a model of the kid that allows them to evaluate the gravity of autism and the signs of autistic children. In this section, we will describe with details the features of this platform.

A. Features

This research is the beginning for what could be a long project. Over time, it may lead to developing a tool for helping professionals diagnose autism. Consequently, flexibility was highlighted as an important feature of this work. The aim of this flexibility is to anticipate, as far as possible, unknown elements that could discredit the work carried out to date. In line with these ideas, the method developed comprises the following phases [20]:

- Acquiring knowledge about autism in its various aspects.
- Definition of criteria and tools for diagnosing autism.
- Design of a diagnostic computer model based on a group of tests.
- Selection of a platform to build agents based on its flexibility and conception of the DIAUTIS architecture.
- Determination the DIAUTIS functional proofs assigned to the engineering staff.

- Conduct additional testing with observers, medical and clinical staff.

DIAUTIS proposes a set of tests grouped into seven kinds linked to the troubles identified in DSM-V manual. Each kind contains a set of elements to be evaluated and the evaluating agents that intervene in DIAUTIS (control agent, design agent, cognitive agents for sound, gaze and movement, affective agents, pedagogical agents, rule learning agents, evaluating agents, group evaluating agent, interface agent).

DIAUTIS also uses cameras and sensors to receive information on gaze, face, gestures and movements, as well as software developed in Python to capture emotions and analyze pronunciation and intonation to facilitate analysis of the information provided by the collection of tests proposed by DIAUTIS and approved by medical teams to determine the child's condition. These tests are based on ENT (the test collection generation criterion), fuzzy logic techniques to assess the child's condition and the OOC model introduced in NEOCAMPUS [21] to analyze emotions. Then this platform can facilitate the child's previous diagnostic results and generate a report of each test, indicating the times used, the child's age and the result, which can provide information on the test's difficulty, suitability for a particular age or relationship with the severity of autism.

DIAUTIS agents are independent, intelligent and can work autonomously or with other agents. They have learning capabilities thanks to neural networks and machine learning techniques, as well as specific knowledge to reach affective or cognitive goals. They can collaborate with others when objectives surpass their capabilities, or when another agent needs them. They can be cloned or deleted if necessary, have a natural understanding of language and can receive information from external sensors.

The features of NEOCAMPUS for cooperating and controlling agents [22], [23] have been enhanced to take into account the important set of agents that can try to act simultaneously and the specific roles they perform in DAUTIS.

B. Diagnosis Model

The child's diagnosis prepared by DIAUTIS I is represented by a fuzzy graph consisting of a main node (0) that contains the child's personal details and characteristics, connected to seven other nodes (1-7) representing different test kinds. Each test kind is further divided into subcategories, and the evaluation results of each test are linked to the corresponding category or subcategory node.

These fuzzy sets are then integrated into a single fuzzy set, which is then joined to the main node. The final child's model is obtained by using multi-criteria and incorporated into node 0. The system keeps a record of all diagnosis meetings, allowing analysis and comparison of previous sessions. The integration fuzzy set can be defuzzified into a single value when necessary, making it easy for clinical personnel, tutors, and parents to understand. The system primarily communicates with doctors or clinical teams, who set parameters for the tests and receive immediate results and the final child's model. Communication with parents and tutors is also possible through interviews stored in the system.

DIAUTIS I regularly updates the computer team on system performance and agent operation, including the number and type of agents, cooperation, learning, response time, and diagnosis stages.

DIAUTIS I, in summary, is a software platform that meets the objectives of autism diagnostic aid. However, the use of the results can still be clarified. The information from a diagnostic session provides medical equipment with a clear view of the results obtained and the severity of the disease. This is the essential objective of the platform. Nevertheless, DIAUTIS I can also provide other aids such as:

- Facilitating the comparison of the child's previous diagnostic results.
- Facilitate the history of each test, indicating the periods used, the age of the children who took them and the result they obtained, individually or statistically. In this way, it can provide information on the difficulty of the test, its suitability for a certain age or its relationship with the severity of autism.
- In the light of the last paragraph, DIAUTIS I may in the future begin to develop collections of standardized tests in order to produce test protocols, as indicated by doctors and medical teams, leading to eventual standards.

IV. DIAUTIS II: A MULTI-AGENT PLATFORM FOR THE DIAGNOSIS OF AUTISM AND THE DESIGN OF SERIOUS GAMES

A. Features

DIAUTIS II extends the capabilities of DIAUTIS I by adding a methodology for designing serious games based on four dimensions: Knowledge, Affect, Senses, and Pedagogy. The KASP methodology enables DIAUTIS II agents to design games from a set of more than 80 templates, considering the child's background [24].

The results of the tests carried out through DIAUTIS are analyzed in order to deduce the child's basic abilities by developing a result containing five specifications: motor, behavioral, cognitive, socio-emotional and sensory. Using machine-learning techniques, an intelligent system will be set up to classify these specifications, which will indicate the type of disorder the diagnosed child suffers from. The authors propose using SVM, a supervised type algorithm, to classify a child's disorder using an intelligent classifier on selected diagnostic specifications.

DIAUTIS I has been enhanced with KASP (Knowledge, Affect, Sensory, Pedagogy) [25], a new approach to the conception of serious learning games. This is a new solution to aid children with learning disabilities to exceed these barriers by considering their cognitive, emotional and sensory aspects.

B. Serious Game as an Evaluation Tool for the Autistic Children

Headings, A game is a narrative that combines an intention, genre, main concept, and objectives. The balance between the objective and the concepts is crucial for a coherent and interesting story. To assess a child's assimilation of a concept with Autism Spectrum Disorder (ASD), it is necessary to consider the

sub-concepts building the main concept. Mathematically, comparing the child's sub-concept weights to the expert's weights helps identify actions that cause significant degradation. The child's actions influence the sub-concepts' weights, generating a new vector with new values. The expert is then encouraged to offer a serious game to assess a concept in children with ASD, consisting of several scenes [26]:

$$\text{Game } S = \{S\alpha, S\beta, S\gamma, \dots\} \text{ where } S_i \text{ a game scene}$$

The game's main objective is the same as the expert's assessment. Each scene consists of multiple objects representing sub-concepts, which interact with each other based on the child's actions:

$S\gamma = (C\gamma, A\gamma)$ where $\{C\gamma = \{C\gamma1, C\gamma2, C\gamma3, \dots\}\}$ is the set of sub-concepts of the scene $S\gamma$ and

$A\gamma = \{A\gamma1, A\gamma2, A\gamma3, \dots\}$ is the set of the actions of the scene $S\gamma$.

Each action is identified by a weight. The Likert scale (Table I) is a reliable tool for measuring perceptions, measures the influence of an action on a concept through a weight, consisting of five levels [27].

$$\forall A\gamma_i \Rightarrow W\gamma_i \in [1, 5] \quad (1)$$

Likert's scale can also be normalised by dividing its values by 5. So $\{0.2, 0.4, 0.6, 0.8, 1\}$.

TABLE I. LIKERT'S SCALE

1	2	3	4	5
Very bad action	Bad action	Acceptable action	Correct Action	Very good action

In addition, the expert attributes a weight to each concept (Table II) to describe its importance in relation to the main concept described on DIAUTIS [21]. The weighting varies from one scene to another:

$$\forall C\gamma_i \rightarrow V\gamma_i \in [1, 2, 3, 4, 5] \quad (2)$$

TABLE II. WEIGHTS ATTRIBUTED BY THE EXPERT

Concepts	$C\gamma1$	$C\gamma2$	$C\gamma3$	$C\gamma4$
Weight/Concept principal	$V\gamma1$	$V\gamma2$	$V\gamma3$	$V\gamma4$

The expert creates a semantic network of the scene (Fig. 1), representing all concepts and actions, and their weights. A node represents each concept, with an oriented arc connecting two nodes indicating the influence of action on the destination concept. The expert must specify at least five actions for each concept.

After a game session, a child's semantic subnet is created (Fig. 2), inheriting the expert's network and containing only the child's actions and associated concepts.

After that, the semantic network generates two matrices: the expert's matrix (Table III) and the child's matrix (Table IV). The expert's matrix contains all types of actions and concepts, while the child's matrix is a submatrix derived from the expert's matrix. The expert and child's action weights are typically different, as

the expert's matrix contains all the varieties of actions and concepts, while the child's matrix is a submatrix derived from the expert's matrix.

Fig. 1. Expert's semantic network: Scene Sa.

Fig. 2. Child's semantic network: Scene Sa.

TABLE III. EXPERT'S MATRIX: SCENE SA

	Ca1	Ca2	Ca3	Ca4	Ca5	Ca6
Action	WACa1	WACa2	WACa3	WACa4	WACa5	WACa6
Action	WACa1	WACa2	WACa3	WACa4	WACa5	WACa6
Action	WACa1	WACa2	WACa3	WACa4	WACa5	WACa6
Action	WACa1	WACa2	WACa3	WACa4	WACa5	WACa6
Action	WACa1	WACa2	WACa3	WACa4	WACa5	WACa6
...
Action	WACa1	WACa2	WACa3	WACa4	WACa5	WACa6
Action	WACa1	WACa2	WACa3	WACa4	WACa5	WACa6

TABLE IV. CHILD'S MATRIX: SCENE SA

	Ca1	Ca2	Ca3	Ca4	Ca5
Action	WACa1	0	0	0	0
Action	0	WACa2	0	0	0
Action	0	WACa2	0	0	0
Action	0	WACa2	0	0	0
Action	0	0	WACa3	0	0
Action	0	0	0	WACa4	0
Action	0	0	0	WACa4	0
Action	0	0	0	0	WACa5

Then, we have received:

- The expert assigns weights V_{ai} to scene sub-concepts, which can be represented as an n-dimensional vector, representing the number of scene sub-concepts (Table II).
- The child's sub-concept weights V'_{ai} can now be expressed as: $V'_{ai} = W_{aj} \times W_{ak} \times W_{al} \times \dots \times V_{ai} = \Pi W_{aj} \times V_{ai}$

The W_{aj} and V_{ai} are the normalized child's and expert weights; they are vectors of n dimensions, with some components potentially being 0, based on normalized Likert's scale.

- The cosine of two vectors, a real number between -1 and 1, measures the child's ability to assimilate key concepts.

The study found that an acute angle between two vectors leads to higher understanding in a child, while an obtuse angle makes the main concept unclear. This allows experts to better analyze a child's perception of a concept using ADS measurements, enhancing their understanding of the concept.

- We identify actions causing significant sub-concept weight degradation, selecting actions with a weight $WAC_{ai} \leq 3$ for each scene, ensuring accuracy:
 - If $WAC_{ai} \leq 3$, a significant degradation is applied to the sub-concept.
 - If $4 \leq WAC_{ai} < 5$, The sub-concept is subjected to low degradation.
 - If $WAC_{ai} = 5$, The weighting of the sub-concept remains unchanged.

The expert will identify difficult concepts for each child, allowing tutors to adapt learning programs and highlight gaps in

the proposed technique to strengthen understanding for the child with ADS.

V. DIAUTIS III: A FUZZY AND AFFECTIVE PLATFORM FOR OBTAINING AUTISM MENTAL MODELS AND LEARNING AIDS

A. Features

DIAUTIS III extends the capabilities of DIAUTIS II by adding a methodology for formalization of the elaborated mental model of autism (fuzzy graph) based on mathematical theory of categories. That way autism mental models can be automatically obtained. The theory of categories will be used to formalize the graph as well as its operations. We will explain in next sections the steps of this formalization.

The DIAUTIS III tests, based on KASP methodology, analyze the fuzzy mental model's elements. A collection of serious games is designed to cover all deficiencies in the seven families of the model. These games are divided into two kinds: basic discovery of deficiencies and deep exploration of problems, revealing details, intensities, features, and concept assimilation. This allows for a deeper understanding of learning problems and their evolution. The games are displayed on a computer, allowing children to see moving objects, colors, and sounds.

DIAUTIS III has been enhanced with the theory of categories which will be used to formalize the fuzzy and affective mental model of autism, a new approach to the presentation of the abstract concepts. The mathematical theory of categories is a suitable formalism for representing the mental model of an autistic child from a blurred graph, allowing operations like CONS and TRA to evaluate the difference between two mental models or the trajectory of a collection. This mental model allows for the creation of games that require low concentration levels and gradually increase them, thereby facilitating learning and allowing the child's mental model to evolve at any time, reflecting their overall learning experience.

B. Mathematical Theory of Categories

There are various perspectives on the nature and purpose of category theory. Carlos Polanco [28] defines category theory as a mathematical branch that focuses on abstract and unified mathematical structures and their relationships. This Theory is a fundamental aspect of modern mathematics, offering a unified framework for understanding and formalizing mathematical concepts and theories.

Hence, Hoare [29] describes category theory as a broad and abstract branch of pure mathematics, providing little assistance in solving specific problems within its sub-disciplines. As a generalist tool, it offers little benefit to practitioners, making it a valuable tool for generalists.

Category theory is a crucial tool in mathematics, organizing and unifying many fields such as algebraic topology, homological algebra, homotopy theory, representation theory, arithmetic geometry, and algebraic geometry [30]. It is essential for the development of new graphical notations and different levels of abstraction in contemporary mathematics. Category theory and its mathematical disciplines use commutative diagrams, leading to philosophical explorations. However, category theorists have also developed systematic and formal graphical languages to express various forms of argumentations. Mathematics has

evolved from being done "up to isomorphism" to "up to equivalence" or "bi-equivalence" or even "n-equivalence." This shift in approach has led to the development of systematic and formal graphical languages to express various forms of argumentations. The level of abstraction in mathematics has evolved from "up to isomorphism" to "up to equivalence" or "bi-equivalence" or "n-equivalence".

Theory of categories focuses on the relationships between structures, offering a highly abstract yet powerful approach to mathematics, focusing on objects and morphisms. The composition operator is a central element, but reducing the theory to a refinement of it is oversimplification and fails for full-featured capture its richness and depth [28]:

1) *Abstraction*: Category theory is a mathematical field that emphasizes the relations between structures, rather than individual elements. It defines categories by their objects and morphisms, rather than their internal aspects. This abstraction allows for generalization across various mathematical contexts, enabling the transfer of concepts and results across seemingly disparate areas of Mathematics.

2) *Unification*: Category theory is a powerful tool that unifies various mathematical fields by drawing parallels between seemingly unrelated concepts. It uses factors and natural transformations to connect different categories, demonstrating that different structures and theories are manifestations of underlying ideas, leading to improved understanding and advancements in various mathematical fields.

3) *General concepts*: Category theory introduces concepts like limits, colimits, and adjunctions, which provide abstract perspectives applicable across various mathematical contexts. Examples include products in abstract algebra and products in topology. This generality enables mathematicians to apply intuitions and results from one area to another, leading to discoveries and advancements in various topics.

4) *Applications in other areas*: Category theory, a fundamental concept in mathematics, has broad applications in fields like computer science, physics, logic, and philosophy. It is utilized in type theory and programming language denotational semantics, while toposes provide a new framework for intuitionistic logic and set theory in logic.

A category is an abstraction based on objects and morphisms, often studied in groups, rings, and topological spaces. Category theory shifts focus from object elements to morphisms between objects. The axioms of a category do not require objects to be sets, making it unnecessary to speak of an object's elements [31].

A category is a collection of data, denoted by $C = (\text{Objects}(C), \text{Morphisms}(C), \circ, \text{Id})$ consisting of these items:

- 1) A set of objects $\text{Objects}(C)$, which contains all the items in the category.
- 2) A set of $\text{Morphisms}(C)$, containing the arrows (or Morphisms) between category objects.
- 3) An operation called composition \circ that joins Morphisms to form another Morphism , and is associative: $(f \circ g) \circ h = f \circ (g \circ h)$, for any f, g , and h in $\text{Morphisms}(C)$.
- 4) Identity Morphisms Id for each object in $\text{Objects}(C)$.

C. Obtainment of the Child's Fuzzy Mental Model

Autism is a group of basic behaviors characterized by difficulties in social reciprocity, communication, and behavioral flexibility. Children with autism spectrum disorder (ASD) struggle to understand others' emotions, feelings, beliefs, and thoughts. Diagnostics for autistic children typically align with existing medical and psychological recommendations, but they do not evaluate all the problems, severities, or individual intensity of the child's symptoms. As they are not repeated, they cannot determine the appearance of new symptoms or deficiencies with age or changes in intensity. Additionally, the diagnosis does not determine the affective states associated with these deficiencies, making aid for autistic children ineffective due to ignorance of these factors. A mental model for autistic children contains all deficits and tasks they cannot perform, but no autism mental model has been developed to date.

In our last article, we propose a fuzzy affective mental model of autism, based on the DSM-V that considers a child's affective states. The model is included their specific deficiencies, intensities, frequencies, and associated affective states. It uses affective computation and fuzzy logic to account for affection and uncertainty. The model can be obtained using the KASP Methodology, and can be obtained in the form of a fuzzy cognitive map or graph. This model can be used to improve learning and social integration for autistic children.

The mental model of an autistic child contains their imperfections, awkward actions, and associated affective states. This model is crucial as it reveals their varied limitations and can help establish techniques or strategies to improve their learning. It is essential for understanding and addressing these difficulties in order to improve their overall development.

1) *Autism: New Fuzzy Affective Mental Model:* The proposed new conceptual fuzzy and affective model of autism will guide the creation of a specific model for each child, encompassing their specific deficiencies, intensities, frequencies, and associated affective states [32].

The mental model serves as a child's mental radiography, allowing for the identification and treatment of each present deficiency and its intensity. This article does not address this crucial issue, but the model goes beyond diagnosis, as per the DSM-V [33]:

- Persistent deficits in the ability to socialize and interact in a wide variety of contexts.
- Iterative patterns of restricted action, attention, or activity manifesting in at least two contexts.
- These symptoms have to be present in the first stage of the development of the disease.
- These symptoms are the result of a loss of distance in one or more areas of normal functioning.
- An intellectual or general developmental problem does not seem to be the best explanation for these disorders.

The mental model should consider a child's deficiencies and their characteristics to provide appropriate techniques. It also emphasizes the importance of the affective states of the autistic

child in learning. Analyzing the link between a deficiency and a specific affective state is crucial for providing emotional and cognitive aids to improve learning deficiencies.

A universal fuzzy model cannot be developed for specific learning deficiencies, as they vary with autistic children's age and present unique characteristics. However, a list of general and concrete deficiencies can guide in expanding, detailing, or specifying them in each case.

The first list of deficiencies has been grouped into seven families:

1) *Affective or emotional:* This family contains deficiencies related to emotions of the autistic child and her/his affective state when her/his environment changed or meeting people.

2) *Verbal and language comprehension:* The second family includes all the deficiencies related to the communications and expression that the child with ASD suffers from in her/his daily life and/or in classroom.

3) *Monitoring of visual objects:* Researchers have identified eight visual processing disorders, each affecting different abilities and presenting unique challenges. These disorders include visual discrimination, optical sequencing, visual figure-ground differentiation, pictorial memory, visual-spatial relation, visual closing, letter and symbol reversal, and visual-motor processing.

4) *Attention and response to basic sounds:* This family consists of the difficulties related to the identification of sounds, the memory of oral instructions or the sensitivity to the noise...etc.

5) *Other social behaviors:* The fifth family presents common disabilities and atypical social behaviors of autistic children.

6) Combined tests and deficiencies.

7) Group behaviors.

To better represent the autistic child's specific conditions, each family should include specific deficiencies, rather than general ones, which may belong to multiple families based on the child's characteristics or decompose in multiple families.

Each deficiency has a fuzzy set associated (Table V), with elements as below:

- Severity or intensity: Described by a number that belongs to the whole $[0, 1]$.
- Frequency with which this defect occurs: A number belonging to the range $[0, 1]$ marks it.
- The most commonly associated emotional state. It is defined first by the number of the affective state that belongs to Family 1.
- The intensity of this association is a real number that belongs to $[0, 1]$.

2) *Obtaining and Formalization the Fuzzy Mental Model:* The autistic fuzzy mental model is typically diagnosed through a student progress study to identify learning issues.

To do this, we have implemented the KASP methodology, already tested and used, enables the development of tests based on the theory of serious games. Serious games, which aim beyond entertainment, have significant potential due to the impact of emotions on learning. However, there is a significant academic literature on the nature, composition, and effects of these games.

This methodology evaluates learning deficiencies in autistic children by measuring preschool children's concept assimilation, offering advantages such as identifying continuous learning strategies. It also aids in assessing their learning abilities.

A collection of serious games using KASP methodology has been designed to cover all deficiencies in the seven families of the model. Divided into two categories, the first allows basic discovery of deficiencies, while the second allows deep exploration of problems, revealing details, intensities, features, and concept assimilation. The games are displayed on a computer, allowing children to see moving objects, colors, and sounds.

The process of obtaining the mental model passes via these phases:

- Through the first kind of serious games, or diagnosing, various crucial deficiencies are detected.

- In order to identify new learning issues, serious games of the first kind are used.
- The games of the second kind are used to go deeper into the problems found in phase 1. Getting their intensities, severities and associated emotional states.
- The games of the second kind are used to go deeper into the problems found in phase 2. Getting their intensities, severities and associated emotional states.
- Creation of the fuzzy cognitive map (Fig. 3).

The mental model that is described can be formalized as a fuzzy cognitive map or a fuzzy graph (Fig. 3), which is characterized by its levels:

Level 1: The name of the child with autism, her/his birth date.

Level 2: The seven families of deficiencies presented above.

Level 3: List of deficiencies contained in each family [32].

Level 4: For each deficiency, the associated fuzzy set formed by: intensity or severity of the deficiency, frequency, associated emotional state, and intensity of that association.

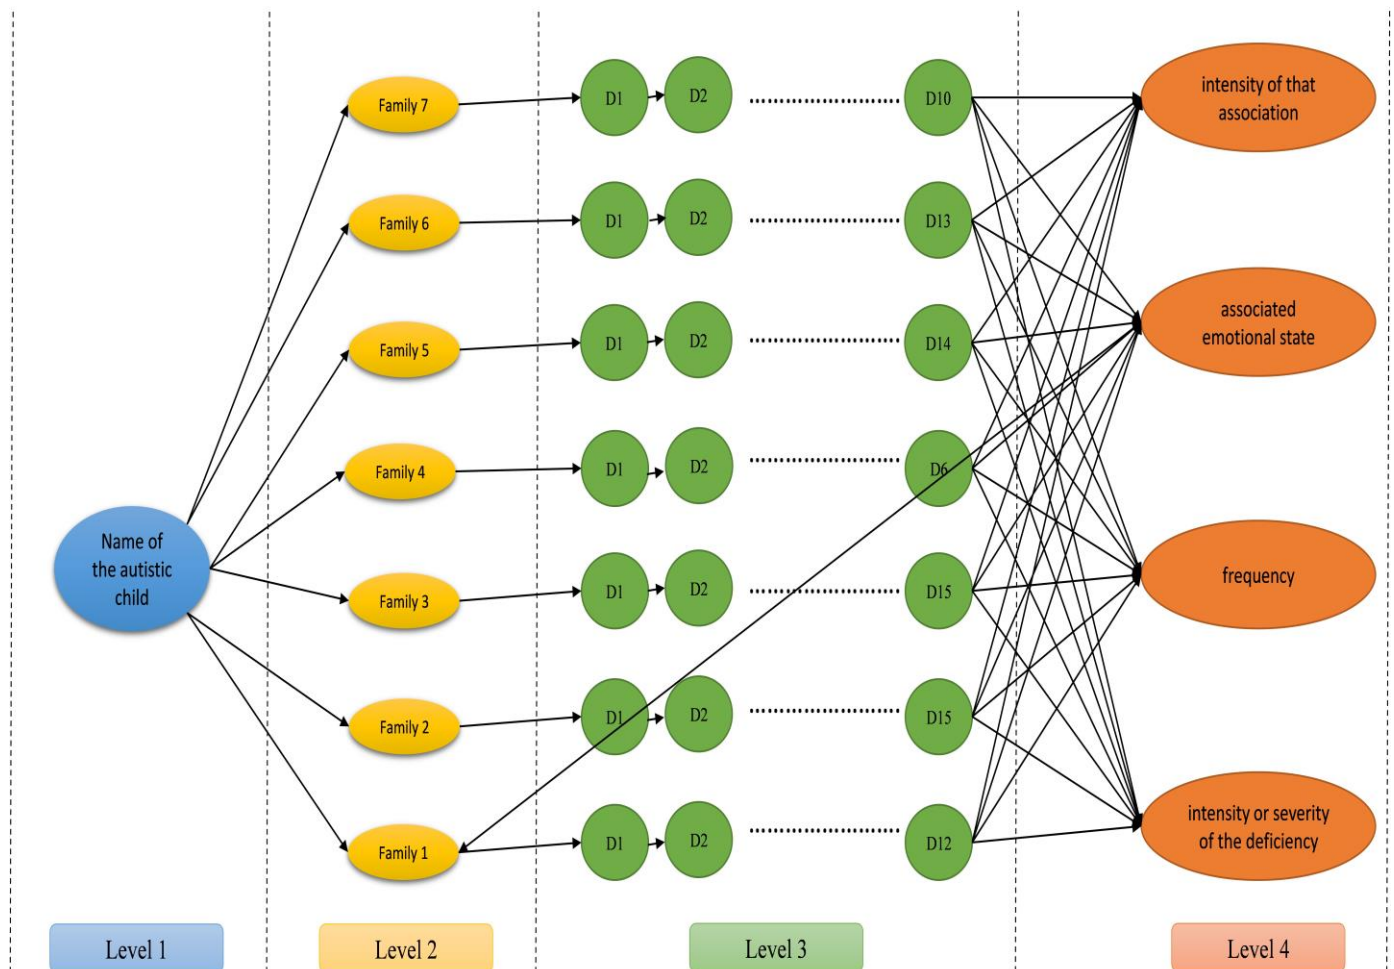

Fig. 3. Detail of the fuzzy cognitive map.

TABLE V. THE ASSOCIATED FUZZY SET OF EACH ELEMENT OF DEFICIENCY

Elements	The associated fuzzy set			
Intensity of the deficiency	[0,0.25] (weak)	[0.25,0.5] (medium)	[0.5, 0.75] (important)	[0.75, 1] (very important)
Frequency of the deficiency	[0, 0.25] (weak)	[0.25,0.5] (medium)	[0.5, 0.75] (important)	[0.75, 1] (very important)
The most frequent emotional state associated	It is determined by the number of the emotional state that appears in Family 1 at the list of deficiencies.			
The intensity of association	[0, 0.25] (light)	[0.25,0.5] (medium intense)	[0.5,0.75] (intense)	[0.75, 1] (very intense)

D. Metrics for the Evaluation of the Difference Between Fuzzy Mental Models of the Same Child

So far, we have used the fuzzy graph as a formalization of the elaborated mental model of autism, composed of a three-level graph. The first, of a single node, is constituted by the name of the child and the date on which the mental model is carried out; the second level has as many nodes as families of learning problems we have considered. The third level is formed by the nodes that represent the different learning problems, in total n, that we have found in the child, corresponding to each family (Fig. 3).

This fuzzy graph will be used as the basis of the mathematical concepts we are going to introduce. Next, we will consider first the theory of categories [34], to formalize the graph as well as its operations. We will try to explain in an intuitive manner the steps of this formalization. Subsequently, we will incorporate topological notions, vector spaces and basic algebraic structures.

