information. Multimodal analysis adds acoustic and visual information on the basis of text information, and with the help of the association between multimodal data, it can show the information that may be hidden in text data, so as to achieve more accurate recognition [4, 5]. Taking ironic emotion recognition as an example, by extracting acoustic and visual information from human intonation and body movements, ironic information can be accurately recognized. Multimodal analysis has achieved remarkable results in dealing with understanding in various scenarios, and has attracted more and more researchers' attention [6, 7]. However, there are still some challenges in the research of multimodal analysis-multimodal association mining and multimodal collaborative learning.

In response to these challenges, this paper considers the association information between modes and contexts in the process of multimodal analysis based on deep learning technology. It uses the improved Transformer framework to mine intertwined and intricate associations to achieve tight coupling of multimodal data. Focusing on the mapping relationship between multimodal representations and sample labels, multimodal collaborative learning under unbalanced information distribution is realized with the help of a multi-task learning framework. Multimodal fusion is properly sorting and tightly coupling data from two or more modes. The most significant difference between multimodal analysis and traditional single-modal analysis is that the former can obtain more reliable prediction results with the help of information gained by multi-source data. According to the different stages, the existing multimodal fusion methods can be divided into three categories: feature-level, decision-level, and hybrid-level. Multimodal analysis based on Transformer and multi-task learning has essential application significance. However, its research results can also provide a basis and support for cross-media perceptual computing, analytical reasoning, and multimodal deep learning research in artificial intelligence. Has important research significance.

II. MULTIMODAL ANALYSIS BASED ON TRANSFORMER

A. Transformer for Linguistics Guidance

The traditional multi-head attention mechanism is mostly applied to machine translation problems. When calculating the attention score, the operation can be performed parallelly to accelerate the training of the model [8, 9]. This paper applies this idea to the multi-modal problem, hoping to find the mapping relationship between multiple modes. Specifically, when using the attention mechanism to learn a mode, the text mode is used

*Corresponding Author.

as a guide to mine the association between various modes, and finally a linguistic-guided Transformer (LGT) is constructed.

LGT includes Multi-Head Attention (MHA) and Forward Neural Networks (FNN) [10].

Fig. 1. Transformer model based on multimodal.

As shown in Fig. 1, the model takes text mode as the main component, speech mode, and image mode as the secondary components, and the characteristics of the three modes are respectively input into the multi-head attention module. Through this setting, the text data containing rich information can guide the voice and image data, which can be used to mine multi-modal association information. The process of calculating the text feature attention score with this module is as follows:

Firstly, the text features are divided into three vectors: query vector Q_l , keyword vector K_l and true value vector V_l , and all the vectors are linearly transformed; Then, Q_l and K_l are sent to calculate the attention score, and the dimension K_l is used to limit the calculation result to ensure that the inner product is not too large; Finally, the final calculation result is obtained by weighted summation of attention score and V_l . Specifically, as shown in Formula (1).

$$Attention(Q_l, K_l, V_l) = \text{softmax}((Q_l K_l^T) / \sqrt{d_k}) V_l \quad (1)$$

The above calculation process is performed multiple times, and each calculation is regarded as a head [11, 12]. By splicing the results of multiple heads, the final multi-head attention calculation result can be obtained, as shown in Formulas (2) and (3).

$$head_i = Attention(Q_l W^Q, K_l W^K, V_l W^V) \quad (2)$$

$$F_{(i)} = MHA(Q_l, K_l, V_l) = Concat(head_1, \dots, head_h) W^O \quad (3)$$

After getting the calculation result of attention, it is passed into FNN to mine the nonlinear relationship of features, so as to enhance the performance ability of features, as shown in Formula (4).

$$FFN = Relu(H'W^l + b^l) W^2 + b^2 \quad (4)$$

Each layer in the LGT needs to be processed, as shown in Formula (5).

$$F(x) = LayerNorm(x + Sublayer(x)) \quad (5)$$

For minor components such as speech features and image features, the query vector comes from the text mode, and the keyword vector and the true value vector come from the speech and image modes when calculating the multi-head attention [13, 14]. When processing speech and image features, text features are used to introduce information from different representation spaces, as shown in Formulas (6) and (7).

$$F_{(a)} = MHA(Q_l, K_a, V_a) = Concat(head_1, \dots, head_h) W^O \quad (6)$$

$$F_{(v)} = MHA(Q_l, K_v, V_v) = Concat(head_1, \dots, head_h) W^O \quad (7)$$

B. Soft Mapping Module

The model has learned the interaction information between the modes and needs to project the learned results of each mode into a new performance space in the soft mapping module for fusion before classification [15]. Precisely, the results output by the forward propagation network are first mapped to a higher-dimensional space, as shown in Formula (8).

$$NewMatrix = W_m M \quad (8)$$

Then the soft attention is calculated for each matrix in the high-dimensional space, and then the weighted sum of the results is integrated into the vector to obtain the calculation result of soft attention [16, 17]. This calculation process is shown in Formulas (9) and (10).

$$p_i = \text{softmax}((v_i^p)^T (NewMatrix)) \quad (9)$$

$$SoftAttention_i(M) = m_i = \sum_{j=0}^N (p_{ij} M_j) \quad (10)$$

Finally, after stacking these results, you can get the results of Soft Mapping, as shown in Formula (11).

$$s = \text{Stacking} \left(\sum_{j=0}^N (m_j) \right) \quad (11)$$

Note that a residual calculation and Layer Normalization are performed at the end of this process to ensure that the next round of input includes the results of the previous round, as shown in Formula (12).

$$M = \text{LayerNorm}(M + s) \quad (12)$$

The result s obtained above is the result after processing the respective output matrix M of each mode, and the vectors obtained by each mode are summed in order of elements, and the summed results are classified and predicted according to Formula (13).