1) *Concept of mental model:* The mental model j of the autistic child i, which we represent by Mentij, is composed of a set of three sub-sets, which are:

a) A subset Dij = (a,b,c,..s) of some (or all) of the nodes of level 3 of the fuzzy, which are the difficulties presented by the autistic child. In the particular case adopted in this paper, the total number of learning problems considered in the seven families is:

$$N = 10+13+14+6+15+15+12 = 85 \quad (3)$$

The cardinal of Dij, i.e. the number of elements containing this subset is s, which will vary in each case of autism. This number s will always be less than or equal to N.

b) A set Cij=(Cija, Cijb,..., Cijs) of s fuzzy sets that hang from the nodes of the level 3 of the fuzzy graph, corresponding to the problems of the child. In our case, as we have already said, s<=85.

c) A set of Morphisms and morphisms, Mij = (Morfija, Morfijb,...Morfijs, morfijr,n,... morfijh,t); the Morphisms, called Morfijq apply the fuzzy set Cijq to the node q of level 3. These Morphisms, (with capital letter), are the first-class morphisms; besides, there are other morphisms, (with lower case): morfijr,n,...,morfijh,t, which swap the fuzzy sets Cijr and Cijn hanging on the nodes r and n.

So, the mental model is composed of:

$$Ment^{ij} = (Dij, Cij, Mij) ; Dij = (a,b,c,..r) ; \text{its cardinal } s \leq N$$

$$Cij = (Cija, Cijb, ..., Cijr) ; \text{its cardinal is } s \leq N; \quad (4)$$

$$Mij = (Morfija, Morfijb, \dots, Morfijs, morfijr, n, \dots, morfijh, t) ;$$

If we consider that morfijr,n equivale a morfijn,r, its cardinal is $s+(s-1)+\dots+2+1 = (s+1).s/2$

d) Moreover, it has two operations, dom and codom, assigned to each Morphism or morphism. For Morphisms, Morfijs, the dom is the fuzzy set to apply, which is Cijs, and the codom is s, the node of the learning problem to which it is applied. For morphisms, morfijh,t the dom is the starting node, h, and the codom is its new position, t, of the node. In short:

$$\text{dom} (Morfijs) = Cijs , \quad \text{codom} (Morfijs) = s, s \in Dj$$

$$\text{dom} (morfijh,t) = h, h \in Dj , \quad \text{codom} (morfijh,t) = t, t \in Dj \quad (5)$$

The first Morphisms are those that assign a fuzzy set to a node; without them there is no mental model. The second morphisms exchange the nodes and the fuzzy sets hanging from them. Although dom(morfijh,t) and codom(morfijh,t) are different from dom(morfijt,h) and codom (morfijt,h) we consider both morphisms equivalent, because their effect on the fuzzy sets is the same.

e) It also has an id operation, which assigns to each node b of level 3, or to each fuzzy set h, the morphism idh which is the identity of h, so that its dom and codom coincide with h. In addition, it is verified:

- Identity law: $idh.Morfijh = Morfijh$, when h is a node; $Morfijh.idh = Morfijh$ when h is a fuzzy set; in this last case the composition $idh.Morfijh$ cannot be done
- Identity law: $idh.morfijr,h = morfijr,h$, when h is a node; $morfijh,t.idh = morfijh,t$ when h is a node; when h is a fuzzy set the compositions $idh.morfijr,h$ or $morfijr,h.idr$ cannot be done.

f) It also has a composition operation of two morphisms (f.r) such that:

- The dom of (f.r) is the dom of r, and
- The codom of (f.r) is the codom of f.

It is worth remembering that, as in other mathematical formalisms, composite expressions or formulas are read from right to left, that is, in the case of (f.r), first acts r, and then f. In order for this composition to exist, the morphisms f and r must have a particular nature; r must be a Morphism (with capital letter) to be able to act on f, which must be one morphism with lower case. This way:

$$\text{dom} (morfijh,t.Morfijh) = \text{dom} (Morfijh) ; \text{codom} (morfijh,t.Morfijh) = \text{codom} (morfijh,t) \quad (6)$$

g) Composition is also complied with:

$$\text{Associative law } (\text{morfijg,h.morfijb,g}).\text{Morfijb} = \text{morfijg,h.}(\text{morfijb,g.Morfijb})$$

When, as previously verified

$$\text{codom}(\text{Morfijb}) = \text{dom}(\text{morfijb,g}) \text{ and } \text{codom}(\text{morfijb,g}) = \text{codom}(\text{morfijg,h}) \quad (7)$$

In this associative law must appear a Morphism (with capital letter), because without it there is no mental model; only one can appear, because if more are included the conditions of equality required of doms and codoms cannot be fulfilled. On the other hand, this Morphism must be the first on the right, for the same reason of equality of doms and codoms.

The associative law is also fulfilled with three morphisms (with lower case), when the appropriate conditions of doms and codoms are verified, since as there is no Morphism, there is not any fuzzy set in any node, therefore, the changes of the material hung in the nodes are inoperative. The mental model does not actually exist because the learning problem nodes do not have any fuzzy set to evaluate them.

We will elementally check that this associative law, which we will describe intuitively in a particular case, is complied with.

Suppose a set of five segments followed by numbers 1 to 6; these numbers represent the positions of the third-level nodes of the fuzzy graph, i.e., the learning problems observed in this autistic case:

$$1 \text{----} 2 \text{----} 3 \text{----} 4 \text{----} 5 \text{----} 6$$

Let's imagine that, initially, under each node hangs an empty box or contains a fuzzy set in the box. Each box, though empty, contains the number of the node it initially hangs from

$$\begin{array}{cccccc} 1 \text{----} 2 \text{----} 3 \text{----} 4 \text{----} 5 \text{----} 6 \\ ! & ! & ! & ! & ! & ! \\ U1 & U2 & U3 & U4 & U5 & U6 \end{array}$$

If we consider the associative law $(\text{morf4,6.morf2,4}).\text{Morf2} = \text{morf4,6.}(\text{morf2,4.Morf2})$ we have:

When performing the right hand member of this equation we find:

- According to the parenthesis, Morf2 hangs the fuzzy set C2 in the box U2. And subsequently morf2,4 transfers C2 to the box U4.
- Subsequently morf4,6 moves the fuzzy set C2 from the box U4 to the box U6. That's the final state.

By now carrying out the left hand member of the equation, we have:

- Morf2 hangs the fuzzy set C2 in the box U2.
- According to the parenthesis, morf2,4 changes C2 from the box U2 to U4, and morf4,6 also to U6.

Both end states corresponding to the left hand and right hand members of the last equation coincide.

The formal demonstration of this general associative law would follow the same steps commented, only that instead of using concrete numbers for nodes like 2, 4, and 6, we would use generic denominations like r, s, and t. and an arbitrary number of nodes. Accordingly, it can be said:

Theory 1. The Mentij mental model is a finite category.

Theory 2. The number of Morphisms (with capital letter) is s.

Theory 3. The number of morphisms (with lower case) also depends on s and is $s+(s-1)+ (N-2)+...1= s(s+1)/2$

It can also be demonstrated that:

Theory 4. The set of Morphisms constitutes an isomorphism between the subset of learning problems (nodes), and the subset of fuzzy sets that assess the intensity and other characteristics of these problems.

For if the doms of two Morphisms are different, so are their codoms and reciprocally.

Theory 5. The set of morphisms constitutes an epimorphism between the set of learning problems (nodes), and itself.

Indeed, if we remember that in monomorphisms, if the doms are different, the codoms must also be, we see that in this case it is not fulfilled, because several doms can lead to the same codom. In the case of isomorphism, all of them with different domains, have different codoms, and also different codoms also correspond to different doms. It is an epimorphism. Whose morphisms cover all nodes as doms and codoms.

Let us now present a concrete example to demonstrate this formalism.

2) Example: mental model of the autistic child Juanito: Since we will only consider one mental model for the time being, we can remove the first subindex, i, of Mentij, and place the name of the child in place of the second sub-index, j. So, we will have as the name of this mental model MentJuanito.

Suppose now that the autistic child Juanito has: problems learning grammar (family 2, number 7), he experiences disgust when writing (family 3, problem 6), and he does not allow or maintain social relationships with his peers (problem 13 of family 5). These problems are associated respectively with a tendency to be distracted (problem 2 of family 1), with irritability and physical over activity (problem 9 of family 1) and feelings of anxiety (problem 4 of family 1).

In this case, the fuzzy graph of Juanito's mental model (Fig. 4) has only three nodes at level 3, which are his three learning problems, which correspond with the numbers $19= (12+7)$, $36= (12+18+6)$, and $64= (12+ 18+15+6+13)$. We have replaced the numbering by the family and their respective number, by a total numbering that already includes the family number.

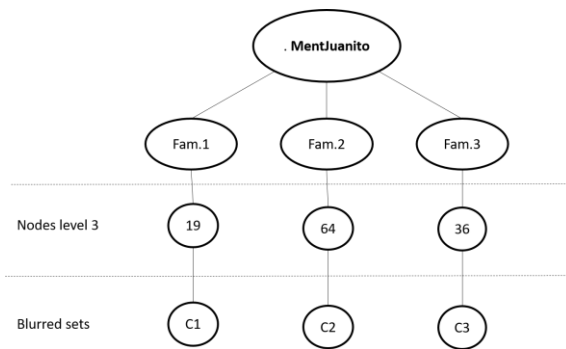

Fig. 4. Juanito's fuzzy graph.

In addition, three fuzzy sets have been obtained that reflect the intensity of the three problems, and are:

- a) C1=[intensity 0.4, frequency 0.4, associated affective problem 2, association intensity 0.], for node 19.
- b) C2=[intensity 0.5, frequency 0.5, associated affective problem 9, association intensity 0.4], for node 36.
- c) C3=[intention 0.6, frequency 0.4, associated affective problem 4, association intensity 0.4], for node 64.

The Morphisms, (with capital letter), available in this case, which we could intuitively consider as arrows, are three: the first, MorfC1-19, takes the first fuzzy set and hangs it on node 19; the second, morfC2-36, takes the second fuzzy set and hangs it on node 36, and the third, morfC3-64, does the same with the third fuzzy set and hangs it on node 64. These Morphisms create a bi-univocal relationship between the set of the three nodes of the mental model and the three fuzzy sets; therefore, they constitute an isomorphism between these two sets.

The morphisms, (with lower case) that we have, are like circles that swap the position and hanging content of two nodes. Therefore, for example, the morf19-36, exchanges node 19 and what hangs from it with node 36. The number of existing morphisms in this example is 3: the morf19-36, the morf19-64, and the morf36-64; as we have already said, we consider morphism morf36-19 equivalent to morf19-36, because their effect on the fuzzy sets is the same (Fig. 5).

Fig. 5. Existing morphisms.

Furthermore, for each node, the 19 is considered as an example, the morphism id19 that does not change anything of that element, and that satisfies the:

$$\text{identity law: id19.Morf1-19} = \text{Morf1-19}; \text{Morf1-19.id19} = \text{Morf1-19} \quad (8)$$

and the same would happen with the Morphisms associated with nodes 36 and 64.

Similarly, for existing morphisms it is verified:

$$\text{identity law: id36.morf19-36} = \text{morf19-36}; \text{morf19-36} = \text{morf19-36.id19} \quad (9)$$

Furthermore, the following properties are met for the morphism composition operation:

$$\text{Associative law (morf19-36.morf19-36).MorfC1-19} = \text{morf19-36 (morf19-36.MorfC1-19)} \quad (10)$$

Because here it is verified

$$\text{codom(MorfC1-19)} = \text{dom(morf19-36)}, \text{ and } \text{codom(morf19-36)} = \text{dom (morf19-36)} \quad (11)$$

In this associative law must appear a Morphism of the first class, because without it there is no mental model; only one can appear, because if more are included the conditions of equality required of domains and codominions cannot be fulfilled. On the other hand, this first-class Morphism must be the last of the right, for the same reason of equality of domains and co-dominions.

The association law is also complied with:

$$\text{(morf64-19.morf36-64).morf19-36} = \text{morf64-19.(morf36-64.morf19-36)} \quad (12)$$

However, it is a trivial law, because since no Morphism intervenes, no node has hanged a fuzzy set of evaluation; therefore, it does not produce the MentJuanito model.

Consequently, Juanito's mental model is a category.

3) *New transactions with categories:* Next, we will define several operations with mental models of the same autistic child. We will try to obtain metrics to evaluate the difference among them.

Value consequence of two mental models

Let us now go to the study of a new operation between two mental models of the same child, which somehow calculates the separation that exists between them. For this, it is necessary to introduce, in addition to the categories, notions of elementary topology, and algebraic structures; for the time being the arithmetic operations of numbers, and their algebraically structures, may suffice. Thus, it is possible to define as a value consequence of two mental models of a child, CONS(Ment_{ij}, Ment_{il}), as a new mental model Ment_{ijl} defined as:

$$\text{CONS(Ment}_{ij}, \text{Ment}_{il}) = \text{Ment}_{ijl} \quad (13)$$

a) Ment_{ijl} contains the same D_{ij} set of Level 3 nodes of Ment_{ij} and Ment_{il}, which reflect their learning problems.

b) It has the same morphisms and morfisms as the two previous models.

c) As for their collection of fuzzy sets, each of them is obtained as an arithmetic difference of the numerical values that make up them.

Thus, if the fuzzy set of a certain learning problem in the first model is $C_{ija} = [0.5, 0.4, 9, 0.3]$, and in the second model is $C_{ila} = [0.3, 0.3, 9, 0.2]$, $CONS(Ment_{ij}, Ment_{il})$ has as fuzzy set for that node, $C_{ijla} = [0.5-0.3, 0.4-0.3, 9-9, 0.3-0.2] = [0.2, 0.1, 0, 0.1]$

The positive values of this latter set indicate the benefits or achievements obtained from the first mental model to the second.

However, the following abnormalities may occur:

a) One of the obtained values is negative. That must trigger an alarm that starts a collateral study of the causes that have motivated it, to try to overcome them.

b) The second mental model obtained contains more nodes of level 3 that reflect the difficulties of the autistic child, and therefore more fuzzy sets relative to these new nodes. This happens when new problems arise in his/her evolution. In this case, we have to equalize the number of nodes of the problems, incorporating new rows in the first mental model, as well as increasing the Morphisms and morphisms to include these new nodes.

The values of the fuzzy sets created, relative to these new problems of the first mental model are all null values, according to the operation to be performed (in this first case, arithmetic rest); therefore, they would all be zeros. When performing the rest of the numerical values, the values of the new blurred $CONS(Ment_{ij}, Ment_{il})$ set appear with a negative sign causing the corresponding alarm for indicating the appearance of new learning problems.

This new operation has the following properties:

a) There is no commutative property, or rather, there is the anti-commutative property reflected by:

$$a.b = -b.a, \text{ that is:}$$

$$CONS(Ment_{ij}, Ment_{il}) = -CONS(Ment_{il}, Ment_{ij}) \quad (14)$$

b) There is a neutral element only on the right, when $Ment_{il}$ matches $Ment_{ij}$. which has all its elements equal to 0.

$$CONS(Ment_{ij}, Ment_{ij}) = Ment_{nulo}$$

$$CONS(Ment_{ij}, Ment_{nulo}) = Ment_{ij} \quad (15)$$

This null element only acts on the right, because:

$$CONS(Ment_{nulo}, Ment_{ij}) = -Ment_{ij} \quad (16)$$

c) There is an associative property:

$$CONS(Ment_{ik}, CONS(Ment_{ij}, Ment_{il})) = CONS(CONS(Ment_{ik}, Ment_{ij}), Ment_{il}), \quad (17)$$

because,

$$CONS(Ment_{ik}, Ment_{ij}) = Ment_{ikj}; \quad CONS(Ment_{ik}, Ment_{il}) = Ment_{ikl}$$

d) There is the reverse of every mental model, which is himself, as we have seen in (2). Accordingly, it can be said:

Theory 6. The $CONS$ operation between categories constitutes a non-Abelic semigroup.

Estimation of the trajectory of several mental models of the same child

It is also possible to analyze a whole trajectory of mental models of a child,

$$TRA(Ment_{ij}, Ment_{ik}, Ment_{il}, \dots, Ment_{is}) = Ment_{ikl\dots s}$$

to evaluate the overall performance. To do this we will consider the summary of all your mental models as the following mental model, $Ment_{ikl\dots s}$ such that:

a) Contains the same set of nodes of level 3 as the mental models $Ment_{ij}, Ment_{ik}, Ment_{il}, \dots, Ment_{is}$

b) It has the same Morphisms and morphisms as the previous models.

With regard to the contained fuzzy sets, there are several ways to get them. One would be to obtain the arithmetic average of the corresponding values of the mental models of the trajectory. However, after studying several practical cases, it seems more appropriate to use the geometric average of these values. In any case, both averages can be used. This new TRA operation has the following properties:

a) It is commutative, because it is the product or sum of the numbers that make up the mental models of the trajectory.

b) It is associative, for the same reason above, the associativity of the sum or product of numbers.

c) It has an identity, formed by the mental model whose numerical components are all equal to 1.
d) It does not have an inverse element, because there are no fuzzy sets with numbers greater than 1.

Accordingly:

Theory 7. The TRA operation constitutes an Abelian semigroup with the arithmetic operation $+$ (sum) or \times (product).

Example: Juanito's mental model

Suppose now that Juanito has two mental models; in the first one he shows two learning problems corresponding to nodes 19 and 36 of the third level of the fuzzy graph, and their associated fuzzy sets are:

$$C1 = [0.5, 0.4, 9, 0.3]; \quad C2 = [0.4, 0.4, 13, 0.2]$$

In the second mental model the associated fuzzy sets are:

$$C1 = [0.3, 0.3, 9, 0.2]; \quad C2 = [0.3, 0.2, 13, 0.1]$$

The $CONS$ model obtained from these two previous models has as its first fuzzy set:

$$C1 = [0.5-0.3, 0.4-0.3, 9-9, 0.3-0.2] = [0.2, 0.1, 0, 0.1]$$

and as the second set:

$$C2 = [0.4-0.3, 0.4-0.2, 13-13, 0.2-0.1] = [0.1, 0.2, 0, 0.1]$$

The positive values of these fuzzy sets indicate the benefits or achievements obtained from the first mental model to the second.

Let us now apply the TRA operation, assuming that Juanito has three models of his autistic trajectory, with two learning problems associated with nodes 19 and 36.

If the fuzzy sets associated with these two problems are:

First model: C1 = [0.6, 0.5, 9, 0.4], C2= [0.5, 0.5, 13, 0.3]

Second model: C1= [0.6, 0.4, 9, 0.3], C2= [0.5, 0.4, 13, 0.2]

Third model: C1= [0.4, 0.4, 9, 0.3], C2= [0.4, 0.3, 13, 0.2]

The final values of the fuzzy sets of TRA will be, if we use the geometric average:

$$C1=[(0.6 \times 0.6 \times 0.4)^{1/3}, (0.5 \times 0.4 \times 0.4)^{1/3}, (9 \times 9 \times 9)^{1/3}, (0.4 \times 0.4 \times 0.3)^{1/3}] = [0.524, 0.43, 9, 0.363]$$

$$C2=[(0.5 \times 0.5 \times 0.4)^{1/3}, (0.5, 0.4, 0.3)^{1/3}, (13 \times 13 \times 13)^{1/3}, (0.3 \times 0.2 \times 0.2)^{1/3}] = [0.033, 0.02, 13, 0.04]$$

a) *Vector Formalism*: Another formal way of considering the mental model is to use vector spaces. In this case it can be assimilated to a column vector in which the fuzzy sets has been aligned within that column; thus the vector has as number of rows 4xs, being s the number of learning problems corresponding to that model.

Using this formalism it is easy to carry out the operations set out in the previous paragraph, which are CONS and TRA. So the result of $CONS(Ment_{ij}, Ment_{il}) = Ment_{ijl}$ can be obtained as the difference between the numerical values of both vectors.

Given that all numerical values are ≤ 1 except the third number of each fuzzy set that is ≥ 1 , it is convenient, though not necessary, to normalize that learning problem number by dividing it by the total number of mental problems of your family, and thus all of them will be ≤ 1 . The difference vector shows us in its positive terms the advantages achieved, and in the possible negative ones, the alarms for the emergence of new problems or deterioration of the existing ones.

New metric offered by vector space. An integral or metric evaluation that allows directly to obtain this formalism is the obtaining of the cosine of the angle that the component models of CONS present. For this we have to take into account that, given two vectors A, and B, it is verified that their scalar product $A \cdot B$ is equal to the product of their modules by the cosine of the angle they form; from that expression we can get the cosine of the angle they form.

4) *Implementation of these new operations*: If we consider each fuzzy set as a column vector, whose components are real numbers belonging to the set [0,1], except for the third which is an integer number, we can construct the matrix formed by these vector columns of learning problems of the autistic child. Thus, each column of the matrix contains all the column vectors of the different learning problems of a mental model.

Considering the previous example of a trajectory consisting of three mental models and their fuzzy sets, which in this case are two, corresponding to two mental problems, the matrix obtained is (Table VI):

TABLE VI. CHILD'S MATRIX

Fuzzy sets	Mental models		
	<i>Mentij</i>	<i>Mentil</i>	<i>Mentis</i>
Fuzzy set 1	0.6	0.6	0.4
	0.5	0.4	0.4
	8	8	8
	0.4	0.3	0.3
Fuzzy set 2	0.7	0.3	0.3
	0.5	0.4	0.2
	6	6	6
	0.5	0.2	0.2

As you can see, each column vector represents a mental model of the child and contains the two fuzzy sets, related to the two learning problems.

Now we can apply the TRA operation, which using the arithmetic average produces us the vector column: [0.533 0.4333 8 0.333 0.4 333 0.3666 6 0.3]

Similarly, another column vector would be obtained using the geometric average, which would be the cubic root of the product of the terms of each row.

E. DIAUTIS III: Agent Architecture

The various types of agent used in DIAUTIS III are as follows:

1) The control agent is responsible for cloning or eliminating agents, coordinating performance, and resolving conflicts. It grants control to affective or pedagogic agents when requested, centralizes communication with users, and handles initial interviews with parents or instructors. It can communicate with any agent.

2) The design agent is responsible for designing tests based on clinical team indications and criteria. They maintain a database of tests and prepare test records. They communicate with control agents, interface, affective, cognitive, and possibly pedagogic agents, and direct diagnosis achievement. They also design future normalized diagnosis protocols based on qualifications, experience, and medical equipment indications, including the possibility of incorporating affective and pedagogic agents.

3) Cognitive agents (type A) manage voice and sound analysis, collaborating with other pedagogic agents. They receive test information and have a sonorous model of the world. They communicate evaluation inputs from negative elements, design agent, and children's group.

4) Cognitive agents (type B) analyze and answer child's appearance tests, collaborating with other agents and control and design agents. They communicate with evaluation and group evaluation agents, ensuring test evaluation accuracy.

5) Cognitive agents (type C) monitor child movements, analyze movements, and use intelligent toys. They have a spatial model and perform tasks and communications similar to agents A and B.

6) Affective agents analyze a child's emotional state during tests using sensor data, communicate with cognitive agents, and sometimes, under clinical advice, improve their emotional state.

7) Pedagogic agents collaborate on test demonstrations, assuming test voice or recommendations, using simple voices, animals, or friendly objects to gain child confidence and interest.

8) Rule learning agents present various tests using videos, images, or intelligent simulations, similar to cognitive agents, with tasks and communication obligations.

9) The evaluation agent is responsible for obtaining tests, integrating evaluations, and defuzzing them into categories, while maintaining a child's cognitive and affective record and diverse diagnosis possibilities.

10) The group evaluation agent, when present, performs the same tasks as the evaluation agent but differentiates the child suffering from the rest of the group members.

11) The interface agent personalizes the interface based on test situations and the child's state, using elements like screen color, scene background, potential pedagogic agents, messages, and sounds.

F. Validation

Previous experience in assessing Intelligent E-learning Systems [35, 36, 37], has been initially applied and enhanced to take into account the specific features of this platform. According to our methodology already established [39,39], quality assessment of DIAUTIS III has been obtained by working at two different levels: the functional evaluation level and the overall evaluation level. So far, no child has participated in the quality assessment tests. Instead, some errors or anomalous behaviours, randomly chosen, similar to those presented by autistic children, have been introduced as the child's response to the tests, in order to simulate the diagnosis process.

The first level or functional level, with a more reduced scope, follows closely traditional methodologies. The following tests have been carried out:

1) Experimental cross-check of functions (agents) and of auxiliary hardware: design of follow-up exercises with several objects, language questions, social or affective behaviour, by four groups of five observers.

2) Experimental cross-check of the design of simple tests according to doctors' indication and initial test qualification such as: colour, object, words, questions, etc.

3) Experimental cross-check of the design of collection of tests from doctor's indications by using ENT and its built-in criteria.

4) Experimental cross-check of the fuzzy tests evaluations by five observers and members of the clinical equipment.

5) Experimental cross-check of the tests integration into the category fuzzy set and into the child's model by five clinical equipments.

The second level or overall evaluation requires a more creative approach. It includes the evaluation of four different aspects: overall functionality tested by six groups of experts and clinical members, reliability considering that the system learning capability will allow the platform to change parameters according to its experience, evidential validity [40, 41, 42]. In addition, consequential validity [43, 44].

G. Results

The information highlighted in this paper, shows that DIAUTIS III is a software framework that achieves the following objectives:

- Capable of getting for the first time the mental model of an autistic child as a fuzzy graph, by means of affective computing and fuzzy logic.
- Facilitating of the comparison of previous child diagnoses and facilitating their results.
- Providing a comprehensive history of each test, including its usage, age, and results, to understand test difficulty, adequacy at specific ages, and its correlation with autism severity.
- Providing a technique for assessing learning deficits in autistic children that allows the degree of assimilation of a concept by a preschool child to be measured, based on our KASP methodology, that already tested and used, allows the elaboration of the tests, based on the theory of serious games.
- Incorporating the application of the mathematical theory of categories to establish the formalization of the mental model and several other applications.
- Evaluating the difference existing between two mental models, or the trajectory of a collection of mental models of the Autistic child using the metrics of the categories theory.

VI. FUTURE WORKS

The authors suggest using a fuzzy logic approach to establish an efficient evaluation of the KASP based learning system and with the aid of metrics of category theory can extend the functionalities of DIAUTIS III.

For this purpose, we suggest as future works:

- Layout the intensive tests for children, involving doctors, medical equipment, schools, families, and associations. This system can provide crucial aid to all individuals involved with autism, as assessed in previous assessments.
- Design of normalized protocols or tests for autism diagnosis may eventually contribute to the adoption of standards, with the relevance and discriminant power of these tests determined by their history and results.
- Enhance DIAUTIS III with new sensors, software, functionalities, diagnostic tests, and algorithms of artificial intelligence, presenting a new world of possibilities due to rapid technological advancements.
- Use the category theory for a better, deeper, and balanced understanding, of the dimensions and characteristics of autism. Among the many ways in which this better understanding could be achieved, it is necessary to identify patterns, relationships, and underlying structures in the behavior and cognition of autistic children.
- Another line of future work is aimed at the analysis of feelings. This is a recent research issue that opens with

great possibilities. So far it has been applied to the analysis of the feelings contained in the written language that is usually sent to social networks to extract opinions and even future actions. It could also be applied to extract deep motivations from the autistic child, analyze them, and even try to modify them where appropriate.

VII. CONCLUSIONS

Multi-agent systems with learning, fuzzy, and affective skills have great potential in autism diagnosis and patient assistance, particularly in learning, as they can help with various issues.

DIAUTIS III is a platform designed to assist individuals with autism, particularly in diagnosing this condition.

DIAUTIS III is a diagnostic tool that considers a child's affective and anomalous behavior to accurately diagnose and understand the severity of their illness.

DIAUTIS III is a framework that provides:

1) The mathematical theory of categories constitutes an appropriate formalism to represent the mental model of the autistic child from the blurred graph, and formulate operations such as CONS and TRA that allow evaluating the difference existing between two mental models, or the trajectory of a collection of mental models of the Autistic child.

2) Other formalisms, such as the vector spaces, also allow obtaining the difference between two mental models, as it may be from the cosine of the angle formed by the vectors representing them.

3) The vector formalism also allows a convenient implementation to obtain the CONS and TRA final values. However, some limitations concerning the results of the platform have to be established:

- DIAUTIS III cannot be applied for the study of other syndromes besides autism.
- It works according to the DSM-V Manual, therefore the platform has to assume all future changes advised by APA.

Abstract—The stock market is a financial marketplace where investors may participate through the acquisition and sale of stocks in publicly traded companies. Predicting stock prices in the securities sector may be challenging due to the intricate nature of the subject, which necessitates a comprehensive grasp of several interconnected factors. Numerous factors, including politics, society, as well as the economy, have an impact on the stock market. The primary objective of financial market investing is to exploit larger profits. Financial markets provide many opportunities for market analysts, investors, and researchers in several industries due to significant technology advancements. Conventional approaches encounter difficulties in capturing the complex, non-linear connections that exist in market data, which requires the implementation of sophisticated artificial intelligence models. This paper presents a new approach to tackling certain issues by suggesting a unique model. It combines the long short-term memory method and Empirical Mode Decomposition with the Manta Ray Foraging Optimization. When tested in the current study's dynamic stock market, the EMD-MRFO-LSTM model outperformed other models regarding performance and efficiency. The Nasdaq index data from January 2, 2015, to June 29, 2023, were used in this study. The findings demonstrate how the suggested model is capable of making precise stock price predictions. The suggested model offers a workable approach to studying and predicting stock price time series by obtaining values of 0.9973, 91.99, 71.54, and 0.57, for coefficient of determination (R^2), root means square error (RMSE), mean absolute error (MAE), and mean absolute percentage error (MAPE), respectively. Compared to other methods currently in use, the proposed model has a higher accuracy in forecasting and is more physically relevant to the dynamic stock market, according to the outcomes of the experiment.

Keywords—Stock price; hybrid forecasting method; Manta Ray Foraging Optimization; empirical mode decomposition; Nasdaq index

I. INTRODUCTION

Having a thorough understanding of the stock market is essential for anyone working in the finance sector. To reduce risk and maximize returns, investors have to be able to correctly forecast stock prices. Macroeconomic policies, stock options, capital movements of significant firms, and changes in ownership are only a few of the important variables that might affect stock prices. Making precise predictions is

difficult due to the unpredictable nature of price fluctuations, which are characterized by non-linear, non-stationary, stochastic noise, and fluctuating [1]. Although econometric and statistical methods could be employed to forecast asset market-related series statistics analysis is constrained by excessive noise and non-linearity.

Artificial intelligence models are preferred over traditional methods for learning complex and non-linear relationships. In the domain of quantitative analysis in finance, their popularity is on the rise because of their ability to extract valuable data from input variables. They are used to detect patterns in historical data and forecast future trends [2], [3]. Deep learning has developed a number of sophisticated structures that address a variety of issues when it comes to varied data sets. A well-known model of neural networks that only processes data in one direction is called feedforward. However, working with sequential data in which earlier occurrences are crucial to projecting future results, can be challenging. As a result, such models have trouble correctly forecasting outcomes in such situations. To handle sequential data more successfully, there are sophisticated neural network models like recurrent neural network (RNN) as well as long short-term memory (LSTM). Data can be conveyed from one step to the next thanks to the RNNs' loop-based structural design, which allows them to retain critical data across time [4]. To train an RNN, a labeled training dataset is utilized to compute the error or cost between the actual and predicted values. The network's biases and weights are then continually adjusted to lower the error until it reaches the lowest practicable level. A gradient is used in the training process to calculate how much each parameter raises the cost [5]. Utilizing the gradient as a guide, backpropagation is used to iteratively change the error surface's parameters. Errors are propagated through this procedure between the intake and output layers. The main issue with this strategy is that to compute the gradient, partial derivatives must be generated for each parameter. Vanishing gradients are a typical problem during neural network training when gradients disappear or get smaller as they go back through the networks [6], [7]. The vanishing gradient problem was addressed through recurrent neural network development, including LSTM. The fundamental advantage of LSTM is that it can sustain long-term memory, which makes it a great option for tasks requiring long-term memory [8]. The vanishing gradient

problem makes it impossible for traditional recurrent neural networks to retain long-term dependencies, however, LSTM is made to get around these limitations.

The process of decomposing time series data using empirical mode decomposition (EMD) involves separating the data into interpretable intrinsic mode functions (IMFs) and a residue that represents the trend [9]. Obtaining immediate frequency data from natural signals, which often exhibit nonlinear and nonstationary characteristics, is a technique supported by actual evidence.

As opposed to previous methods, the optimization process has witnessed breakthroughs recently, making it more efficient in handling challenges associated with confined, rigid, or unidentified search areas. The genetic algorithm (GA), a powerful computer-based technique, mimics natural selection to find the best solutions. GA utilizes a set of potential solutions called individuals and genetic operations involving selection, crossover, and mutation to produce new individuals [10]. A set of optimization techniques known as meta-heuristic algorithms was developed to overcome the constraints of mathematical computation, convergence issues, and the need for informed guesses [11]. By continually iterating through a collection of initial random replies, these distinct kinds of optimization strategies seek the best general solutions for specific problems. battle royale optimization (BRO), manta ray foraging optimization (MRFO), and grey wolf optimization (GWO) are three of the most well-known techniques in the field [12], [13], [14]. In response to gray wolves' social foraging behavior, the Gray Wolf Optimizer algorithm, a meta-heuristic optimization technique, was created [13].

The motivation for this research is multifaceted and is rooted in the complexity and non-linearity that are inherent in stock markets. These complex relationships are not adequately captured by conventional linear models, which is why advanced models are necessary to make more precise predictions. The unprecedented opportunity to improve stock price forecasting is presented by the accelerated advancements in artificial intelligence and machine learning, which can be employed to implement sophisticated algorithms such as LSTM networks and optimization techniques like MRFO. For investors, analysts, and financial institutions, accurate predictions are essential for making informed investment decisions, optimizing portfolios, mitigating risks, and maximizing returns. The dynamic and volatile nature of stock markets presents a challenge for conventional methods, underscoring the necessity of innovative approaches that provide reliable performance in real-world scenarios. The powerful combination of EMD and LSTM networks is achieved through the synergy between the two. EMD decomposes complex time series data into simpler components, enabling LSTM to accurately represent them. The efficacy of the model is further improved by the integration of advanced optimization methods, such as MRFO, for hyperparameter tuning. The value of accurate stock price prediction models in trading and investment contexts can be underscored by the EMD-MRFO-LSTM model's superior performance on Nasdaq index data, which can demonstrate

their practical application and real-world relevance. Following are the contributions of the investigation:

- A novel hybrid model that integrates EMD, LSTM network, and MRFO is introduced in this research. The accuracy and robustness of stock price predictions are improved by this combination, which capitalizes on the assets of each method.
- This research contributes to a more profound comprehension of market dynamics by effectively capturing the complex, non-linear relationships in stock market data. The model's capacity to analyze and process complex financial data is crucial in identifying the factors that influence stock price fluctuations.
- The research offers a thorough assessment of a variety of stock price forecasting models, such as EMD-LSTM, LSTM, EMD-GA-LSTM, EMD-BRO-LSTM, and EMD-GWO-LSTM. The study provides vital insights into the relative performance of these models and the advantages of the proposed EMD-MRFO-LSTM model by benchmarking them.

The following text comprises the remaining contents of the paper. The background of the study is covered in Section II. Related works are specified in Section III. The materials, data gathering, decomposition, evaluation metrics, and methodology are detailed in Section IV. The experimental results are reported in Section V. The discussions of the results are presented in Section VI. In the concluding section, the study's findings are briefly discussed in Section VII. The prospects and challenges are discussed in Section VIII.

II. BACKGROUND

A multitude of determinants impact the stock market, which is a dynamic and intricate system. These determinants comprise investor sentiment, geopolitical events, and [15], [16], [17]. Accurately forecasting stock prices is critical in order to facilitate well-informed investment decision-making and proficient risk management. Conventional financial models, which heavily depend on technical and fundamental analysis, frequently fail to encompass the intricacies of market dynamics. Conventional approaches frequently encounter challenges in capturing the complex patterns and non-linear associations that are intrinsic to market data. The utilization of artificial intelligence models in finance is becoming more prevalent due to their capacity to extract valuable insights from historical data as well as to discover complex relationships among input variables, as discussed in this study. In addition to price forecasting, trend analysis, and anomaly detection, ML algorithms have been implemented in a variety of stock market prediction domains. These methods assist in discerning parallels and distinctions between equities, identifying market anomalies, and revealing concealed correlations that could potentially impact price fluctuations. The article's primary contribution is the introduction of the GWO-LSTM hybrid model, which integrates the operational characteristics of LSTM and GWO to enhance the accuracy of stock price forecasts [18], [19]. To verify the efficacy of the hybrid model, the research utilizes a stringent methodology

that includes data analysis, model evaluation, and comparison with alternative techniques.

III. RELATED WORKS

The Shanghai Index's close price for the next day was predicted by Lu et al. [20] using the convolutional neural network (CNN) and LSTM approach. CNN's primary objective was to identify the most valuable features in the data, as well as the closing stock price was predicted using the LSTM approach. The problem stemmed from CNN's inability to identify the optimal feature from the input data. Rezaei et al. [21] introduced two hybrid algorithms called EMD-CNN-LSTM for stock price prediction. On the historical data of the S&P 500, Dow Jones Industrial Average, and Hang Seng Index dataset, Qiu et al. [22] constructed an LSTM-based model. Using the stock trading data from the S&P 500, to forecast the stock price for the ensuing 1, 5, and 10 minutes, Lanbouri et al. [23] employed the LSTM model for the high-frequency. To forecast the close price of the National Stock Exchange and NIFTY50 index, Yadav et al. [24] employed deep learning using the LSTM-based approach. According to the findings, a stateless LSTM model was discovered to be preferable due to its increased stability for time series forecasting problems. For the purpose of stock forecasting using time series data, Dash et al. [25] developed a novel machine learning (ML) technique that makes use of an optimized form of support vector regression. Zhang et al. [26] developed a two-stage prediction methodology that can accurately forecast stock prices. Three machine learning models, a nonlinear ensemble technique, and a decomposition algorithm are all incorporated into this mode. In the first stage, they decomposed stock price time series into sub-series using variational mode decomposition (VMD) as well as then used extreme learning machine (ELM), support vector regression (SVR), and deep neural network (DNN) to forecast each sub-series. Rao et al. [27] addressed the challenge of accurate stock market forecasting by proposing a hybrid machine learning model for stock market prediction. Accounting et al. [28] employed LSTM for predicting the Tehran stock market. The CatBoost algorithm has been utilized to predict financial distress, and the dataset was gathered from the Chinese stock market between 2016 and 2020 by Zhao et al. [29]. Kumar et al. [30] suggested a hybrid deep learning model that combines adaptive particle swarm optimization (PSO) as well as LSTM network.

IV. MATERIALS AND METHOD

A. Data Description

This study employs time series data, which are distinguished by their temporal dependencies. It is crucial to look at the volume of financial data and the open, high, low, and close prices (OHLC) over a specific period to conduct a thorough analysis. Open price is the initial price agreed upon by vendors and purchasers to conduct business following the market's regular trading hours. The open price holds considerable importance as it establishes the security's initial value for the course of the trading day. The term high price refers to the maximum price that fluctuates during a particular trading session for a given security. It represents the highest value point that the security price has reached during that

particular period. The high price is indicative of the peak level of investors' demand and enthusiasm for the security throughout the trading session. In the context of a given trading process, a low price denotes the lowest price at which a specific security was transacted. The expression close price denotes the ultimate price at which certain securities were exchanged after a trade. It is the final price at which a transaction occurs just before the market's closing time. Volume denotes the aggregate quantity of shares or contracts that have been traded. As a result, information was gathered between January 2, 2015, and June 29, 2023, from the Yahoo Finance website's Nasdaq index.

The aforementioned information is contained within the dataset used in the investigation. Following the acquisition of the dataset, a comprehensive process of data cleansing was executed in order to preserve the precision and uniformity of the forecasting models. The multi-step procedure was designed to protect the dataset's integrity and avoid any inaccurate or incomplete information from being added that would cause problems. One of the critical stages required a careful analysis of the data to identify any outliers, anomalies, or discrepancies that can potentially undermine the validity of the outcomes. The information was preprocessed and cleaned using a variety of methods to ensure its suitability for use. To prevent gradient errors and inconsistent training results, the data was scaled and normalized. The data were normalized before training using the Min-Max-Scaler method, which helped to guarantee a stable model and avoid having too high weight values. Prices and volume for OHLC were used as the training data, which was fed into the model. High price, low price, open price, as well as volume data were given to the model for testing. The data were divided into 20% for testing and 80% for training.

By preprocessing the data to preserve its accuracy and consistency, it can be guaranteed that the models can accurately learn from historical stock price trends and make precise predictions. The inclusion of OHLC prices and volume data provided a comprehensive view of market activities, allowing the model to capture intricate patterns and dependencies in the stock market data.

B. Empirical Mode Decomposition

The empirical mode decomposition is a technique utilized to break down time series data into two components: a residual component that represents the trend, and a collection of interpretable intrinsic mode functions (IMFs) [31]. It is a technique that is backed by empirical evidence and used to obtain immediate frequency data from natural signals, which frequently display nonlinear and nonstationary properties. An IMF is a mathematical function that has an average value of zero and one extreme value between each time it crosses zero. Fig. 1 to 5 demonstrate the decomposition of a variety of stock market characteristics, including the Open, High, Low, Volume, and Close prices, using EMD. Each figure commences with the original time series data at the top, followed by 11 IMFs that capture various frequency components of the data. The highest frequency is captured in IMF 1, and subsequent IMFs progress to lower frequencies. After extracting the IMFs, the residual component is represented by the bottom plot in each figure, which illustrates

the long-term trend. In addition to enhancing prediction models, this decomposition process also facilitates a detailed

analysis by isolating various patterns within the stock market data.

Fig. 1. The decomposition of Open price by EMD.

Fig. 2. The breakdown of High price using EMD.

Fig. 3. The breakdown of Low price using EMD.

Fig. 4. The decomposition of Volume by EMD.

Fig. 5. The decomposition of Close price by EMD.

The method employed by EMD to decompose respiratory motion into IMFs is explained as follows [31].

- Z_1 is the mean value of the upper and lower boundaries of a time series signal $x(t)$. These boundaries are determined by interpolating the local maximum and minimum points.
- Deducting Z_1 from the original time series $x(t)$ yields the initial component P_1 , which is defined as $p_1 = x(t) - Z_1$.
- Let P_1 represent the data in which the means of the upper and lower envelopes are Z_{11} during the second shifting process; $p_{11} = p_1 - z_{11}$.
- By the following conditions, the shifting process is terminated k times: (a) z_{1k} approaches zero; (b) the distinction between zero-crossings and the p_{1k} number of extrema does not surpass one, or (c) the maximum number of iterations has been completed. When this occurs, the IMF, denoted as p_{1k} , can be determined by dividing $p_{1k} = p_{1(k-1)} - z_{1k}$.
- The initial IMF (the shortest component of the data), represented by $a_1 = p_{1k}$, is subtracted from the data as $x(t) - a_1 = y_1$. This operation is repeated for each of the following values of $y_2 = y_1 - a_2, \dots, y_n = y_{n-1} - a_n$.

Consequently, the initial time series $x(t)$ is reduced to the collection of IMF functions shown below:

$$x(t) = (\sum_{i=1}^n a_i + y_n) \quad (1)$$

C. Manta Ray Foraging Optimization

1) *Inspiration*: Manta rays are complex organisms despite their menacing appearance. They are among the largest marine organisms known to science [14]. Manta rays are flat-bodied from top to bottom as well as have two pectoral fins; they swim elegantly while birds soar effortlessly. Furthermore, they possess a pair of cephalic appendages that protrude anterior to their enormous, terminal jaws. They funnel prey as well as water into their jaws utilizing horn-shaped cephalic lobes while foraging. Then, using modified gill rakers, the prey is removed from the water. Two distinct species are identified as manta rays. The reef manta ray (*Manta alfredi*) is one of them that can attain a width of 5.5 meters and inhabits the Indian Ocean, western Pacific, and southern Pacific. The other is the 7-meter-wide giant manta ray (*Manta birostris*), which inhabits mild temperate, tropical, and subtropical oceans [14]. Their estimated age of existence is five million years. Many do not live to be the average age of 20 years due to the fact that they are pursued by fishermen. The illustration of MFRO is covered in Fig. 6.

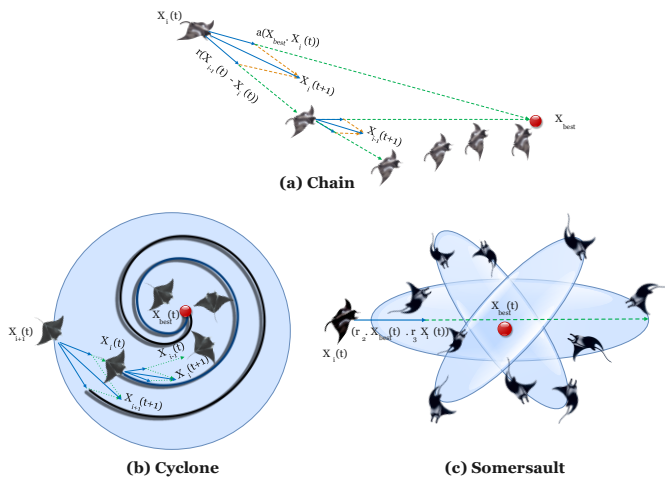

Fig. 6. The illustration of MRFO.

MRFO has been impacted by three distinct foraging behaviors: cyclone foraging, chain foraging, as well as somersault foraging.

2) *Chain foraging*: Manta rays can travel in the direction of plankton they detect using MRFO. An elevated plankton concentration correlates with a more favorable geographical location. While the optimal solution remains unknown, MRFO hypothesizes that the ideal solution thus far is the high-concentration plankton that manta rays desire to consume. A foraging chain is formed when manta rays are arranged from head to tail. At the same moment that individuals approach the food, they also approach the item that is immediately in front of them. Put simply, in each iteration, each individual gets revised with the best possible option that has been identified thus far, in addition to the solution that is currently in front of it. This is a representation of the chain foraging theoretical framework:

$$x_i^d(t+1) = \begin{cases} x_i^d(t) + r \cdot (x_{best}^d(t) - x_i^d(t)) \\ + \alpha \cdot (x_{best}^d(t) - x_i^d(t)) & i = 1 \\ x_i^d(t) + r \cdot (x_{i-1}^d(t) - x_i^d(t)) \\ + \alpha \cdot (x_{best}^d(t) - x_i^d(t)) & i = 2, \dots, N \end{cases} \quad (2)$$

$$\alpha = 2 \cdot r \cdot \sqrt{|\log(r)|} \quad (3)$$

where $x_i^d(t)$ denotes the location of the i -th individual at time t in the d -th dimension, r signifies an arbitrary vector from 0 to 1, α denotes the value of the ratio, and $x_{best}^d(t)$ represents the plankton with the highest concentration. The current status of the i -th individual is established using the situation $x_{i-1}(t)$ as well as the position $i - 1$ -th of the food at the time $x_{best}(t)$ respectively.

3) *Cyclone foraging*: When a group of manta rays detects a region of deep-water plankton, they will spiral in their pursuit of the food in a continuous foraging chain. In contrast,

as part of their cyclone foraging strategy, manta ray clusters swim each individual manta ray in the direction of the one in front of it, as opposed to spiraling towards the food. In other words, manta ray colonies engage in spiral foraging in a helical formation. An individual not only replicates the motion of the one preceding it but also proceeds in a spiral trajectory toward sustenance. The expression in mathematics that characterizes the spiral motion of manta rays in a two-dimensional space is as follows:

$$\begin{cases} X_i(t+1) = X_{best} + r \cdot (X_{i-1}(t) - X_i(t)) \\ + e^{bw} \cdot \cos(2\pi w) \cdot (X_{best} - X_i(t)) \\ Y_i(t+1) = Y_{best} + r \cdot (Y_{i-1}(t) - Y_i(t)) \\ + e^{bw} \cdot \sin(2\pi w) \cdot (Y_{best} - Y_i(t)) \end{cases} \quad (4)$$

where w represents a random number from zero to one.

This behavior of motion is extensible to n_D space. Theoretical representation of cyclone scavenging may be defined succinctly as:

$$x_i^d(t+1) = \begin{cases} x_{best}^d + r \cdot (x_{best}^d(t) - x_i^d(t)) \\ + \beta \cdot (x_{best}^d(t) - x_i^d(t)) & i = 1 \\ x_{best}^d + r \cdot (x_{i-1}^d(t) - x_i^d(t)) \\ + \beta \cdot (x_{best}^d(t) - x_i^d(t)) & i = 2, \dots, N \end{cases} \quad (5)$$

$$\beta = 2e^{r_1 \frac{T-t+1}{T}} \cdot \sin(2\pi r_1) \quad (6)$$

The variables denoted as $[0,1]$, T the maximal number of iterations, β the weight coefficient, and r_1 the rand number.

Each individual conducts the search in a random manner, using the food as their reference position. As a result, the region where the most effective solution has been identified thus far benefits from cyclone foraging. Additionally, this behavior serves to significantly enhance the exploration process. By designating each individual, a reference position that is arbitrary and distinct from the current optimal one, we can compel them to seek out a new position. The mathematical equation for this mechanism, which enables MRFO to conduct an exhaustive global search and is primarily concerned with exploration, is provided below.

$$x_{rand}^d = Lb^d + r \cdot (Ub^d - Lb^d) \quad (7)$$

$$x_i^d(t+1) = \begin{cases} x_{rand}^d + r \cdot (x_{rand}^d - x_i^d(t)) \\ + \beta \cdot (x_{rand}^d - x_i^d(t)) & i = 1 \\ x_{rand}^d + r \cdot (x_{i-1}^d(t) - x_i^d(t)) \\ + \beta \cdot (x_{rand}^d - x_i^d(t)) & i = 2, \dots, N \end{cases} \quad (8)$$

The variable x_{rand}^d denotes a position generated at random within the search space. Lb^d as well as Ub^d represent, respectively, the d -th dimension's minimum and maximum boundaries.

4) *Somersault foraging*: This behavior is characterized by the food's position being considered a pivot. Every individual undergoes a series of back-and-forth swims that involve a pirouette to a different position. As a result, they continuously adjust their positions in accordance with the most advantageous one discovered thus far. The formulation of the mathematical model is as follows:

$$x_i^d(t + 1) = x_i^d(t) + S \cdot (r_2 \cdot x_{best}^d - r_3 \cdot x_i^d(t)), i = 1, \dots, N \quad (9)$$

where S is the somersault factor that controls the variety of somersaults that manta rays perform. $S = 2$, r_2 and r_3 are two arbitrary values from the interval $[0,1]$. The framework of MRFO can be displayed in Fig. 7.

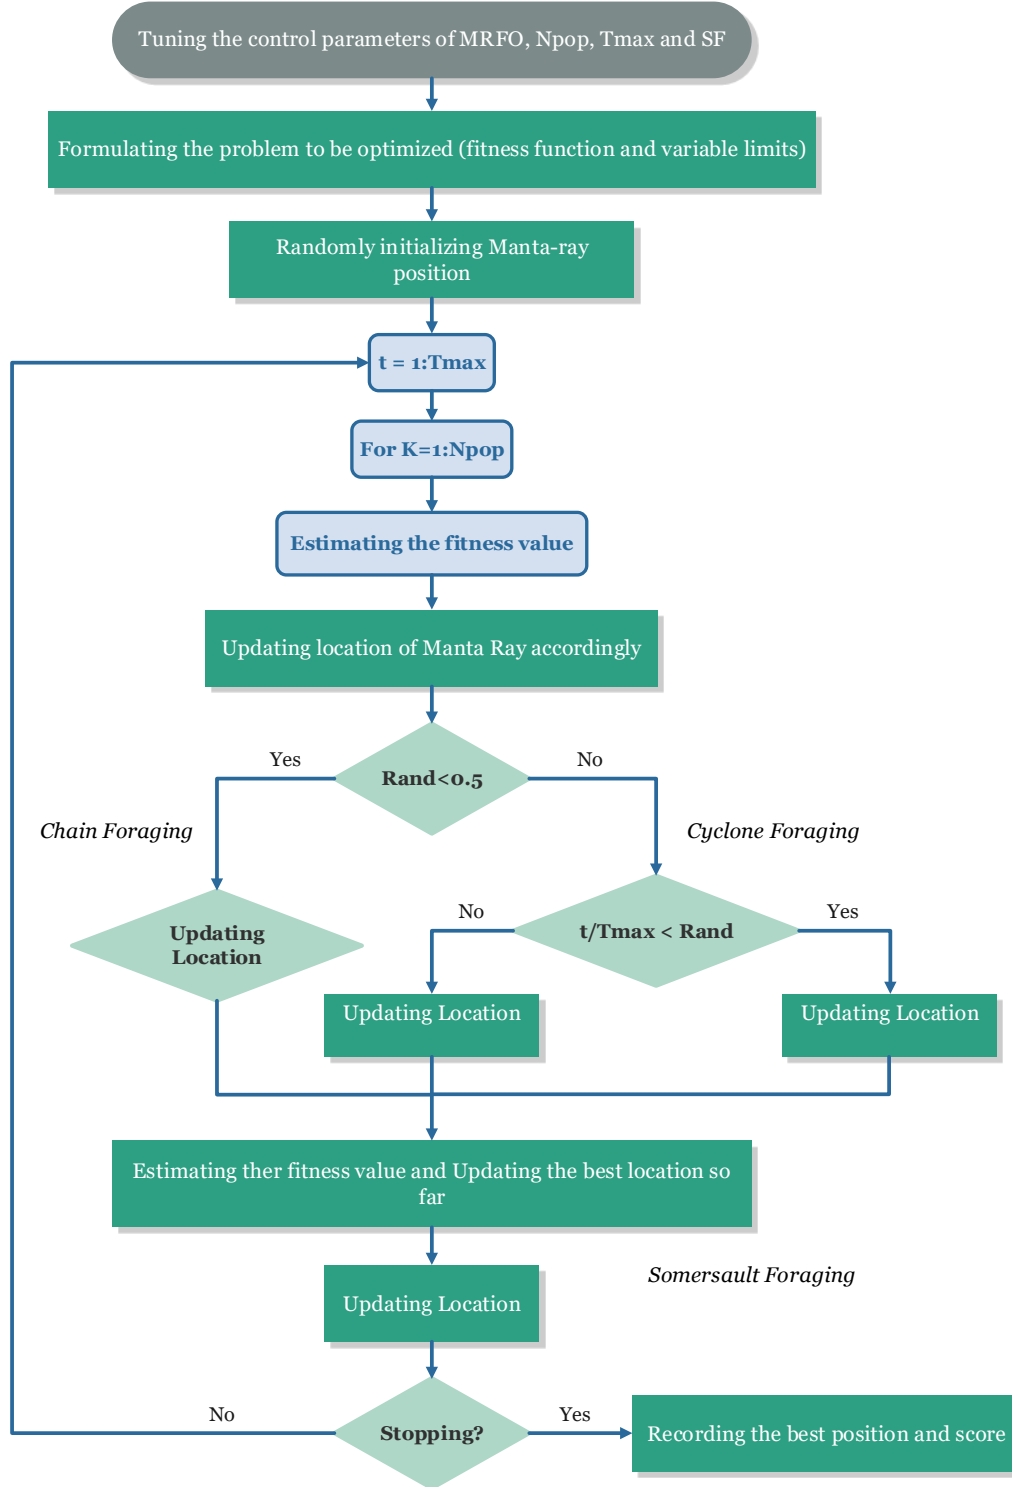

Fig. 7. The framework of MRFO.

D. Long Short-term Memory

The long short-term memory is a very well-liked and successful deep learning method. It is an effective tool for a variety of applications since it is built to handle and process enormous amounts of data [8]. Three a memory unit and gating units are used by the LSTM model to process incoming input. Together, these components control the flow of data, eliminating any extraneous material and generating output that is both brief and pertinent. The forgetting gate removes any potentially present irrelevant information, whereas the input gate handles the processing of incoming data. The function of the output gate is to regulate the flow of data that has been processed and generate a precise and relevant output. The gate formulas are used to sort, process, and store data, while the memory unit stores pertinent information for later use. The LSTM model may exclude any extraneous data by employing these algorithms, ensuring that only essential data is retained. As a result, it is a very effective method for handling vast amounts of data without creating extra clutter. The LSTM method is a significant asset in the field of deep learning since it is a strong and dependable tool for processing complex data sets [32]. The LSTM's operation is shown in the following equations. The forget gate decides whether to preserve or discard the information. A sigmoid layer processes the current input and the prior hidden state. The value that this layer output ranges from 0 to 1. Keep the data if the result value is more closely related to 1. Otherwise, disregard the knowledge.

$$f_t = \sigma(W_f \times [h_{t-1}, x_t] + b_f) \quad (10)$$

where σ denotes the sigmoid function, W_f is the mass that is linked to the forget gate, the prior hidden state demonstrates as h_{t-1} , the input value is x_t , as well as b_f denotes the bias associated with the forget gate.

The gate that accepts input is responsible for modifying the cell state. An individual sigmoid layer and a tan layer process the present input as well as the prior hidden state first. A data value is transformed by the sigmoid layer into a value that ranges from 0 to 1. Using the tanh layer, a data value is transformed into a value between -1 and 1. The outputs of the sigmoid layer and the tanh layer are multiplied by a point-wise procedure. then computes the new cell state value.

$$i_t = \sigma(W_i \times [h_{t-1}, x_t] + b_i) \quad (11)$$

The weight that is expressed as a symbol for the input gate by W_i and b_i is the component of the input gate that introduces bias.

The below equation is used to calculate the output of the tanh layer:

$$\tilde{C}_t = \tanh(W_c[h_{t-1}, x_t] + b_c) \quad (12)$$

Equation below is used to calculate the new cell state:

$$C_t = f_t \times C_{t-1} + i_t \times \tilde{C}_t \quad (13)$$

The output gate decides what secret state will be shown next. A sigmoid layer processes the input at hand in addition

to the preceding hidden state at the beginning. The changed cell state is then transmitted to a tan layer. The outputs of the sigmoid layer and the tanh layer are multiplied point-wise to find the subsequent hidden state. The new cell state as well as the next concealed state are then transferred to the following time step.

$$o_t = \sigma(W_o[h_{t-1}, x_t] + b_o) \quad (14)$$

where b_o denotes the bias associated with the output gate and w_o is the weight associated with the output gate.

$$h_t = o_t \tanh(C_t) \quad (15)$$

Using the following equation, the subsequent hidden state is determined:

$$h_t = o_t \tanh(C_t) \quad (16)$$

E. Genetic Algorithm

The genetic algorithm is a method of computation that simulate natural selection's technique to handle optimization and search issues [10]. With this algorithm, a collection of probable solutions known as people is created. To create new individuals, these individuals are then subjected to genetic processes like mutation, recombination, and selection. The illustration and framework of GA can be seen in Fig. 8 and 9. This evaluation procedure is iterative and is performed over several generations until a workable answer is discovered. As a result, GA is a potent instrument that is frequently employed in many different industries, involving engineering, finance, and science, to name a few [33]. Three components are essential to GA [34]. A chromosome is an encoded string of numbers or characters that is given to each individual by the encoding component. Encoding methodology is determined by the precise problem that must be resolved. Following this, the fitness metric is applied to assess how each individual embodies the solution. The ability to exercise has been deliberately designed to mitigate the present issue. Evolutionary operators utilize the crossing, transformation, and choice procedures. When two people's chromosomes crossover, a new being is created, mutation indiscriminately modifies an individual's chromosomes, and selection is used to determine which individuals are the most fertile.

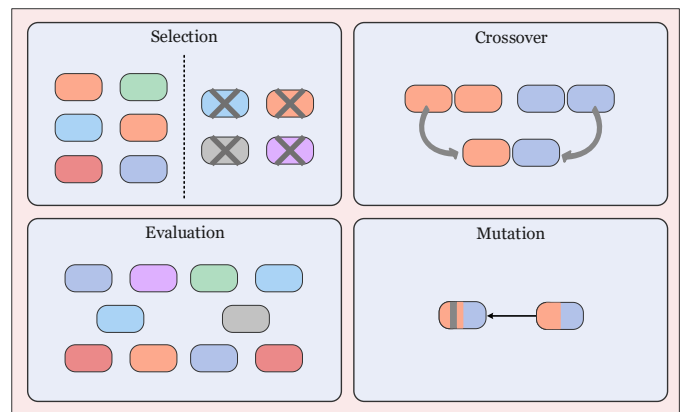

Fig. 8. The illustration of GA.

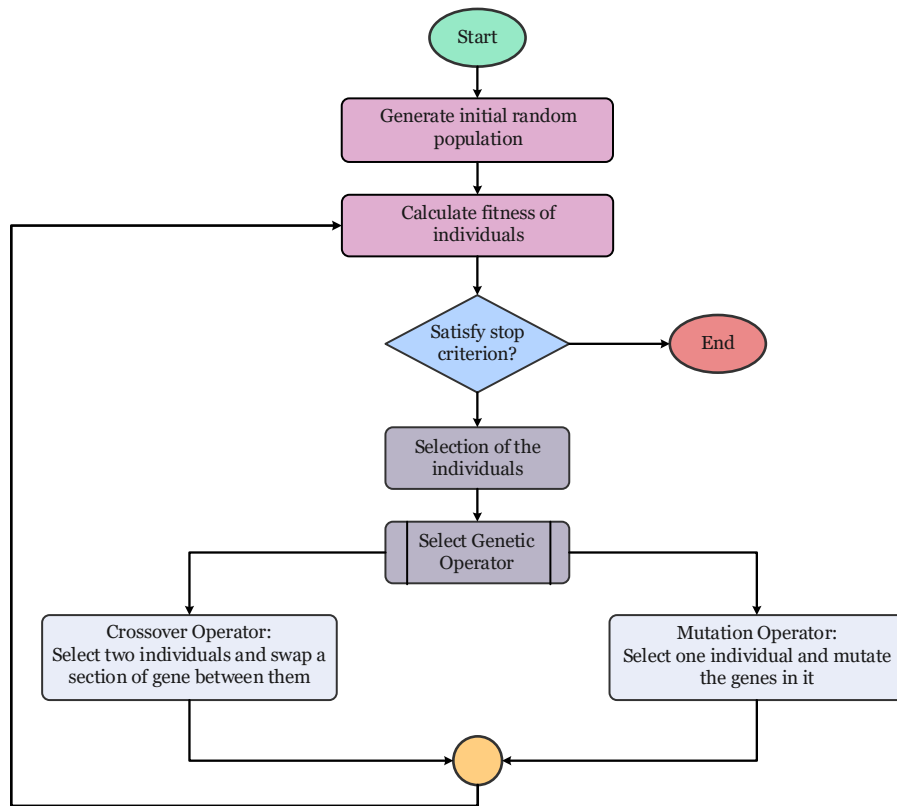

Fig. 9. The framework of GA.

F. Battle Royale Optimizer

The battle royale optimizer is the name of a meta-heuristic algorithm that Farshi proposed [12]. The algorithm was inspired by a popular multiplayer online game in which players must eliminate rivals to find a safe haven to survive. Stepping outside the safe zone in the game puts the player at risk of getting hurt or being eliminated [12]. The damage rate of the injured player is calculated using the equation shown below:

$$x_i. damage = x_i. damage + 1 \quad (17)$$

Injured players strive to switch to other positions to confront the enemy. The equation that follows shows the players' newest placements:

$$x_{dam,d} = x_{dam,d} + r(x_{best,d} - x_{dam,d}) \quad (18)$$

where $x_{dam,d}$ denotes the location of the wounded player in the dimension d , the best solution in dimension d is indicated by the notation $x_{best,d}$, and r is a random number generated from a uniform distribution between 0 and 1. The search agents are distributed at random throughout the problem space and cover it equally.

In a d -dimensional problem space, the upper limit and lower bound are represented by ub_d and lb_d the following equation:

$$x_{dam,d} = r(ub_d - lb_d) + lb_d \quad (19)$$

The best approach is shown in the formula below, and the worst-fitting options are discarded. Considering this, the starting value Δ is $\log_{10}(MaxCicle)$, where MaxCicle is the number of repetitions:

$$\Delta = \Delta + round\left(\frac{\Delta}{2}\right) \quad (20)$$

G. Gray Wolf Optimizer

A meta-heuristic technique has been used to create a novel optimization process known as the gray wolf optimizer. The approach, which mimics the seeking strategies and social organization of gray wolves, was first presented by Mirjalili et al. [13]. The best solution is Alpha, while there are four alternatives in the leadership hierarchy, Omega is the last competitor: Beta, Alpha, Omega, and Delta.

The strategy employs three primary hunting techniques to mimic wolf behavior: pursuing prey, enclosing prey, and attacking prey.

$$\begin{aligned} \vec{D} &= |\vec{C} \cdot \vec{X}_p(t) - \vec{X}(t)| \\ \vec{X}(t+1) &= \vec{X}_p(t) - \vec{A} \cdot \vec{D} \end{aligned} \quad (21)$$

where \vec{C} and \vec{A} represent coefficient vectors, \vec{D} signifies motion, t is the current stage of iteration, as well as \vec{X} represents the whereabouts of a gray wolf. The construction of the parameter variables (\vec{A} and \vec{C}) is based on the subsequent relationships:

$$\begin{aligned} \vec{A} &= 2\vec{a} \cdot \vec{r}_1 - \vec{a} \\ \vec{C} &= 2 \cdot \vec{r}_2 \end{aligned} \quad (22)$$

The location of new search reps that involve omegas is adjusted utilizing the data from alpha, beta, and delta as follows:

$$\begin{aligned} \vec{D}_\alpha &= |\vec{C}_1 \cdot \vec{X}_\alpha - \vec{X}|, \vec{D}_\beta = |\vec{C}_2 \cdot \vec{X}_\beta - \vec{X}|, \vec{D}_\delta \\ &= |\vec{C}_3 \cdot \vec{X}_\delta - \vec{X}| \end{aligned} \quad (23)$$

$$\begin{aligned} \vec{X}_1 &= \vec{X}_\alpha - \vec{A}_1 \cdot \vec{D}_\alpha, \vec{X}_2 = \vec{X}_\beta - \vec{A}_2 \cdot \vec{D}_\beta, \vec{X}_3 \\ &= \vec{X}_\delta - \vec{A}_3 \cdot \vec{D}_\delta \end{aligned} \quad (24)$$

$$\vec{X}(t+1) = \frac{\vec{X}_1 + \vec{X}_2 + \vec{X}_3}{3} \quad (25)$$

where the wolves are indicated by the subscripts α, β , and δ to mount a final attack to complete the task. \vec{a} is used to mimic the last attack by changing a value from 2 to 0, whereas a is a random variable between $-2\vec{a}$ and $2\vec{a}$. As a result, decreasing \vec{a} would also cause \vec{A} to decrease. The wolves were forced by $|\vec{A}| < 1$ to cling to their prey. After following the leader wolf on a pack search, gray wolves disperse to collect sustenance before reconvening for an assault. In pursuit of prey, wolves may divide into groups if the value of $|\vec{A}|$ exceeds unity at random. Two of the most critical settings for the algorithm used by GWO are the number of wolves and generation. Generation after generation signifies a wolf's conclusive action. In addition, the number of wolves precisely reflects changes in performance estimates over time. In other words, the generation size multiplied by the wolf population will result in an equivalent quantity of objective function evaluations.

$$OFEs = N_W \times N_G \quad (26)$$

H. Performances Metrics

Several performance metrics were utilized to determine the dependability of future estimates. The root means square error (RMSE), mean absolute error (MAE), coefficient of determination (R^2), and mean absolute percentage error (MAPE) were some of these. The accuracy of forecasting models can be evaluated using these metrics, which additionally helps to ensure that the estimates are solid and reliable.

$$RMSE = \sqrt{\frac{\sum_{i=1}^n (y_i - \hat{y}_i)^2}{n}} \quad (27)$$

$$MAPE = \left(\frac{1}{n} \sum_{i=1}^n \left| \frac{y_i - \hat{y}_i}{y_i} \right| \right) \times 100 \quad (28)$$

$$R^2 = 1 - \frac{\sum_{i=1}^n (y_i - \hat{y}_i)^2}{\sum_{i=1}^n (y_i - \bar{y})^2} \quad (29)$$

$$MAE = \frac{\sum_{i=1}^n |y_i - \hat{y}_i|}{n} \quad (30)$$

where \bar{y}_i is the sample mean, \hat{y}_i is the predicted value, and y_i is the actual value.

V. EXPERIMENTAL RESULTS

A. Statistical Values

Table I which contains comprehensive statistical data about the dataset is included in this section of the study. The data are made more understandable by the table's inclusion of OHLC prices and volume figures. A robust dataset for analysis is provided by the 2137 observations in this table. This provides a clear indication of the data's scope and the extensive period over which it was collected by presenting the count. The central tendencies of the dataset are represented by the mean values in the table, which provide an average perspective on the market's performance during the analyzed period. For example, the mean closing price of 8745.8210 serves as a foundation for comprehending typical market behavior. In the same way, the minimum and maximum values capture the extremes within the dataset, indicating the lowest and highest market activities observed, such as the minimum volume of 706.880 and the maximum closing price of 16057.440. Additionally, the table contains skewness values, which provide a deeper understanding of the asymmetry in the data distribution. The skewness, which is nearly zero, indicates that the distribution is fairly symmetrical, indicating that the data does not significantly favor one tail. This information is essential for comprehending the fundamental patterns in the data, which can have a substantial impact on modeling endeavors.

TABLE I. SUMMARY STATISTICS FOR THE DATA SET

	Open	High	Low	Volume	Close
count	2137	2137	2137	2137	2137
mean	8744.3560	8805.2870	8677.5740	3143.80	8745.8210
minimum	4218.810	4293.220	4209.760	706.880	4266.840
maximum	16120.920	16212.230	16017.230	11621.190	16057.440
skewness	0.4993140	0.493110	0.5027470	1.0283760	0.4977320

B. Models' Outcomes

Using data from Nasdaq Finance, the proposed method was both trained and evaluated. To forecast a numerical value,

regression analysis is implemented. A large number of vendors, purchasers, and investors participate in the stock market, an extremely risky investment destination. A share typically signifies ownership in a corporation. Recognizing

stock price patterns and making investments at the optimal time and location are the sole prerequisites for potentially generating profits. Determining as well as evaluating the hybrid algorithm that is most efficient in predicting stock pricing is thus the primary objective, provided that an event is accurately predicted at the appropriate moment. Determining and evaluating the most effective hybrid algorithm for investing price forecasts is the principal aim of this study. Elaborate variables that influence stock market patterns have been analyzed in conjunction with the development of forecasting models. The goal was to provide insightful

information that would aid investors and analysts in making prudent investment decisions. A detailed assessment of the performance of each mode, as well as an examination of its effectiveness, is presented in Table II. The principal goal of this investigation is to ascertain as well as evaluate the most efficient hybrid method for predicting stock prices. Through the development of predictive models and an understanding of the fundamental factors that influence stock market trends, this research aims to assist analysts and investors in making well-informed investment choices.

TABLE II. EVALUATION FINDINGS OF THE SIX BENCHMARKING ALGORITHMS' STATISTICAL FORECASTS

MODEL/METRICS	TRAIN SET				TEST SET			
	R ²	RMSE	MAE	MAPE (%)	R ²	RMSE	MAE	MAPE (%)
LSTM	0.9766	449.05	383.63	5.62	0.9609	311.60	259.87	2.06
EMD-LSTM	0.9817	396.55	247.51	2.59	0.9703	271.63	208.55	1.70

VI. DISCUSSION

To assess the efficacy of the data analysis, four widely used metrics—RMSE, MAPE, MAE, and R²—were applied. To fully evaluate the results, a comprehensive assessment of the accuracy of the analysis, precision, as well as overall performance can be done using these metrics. R², RMSE and MAPE criteria were assessed for the LSTM model using EMD decomposition both with and without the optimizer. During the evaluation period, LSTM achieved a R² value of 0.9609, as shown in Table II and Fig. 10 and 11. Frequently, the process of decomposing a problem reveals functions or recurrent patterns that apply to numerous components. The act of reusing modules or components serves to enhance stability, decrease the probability of errors, and accelerate the development process. In light of the data provided in this section, Clearly, it is apparent that the utilization of EMD decomposition decreases the value of MAE to 208.55 and 247.51, respectively, during the testing and training phases. When optimizers are added to the LSTM model, its efficacy is substantially enhanced. By enabling the efficient modification of model parameters, optimizers mitigate performance degradation. In order to achieve a convergent set of

parameters, a multitude of optimizers implement unique strategies, including adaptive learning rate, slope descent, momentum, and others. This degree of effectiveness accelerates the convergence process during training. The cited examples demonstrate that the simultaneous implementation of the GA optimizer and EMD decompose produces a more precise outcome and reduces calculation error, as shown in Table II. Moreover, in conjunction with GA, the BRO optimizer exhibited enhanced performance, as indicated by its reduced RMSE value. By attaining an MAE score of 93.96, EMD-GWO-LSTM demonstrated superior efficacy in comparison to EMD-BRO-LSTM. According to regression analysis, the EMD-MRFO-LSTM model is an exceptionally precise and reliable instrument. The respective R² score of the model for the testing dataset was 0.9973. The outcomes of this study illustrate the model's robust predictive capability and its ability to explain nearly all of the variability in the data. Decreased values signify greater precision, as they represent the discrepancy between the predicted and realized values. In light of the exceptional accuracy demonstrated by both the training and assessment datasets, the EMD-MRFO-LSTM model has been validated.

Fig. 10. Evaluation values for each model in the training set.

Fig. 11. Evaluation values for each model in the testing set.

The EMD-MRFO-LSTM model's ability to forecast the Nasdaq index during both the training and testing phases is illustrated in Fig. 12 and 13. The black line in Fig. 12, which illustrates the training phase, represents the actual Nasdaq index, while the red line illustrates the predicted values from the model. The model's capacity to learn from historical data is underscored by the close alignment of the two curves. Particularly, the Nasdaq index's reversal points, peaks, and troughs are precisely captured by the model. The predicted values closely follow the actual values at reversal points, where the market changes direction. The model also accurately predicts the market's peaks and troughs, matching them with precision. The model's capacity to learn intricate market dynamics and patterns is illustrated by this precise fit. The EMD-MRFO-LSTM model's robustness and

generalization capability are validated by its continued performance in Fig. 13, which represents the testing phase. The model closely aligns the predicted peaks and troughs with the actual market values and maintains its accuracy in predicting reversal points, where the market shifts direction. This consistency in the testing phase, during which the model encounters new, unseen data, emphasizes its reliability and effectiveness in real-world applications. The model's ability to accurately capture critical market prices is demonstrated by the detailed fit between the predicted and actual curves in both phases, rendering it a valuable tool for investors and analysts. The EMD-MRFO-LSTM model's utility in stock market prediction is confirmed by its ability to accurately predict future market trends, which aids in the making of informed investment decisions.

Fig. 12. Training-generated forecasting curve employing EMD-MRFO-LSTM.

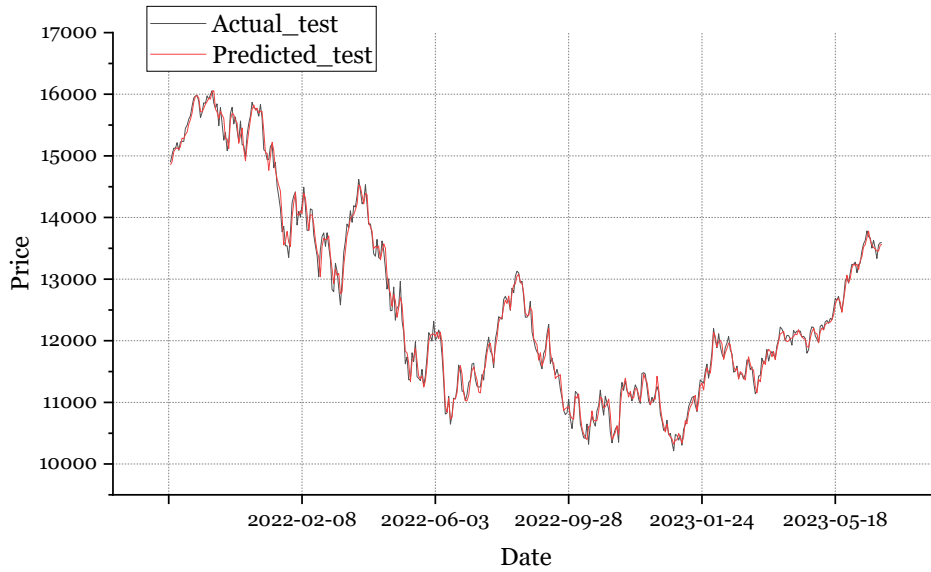

Fig. 13. Testing-generated forecasting curve employing EMD-MRFO-LSTM.

According to Table III, in comparison to both traditional and advanced benchmark models, such as support vector regression (SVR), random forest (RF), multilayer perceptron (MLP), and long short-term memory (LSTM), the proposed EMD-MRFO-LSTM model has exhibited remarkable superiority in predicting stock market prices. In particular, the model attains an R^2 value of 0.9973, which is statistically significantly greater than those of SVR (0.9097), RF (0.9258), MLP (0.9442), and LSTM (0.9609). The EMD-MRFO-LSTM model's high R^2 value suggests that it can account for nearly 99.73% of the variance in the target data, which is a significant improvement over the closest competing model,

LSTM, which explains 96.09%. Additionally, the EMD-MRFO-LSTM model demonstrates superior error metrics, with an RMSE of only 91.99, in contrast to 311.60 for LSTM, 329.03 for MLP, 379.37 for RF, and 418.38 for SVR. The MAE exhibits a comparable pattern, as evidenced by its value of 71.54, which is significantly lower than that of LSTM (259.87), MLP (254.90), RF (287.73), and SVR (361.18). Furthermore, the MAPE of the proposed model is a mere 0.57%, which is a negligible error margin in comparison to 2.06% for LSTM, 2.09% for MLP, 2.24% for RF, and 3% for SVR.

TABLE III. PERFORMANCE OF THE PROPOSED MODEL IN COMPARISON WITH BENCHMARK MODELS

MODEL/METRICS	TEST SET			
	R^2	RMSE	MAE	MAPE (%)
SVR	0.9097	418.38	361.18	3
RF	0.9258	379.37	287.73	2.24
MLP	0.9442	329.03	254.90	2.09
LSTM	0.9609	311.60	259.87	2.06
EMD-MRFO-LSTM	0.9973	91.99	71.54	0.57

The EMD-MRFO-LSTM model's stability and reliability are further demonstrated by its consistent results across various cross-validation methods, as illustrated in Table IV. The model achieves an R^2 of 0.9967, an RMSE of 92.82, an MAE of 72.33, and a MAPE of 0.58% through 5-fold cross-validation. The model maintains this high-performance level with an R^2 of 0.9970, an RMSE of 92.18, an MAE of 71.91, and a MAPE of 0.57% when a 10-fold cross-validation is implemented. The model's potential as a dependable tool for financial forecasting is underscored by these results, which are capable of delivering precise and stable predictions under varying conditions.

The EMD-MRFO-LSTM method utilized in the current study has the highest R^2 value among other methodologies in the literature, as illustrated in Table V. This model outperforms linear regression, support vector machine (SVM), multi-layer stacked long short-term memory (MLS-LSTM), convolutional neural network-bidirectional long short-term memory with attention mechanism (CNN-BiLSTM-AM), and combinations of long short-term memory and deep neural networks (LSTM and DNN) in terms of stock price prediction accuracy. This implies that the current model can account for nearly all of the variability in the stock market data. The incremental improvements in R^2 in comparison to existing methods underscore the effectiveness of integrating EMD with the MRFO and LSTM networks.

TABLE IV. PERFORMANCE OF THE PROPOSED MODEL WITH DIFFERENT CROSS-VALIDATIONS

<i>K-folds/METRICS</i>	<i>TEST SET</i>			
	<i>R²</i>	<i>RMSE</i>	<i>MAE</i>	<i>MAPE (%)</i>
Without k-fold	0.9973	91.99	71.54	0.57
5-fold	0.9967	92.82	72.33	0.58
10-fold	0.9970	92.18	71.91	0.57

TABLE V. COMPARISON OF THE COEFFICIENT OF DETERMINATION FOR A DIVERSE ARRAY OF STOCK MARKET PREDICTION METHODOLOGIES IN LITERATURE

<i>References</i>	<i>Frameworks</i>	<i>R²</i>
[35]	Linear regression	0.735
	SVM	0.931
	MLS-LSTM	0.95
[36]	LSTM	0.981
[37]	CNN-BiLSTM-AM	0.98
[38]	LSTM and DNN	0.972
Present study	EMD-MRFO-LSTM	0.9973

The EMD-MRFO-LSTM model is capable of forecasting stock market trends. This model has the potential to assist investors in making more informed decisions regarding the purchase, sale, or retention of stocks by predicting the future values of stock indices, such as the Nasdaq. Portfolio managers and financial advisors may find the EMD-MRFO-LSTM model advantageous for optimizing their investment portfolios. The model can help diversify portfolios to reduce risk and enhance returns by predicting the potential future performance of a variety of assets. It has the potential to offer valuable insights into the most advantageous times to rebalance portfolios by identifying the optimal moments to adjust the allocation of various assets. The EMD-MRFO-LSTM model may be implemented by financial institutions to evaluate and mitigate risks. The model can assist in the identification of potential periods of high volatility or downturns by forecasting market trends. This allows institutions to employ risk mitigation strategies, such as adjusting their exposure to specific assets or hedging, to potentially safeguard their investments from adverse market movements.

VII. CONCLUSIONS

Forecasting stock prices is a complex and multifaceted process that poses numerous challenges. Social, political, and economic changes, as well as other factors, all have an impact on the stock market, which is an ever-evolving and dynamic system. Future stock prices must be correctly predicted by considering a variety of factors. Constraints and variables abound in the procedure of forecasting stock prices, which can make it difficult to develop accurate and dependable prediction models. It is imperative to comprehend the market's non-linear and unpredictable characteristics to achieve this objective. Thankfully, the EMD-MRFO-LSTM model has proven to be dependable and precise, providing a workable solution to these issues. The current study evaluated the

efficacy of various stock price forecasting models, such as EMD-LSTM, LSTM, EMD-GA-LSTM, EMD-BRO-LSTM, as well as EMD-GWO-LSTM. The hyperparameter optimization techniques GA, BRO, MRFO, and GWO were utilized to enhance the LSTM's parameters. Nevertheless, optimal outcomes were achieved when the MRFO optimization method was coupled with LSTM. From January 2, 2015, to June 29, 2023, OHLC pricing and the Nasdaq index's volume comprised the dataset employed in the research. According to the analysis, the EMD-MRFO-LSTM model was highly reliable and accurate at forecasting stock prices. The EMD-MRFO-LSTM model consistently displayed superior accuracy and efficacy in its predictions compared to other models tested during the study by having 0.9973, 91.99, 71.54, and 0.57 values for R^2 , RMSE, MAE, and MAPE for the testing, respectively. In general, the EMD-MRFO-LSTM model demonstrates efficacy as a stock price forecasting instrument and the investor supplies astute information to enable prudent investment choices.

VIII. CHALLENGES AND PROSPECTS

A. Challenges

Numerous variables impact stock market data, which is inherently chaotic. Deriving significant patterns and trends from the data is a difficult task due to its intricate nature. Conventional feedforward neural networks encounter difficulties when confronted with sequential data in which past events hold significant importance in forecasting future outcomes. Gradients in models may dissolve or become extremely small during training, making it challenging for the network to effectively learn long-term dependencies. To make accurate predictions, it is vital to identify pertinent characteristics of the supplied data. The process of regard to the optimization for complex models necessitates traversing extensive parameter spaces. The evaluation of various models and techniques necessitates the use of rigorous metrics for

assessment and methodologies. When evaluating the precision and efficacy of different methodologies, it is imperative to meticulously contemplate elements such as the origins of the data, the structures of the models, and the optimization strategies.

B. Prospects

Potentially more accurate and dependable stock market forecasts could result from the combination of sophisticated artificial intelligence models LSTM and optimization techniques (gray wolf optimization and meta-heuristic algorithms). These models have the potential to optimize forecasting capabilities by more effectively capturing the intricate relationships and patterns that are intrinsic in stock market data. The finance industry relies heavily on precise stock market forecasts to manage risk effectively. The proposed models have the potential to aid financial institutions and investors in making well-informed decisions related to risk mitigation and return optimization through the provision of more dependable forecasts. Investment firms and financial institutions that implement sophisticated predictive analytics methods are likely to gain a competitive advantage in the marketplace. By investing in modern technologies to improve decision-making procedures, these institutions can strengthen their financial achievements and maintain an excellent market position. The creation and implementation of advanced forecasting models offer educational programs and academic institutions with a vision to offer courses and seminars covering areas such as machine learning in the financial sector, optimization methodology, and quantitative analysis. This can help develop the next generation of professionals who have the expertise to handle complex financial issues.

Modified TOPSIS Method for Neutrosophic Cubic Number Multi-Attribute Decision-Making and Applications to Music Composition Effectiveness Evaluation of Film and Television

Liang Yang*, Jun Zhao

Anhui Broadcasting and Television Vocational and Technical College, Hefei, 230011, Anhui, China

Abstract—Contemporary music composition for film and television has exhibited a trend towards diversification, which is reflected in various aspects such as the diversity of musical styles, the integration of music and visuals, as well as the technical means of music creation. With the continuous advancement of music production technology and film/television production technology, the creation of music for film and television has increasingly emphasized the organic integration of music and visuals, as well as the role of music in emotional expression and atmosphere creation. Meanwhile, the fusion and innovation of different musical styles have also brought more possibilities and space to the creation of music for film and television. This trend of diversification not only enriches the artistic expressiveness of film and television works, but also provides audiences with a more diverse audiovisual experience. The music composition effectiveness evaluation of film and television is multi-attribute decision-making (MADM) problem. In this paper, the TOPSIS method is extended to the framework of neutrosophic cubic sets (NCSs) to address MADM problems. The CRITIC method is employed to obtain the weights of the attributes, ensuring a systematic and objective approach to determining their relative importance. Furthermore, the neutrosophic cubic number TOPSIS (NCN-TOPSIS) approach is established for MADM scenarios. To demonstrate the applicability of the proposed NCN-TOPSIS model, a numerical example focused on the music composition effectiveness evaluation in film and television is presented. Additionally, comparative analyses are conducted to showcase the advantages of the NCN-TOPSIS approach over other decision-making methods. By extending the TOPSIS technique to the NCSs environment and integrating the CRITIC method, this research contributes to the field of MADM by providing a robust and efficient decision-making tool for complex, multi-criteria problems, as exemplified by the music composition evaluation in the film and television industry.

Keywords—Multi-Attribute Decision-Making (MADM); NCSs; TOPSIS approach; music composition effectiveness evaluation

I. INTRODUCTION

The development of contemporary music production technology has had a profound impact on film and television music creation [1, 2]. With the progress of technology, music production tools and techniques have been continuously updated, providing more possibilities and innovative space for film and television music creation. These technologies not only improve the efficiency and quality of music production, but also

make the integration of music and visuals more intimate and natural [3, 4]. The continuous advancement and innovation of technological means is undoubtedly a key driving force in promoting the sustained prosperity of film and television music creation. As music production technology evolves rapidly, film and television music creation is gradually breaking free from traditional constraints and showcasing unprecedented creativity and imagination [5, 6]. Modern music production technology not only provides more convenient creation and editing tools, but also enables composers to easily explore the integration of various timbres and styles, creating unique and highly engaging musical works. The widespread application of these technological means not only enriches the connotation and extension of film and television music creation, but also, while driving the innovative development of film and television music, brings more diversified and personalized audiovisual experiences to the audience [7, 8]. Therefore, we must fully recognize the important role of technological means in film and television music creation, and continue to promote their progress and innovation, contributing to the flourishing development of film and television music art [9]. In contemporary film and television music creation, the phenomenon of musical style integration not only showcases the infinite possibilities of art, but also becomes a vivid manifestation of cultural exchange and collision [10, 11]. Against the backdrop of globalization, the mutual penetration and integration of different cultures and music styles have provided a vast space for innovation in film and television music composition [12-14]. With an open mindset and unique perspectives, composers skillfully blend elements of classical elegance, popular vernacular, rock passion, and avant-garde electronics, breaking the boundaries of traditional music styles and creating film and television music works that have both depth and breadth [15, 16]. This cross-border integration of musical styles has greatly enriched the expressiveness and emotional depth of film and television music, allowing audiences to experience the unique charm of music and audiovisual art, and enjoy an unprecedented visual and auditory feast [17-19]. This integration phenomenon not only drives the progress of film and television music creation, but also further promotes the exchange and understanding between different cultures, demonstrating the power and allure of art [20-22].

MADM is a branch of decision theory that focuses on making decisions when there are multiple, often conflicting,

*Corresponding Author.

attributes or objectives that need to be taken into account [23-27]. These attributes can be both quantitative (e.g., cost, performance) and qualitative (e.g., aesthetic appeal, brand reputation) in nature [28-32]. The goal of MADM is to help DMs systematically evaluate the available alternatives and make an informed choice that best aligns with their preferences and priorities. MADM has a wide range of applications across various domains, including product design, resource allocation, policy making, and personal decision-making. For example, in the context of urban planning, MADM can be used to evaluate and prioritize infrastructure projects based on factors such as cost, environmental impact, accessibility, and economic benefits [33-37].

The evaluation of music composition effectiveness in film and television is often considered a MADM problem. However, the existing literature lacks research on the application of the TOPSIS method [38, 39] for MADM in this domain under NCNs [40]. Given the importance of MADM in various real-world applications, including the music composition effectiveness evaluation of film and television, it is essential to further explore the use of the TOPSIS method under NCNs environments. The primary objective of this study is to develop a novel technique that could more efficiently solve certain MADM problems using the NCN-TOPSIS approach. The key highlights of this work are illustrated: (1) The CRITIC technique is illustrated for the weights of the attributes; (2) The NCN-TOPSIS technique is defined and formalized for decision-making under NCNs; (3) numerical example focusing on the music composition effectiveness evaluation of film and television is illustrated the application of the NCN-TOPSIS approach. Comparative analyses are conducted to showcase the decision-making advantages of the proposed NCN-TOPSIS approach. By addressing the gap in the existing literature and proposing a novel NCN-TOPSIS method, this research aims to contribute to the field of MADM, particularly in the context of film and television music composition evaluation and other relevant domains. The demonstrated application of the NCN-TOPSIS method in the labor education context further highlights its potential for solving complex decision-making issues involving multiple, often conflicting, attributes.

The remainder of this paper is structured as follows: Section II introduces the NCSs, providing the necessary background for the proposed approach. Section III illustrates several fused operators of NCSs, which are essential for the development of the decision-making method. In Section IV, the NCN-TOPSIS approach is devised for MADM. It provides an empirical example focusing on the music composition effectiveness evaluation of film and television. This section demonstrates the application of the NCN-TOPSIS method and includes comparative analyses to highlight the decision-making

advantages of the proposed approach. Finally, Section V draws a satisfactory conclusion to the study.

II. PRELIMINARIES

Ail et al. [40] illustrated the NCSs in light with SVNSSs [41] and IVNSSs [42].

Definition 1 [40]. The NCSs is illustrated:

$$UA = \left\{ \left(x, \left(UR_A(x), US_A(x) \right) \right) \mid x \in X \right\} \quad (1)$$

where $UR_A(x)$ is IVNSSs and $US_A(x)$ is SVNSSs.

$$UR_A(x) = \left[\begin{array}{l} [UT_A^L(x), UT_A^R(x)], \\ [UI_A^L(x), UI_A^R(x)], \\ [UF_A^L(x), UF_A^R(x)] \end{array} \right] \quad (2)$$

$$US_A(x) = (UT_A(x), UI_A(x), UF_A(x)) \quad (3)$$

$$\left[UT_A^L(x), UT_A^R(x) \right], \left[UI_A^L(x), UI_A^R(x) \right], \quad (4)$$

$$\left[UF_A^L(x), UF_A^R(x) \right] \subseteq [0, 1]$$

$$UT_A(x), UI_A(x), UF_A(x) \in [0, 1] \quad (5)$$

$$0 \leq UT_A^R(x) + UI_A^R(x) + UF_A^R(x) \leq 3, \quad (6)$$

$$0 \leq UT_A(x) + UI_A(x) + UF_A(x) \leq 3$$

The neutrosophic cubic number (NCN) is illustrated as:

$$UA = \left\{ \left(\left[UT_A^L, UT_A^R \right], \left[UI_A^L, UI_A^R \right], \left[UF_A^L, UF_A^R \right] \right), \left(UT_A, UI_A, UF_A \right) \right\}.$$

Definition [40]. Let

$$UA = \left\{ \left(\left[UT_A^L, UT_A^R \right], \left[UI_A^L, UI_A^R \right], \left[UF_A^L, UF_A^R \right] \right), \left(UT_A, UI_A, UF_A \right) \right\} \quad \text{and}$$

$$UB = \left\{ \left(\left[UT_B^L, UT_B^R \right], \left[UI_B^L, UI_B^R \right], \left[UF_B^L, UF_B^R \right] \right), \left(UT_B, UI_B, UF_B \right) \right\},$$

the operations laws are illustrated:

$$(1) UA \oplus UB = \left\{ \left(\left(UT_A^L + UT_B^L - UT_A^L UT_B^L, UT_A^R + UT_B^R - UT_A^R UT_B^R \right), \left[UI_A^L UI_B^L, UI_A^R UI_B^R \right], \left[UF_A^L UF_B^L, UF_A^R UF_B^R \right] \right), \left(UT_A + UT_B - UT_A UT_B, UI_A UI_B, UF_A UF_B \right) \right\};$$

$$(2) A \otimes B = \left\{ \left(\begin{array}{l} [UT_A^L UT_B^L, UT_A^R UT_B^R], \\ [UI_A^L + UI_B^L - UI_A^L UI_B^L, UI_A^R + UI_B^R - UI_A^R UI_B^R], \\ [UF_A^L + UF_B^L - UF_A^L UF_B^L, UF_A^R + UF_B^R - UF_A^R UF_B^R] \end{array} \right) \right\};$$

$$(3) \lambda UA = \left\{ \left(\begin{array}{l} [1 - (1 - UT_A^L)^\lambda, 1 - (1 - UT_A^R)^\lambda], \\ [(UI_A^L)^\lambda, (UI_A^R)^\lambda], [(UF_A^L)^\lambda, (UF_A^R)^\lambda] \end{array} \right), \left(\begin{array}{l} 1 - (1 - UT_A)^\lambda, \\ (UI_A)^\lambda, (UF_A)^\lambda \end{array} \right) \right\}, \lambda > 0;$$

$$(4) (UA)^\lambda = \left\{ \left(\begin{array}{l} [(UT_A^L)^\lambda, (UT_A^R)^\lambda], \\ [1 - (1 - UI_A^L)^\lambda, 1 - (1 - UI_A^R)^\lambda], \\ [1 - (1 - UF_A^L)^\lambda, 1 - (1 - UF_A^R)^\lambda] \end{array} \right), \left((UT_A)^\lambda, 1 - (1 - UI_A)^\lambda, 1 - (1 - UF_A)^\lambda \right) \right\}, \lambda > 0.$$

Definition

3[43].

Let

$$UA = \left\{ \left(\begin{array}{l} [UT_A^L, UT_A^R], [UI_A^L, UI_A^R], [UF_A^L, UF_A^R] \end{array} \right), \right. \\ \left. (UT_A, UI_A, UF_A) \right\},$$

the NCN score values (NCNSV), NCN accuracy values (NCNAV), NCN certainty values (NCNCV) are illustrated:

$$NCNSV(UA) = \frac{(6 + UT_A^L + UT_A^R + UT_A - UI_A^L - UI_A^R - UF_A^L - UF_A^R - UI_A - UF_A)}{9} \quad (7)$$

$$NCNAV(UA) = \frac{(UT_A^L + UT_A^R + UT_A - UI_A^L - UI_A^R - UF_A)}{3} \quad (8)$$

$$NCNCV(UA) = \frac{(UT_A^L + UT_A^R + UT_A)}{3} \quad (9)$$

Definition 4[43]. Let

$$UA = \left\{ \left(\begin{array}{l} [UT_A^L, UT_A^R], [UI_A^L, UI_A^R], [UF_A^L, UF_A^R] \end{array} \right), \right. \\ \left. (UT_A, UI_A, UF_A) \right\}$$

and

$$UB = \left\{ \left(\begin{array}{l} [UT_B^L, UT_B^R], [UI_B^L, UI_B^R], [UF_B^L, UF_B^R] \end{array} \right), \right. \\ \left. (UT_B, UI_B, UF_B) \right\}$$

, The comparison analysis for NCNs is illustrated:

1) if $NCNSV(UA) < NCNSV(UB)$, then, $UA < UB$;

2) if $NCNSV(UA) = NCNSV(UB)$, and $NCNAV(UA) < NCNAV(UB)$, then $UA < UB$;

3) if $NCNSV(UA) = NCNSV(UB)$ and $NCNAV(UA) = NCNAV(UB)$, and $NCNCV(UA) < NCNCV(UB)$, then, $UA < UB$;

4) if $NCNSV(UA) = NCNSV(UB)$ and $NCNAV(UA) = NCNAV(UB)$, and $NCNCV(UA) = NCNCV(UB)$, then, $UA = UB$.

Definition 5[44]. Let

$$UA = \left\{ \left(\begin{array}{l} [UT_A^L, UT_A^R], [UI_A^L, UI_A^R], [UF_A^L, UF_A^R] \end{array} \right), \right. \\ \left. (UT_A, UI_A, UF_A) \right\}$$

and

$$UB = \left\{ \left(\begin{array}{l} [UT_B^L, UT_B^R], [UI_B^L, UI_B^R], [UF_B^L, UF_B^R] \end{array} \right), \right. \\ \left. (UT_B, UI_B, UF_B) \right\}$$

, then the NCN Euclid distance (NCNED) is illustrated:

$$NCNED(A, B) = \sqrt{\frac{1}{9} \left(|UT_A^L - UT_B^L|^2 + |UT_A^R - UT_B^R|^2 + |UI_A^L - UI_B^L|^2 + |UI_A^R - UI_B^R|^2 + |UF_A^L - UF_B^L|^2 + |UF_A^R - UF_B^R|^2 + |UT_A - UT_B|^2 + |UI_A - UI_B|^2 + |UF_A - UF_B|^2 \right)} \quad (10)$$

III. NCN-TOPSIS APPROACH FOR MAGDM WITH NCSS

The NCN-TOPSIS approach is illustrated for MADM. Let $UY = \{UY_1, UY_2, \dots, UY_m\}$ be alternatives. Let $UZ = \{UZ_1, UZ_2, \dots, UZ_n\}$ be attributes, $uw = \{uw_1, uw_2, \dots, uw_n\}$ be weight for UZ_j , $uw_j \in [0, 1], \sum_{j=1}^n uw_j = 1$. And

$$UQ = (UQ_{ij})_{m \times n} = \left\{ \begin{array}{l} \left([UT_{ij}^L, UT_{ij}^R], [UI_{ij}^L, UI_{ij}^R] \right), \\ \left([UF_{ij}^L, UF_{ij}^R] \right) \\ (UT_{ij}, UI_{ij}, UF_{ij}) \end{array} \right\}_{m \times n}$$

$$NUQ_{ij} = \left\{ \begin{array}{l} \left([UT_{ij}^{NL}, UT_{ij}^{NR}], [UI_{ij}^{NL}, UI_{ij}^{NR}], [UF_{ij}^{NL}, UF_{ij}^{NR}] \right), \\ (UT_{ij}^N, UI_{ij}^N, UF_{ij}^N) \end{array} \right\}$$

$$= \left\{ \begin{array}{l} \left([UT_{ij}^L, UT_{ij}^R], [UI_{ij}^L, UI_{ij}^R], [UF_{ij}^L, UF_{ij}^R] \right), \\ (UT_{ij}, UI_{ij}, UF_{ij}) \end{array} \right\}, \text{ } UZ_j \text{ is benefit criterion} \quad (11)$$

$$= \left\{ \begin{array}{l} \left([UF_{ij}^L, UF_{ij}^R], [1 - UI_{ij}^R, 1 - UI_{ij}^L], [UT_{ij}^L, UT_{ij}^R] \right), \\ (UF_{ij}, 1 - UI_{ij}, UT_{ij}) \end{array} \right\}, \text{ } UZ_j \text{ is cost criterion}$$

$$NCNCCN_{jt} = \frac{\left(\sum_{i=1}^m (NCNSV(NUQ_{ij}) - NCNSV(NUQ_{it})) \right)}{\left(\sqrt{\sum_{i=1}^m (NCNSV(NUQ_{ij}) - NCNSV(NUQ_{jt}))^2} \right) \times \left(\sqrt{\sum_{i=1}^m (NCNSV(NUQ_{it}) - NCNSV(NUQ_{jt}))^2} \right)}$$

$j, t = 1, 2, \dots, n, (12)$

where

$$NCNSV(NUQ_j) = \frac{1}{m} \sum_{i=1}^m NCNSV(NUQ_{ij})$$

$$NCNSV(NUQ_t) = \frac{1}{m} \sum_{i=1}^m NCNSV(NUQ_{it})$$

2) Illustrate the NCN standard deviation numbers (NCNSDN).

is the NCN-matrix. Subsequently, NCN-TOPSIS method is illustrated for MADM.

Step 1. Normalize the $UQ = (UQ_{ij})_{m \times n}$ to $NUQ = [NUQ_{ij}]_{m \times n}$.

Step 2. Illustrate the weight through CRITIC technique.

The CRITIC [45] is illustrated for the weights.

1) The NCN correlation coefficient numbers (NCNCCN) are illustrated.

$$NCNSDN_j = \sqrt{\frac{1}{m-1} \sum_{i=1}^m (NCNSV(NUQ_{ij}) - NCNSV(NUQ_j))^2}$$

(13)

where $NCNSV(NUQ_j) = \frac{1}{m} \sum_{i=1}^m NCNSV(NUQ_{ij})$.

3) Illustrate the weight information.

$$uw_j = \frac{NCNSDN_j \sum_{t=1}^n (1 - NCNCCN_{jt})}{\sum_{j=1}^n \left(NCNSDN_j \sum_{t=1}^n (1 - NCNCCN_{jt}) \right)}$$

(14)

where $uw_j \in [0, 1], \sum_{j=1}^n uw_j = 1$.

Step 3. Illustrate the NCN positive ideal solution (NCNPIS) and NCN negative ideal solution (NCNNIS):

$$NCNPIS = \{NCNPIS_j\}, j = 1, 2, \dots, n. \quad (15)$$

$$NCNNIS = \{NCNNIS_j\}, j = 1, 2, \dots, n. \quad (16)$$

$$NCNPIS_j = \left\{ \left(\left[UT_j^{NL+}, UT_{ij}^{NR+} \right], \left[UI_j^{NL+}, UI_j^{NR+} \right], \right), \left(\left[UF_j^{NL+}, UF_j^{NR+} \right], \left(UT_j^{N+}, UI_j^{N+}, UF_j^{N+} \right) \right) \right\} \quad (17)$$

$$NCNNIS_j = \left\{ \left(\left[UT_j^{NL-}, UT_{ij}^{NR-} \right], \left[UI_j^{NL-}, UI_j^{NR-} \right], \right), \left(\left[UF_j^{NL-}, UF_j^{NR-} \right], \left(UT_j^{N-}, UI_j^{N-}, UF_j^{N-} \right) \right) \right\} \quad (18)$$

$$NCNPIS_j = \max_j NCNSV \left\{ \left(\left[UT_{ij}^{NL}, UT_{ij}^{NR} \right], \left[UI_{ij}^{NL}, UI_{ij}^{NR} \right], \right), \left(\left[UF_{ij}^{NL}, UF_{ij}^{NR} \right], \left(UT_{ij}^N, UI_{ij}^N, UF_{ij}^N \right) \right) \right\} \quad (19)$$

$$NCNNIS_j = \min_j NCNSV \left\{ \left(\left[UT_{ij}^{NL}, UT_{ij}^{NR} \right], \left[UI_{ij}^{NL}, UI_{ij}^{NR} \right], \right), \left(\left[UF_{ij}^{NL}, UF_{ij}^{NR} \right], \left(UT_{ij}^N, UI_{ij}^N, UF_{ij}^N \right) \right) \right\} \quad (20)$$

Step 4. Illustrate the distances from NCNPIS and NCNNIS:

Step 5. Illustrate the NCN correlation coefficient (NCNCC) from NCNNIS:

$$NCNCC(UY_i) = \frac{NCNNISED(UY_i)}{NCNPISED(UY_i) + NCNNISED(UY_i)} \quad (23)$$

Step 6. In light with $NCNCC(UY_i)$. The highest $NCNCC(UY_i)$ is the optimal alternative.

$$NCNPISED(UY_i) = \sum_{j=1}^n uw_j NCNED(NUQ_{ij}, NCNPIS_j) = \sum_{j=1}^n uw_j \sqrt{\frac{1}{9} \left(\left| UT_{ij}^{NL} - UT_j^{NL+} \right|^2 + \left| UT_{ij}^{NR} - UT_{ij}^{NR+} \right|^2 + \left| UI_{ij}^{NL} - UI_j^{NL+} \right|^2 + \left| UI_{ij}^{NR} - UI_j^{NR+} \right|^2 + \left| UF_{ij}^{NL} - UF_j^{NL+} \right|^2 + \left| UF_{ij}^{NR} - UF_j^{NR+} \right|^2 + \left| UT_{ij} - UT_j^+ \right|^2 + \left| UI_{ij} - UI_j^+ \right|^2 + \left| UF_{ij} - UF_j^+ \right|^2 \right)} \quad (21)$$

$$NCNNISED(UY_i) = \sum_{j=1}^n uw_j NCNED(NUQ_{ij}, NCNNIS_j) = \sum_{j=1}^n uw_j \sqrt{\frac{1}{9} \left(\left| UT_{ij}^{NL} - UT_j^{NL-} \right|^2 + \left| UT_{ij}^{NR} - UT_{ij}^{NR-} \right|^2 + \left| UI_{ij}^{NL} - UI_j^{NL-} \right|^2 + \left| UI_{ij}^{NR} - UI_j^{NR-} \right|^2 + \left| UF_{ij}^{NL} - UF_j^{NL-} \right|^2 + \left| UF_{ij}^{NR} - UF_j^{NR-} \right|^2 + \left| UT_{ij} - UT_j^- \right|^2 + \left| UI_{ij} - UI_j^- \right|^2 + \left| UF_{ij} - UF_j^- \right|^2 \right)} \quad (22)$$

IV. NUMERICAL EXAMPLE AND COMPARATIVE ANALYSIS

A. Numerical Example

Music for film and television, as an essential component of audiovisual works, not only adds emotional tones to the visuals, but also plays a crucial role in narrative, atmosphere creation, and audience emotional experiences. Through elements such as melody, rhythm, and timbre, it can interact with the visuals to jointly construct the unique atmosphere and emotional tonality

of a work. In recent years, with the continuous advancement of technology and creative concepts, contemporary music composition for film and television has exhibited a trend towards diversification. The diversity of musical styles, the integration of music and visuals, as well as the innovation of technical means have all injected new vitality into music for film and television. In audiovisual works, the close integration of music and narrative often deepens the audience's emotional resonance. For example, in tense and exciting storylines, stirring music can enhance the creation of a tense atmosphere,

making the audience feel more immersed; while in sad or sentimental scenes, gentle music can touch the audience's hearts and strengthen emotional resonance. This mutual reflection between music and narrative not only enriches the artistic expressiveness of the film, but also allows the audience to gain a deeper emotional experience during the viewing process. Therefore, the diversification trend of music composition for film and television is of great significance for improving the artistic quality and audience satisfaction of audiovisual works. The compatibility between musical styles and the themes of audiovisual works is not only about the conveyance of emotions, but also the resonance of cultures. For example, in some films with historical backgrounds or regional characteristics, the use of representative ethnic music or folk songs can not only create a unique cultural atmosphere, but also allow the audience to feel the charm and depth of the culture through the melodies. This combination of music and culture enables audiovisual works to convey not only emotions, but also cultural values and historical memories, thereby enriching the connotation and depth of the film. Therefore, the choice of musical styles plays a crucial role in audiovisual creation and is one of the key factors determining the success of a film. The music composition effectiveness evaluation of film and television is viewed as the MAGDM. Five potential film and television music $UY_i (i = 1, 2, 3, 4, 5)$ are assessed with four attributes: ① UZ_1 is establishment of correct labor values;

② UZ_2 is cultivation of noble labor morality; ③ UZ_3 is Acquisition of comprehensive labor knowledge and skills; ④ UZ_4 is Cultivation of good working habits. Evidently, all attributes are beneficial attribute. NCN-TOPSIS procedure is illustrated for music composition effectiveness evaluation of film and television.

Step 1. Illustrate the NCN-matrix $QQ = (qq_{ij})_{5 \times 4}$ (Table I).

Step 2. The NCN-matrix does not require normalization as all its attributes are advantageous.

Step 3. Illustrate the weights with CRITIC (Table II).

Step 4. Illustrate the NCNPIS and NCNNIS (see Table III).

Step 5. Illustrate the $NCNPISED(UY_i)$ and $NCNNISED(UY_i)$ (see Table IV):

Step 6. Illustrate the $NCNCC(UY_i)$ (see Table V).

Step 7. In light with $NCNCC(UY_i)$, the order is: $UY_5 > UY_2 > UY_4 > UY_3 > UY_1$ and UY_5 is the best one.

UY ₄	0.5238	3
UY ₅	0.6971	1

B. Comparative Analysis

The NCN-TOPSIS approach is compared with NCNWAA approach and NCNWGA approach [46], NC-
VIKOR approach [47], NCN-GRA approach[48].
Eventually, the final results are depicted in Table VI.

Derived from the results presented in Table VI, it is evident that the obtained best choice is UY_5 , while the worst alternative is UY_1 . In other words, the rankings produced by the different decision-making methods are slightly different. This observation suggests that the various approaches could

effectively tackle the MADM from different perspectives. The NCN-TOPSIS approach, in particular, is a commonly used comprehensive evaluation approach that can make full use of the information contained in the original data. The results generated by the NCN-TOPSIS method can accurately reflect the relative performance gap between the evaluated alternatives. This is a key advantage of NCN-TOPSIS approach, as it provides DMs with a more nuanced and informative understanding of the alternatives under consideration. The slightly different rankings produced by the various methods highlight the importance of employing multiple decision-making techniques in complex, multi-criteria decision problems.

TABLE VI. ORDER FOR DIFFERENT APPROACHES

Approaches	Order
NCNWAA approach [46]	$UY_5 > UY_2 > UY_4 > UY_3 > UY_1$
NCNWGA approach [46]	$UY_5 > UY_2 > UY_4 > UY_3 > UY_1$
NC-VIKOR approach [47]	$UY_5 > UY_2 > UY_3 > UY_4 > UY_1$
NCN-GRA approach [48]	$UY_5 > UY_2 > UY_4 > UY_3 > UY_1$
The proposed NCN-TOPSIS approach	$UY_5 > UY_2 > UY_4 > UY_3 > UY_1$

V. CONCLUSION

The trend towards diversification in film and television music creation has had a profound impact on the artistic expressiveness of audiovisual works. With the integration and innovation of musical styles, film and television music is no longer limited to traditional background music or emotional scoring, but has become an important component of audiovisual works. The diversified musical styles provide richer means of emotional expression and atmosphere creation for audiovisual works, making the works more layered and deeper in terms of emotion, rhythm, and ambiance. This organic integration of music and visuals not only enhances the artistic appeal of the audiovisual works, but also improves the audience's viewing experience. The music composition effectiveness evaluation of film and television is MADM. In this work, the NCN-TOPSIS approach is devised for MADM, building upon the TOPSIS technique. The weight numbers of the attributes are determined using the CRITIC technique, ensuring an objective and systematic approach to assigning importance to the decision criteria. Furthermore, a novel NCN-TOPSIS method is developed for the context of MADM, and the detailed computational steps are provided. To demonstrate the efficacy of the proposed approach, an empirical example focused on the music composition effectiveness evaluation in the film and television industry is presented. This example showcases the superiority of the NCN-TOPSIS method in addressing complex, multi-criteria decision problems. The major contributions of this research are summarized: (1) The CRITIC method is utilized to objectively determine the weights of the attributes; (2) The NCN-TOPSIS method is developed within the framework of NCSs, extending the TOPSIS technique to this more generalized decision-making environment; (3) A numerical example on the music composition effectiveness evaluation in the film and television industry is provided, and

comparative analyses are conducted to highlight the advantages of NCN-TOPSIS approach. By integrating the CRITIC method, developing the NCN-TOPSIS technique, and demonstrating its application in a real-world decision-making scenario, this research contributes to the advancement of MADM and MAGDM methodologies, offering DMs a robust and effective tool for addressing complex problems.

Heuristic Intelligent Algorithm-Based Approach for In-Depth Development and Application Analysis of Micro- and Nanoembedded Systems

Buzhong Liu

School of Electronic Engineering, Jiangsu Vocational College of Electronics and Information, Huai'an 223003, Jiangsu, China

Abstract—Developing application analysis and testing methods is an important part of the in-depth development of micro-nano embedded systems under complex integrated architectures. Therefore, the research on application analysis and testing models is of great significance for the in-depth development and efficient design of embedded systems. In order to fully explore the effective information of test analysis data in the in-depth development of micro-nano embedded systems under complex integrated architectures and improve the analysis and prediction accuracy of test analysis models, a development test analysis model based on the photon search algorithm and LightGBM is proposed. First, the development process of micro-nano embedded systems under complex integrated architectures is analysed, and a system analysis architecture is designed to propose test analysis factors. Second, a development test analysis model is established by combining the photon search algorithm and LightGBM. Subsequently, the feasibility and efficiency of the model are proposed by analysing the data of the development process. The analysis of data examples shows that the LightGBM test analysis model has high analysis and prediction accuracy and generalisation performance.

Keywords—Photon search algorithm; deep development of micro- and nanoembedded systems; application test and analysis methodology; LightGBM

I. INTRODUCTION

With the continuous development of microelectronics technology, the application of micro-nano embedded systems in various industries is becoming more and more widespread, especially in the fields of Internet of Things, intelligent sensing, healthcare, and communication technology [1]. With the increased complexity and computational volume of micro-nano embedded system applications, the development of micro-nano embedded systems is becoming more and more difficult, which leads to an increased probability of security risks in the iterative updating of development and application work [2]. At the same time, the micro-nano embedded system application function diversification makes the micro-nano embedded system development workers in-depth design and development, which leads to the micro-nano embedded system test and evaluation index feature dimension increase, the traditional test algorithm cannot build complex model relationship [3]. In order to alleviate the problems of insufficient testing means and insufficient accuracy, the system design-oriented development application test and analysis model intelligence has become a development trend [4]. Therefore, the study of constructing an efficient development and application test analysis model has

received more and more attention from experts and scholars, which is of great significance for the development of micro and nano embedded systems to solve the problem in reality.

The deep development and application analysis intelligence of micro and nano embedded systems under complex integrated architecture improves the design efficiency in two main aspects, i.e., deep intelligent development of system and intelligent testing of application analysis [5]. System deep intelligent development requires high fidelity mathematical models and also high precision model generation methods [6]. Micro-nano embedded system development application analysis intelligent testing is an important part of the development and design process, generally using test analysis algorithms to simulate the system development and testing process [7]. Currently, test analysis algorithms include hierarchical analysis method [8], expert system method [9], neural network method [10], integrated learning method [11], deep learning method [12] and so on. Since the process of in-depth development of micro-nano embedded systems under complex integration-oriented architecture is a complex process with high dimensionality of relevant data parameters, current test analysis algorithms are unable to construct accurate test results, and the real-time nature of test analysis is unable to meet the demand [6-13]. In addition, test analysis algorithms in the complex integration architecture of micro-nano embedded systems in the depth of the development process is relatively small, in order to improve the design efficiency, need to design targeted test analysis algorithms [6-14]. In this paper, the initial choice of integrated learning algorithm is taken to construct the test analysis algorithm, but the integrated learning algorithm is easy to fall into the local optimum in the learning training in the problem of high dimensionality and complex process, therefore, the debugging optimization of the designed test analysis algorithm is needed [15].

In view of the above problems, this paper proposes a development test analysis algorithm based on intelligent optimization algorithm and integrated learning technology around the deep development process of micro-nano embedded system under complex integration architecture. For the development and test analysis problem, the mechanism of the deep development process of micro-nano embedded system under the complex integration architecture is analyzed, and the relevant test and analysis parameters are extracted; for the development and test analysis model construction problem, the hyperparameters of lightweight gradient lifter are optimized by combining with photon search algorithm, and the development

and test analysis model based on photon search algorithm to improve lightweight gradient lifter is put forward; and the development and test analysis method put forward has high analysis and prediction accuracy and generalization performance through the application of examples. The proposed development test analysis method has high analysis and prediction accuracy and generalization performance, which provides a new method for the in-depth development process testing of micro-nano embedded systems under the complex integration architecture.

II. IN-DEPTH DEVELOPMENT OF MICRO- AND NANO-EMBEDDED SYSTEMS FOR COMPLEX INTEGRATED ARCHITECTURES

A. System Architecture

1) *Micro-nano embedded system*: Micro-nano embedded systems are embedded systems that integrate microelectromechanical systems and nanotechnology. These systems usually contain micromechanical devices, sensors, actuators, and electronic circuits, which can vary in size from the micron to the nanometer level [16], as shown in Fig. 1.

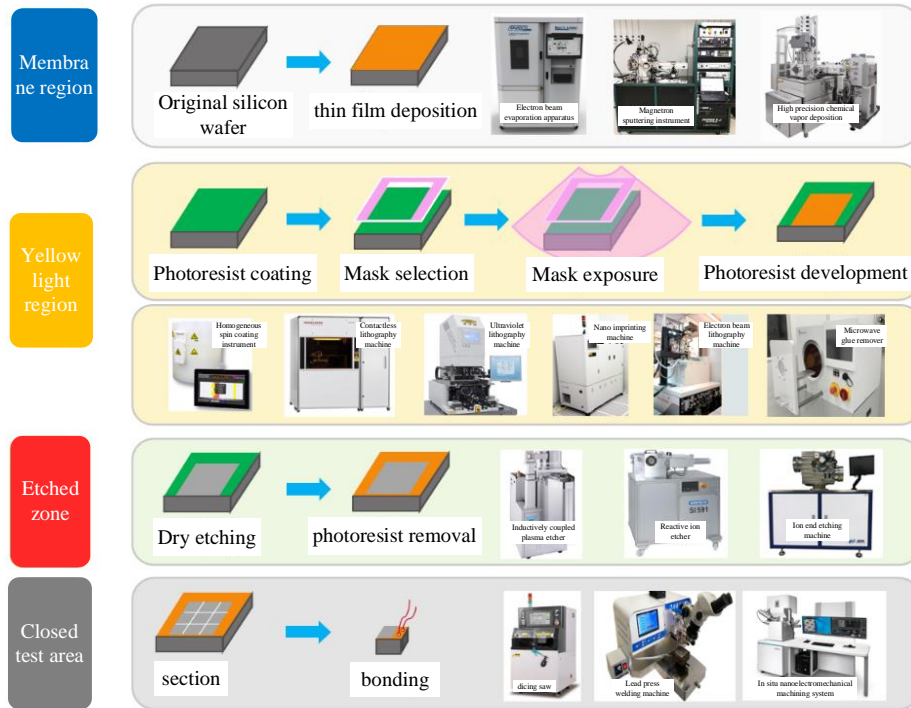

Fig. 1. Schematic diagram of a micro-nano embedded system.

Micro-nano embedded systems have the following characteristics (as shown in Fig. 2): 1) miniaturization; 2) low power consumption; 3) high performance; 4) multifunctionality; 5) integration; 6) intelligence; 7) formulatability; 8) real-time; 9) reliability; and 10) ease of portability [17]. Micro-nano embedded systems have a wide range of applications in several fields due to the above advantageous features, including smartphones, wearable devices, Internet of Things, healthcare, energy and environmental protection, national security and defense, etc. [18], as shown in Fig. 3.

Fig. 3. Micro-Nano embedded system application.

2) *In-depth development process of micro- and nano-embedded systems*: The in-depth development of micro- and nano-embedded systems is a complex process involving close collaboration between hardware and software [19], and the key steps of the process (see Fig. 4) are as follows:

- Requirements analysis. Before development, it is necessary to carefully analyze and clarify the requirements of the micro-nano embedded system, including functional requirements, performance indicators,
- System design. Based on the hardware platforms, software architecture and so on. results of the micro- and nano-embedded system requirements analysis, system

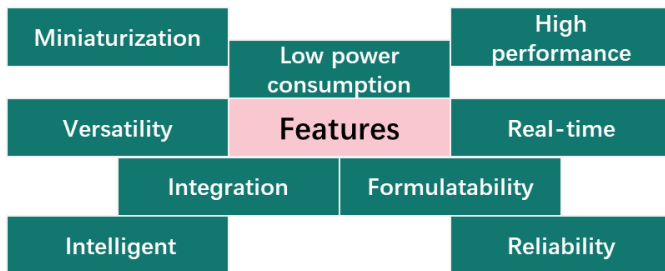

Fig. 2. Characteristics of micro-nano embedded systems.

design is carried out to select the appropriate hardware platform and software architecture, define the modules and interfaces of the system, as well as to develop the system testing and validation plan.

- Hardware design. Select and configure the processor, memory, sensors, communication interfaces, etc.
- Software development. Realize the function and control logic of the system, i.e., write the underlying driver, customization of the operating system, implementation of algorithms, etc.
- Integration and Testing. Integrate hardware and software components into a complete system for system-level functional and performance testing.
- Optimization and debugging. Optimize and debug the system to ensure that it meets the performance requirements and has good stability and reliability.
- Deployment and Maintenance. Complete the deployment of the developed embedded system to the target device or system and perform maintenance and support.

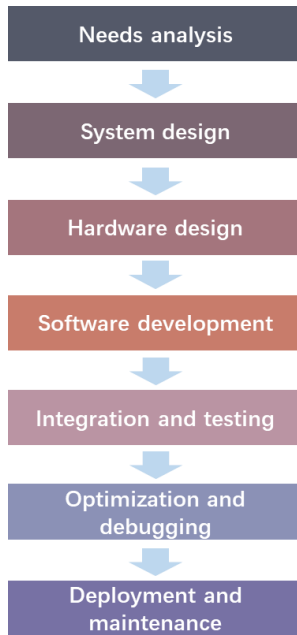

Fig. 4. Development process of micro-nano embedded system.

3) *Framework of test and analysis system for in-depth development of micro- and nano-embedded systems:* In the process of deep development of micro-nano embedded system, the integration test of hardware and software as well as optimization debugging as an important part of the system development can help designers to find and solve the potential problems and defects of micro-nano embedded system [19]. In order to help developers of micro-nano embedded system design management, improve the efficiency of micro-nano embedded system in-depth development, and increase the prediction accuracy of development test analysis, this paper

combines intelligent optimization algorithms and integrated learning algorithms to study the optimization model of micro-nano embedded system in-depth development test, and therefore designs an intelligent test analysis framework for the in-depth development of micro-nano embedded system based on intelligent optimization algorithms to improve the integrated learning technology (see Fig. 5).

Fig. 5. Intelligent test and analysis framework for the development of micro and nano embedded systems.

B. Key Technical Content

According to the analysis framework, the research on intelligent test analysis method for deep development of micro-nano embedded system based on intelligent optimization algorithm to improve the integrated learning technology mainly includes four parts, including system development process analysis, system test analysis factor extraction, system test analysis data processing, and system development and test analysis model construction, as shown in Fig. 6.

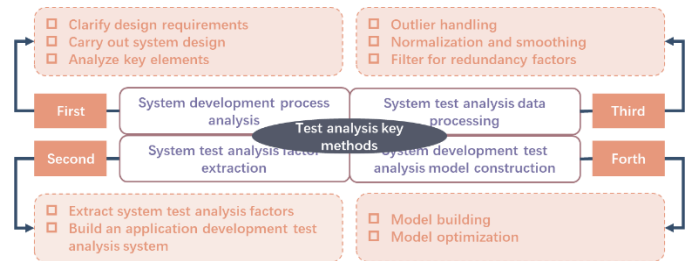

Fig. 6. Key technologies for intelligent test and analysis of micro and nano embedded system development.

1) *Analysis of the system development process:* The system development process analysis is mainly to clarify the micro-nano embedded system design requirements, carry out the system design, and analyze the key elements of the in-depth development process of micro-nano embedded system.

2) *Extraction of factors for systematic test analysis:* According to the principles of systemic, holistic, and process, the system test analysis factors are extracted from the key elements of the in-depth development process of micro- and nanoembedded systems, and the application development test analysis system is constructed.

3) *System test and analysis data processing:* Extract the system test analysis factor data from the test data, and then annotated to construct the data set, for the abnormal values and outliers, the use of proximity to take the value of the correction data, for the vacant value of the random forest model to fill in the prediction method, and after that the data normalization and smoothing, through the Pearson correlation coefficient method of filtering the redundant factors, to get the input data matrix, as shown in Fig. 7.

Fig. 7. Data processing.

4) *System development test analysis model construction:* Taking the labeled data matrix as input and the test analysis values as output, the lightweight gradient boosting machine is used to construct a test analysis model for the development of micro-nano embedded systems; at the same time, the photon search algorithm is used to optimize the test analysis model for the development of micro-nano embedded systems based on the lightweight gradient boosting machine algorithm, and the specific constructive optimization paradigm is shown in Fig. 8.

Fig. 8. Optimization paradigm for building test and analysis models for development of micro and nano embedded systems.

III. APPLICATION ANALYSIS MODELING AND OPTIMIZATION FOR MICRO-NANO EMBEDDED SYSTEM DEVELOPMENT

A. LightGBM Algorithm

Lightweight Gradient Boosting Machine (LightGBM) [20] is a gradient boosting tree-based boosting method in integrated learning, which was proposed by Microsoft in 2017, and is currently one of the best-performing boosting methods. While the traditional GBDT method greatly increases the computational complexity and memory usage of the model when the amount of sample data and features grows, LightGBM accelerates the model training speed without affecting the model accuracy [21].

In order to reduce the amount of training data, LightGBM adopts the gradient one-sided sampling algorithm, which gives different sampling weights to the data according to the gradient values, retains the data with large gradients (i.e., not yet trained, which contributes more to the improvement of the information gain), and randomly samples the data with small gradients and maintains the original distribution of the data, as shown in Fig. 9. This sampling method results in more accurate information gain compared to uniform random sampling. In order to reduce the sample features during training, LightGBM uses an independent feature merging algorithm to bind mutually exclusive features (several features that are not zero at the same time, e.g., unique heat coding) from high-dimensional features together to form a single feature, thus reducing the feature dimension and improving the training speed without affecting the accuracy.

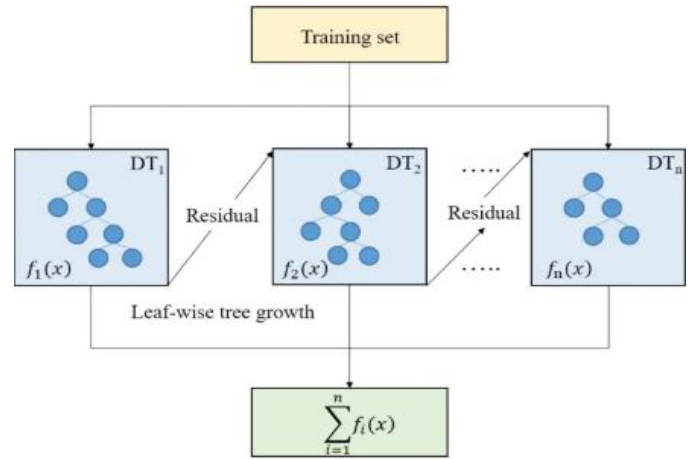

Fig. 9. Structure of LightGBM algorithm.

The LightGBM initial model objective function consists of a loss function with regularization:

$$O_{bj} \approx \sum_{i=1}^I Loss(y_i, \hat{y}_i) + \sum_{t=1}^T \Omega(f_t) \quad (1)$$

where, O_{bj} denotes the objective function, $Loss$ is the loss function, $\Omega(f_t)$ is the regularization term, I is the tree depth, y_i is the true value, \hat{y}_i is the predicted value, T is the number of cotyledons, and f_t is the t th generation prediction function.

A second-order Taylor expansion is performed on the objective function determined from the t th generation prediction results:

$$O_{bj} \approx \sum_{i=1}^n \left[Loss(y_i, \hat{y}_i^{t-1}) + g_i f_i(x_i) + \frac{1}{2} h_i f_i^2(x_i) \right] + \gamma T + \frac{1}{2} \lambda \sum_{j=1}^T w_j^2 \quad (2)$$

where, $f_t(x_i)$ denotes the new prediction function when the model is iterated, g_i is the first-order derivative of $Loss$, h_i is the second-order derivative of $Loss$, γ is the new node complexity cost parameter, and w_j is the leaf node value, λ indicates the leaf node value coefficient.

Accumulate the first-order and second-order gradients, and then make the first-order derivative of the objective function with respect to w_j is 0, i.e., take the extreme point:

$$O'_{bj} \approx -\frac{1}{2} \sum_{j=1}^T \frac{G_j^2}{H_j + \lambda} + \gamma T \quad (3)$$

where, G_j denotes the first order gradient accumulation value and H_j denotes the second order gradient accumulation

value, λ denotes the complexity cost parameter of the new node.

The optimal tree is the one that minimizes the value of the objective function among the different arrangement structures. Use the splitting gain formula G_{ain} to evaluate whether to split leaf nodes or not. If $G_{ain} > 0$, continue splitting to improve the model performance, otherwise stop splitting. After repeated iterations, the LightGBM strong learner algorithm model is finally obtained.

LightGBM has the following features (Fig. 10): 1) histogram-based decision-making algorithm (Fig. 11) improves computational speed and reduces memory usage; 2) adopts a leaf growth strategy, which helps to improve model accuracy; 3) one-sided gradient sampling accelerates learning and reduces computational complexity; 4) mutual exclusion feature bundling reduces the number of features and improves computational efficiency; 5) supports parallel and distributed learning; 6) Cache optimization accelerates the data exchange speed; 7) Supports a variety of loss functions to meet different business needs; 8) Regularization and pruning strategies control the model complexity and prevent overfitting; 9) The algorithm has good model interpretability [22].

Fig. 10. Characteristics of LightGBM algorithm.

Fig. 11. Histogram based decision making algorithm.

LightGBM is widely used in binary classification, multiclassification, and sorting scenarios, for example, in personalized product recommendation, risk management, and market analysis. It can handle a large number of features and samples and is suitable for industrial-grade data analysis and complex machine learning tasks [23].

B. Photon Search Algorithm

Photon Search Algorithm (PSA) [24] is a heuristic algorithm based on physical phenomena proposed in 2019. The theoretical basis of the algorithm is derived from the photon hypothesis and

quantum theory proposed by physicists Max Planck, Einstein and Broglie. The photon search algorithm has been studied for its strong global exploration ability and high search efficiency, but it underperforms in local exploitation ability and has low convergence accuracy.

1) *Optimization principle:* The working principle of the photon search algorithm involves the initialization of the photon's motion, the observation behavior and the search exclusion principle. In the algorithm, the position of the photon is updated taking into account the distance to the global best fitness value photon and the distance passed by the photon in the iteration. In addition, the algorithm designs the observation behavior to model the quantum uncertainty principle and the search exclusion principle based on the bubbleley incompatibility principle to avoid photons occupying the same position [25].

In the PSA algorithm, each photon represents a search agent that aims at the optimal solution, obtains a fixed speed, goes through iterations, and outputs the optimal solution.

The specific optimization strategies are as follows:

a) Photon motion

Define photonic individual:

$$X_i = (x_i^1, \dots, x_i^d, \dots, x_i^n), i = 1, 2, \dots, N \quad (4)$$

where X_i denotes the i th photon, and x_i^d denotes the d th dimension of photon i .

The mathematical model of photon optimized motion is as follows:

$$x_i^d(t+1) = x_i^d(t) + De \cdot v_i^d(t+1) \quad (5)$$

$$v_i^d(t+1) = \frac{R_{Len}}{R_{ig}} (x_g^d(t) - x_i^d(t)) \quad (6)$$

$$R_{Len} = Scl \cdot \|X_{upper} - X_{lower}\|_2 \quad (7)$$

$$R_{ig} = \|X_i(t), X_g(t)\|_2 \quad (8)$$

$$De = \frac{ext}{t} \quad (9)$$

where, $x_i^d(t)$ denotes the d -dimensional position information of the i th photon in the t th iteration, $v_i^d(t+1)$ denotes the velocity information of the i th photon in the d -dimension in the $t+1$ th iteration, De is the convergence weight, which is used to adjust the convergence speed in the search process, R_{Len} denotes the distance passed by the photon in the photon iteration, R_{ig} denotes the Euclidean distance between

the i th photon and the current optimal photon, $x_g^d(t)$ is the d -dimensional position information of the optimal photon in the t th iteration, ScI denotes the value of the weight, and ext is the convergence coefficient.

b) *Observation of behavior*: In order to simulate the photon uncertainty principle, the observation behavior is designed to calculate the photon position:

$$x_i^d(t) = x_i^d(t) + De \cdot randA \quad (10)$$

Where $randA$ denotes a random number between -1 and 1.

c) *Search exclusion principle*: In the PSA algorithm, based on the principle of bubbly incompatibility, the search exclusion principle behavior is used to update the photon individual positions as follows:

$$x_i^d = x_{low}^d + (x_{up}^d - x_{low}^d) \cdot randB \quad (11)$$

where x_{low}^d and x_{up}^d denote the lower and upper bound ranges of the d th dimension, respectively, and $randB$ denotes a random number between 0 and 1.

2) *Process steps*: According to the above PSA algorithm behavior description, the PSA algorithm flow is shown in Fig. 12 with the following steps:

- Step 1: Initialize the position of the photon X_i ;
- Step 2: Calculate the photon fitness value and calculate the distance passed in the photon iteration R_{Len} ;
- Step 3: Update R_{ig} , the velocity and position of the photon, and update the photon using the observation behavior;
- Step 4: Calculate the photon fitness value and update the global optimal photon;
- Step 5: If $t < Max_T$, return to step 3, otherwise go to step 6;
- Step 6: The algorithm terminates and outputs the optimal solution.

C. PSA-LightGBM Model Application

1) *PSA-LightGBM*: In this paper, we use real number coding to encode the number of cotyledons, tree depth, learning rate and minimum data number of LightGBM algorithm, and the dimensions of photon individuals are 4-dimensional, as shown in Fig. 13. Each photon individual includes the dimensions of the number of cotyledons L, the tree depth D, the learning rate I and the minimum data number S.

Analyzing the application analysis problem of integrated development of micro and nano embedded systems, the problem can be considered as a predictive regression problem, so, RMSE is used as the fitness value in the PSA-LightGBM model.

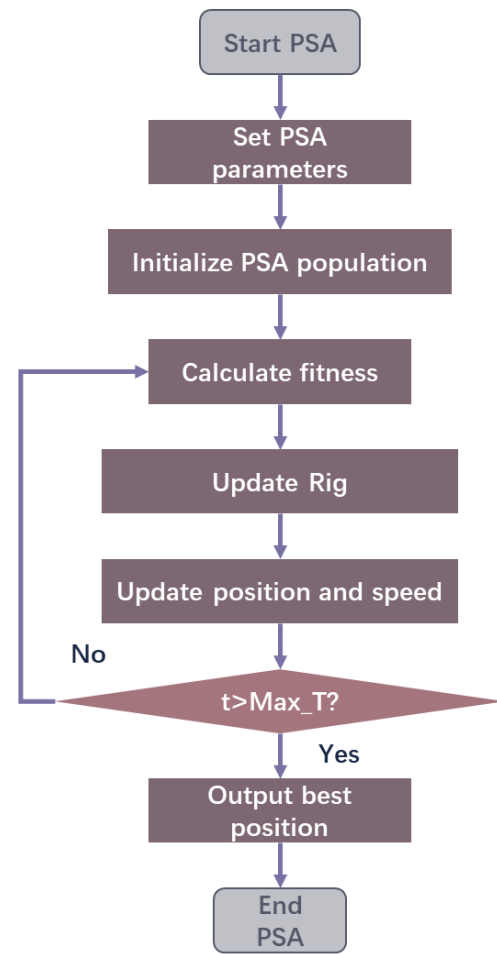

Fig. 12. Flowchart of PSA algorithm.

Fig. 13. PSA-LightGBM algorithm coding method.

According to the coding method and the fitness function, the steps of LightGBM application analysis method based on PSA algorithm (shown in Fig. 14) are as follows: 1) take the number of cotyledons L, the tree depth D, the learning rate I and the minimum number of data S as the optimization objects in the LightGBM model; 2) set the optimization parameter range of the PSA algorithm, the size of the population, and the maximum number of iterations, and initialize the population of the PSA algorithm ; 3) Calculate the fitness value based on RMSE; 4) Update the photon individual positions and velocities based on LightGBM parameters, and output the optimal parameter set to LightGBM; 5) Establish the PSA-LightGBM model based on the optimal parameter combination.

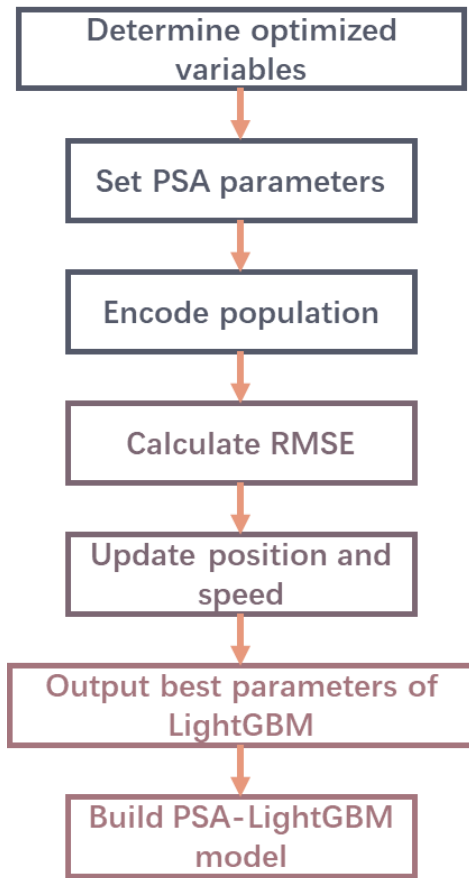

Fig. 14. PSA-LightGBM.

2) *Algorithm application*: In order to construct an application analysis model for the development of micro-nano embedded systems, this paper applies the PSA-LightGBM model to the in-depth development problem of micro-nano embedded systems under the complex integration architecture, and the specific application flow is shown in Fig. 15. The application of PSA-LightGBM algorithm in the in-depth development problem of micro-nano embedded systems under the complex integration architecture is divided into the following flow:

a) Analyze the problem of in-depth development of micro-nano embedded system under complex integrated architecture, extract the analytical characteristic parameters of micro-nano embedded system development and application, and establish the analytical characteristic parameter set;

b) Collect data related to analytical features during the in-depth development of micro-nano embedded systems in complex integrated architectures and use appropriate data processing techniques to obtain normalized dimensionality-reduced datasets;

c) Combine PSA-LightGBM algorithm to construct the mapping relationship between the development application analysis feature parameter values and the development application analysis scores, the specific PSA-LightGBM algorithm application analysis schematic is shown in Fig. 16.

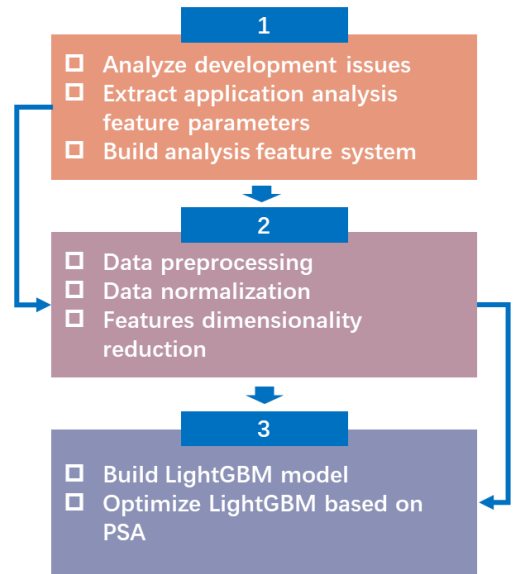

Fig. 15. Application flow of PSA-LightGBM algorithm.

IV. SIMULATION AND ANALYSIS

A. Environmental Settings

This paper uses data from the in-depth development of micro-nano embedded systems under a complex integrated architecture. A total of 3530 data sets are used, with 80% of the data used as the training set for the application analysis model, 10% of the data used as the validation set during the optimisation process, and 10% of the data set used as the test set.

Software environment: programming environment Python 3.8, visualisation software Matlab 2022a, operating system Wins10.

The comparison algorithms include LightGBM, GWO-LightGBM, HHO-LightGBM, TLBO-LightGBM and PSA-LightGBM. The population size of the GWO, HHO, TLBO and PSA algorithms is set to 50, and the maximum number of iterations is 1000 and other parameter settings are shown in Table I.

TABLE I. APPLICATION DEVELOPMENT ANALYSIS MODEL PARAMETER SETTINGS

No.	Algorithms	Settings
1	LightGBM	L=30, I=0.1, S=20
2	GWO- LightGBM	a=[-2,2]
3	HHO-LightGBM	E ₀ =2
4	TLBO-LightGBM	Teaching factor=1.2
5	PSA-LightGBM	No

The range of GWO, HHO, TLBO, and PSA algorithms to optimize the LightGBM parameters number of cotyledons L, tree depth D, and learning rate l with minimum number of data S is shown in Table II.

TABLE II. OPTIMIZED PARAMETER RANGE SETTING

No.	Hyperparameters	Var.	Range
1	The number of cotyledons	L	[20,100]
2	The depth of the tree	D	[3,8]
3	The learning rate	L	[0.01, 0.3]
4	Minimum number of data	S	[1,30]

B. Analysis of Results

In order to further improve the performance of the analytical model for the development and application of micro- and nanoembedded systems, the PSA algorithm is used to find the optimal set of parameters by taking the number of cotyledons L, the depth of the tree D, and the learning rate l with the minimum number of data S as optimization parameters in the LightGBM model. In order to verify the validity set of PSA algorithm's excellent computational efficiency, GWO, HHO and TLBO are compared, and the change curve of each algorithm's adaptability is shown in Fig. 17 (a)-(d). From Fig. 17, it can be seen that the RMSE value of the PSA-LightGBM-based application analysis for the development of micro- and nanoembedded systems converges to the minimum value, and the GWO-LightGBM algorithm has the largest RMSE value, and PSA-LightGBM is better than the other algorithms.

(a) GWO-LightGBM

(b) HHO-LightGBM

(c) TLBO-LightGBM

(d) PSA-LightGBM

Fig. 17. Comparison of the adaptation curves of the algorithms.

The hyperparameter optimization results of LightGBM model based on GWO, HHO, TLBO, and PSA algorithms are shown in Table III. From Table III, it can be seen that the optimal combination of parameters for PSA optimized LightGBM are: the number of mesocotyledons L=65, the tree depth D=5, the learning rate l=0.09 with the minimum number of data S=22.

TABLE III. RESULTS OF OPTIMIZING LIGHTGBM MODEL PARAMETERS BY EACH ALGORITHM

No.	Parameters	GWO	HHO	TLBO	PSA
1	The number of cotyledons	21	29	58	65
2	The depth of the tree	6	5	5	5
3	The learning rate	0.1	0.14	0.1	0.09
4	Minimum number of data	23	21	21	22

The predicted performance of development application analysis model based on LightGBM, GWO-LightGBM, HHO-LightGBM, TLBO-LightGBM, PSA-LightGBM algorithms for micro- and nanoembedded systems is analyzed using the test set. The results of the predicted performance of the development application analysis model based on each algorithm are shown in Fig. 18. From Fig. 18, it can be seen that the ME, MAE, MAPE, RMSE, and R2 values of PSA-LightGBM are 0.043,

1.012, 4.002, 0.477, and 0.99, respectively, and the prediction performance is better than LightGBM, GWO-LightGBM, HHO-LightGBM, and TLBO-LightGBM.

Fig. 18. Predictive performance statistics for each analytical model.

V. CONCLUSION

Focusing on the analysis of application development issues in the deep development of micro-nano embedded systems with complex integrated architectures, this paper proposes a development and application testing analysis method based on machine learning technology and intelligent optimisation algorithms, which achieves accurate prediction of system development and application testing. By analysing the deep development process of micro-nano embedded systems, a development and application testing analysis framework is designed, and the key technical content is introduced. For the problem of constructing an application testing analysis model, a development and application testing analysis method based on PSA-LightGBM is proposed by combining the LightGBM hyperparameter optimisation with the photonic search algorithm. Data analysis and verification show that compared with other algorithms, the PSA-LightGBM algorithm-based micro-nano embedded system development application test analysis method further reduces the test prediction error, and at the same time verifies the application feasibility of the development application test analysis method in the micro-nano embedded system deep development under the complex integrated architecture. The next step is to improve the PSA algorithm and improve the accuracy of the LightGBM model, and at the same time apply PSA-LightGBM and micro-nano embedded system development to other fields to verify the robustness and feasibility of the algorithm model.

Optimization of Knitting Path of Flat Knitting Machine Based on Reinforcement Learning

Tianqi Yang*

Shanghai Institute of Visual Arts, Shanghai 201620, China

Abstract—In the textile industry, the flat knitting machine plays a crucial role as a production tool, and the quality of its weaving path is closely related to the overall product quality and production efficiency. Seeking to improve and optimize the knitting path to improve product effectiveness and productivity has become an urgent concern for the textile industry. This article elegantly streamlines and enhances the intricate weaving process of fabrics, harnessing the formidable power of reinforcement learning to achieve unparalleled optimization of weaving paths on a flat knitting machine. By ingeniously integrating reinforcement learning technology into the fabric production realm, we aspire to elevate both the quality and production efficiency of textiles to new heights. The core of our approach lies in meticulously defining a state space, action space, and a tailored reward function, each meticulously crafted to mirror the intricacies of the knitting process. This model serves as the cornerstone upon which we construct an innovative knitting pathway optimization algorithm, deeply rooted in the principles of reinforcement learning. Our algorithm embodies a relentless pursuit of excellence, learning from its interactions with the dynamic environment, embracing a methodical trial-and-error approach, and continuously refining its decision-making strategy. Its ultimate goal: to maximize the long-term cumulative reward, ensuring that every stitch contributes to the overall optimization of the weaving process. In essence, we have forged a groundbreaking collaboration between the traditional art of fabric weaving and the cutting-edge science of reinforcement learning, ushering in a new era of intelligent and efficient textile production. Through this process of iterative optimization, the agent can gradually learn the optimal knitting path. To verify the effectiveness of the algorithm, we performed extensive experimental validation. The experimental results show that reinforcement learning can significantly improve knitting efficiency, improve the appearance and feel of fabrics. Compared with traditional methods, the method proposed in this article has a higher level of automation and better adaptability, achieving more efficient and intelligent knitting production, with a 10% increase in production efficiency.

Keywords—Flat knitting machine; reinforcement learning; weaving path optimization; textile industry

I. INTRODUCTION

In today's booming textile industry, the flat knitting machine stands as the cornerstone equipment, its performance being a direct determinant of both production efficiency and product quality. Notably, the selection of the knitting path holds immense significance, as it critically shapes the final product's appearance, hand feel, and overall production efficiency [1, 2]. However, traditional knitting path optimization methods are heavily reliant on manual expertise and repetitive trials, making them inefficient and unable to keep pace with the escalating

complexity of knitting requirements. Consequently, the textile industry faces a pressing need to explore novel optimization techniques that can enhance the performance of flat knitting machines.

In recent years, the swift advancements in artificial intelligence technology have offered an efficacious solution for enhancing the operational optimization of microgrids. Notably, the reinforcement learning algorithm stands out as a prominent tool, as it transcends the reliance on historical data and pre-defined labels. Instead, it actively engages with the environment through iterative learning, fostering a dynamic and adaptive approach. Traditionally, the optimization of power system operations entailed modeling the intricate system mechanisms and subsequently solving these models under stringent constraints. However, reinforcement learning disrupts this paradigm by eliminating the need for an explicit physical model of the system. It possesses the remarkable ability to discern and refine the operational model purely from the available data, thereby significantly accelerating the learning process and enhancing the efficiency of modeling the system's operations. This shift underscores the transformative potential of reinforcement learning in driving the future of microgrid optimization. At the same time, based on the "trial and error" behavior of reinforcement learning, continuous learning can be carried out through interaction with the environment, and the accuracy of the model and the optimization of parameters can be continuously improved. Therefore, compared with the traditional micro-grid control mode, reinforcement learning can organically connect the components of the system, interact and cooperate with each other, and complete complex optimization work with a small amount of prior information, improving the operation ability and efficiency of the micro-grid. At the same time, the practical application and improvement of the algorithm in different scenarios can also effectively improve the application effect of reinforcement learning.

The rapid advancements in artificial intelligence have ushered in reinforcement learning as a groundbreaking machine learning technology. Extensively applied to various optimization challenges, reinforcement learning leverages the interactive learning process between an agent and its environment to autonomously discover optimal decision strategies. This approach offers a promising solution for tackling intricate problems, making it a compelling candidate for revolutionizing knitting path optimization in the textile industry. In this context, this paper will discuss the knitting path optimization method of flat knitting machine based on reinforcement learning to improve the knitting efficiency and product quality.

II. MULTI-AXIAL WARP KNITTED FABRIC PRODUCTION EQUIPMENT AND TECHNOLOGY

A. Fibrous Raw Materials

The range of raw materials for warp knitted multi-axial fabrics is very wide. The lining usually adopts high performance fibers with good mechanical properties, such as glass fiber (GF), carbon fiber (CF), Kevlar fiber, ultra-high molecular weight polyethylene fiber (UHMW. PE), etc. It can be a low twist flexible staple yarn or a non-robbing high performance filament yarn. When used as reinforcing yarns, high-performance untwisted filaments are generally used, and sometimes the yarns can be slightly twisted for ease of weaving. Yarns are generally thick, up to about 2500tex.

Polyester low elastic yarn, glass fiber yarn, etc. can be used for ground weave yarn. When polyester yarn is used for ground weave more than glass fiber, due to the high requirements for yarn fineness and bending stiffness, the technical parameters of wire drawing are improved, and thus the cost is greatly increased. Therefore, in actual production, raw materials should be selected according to the requirements of composite material properties and applications.

Glass Fiber (Glass Fiber) is a new type of engineering material, which is made of inorganic glass added with silica oxides such as calcium, boron, sodium, iron and aluminum. The molecular arrangement is a three-dimensional network structure, so the properties of glass fiber are homogeneous [3]. It has excellent properties such as non-combustible, corrosion-resistant, high-temperature resistance, low moisture absorption, and small elongation. It also has excellent characteristics in electrical, mechanical, chemical, and optical aspects, but the disadvantages are brittleness and poor wear resistance.

1) *Production process of glass fiber:* The production of glass fiber has a long history, and there are two main types at present: one is the method of replacing platinum to increase the pot to make glass into balls, and put the balls into the crucible furnace made of platinum pound alloy to make a leak plate, and the glass melt flows out of many leaks on the leak plate, and is wound on the high-speed rotating wire winding Jane; The second is the pool method: the glass powder is directly put into the pool cellar to melt, and the glass melt flows out through the leaky plates and nozzles installed on several sub-channels. The wire drawing method is the same as before. Glass fibers are generally 3-10 um in diameter, and more recently 13um, 15um, 24um monofilament yarns have been used. Due to the characteristics of glass fiber in structure, performance, processing technology, price, etc., it has always occupied an important position in the composite material manufacturing industry.

2) *Types of glass fibers:* Based on their distinct raw materials, glass fibers can be categorized into the following types:

C glass fiber, alternatively known as medium-alkali glass, possesses characteristics that lie between E glass fiber and A glass fiber. While it excels in chemical resistance, its electrical performance is inadequate. Furthermore, its mechanical strength falls short by 10% to 20% compared to alkali-free glass fiber.

In overseas markets, medium-alkali glass fiber is predominantly utilized for the production of corrosion-resistant glass fiber products. Conversely, in China, this type of glass fiber holds a prominent share, exceeding 60% of the total glass fiber output, and finds extensive applications. It is widely employed as reinforcement in Fiber Reinforced Polymers (FRP), as well as in the manufacture of filter fabrics and wrapping materials. This prevalence stems from its cost-effectiveness, offering a significant price advantage over alkali-free glass fiber, thereby fostering robust competitiveness in the domestic market.

High-strength glass fiber: It is characterized by high strength and high modulus. It is mostly used in military industry, space, bulletproof armor and sports equipment. However, due to the high price, it cannot be promoted in civilian use at present, and the world output is only about a few thousand tons.

E-CR glass. This is an enhanced boron-free and alkali-free glass that is utilized to craft glass fibers exhibiting exceptional acid and water resistance. Specifically, its water resistance surpasses alkali-free glass fiber by a remarkable seven to eight times, while its acid resistance significantly outperforms that of medium-alkali glass fiber. It is a new variety specially developed for underground pipelines, storage tanks, etc.

B. The Basic Properties of the Polymer Optical Fibers

The application of optical fiber to luminescent fabric must take into account the necessary properties of luminescent fabric and the performance characteristics of optical fiber. The necessary attributes of luminescent fabric include soft, light, durable and safe for use, high and uniform luminescent brightness, and good performance. The most prominent feature of the luminous fabric is the luminous brightness and flower pattern effect in the dark. The luminous brightness refers to the light flux per unit projected area. Factors such as fabric stretching, fabric type [4], fabric density, number of optical fibers, fiber bending radius, fiber bending loss [5].

The mechanical properties of optical fibers affect their weaving properties [6]. The collusion strength of optical fiber is low, poor elasticity and tolerance, so the optical fiber is easy to break in the process of weaving. Quartz fiber and glass fiber bending performance is poor, polymer fiber fracture tensile rate is larger, good toughness, good bending performance [7], bending radius, but the bending radius of polymer fiber and weaving process when the yarn bending radius is inconsistent, and polymer fiber bending rigidity, not conducive to fiber bending into circles. Therefore, it is difficult to weave polymer optical fiber into circles, and it is easier to weave through the form of floating line. Polymer fiber flexibility, flexure and elongation, good, easy to process and use [8].

Fig. 1 shows knitting path optimization process under the framework of reinforcement learning. The thermal performance of optical fiber affects the dyeing and shaping of optical fiber luminous fabric. Quartz fiber and glass fiber have good heat resistance, polymer fiber has poor heat resistance, low melting point, poor thermal stability [9], and it is easy to damage the fiber in the case of acute heat or cold, increasing the loss of polymer fiber. The working temperature of PS core and PMMA core polymer fiber is less than 80°C, and the working

temperature of PC core polymer fiber is less than 150°C. The heat-resistant polymer fiber can be used in the range of 100°C-

200°C [10, 11], so it is difficult for the polymer fiber fabric to iron, dye, shape, etc.

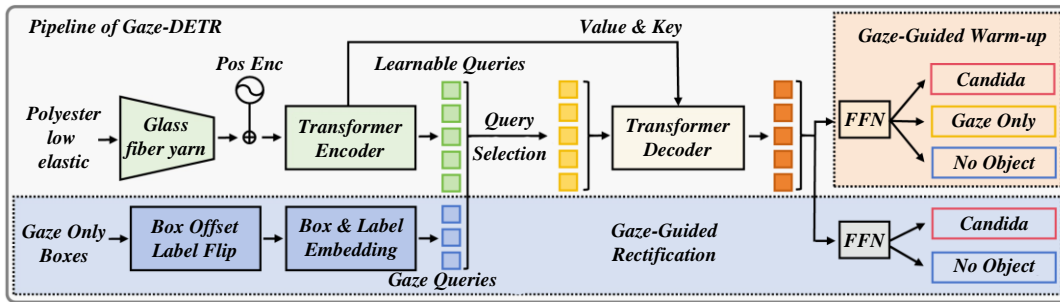

Fig. 1. Knitting path optimization process under the framework of reinforcement learning.

The chemical performance of optical fiber generally depends on its raw materials. For instance, the performance of glass fiber closely resembles that of glass, while the chemical properties of polymer fiber align with those of plastics. However, the unique structure of optical fiber itself can also significantly influence its chemical properties. Specifically, the large surface area of optical fiber facilitates the absorption of moisture and susceptibility to corrosion, thereby diminishing its compressive resistance and light transmittance. While polymer optical fiber exhibits robust acid and alkali resistance, strong corrosion resistance, and aging resistance, it is prone to corrosion by acetone, hexane, acetone mixed reagents, ethyl acetate, and other reagents.

Optical fibers exhibit distinct optical properties, encompassing both light conduction and scattering, which directly impact luminescence brightness, visual effects, and intricate floral pattern manifestations. Notably, polymer fibers are characterized by pronounced dispersion, a high refractive index, and substantial optical transmission attenuation, particularly pronounced in the ultraviolet and infrared spectra. However, within the visible light spectrum, polymer fibers boast high transmittance, making them ideally suited for applications in the realm of decorative lighting, where their unique properties can be harnessed to create captivating visual displays.

In summary, the mechanical properties of polymer optical fiber directly influence its weaving capabilities. Additionally, the mechanical properties of the fiber after exposure to chemical reagents are also impacted, thereby affecting its weaving properties. Therefore, it is crucial to extensively test the mechanical properties of polymer optical fiber, particularly in the context of its weaving performance.

1) *Technological parameters of multi-axial fabrics:* In practical manufacturing, it is often observed that the rationality of the process arrangement for multi-axial warp knitted fabrics significantly influences the weft yarn structure within the fabric and the overall process flow. This can manifest in issues such as the weft yarn not being securely fixed within the ground weave or the fabric surface lacking weft yarn. These conditions often have repercussions on the tensile properties of the fabrics, as well as the mechanical properties of the composites post-molding. The weft-laying process primarily involves factors like fabric weight, weft yarn fineness, weft-laying angle, and the number of weft-laying layers. The processing parameters for multi-axial warp knitted fabrics encompass the fabric's gram

weight, the gram weight of each weft layer, the density of each weft layer, the stitch pattern of the multi-axial fabric (i.e., the density of the stitching yarn), and the fineness of the stitching yarn and weave. The weight and density of the weft are determined by the weft laying process, which plays a pivotal role in the weaving of multi-axial fabrics. Unless there are specific requirements, the gram weight of each layer in a multi-axial fabric is typically calculated by dividing the total gram weight per square meter by the number of yarn layers [12, 13]. The weft density and fineness are key parameters in controlling fabric weight during the weft insertion process.

In actual production, the determination of these two parameters is mainly determined according to the weight per square meter required by customers. When producing axial warp knitted fabrics in more than two directions, when the total square meter gram weight of the fabric is given, the square meter gram weight of each layer of yarn must be determined first. The basis for the determination is that when the axial fabric is made into a composite material, without considering the force requirements in special directions, it is generally believed that only when the fabric as a reinforcing material has various similarities in structure, the composite material can jointly bear the load in all directions and exert the best performance of each component in the material [14, 15]. Therefore, when there is no special requirement, the square meter gram weight of each layer of yarn must be determined by dividing the total square meter gram weight by the average value obtained by the number of layers of yarn as a benchmark. After determining the weight of the next square meter, the specific process parameters are determined according to the calculation method of the weight of the square meter.

For example, in the actual production of biaxial fabrics, in order to make the force bearing capacity in the direction of 0° and 90° equivalent, generally under the condition that the square meter gram weight of the fabric is given, the square meter gram weight of the warp yarn and the square meter gram weight of the weft yarn are allocated according to half of the square meter gram weight of the fabric. Similarly, for multi-axial fabrics, if there are yarns inserted in directions other than 0° and 90°, such as: +45°, the forces in all directions should be considered to determine the yarn parameters [16, 17].

For warp-knitted axial fabrics, the parallel and straight alignment of yarns within the fabric structure ensures minimal fiber bending. As such, the calculation of the square meter gram

weight for yarn in any layer direction of these fabrics is straightforward: simply multiply the gram weight of a one-meter-long yarn segment by the total number of yarns present within that one-meter length. This method accurately reflects the yarn content and density, crucial for assessing fabric quality and suitability in various applications.

III. INTRODUCTION TO REINFORCEMENT LEARNING

A. Basic Theory of Reinforcement Learning

Under the background of new power system construction, the participants of micro-grid are becoming more and more diverse, and the power generation output and load are in a state of random fluctuations, making the operating environment and

mechanism more and more complex. The traditional energy management and scheduling methods are affected by the dynamics of the system and the intermittence of new energy sources, so it is difficult to establish an accurate mathematical model. Concurrently, it is imperative to estimate and fine-tune numerous parameters, encompassing load forecasting, energy supply, and price forecasting, among others. The computational complexity of these tasks is considerable, often rendering it challenging to fully satisfy the demands of practical scenarios. Furthermore, the majority of optimization challenges encountered in actual production processes are non-deterministic polynomial problems, posing certain difficulties in their resolution. Fig. 2 shows knit fabric quality changes over time.

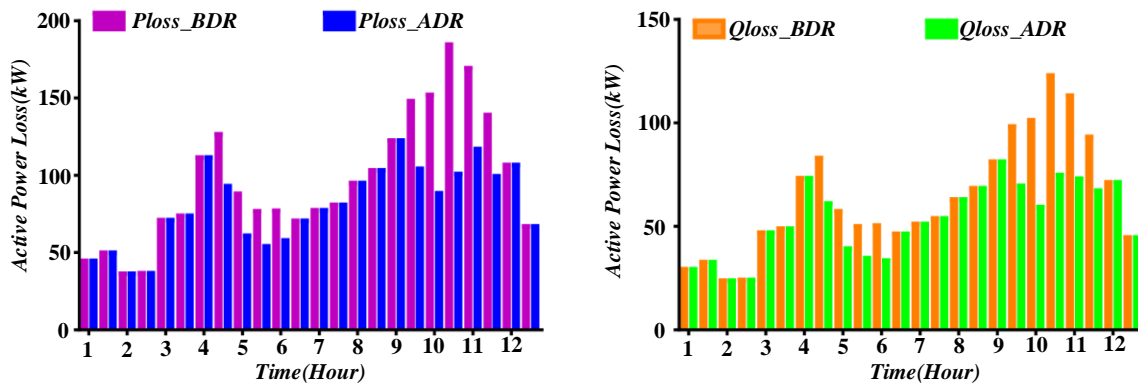

Fig. 2. Knit fabric quality changes over time.

Reinforcement learning evaluates the action based on the reinforcement signals provided by the environment, without determining in advance how the reinforcement learning system will form the correct action. Considering the limited information provided by the external environment, the reinforcement learning system must rely on its own continuous experience to continuously learn [18, 19]. Based on this model, reinforcement learning continuously acquires knowledge in an "action-evaluation" environment, and continuously optimizes action plans to adapt to the environment. The problems faced in the process of reinforcement learning have been widely discussed in biological learning, cybernetics, game theory and other fields. They are used to explain the equilibrium state under the condition of bounded rationality, and are also used to design intelligent interactive systems and unmanned adaptive systems. In recent years, reinforcement learning algorithms that integrate deep learning, transfer learning and other methods have the ability to solve complex problems in the real world, and have reached or surpassed the human level in many fields such as computer games, intelligence competition, automatic driving, intelligent question answering, and industrial production, showing extraordinary application prospects. With the continuous development of algorithms, its application range will become more and more extensive.

B. Technical Features of Reinforcement Learning

Reinforcement learning is known as the three major machine learning technologies together with supervised learning and unsupervised learning because of its powerful exploratory ability and autonomous learning ability. Compared with

supervised learning and unsupervised learning, reinforcement learning has great differences in many aspects such as data acquisition, learning methods, and decision-making methods. Supervised learning has a clear label on each data sample, which corresponds to the reinforcement learning task, which means that every action that should be taken in a certain state has a clear label. This does not match the typical scenario of reinforcement learning. Unsupervised learning does not label the data, and the main purpose is to discover the distribution law of the data. Compared with unsupervised learning, reinforcement learning provides certain "labeling" (that is, reward signals), which can be regarded as a kind of weak labeling learning. Although this mark is a weak mark for a specific action, it is very clear for the entire learning task and directly marks the success or failure of the task. The decision-making process of reinforcement learning is continuous, and at each time step, the agent takes action through interaction with the environment and obtains reward signals. Reinforcement learning is a goal-driven active learning method, which generates learning samples through interaction between initiative and environment. In reinforcement learning, agents need to try new strategies to obtain higher rewards, and at the same time need to use known strategies to maximize known rewards. Therefore, how to improve the quality of interaction (exploration and utilization) is a key core of reinforcement learning. Exploration may lead to too many useless attempts, resulting in a large amount of resources being wasted, and too much use may miss better choices due to too much trust in current experience. However, due to the delayed nature of reinforcement learning rewards, agents must learn how to evaluate the long-term impact of current decisions, that is,

actions made at current moments may affect rewards at multiple future moments [20]. Reinforcement learning usually does not require prior knowledge or environment models, which makes reinforcement learning very useful in dealing with unknown

environments. Therefore, it has good scalability and adaptability, and can deal with problems such as multi-agent, uncertain and dynamic environments. Fig. 3 shows efficiency comparison before and after knitting path optimization.

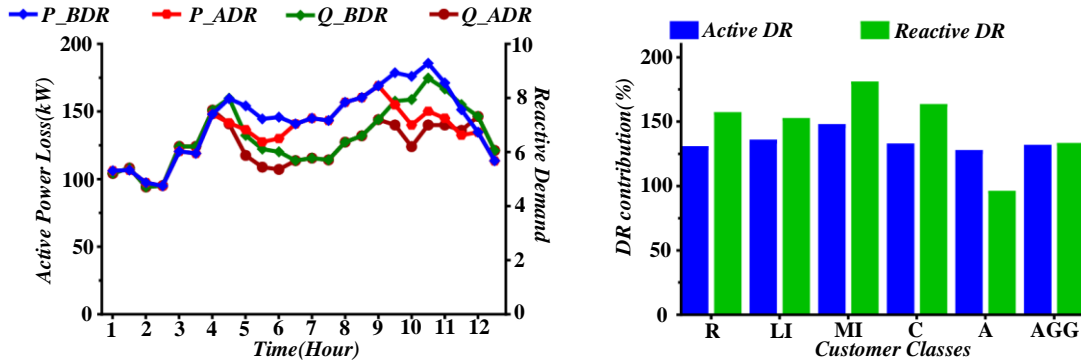

Fig. 3. Efficiency comparison before and after knitting path optimization.

Reinforcement learning embodies a continuous decision-making and strategy optimization process, leveraging intricate internal data structures and algorithms to maximize cumulative rewards through the dynamic interplay between agents and their environment. Initially, the agent engages with the environment guided by a formulated policy, observing and perceiving the current state of the environment after each interaction. Based on this state, the agent selects an action, triggering corresponding rewards or benefits. Over numerous interactions, the agent explores diverse action plans, gradually learning the optimal strategy for executing the most suitable action within a given environment, thereby maximizing overall gain. Presently, reinforcement learning encompasses three core methodologies: the value function algorithm, the policy gradient algorithm, and the "action-evaluation" algorithm, each contributing to the agent's capacity for learning and adaptability.

C. Algorithmic Flow of Reinforcement Learning

Reinforcement learning is widely used in model optimization in automatic control, engineering construction and other fields. Its core is that the agent can obtain the cumulative maximum return or achieve a specific goal through its own learning ability in the process of interacting with the environment, so that the agent has the ability to make the best decision under the current environment. In order to simplify the modeling problem of reinforcement learning, Markov decision process is used to describe and construct the process of reinforcement learning, considering the complexity of the transformation process between environments of reinforcement learning. Fig. 4 shows kit path optimization and model evaluation process.

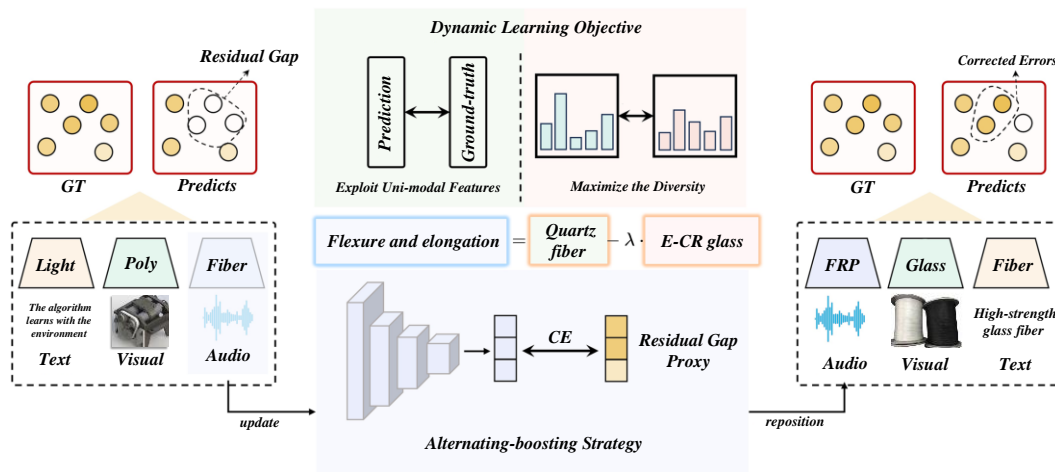

Fig. 4. Kit path optimization and model evaluation process.

Agent: A hypothetical entity that performs actions in an environment for some reward Environment: The scene in which the agent is located.

State: Refers to the current state returned by the environment

The goal of reinforcement learning is to maximize cumulative rewards, and future trends of rewards need to be considered when calculating rewards. Cumulative rewards are defined as the weighted sum of rewards from time t to the end of the learning process, represented as shown in Eq. (1).

$$R_t = \sum_{t'=t}^T \gamma^{t'-t} r_{t'} \quad (1)$$

Where $\gamma \in [0, 1]$ is a constant called the discount factor, used to assess the impact of future rewards on cumulative rewards. The state action function $Q(s, a)$ represents the execution of action a in the current process and loops to the end of learning according to strategy π . The cumulative gain of the agent is shown in Eq. (2).

$$Q^\pi(s, a) = E[R_t | s_t = s, a_t = a, \pi] \quad (2)$$

Where s and a represent the current state and action. For all sets of state actions, if the expected returns of a strategy are greater than or equal to the expected returns of other strategies, the strategy is the optimal strategy. In fact, multiple optimal strategies may use the same state action function. Its mathematical expression is shown in Eq. (3).

$$Q^*(s, a) = \max_{\pi} E[R_t | s_t = s, a_t = a, \pi] \quad (3)$$

Meanwhile, the action function follows the Bellman optimal equation to form the optimal state action function as shown in Eq. (4)

$$Q^*(s, a) = E_{s' \sim s} [r + \gamma \max_{a'} Q^*(s', a') | s, a] \quad (4)$$

Where s denotes the subsequent state and a represents the action corresponding to s , the optimal value function can theoretically be derived through iterative application of the Bellman equation. However, in practical scenarios, due to the complexity of real-world environments, neural networks, linear functions, and other approximation techniques are frequently employed to estimate state-action value functions. This integration of deep learning and reinforcement learning not only enables the accurate approximation of intricate value functions but also fosters the rapid advancement and widespread adoption of reinforcement learning methodologies.

IV. STUDY ON TENSILE PROPERTIES OF MULTIAXIAL FABRIC BY TECHNOLOGICAL PARAMETERS

In the actual production, it is often found that whether the arrangement of weft insertion and knitting technology of multi-axial warp knitted fabrics is reasonable or not will directly affect the structure of weft in the fabric and the progress of the process, such as causing the weft not to be well fixed in the ground weave or causing the fabric surface to lack weft. Because these conditions often affect the tensile properties of fabrics, this chapter mainly studies the effects of different production processes on the tensile properties of multi-axial fabrics from the perspective of weft laying and knitting processes through experimental testing methods [21]. The weft laying process mainly refers to the gram weight of the fabric and the fineness of the weft yarn, and the knitting process mainly refers to the weave structure, needle density, and let-off of the warp knitted yarn (bundled yarn). Because the multi-axial warp knitted fabric is a new material, there is no uniform standard about the performance test of the fabric. In this paper, the fabric tensile test is carried out by GB/T7689.5-2001 standard. The state transition probability formula and the reward function formula are shown in Eq. (5) and Eq. (6).

$$a_k = \frac{\exp(w' \tanh(Uh_k))}{\sum_{j=1}^K \exp(w' \tanh(Uh_j))} \quad (5)$$

$$r_k = \frac{\exp(v(x_k) / \tau_v)}{\sum_{k=1}^K \exp(v(x_k) / \tau_v)} \quad (6)$$

A. Methods and Conditions for Tensile Testing of Fabrics

Utilize an appropriate instrument to stretch fabric strips until rupture, thereby assessing their breaking strength and elongation at break. Both the breaking strength and elongation values can be directly discerned from the instrument's indicator device, or alternatively, derived from the automatically recorded stress-strain curve. Table I comprehensively outlines the pertinent test parameters employed in this analysis.

TABLE I. TEST PARAMETERS

	Unit	Sample parameter
Specimen length	mm	350
Width of specimen (unrimmed)	mm	65
Initial effective length	mm	200
Width of trimmed specimen	mm	50
Tensile speed	mm/min	100

In a humidity-controlled environment adhering to standard conditions of $23^\circ\text{C} \pm 2^\circ\text{C}$ temperature and $50\% \pm 10\%$ relative humidity, the sample undergoes a 16-hour humidity acclimation period. Subsequently, the testing is conducted in an identical environmental setting.

Based on the fabric type, adjust the upper and lower fixtures to achieve the desired effective length of the sample between them, ensuring they are parallel. Position the specimen in a jig with its longitudinal central axis aligning with the jig's leading-edge center. Cut cardboard or similar material along a direction perpendicular to the specimen's central axis. Apply a uniform pretension across the entire width of the specimen, and then securely tighten the other jig.

1) Start the movable fixture and tensile the sample until it is destroyed. The Q-value function update and policy gradient theorem formulas are shown in Eq. (7) and Eq. (8).

$$h(t, \bar{x}_i) = h_0(t) \eta(\bar{x}_i) \quad (7)$$

$$SA(z) = \left(\sigma \left(\frac{qk^T}{\sqrt{K_h}} \right) \right) v \quad (8)$$

2) Record the final breaking strength. Unless otherwise agreed, when the fabric breaks in more than two stages, such as double-layer or more complex fabrics, the maximum strength at the break of the first set of yarns is recorded and used as the tensile breaking strength of the fabric.

3) Record elongation at break, accurate to 1 mm.

4) If a specimen is broken within 10mm of the contact line of either of the two fixtures, the phenomenon will be recorded, but the breaking strength and breaking elongation will not be

calculated in the results, and the new specimen will be re-tested [22].

The reasons for coating resin on the clamping end are:

The surface of carbon and glass fibers is very smooth, and the direct clamping will cause slippage, which will affect the accuracy of the test. The value function iterations and the Bellmann equation formulas are shown in Eq. (9) and Eq. (10).

$$L = \frac{2 \sum_i^N \hat{p}_i y_i}{\sum_i^N p_i^2 + \sum_i^N y_i^2} \quad (9)$$

$$S(e_i, e_{top-k}) = \frac{\sum_{m=1}^M (e_i \times e_{top-k})}{\sqrt{\sum_{m=1}^M (e_i)^2} \times \sqrt{\sum_{m=1}^M (e_{top-k})^2}} \quad (10)$$

The brittleness of carbon and glass fibers is large, and if the clamping force is too large, the sample at the clamping end will be damaged, making the glass fibers at the clamping end of the sample break first under the strong force, resulting in the phenomenon of breaking the clamping head, and then making the test invalid. After coating resin at both ends, the above problems can be effectively solved. The friction between the resin and the collet is much higher than that between the glass

fiber and the collet, which effectively solves the problem of slipping. In addition, after coating the clamping end, the fibers in the clamping part are soaked in the resin. Under the protection of the resin, the glass fiber at the clamping end will be subject to a very small shear force, so that the problem of fiber brittleness can be effectively solved [23].

B. Experimental Data Analysis

In the tensile test, during the tensile load process of the fabric held by the clamp, the yarn in the fabric has obvious different breakage characteristics, which can be accurately judged from the sound produced when the yarn breaks. To some extent, the strength of the yarn in the fabric cannot be fully utilized in the process of application.

Fig. 5 shows reward changes during the iteration of reinforcement learning. The tensile strength of the fabrics with two different weave structures, No. 1 and No. 2, was tested in the direction of yarn 0. Five specimens were tested for each fabric. The action selection strategy and the advantage function calculation formula are shown in Eq. (11) and Eq. (12).

$$\mu_{0,crit} = \frac{2}{(N+2)\sigma^2} \quad (11)$$

$$w_{k+1} = w_k - \frac{1}{2} \mu \nabla_k \quad (12)$$

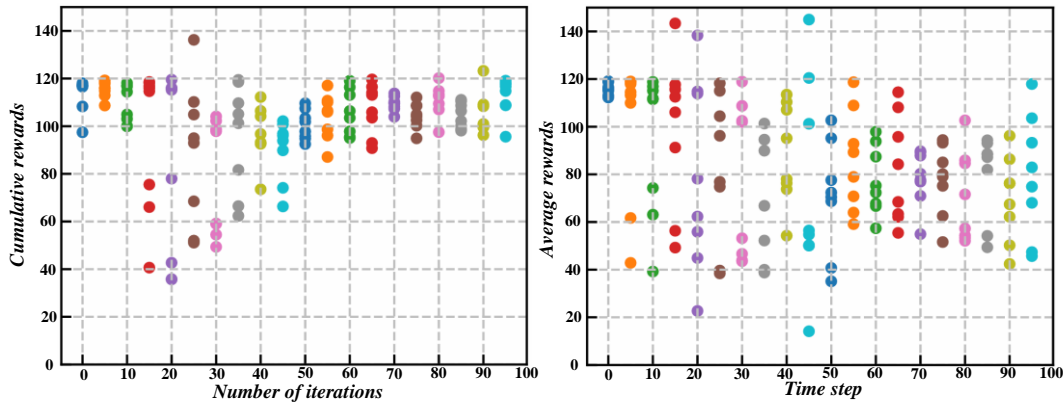

Fig. 5. Reward changes during the iteration of reinforcement learning.

It can be seen from the figure that the tensile properties of the fabrics with Promat as the weave structure are slightly higher than those of the same fabrics with tricot as the weave structure,

and the difference in the tensile strength of the fabrics with tricot as the weave structure is small. Fig. 6 shows effect of learning rate on the effect of path optimization.

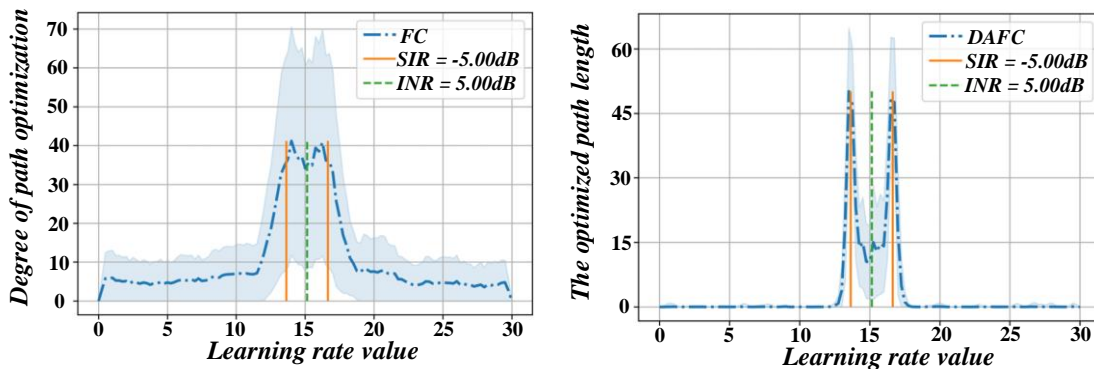

Fig. 6. Effect of learning rate on the effect of path optimization.

As depicted in Fig. 6, the fabric exhibiting the lowest stitch density boasts the highest average tensile strength. However, it is apparent that as the stitch density rises, the subsequent variations in tensile strength compared to this baseline fabric remain relatively modest. The results show that the increase of

stitch density in the range of common stitch density increases the probability of fiber damage caused by needle penetrating yarn, but it has no obvious effect on the strength of fabric. Fig. 7 shows exploration-exploit the effect of trade-offs on pathway search.

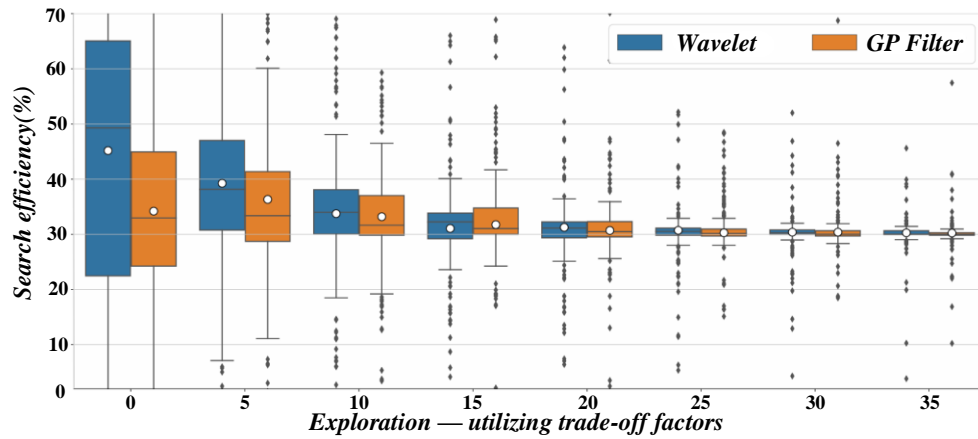

Fig. 7. Exploration-exploit the effect of trade-offs on pathway search.

As depicted in Fig. 7, the tensile strength of the fabric does not exhibit a regular pattern with variations in let-off amount. This is primarily attributed to the consistent weft insertion process and the maintenance of yarn count per unit length. Given the same stitch density, the likelihood of fiber damage within the yarn remains largely unchanged, resulting in insignificant variations in the fabric's ultimate strength. The target network update and knitting model are shown in Eq. (13) and Eq. (14).

$$\bar{n}_c = \frac{1}{a} \int_0^a n_c dr \quad (13)$$

$$x(t+1) = \bar{A}x(t) + \bar{B}u(t) \quad (14)$$

It is imperative to emphasize that warp-knitted yarn commands a premium price, thus, any augmentation in let-off volume directly correlates with an equivalent surge in costs. Conversely, maintaining excessively low let-off values introduces heightened tension within the yarn, which not only accelerates the wear and tear of knitting needles but also poses the risk of yarn breakage, ultimately hindering overall production efficiency. Therefore, for the actual production, we should choose the appropriate let-off amount [24]. The gradient descent optimization formula and the entropy regularization term formula are shown in Eq. (15) and Eq. (16).

$$(F * K)(q) = \sum_{s+t=q} F(s)K(t) \quad (15)$$

$$X_r^A = \frac{1}{C} \sum_{c=1}^C X_r(c) \quad (16)$$

C. Effect of Gram Weight of Fabric on Tensile Properties of Fabric

By increasing the gram weight of the 0° yarn layer, we measured the tensile strength of Fabrics No. 2 and No. 4 in the 0° direction. Specifically, Fabric No. 2 had a 0° yarn layer gram weight of 291.4 g/m², while Fabric No. 4 boasted a gram weight of 582.7 g/m². Notably, the gram weight of the 45° glass yarn layer remained unaltered, and all other process parameters were kept consistent. Fig. 8 shows optimize the comparison of before and after paths.

As Fig. 8 illustrates, as the fabric's gram weight increased, so did its breaking strength in the tensile direction. This phenomenon is primarily attributed to the increased density of the fabric, specifically the augmentation in the density of the 0° yarn. As the density of 0° yarns rises, the count of 0° yarns per unit length correspondingly increases. Consequently, when the fabric undergoes stress, the yarn's force-bearing capacity per unit area intensifies, ultimately contributing to a significant enhancement in the fabric's overall strength.

Fig. 8. Optimize the comparison of before and after paths.

By increasing the gram weight of the 45° glass fiber yarn layer, we measured the tensile strength of Fabrics No. 3 and No. 4 in the 0° direction. Specifically, Fabric No. 3 had a 45° yarn layer gram weight of 601.2 g/m², while Fabric No. 4's 0° yarn layer gram weight stood at 300.6 g/m². The gram weight of the 0° carbon fiber layer remained constant, and all other process parameters remained unchanged [25]. The importance sampling weights and discount factor influence formulas are shown in Eq. (17) and Eq. (18).

$$T_{N\varepsilon} = N\tau_Q + \sum_{i=1}^N \varepsilon_{c,i} \quad (17)$$

$$\sigma_t^2 = \frac{1}{2N-2} \sum_{i,j \neq i} \sigma_{ij}^2 \quad (18)$$

Fig. 9 shows effect of environmental state changes on path planning. As evident in Fig. 9, despite an increase in fabric gram weight, the breaking strength in the tensile direction experienced a marginal increase. The primary reason for this is that the 45° glass yarn does not significantly contribute to the tensile strength in the 0° direction. However, it does play a role in enhancing the fabric's pressure resistance and shares the load, thereby contributing to an increase in fabric strength, albeit not significantly.

Fig. 9. Effect of environmental state changes on path planning.

At the same time, it can also be observed that the tensile strength of No. 3 fabric fluctuates very little while that of No. 4 fabric fluctuates greatly. The reason is that the weft density of No. 4 fabric is too small (4.5 ends/inch), resulting in uneven weft laying and lack of weft. If there is uneven weft laying in the fabric, if the sample is taken in the area of lack of weft during the experiment, the strength value obtained from the test should be low. If the sample is taken in the place where the weft is densely laid, the strength value obtained from the test is very high. As a result, the performance of different parts of the same fabric varies greatly. The multistep return estimation and model prediction error are calculated as in Eq. (19) and Eq. (20).

$$L(q) = \ln \frac{p(x, \gamma, \lambda | y)}{q(x, \gamma, \lambda)}_{q(x, \gamma, \lambda)} \quad (19)$$

$$\hat{x}_i^H B_i \hat{x}_i = \sum_{l=1}^{d_i} \frac{|q_{i,l}|^2}{(1 + \hat{\gamma}_i s_{i,l})^2} \quad (20)$$

With the fabric's weight kept constant, we varied the density of the 45° glass yarn and conducted tensile strength tests on Fabrics No. 4 (45° glass yarn density of 4.5 pieces/inch) and No. 5 (±45° glass yarn density of 2.25 pieces/inch).

Moreover, it becomes apparent that Fabric No. 5 demonstrates pronounced strength variations, primarily stemming from its exceptionally low weft laying density and irregular yarn positioning. This underscores the notion that, under consistent weight conditions, an increase in weft density fosters a direct enhancement in the fabric's tensile properties, as evidenced by prior studies.

Fig. 10. Frequency of path updates during real-time learning.

However, it is worth noting that as the weft laying density increases, the linear density of the weft yarn decreases. Given that the current market prices of glass and carbon fibers rise as their linear density diminishes, it is imperative to comprehensively consider various factors, including fabric requirements, while setting the weft laying process to determine the optimal weft laying density. Fig. 10 shows frequency of path updates during real-time learning.

V. SUMMARY AND PROSPECT

With textile technology's advancement, flat knitting machines are crucial in the industry, with knitting efficiency and product quality as key performance metrics. Recently, reinforcement learning, an advanced ML technique, has been widely applied to optimization problems. This paper delves into utilizing Reinforcement Learning as a means to optimize knitting paths for flat knitting fabrics, with the ultimate goal of elevating both production efficiency and quality. The selection of knitting paths holds paramount importance, as it directly influences the aesthetic appeal, tactile sensation, and overall efficiency of the end product. Traditional optimization techniques, reliant on manual expertise and a cumbersome trial-and-error process, prove inefficient and inadequate for addressing intricate requirements. In contrast, RL facilitates the autonomous discovery of optimal paths through the dynamic interplay between the agent and its environment, thereby significantly advancing knitting efficiency and quality. We introduce an RL model specifically designed for optimizing knitting paths on flat knitting machines, meticulously defining state, action, and reward functions to capture the intricate nuances of the knitting process. By employing a reinforcement learning algorithm, our agent learns and explores within a simulated environment, progressively uncovering the optimal weaving path. Through a large number of experimental verifications, we prove that the knitting path optimization method based on reinforcement learning can significantly improve the knitting efficiency and product quality. In addition, the application effect of different reinforcement learning algorithms in knitting path optimization of flat knitting machine is discussed, and the key factors affecting the optimization effect are analyzed. We find that choosing appropriate algorithm parameters and reward functions is crucial to improve the optimization effect. Furthermore, we acknowledge the limitations of our current research and propose future directions for exploration. In summary, the reinforcement learning-based knitting path optimization for flat knitted fabrics holds immense potential. With continued research, we aim to further enhance knitting efficiency and product quality of flat knitting machines, ultimately contributing significantly to the textile industry's advancement.

Design and Research of Cross-Border E-Commerce Short Video Recommendation System Based on Multi-Modal Fusion Transformer Model

Yiran Hu*

School of Finance and Trade Management, Chengdu Industry and Trade College, Chengdu 611731, China

Abstract—This study designed a cross-border e-commerce short video recommendation system based on Transformer's multimodal analysis model. When mining associations, the model not only focuses on the relationships between modalities, but also improves semantic context by addressing contextual correlations within and between modalities. At the same time, the model uses a cross modal multi head attention mechanism for multi-level association mining, and constructs an association network interwoven with latitude and longitude. In the process of exploring the essential correlation between patterns and subjective emotional fluctuations, the potential context between patterns has been realized. Fully explore correlations and then more accurately identify the truth contained in the original data. In addition, this study proposes a self supervised single modal label generation method. When multimodal labels are known, it does not require complex deep networks and only relies on the mapping relationship between multimodal representations and labels to generate a single modal label. Modal labeling can achieve phased automatic labeling of single modal labels, and quantify the mapping relationship between modal representations and labels from the representation space to generate weak single modal labels. The study also achieved multimodal collaborative learning in the context of limited differential information acquisition due to incomplete labeling, fully utilizing multimodal information. The experimental results on classic datasets in the field of multimodal analysis show that it outperforms the baseline model in terms of accuracy and F1 score, reaching 98.76% and 97.89%, respectively.

Keywords—Multimodal fusion; transformer model; cross-border e-commerce; short video recommendation system

I. INTRODUCTION

With the advent of the era of big data, new social media such as DouYin, Weibo and YouTube will update a large amount of data content every day, in which there are not only objective descriptions of a certain thing, but also a large number of subjective expressions [1, 2]. Mining and identifying the information contained in these data can not only provide information assistance for big data forecasting applications such as financial market trend forecasting, product marketing status forecasting, and even US political election forecasting, but also provide information decision-making such as network public opinion analysis and digital social governance [3]. Providing technical support has extremely important application value and practical significance.

According to the existing research situation, traditional text analysis only uses words, phrases and their semantic associations to judge, which is not enough to identify complex