$$y \sim p = W_p(\text{LayerNorm}(s_t + s_a + s_v)) \quad (13)$$

C. Construction of Recommendation Model Fusing Interaction of Bert and High-order Dominant Features

1) *The overall structure of model fusing Bert interaction with high-order dominant features:* In this paper, according to the actual situation of video recommendation, the Bert model is integrated into the X Deep FM framework. This model can extract text feature vectors with deeper semantics through the Bert model and obtain their text feature vectors by extracting text information such as video titles and tags. Because categorical discrete features such as user ID, video ID, and related attributes are difficult to directly use as inputs to deep learning models [18, 19]. Therefore, Label Encoder is used to convert into categorical codes, discontinuous values or texts are converted into categorical codes, and then Embedding is used to convert them into low-dimensional, dense feature vectors, which are input into the model. Finally, the input feature vector and the user's preference degree value are used to iteratively update the training model to improve accuracy and reliability [20]. The network structure of its overall model is shown in Fig. 2.

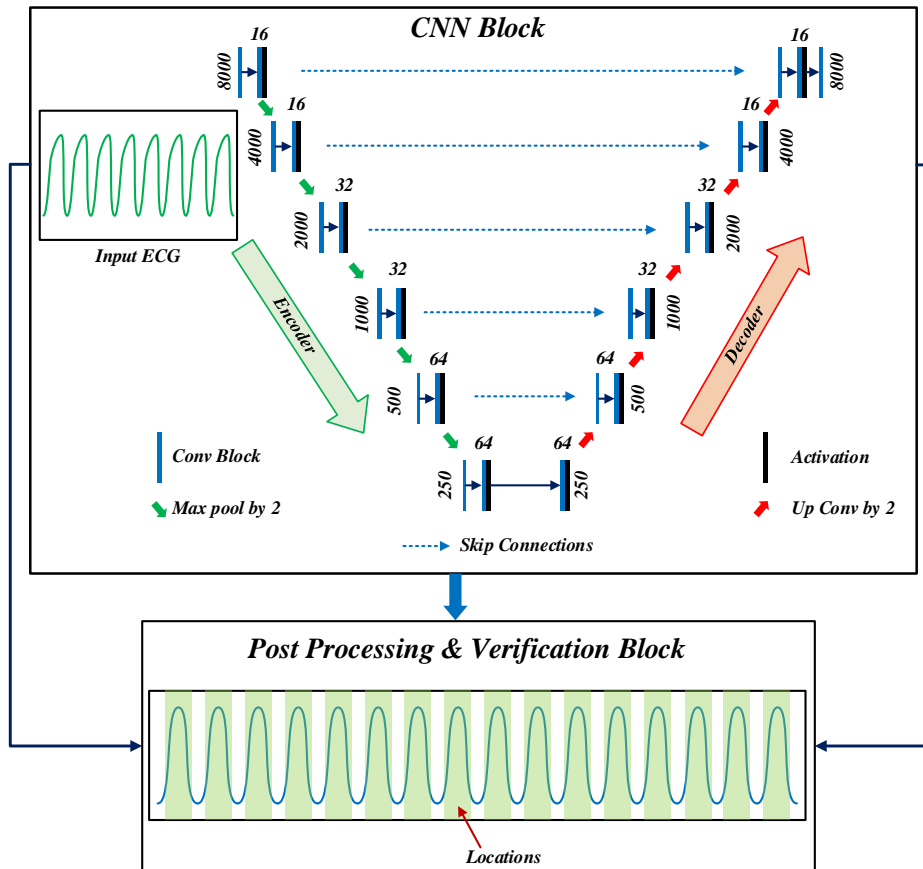

Fig. 2. Fusion model of Bert interaction with high-order explicit features.

The Fig. 2 shows a model that combines Bert and high-order explicit features. It is an end-to-end recommendation model, which has the characteristics of both low-order and high-order feature interactions and implicit and explicit features. The overall structure of the network is composed of four parts: input and text feature extraction, compressed interactive network part, multi-layer neural network and score prediction (that is, output layer), in which the compressed interactive network can extract

high-order explicit cross features of the input layer, and the multi-layer neural network can extract high-order invisible cross features [21, 22].

2) *Extraction of text information features by Bert:* Bert is a bidirectional Transformer-based encoder, which is a bidirectional model obtained by unsupervised training on large-scale corpus. Compared with the GPT model, the Bert model

uses the Encoder structure in Transformer as the main component of the model. The Bert model reads the text, constructs special characters in the text, completes the training through the multi-layer Transformer Encoder [23, 24] structure, and finally uses the vector corresponding to the special characters as the output of the Bert model. In the training task of the language model, the special characters are constructed in the form of filling. By randomly setting [MASK] on the input, let the model predict the words at this position to complete the training of the model. In actual use, it splices special characters [CLS] on the text, so that the output of special characters is matched with the target task to achieve. At present, the Bert model has achieved remarkable results in extractive tasks (SQuAD), sequence labeling tasks (named entity recognition), and classification tasks (SWAG) and other tasks.

3) *Input layer*: The input layer is responsible for transforming users and characteristics into the form required by the model so that input information can be better understood and processed. In the process of processing features, when using categorical discrete features, first use Label Encoder to encode, the value is between 0 and n-1, so that this feature can be recognized by the model. For numerical continuous features (such as playback volume, user level, etc.), they can be directly entered into the model as input features for calculation [25]. For text-like features, we use the previous Bert model to extract sentence vectors. Since the dimension of each sentence vector is 768 dimensions, all features are spliced together to form the final input vector.

The combination of the sub-types and continuous numerical types processed by the above three methods will cause problems such as dimension explosion and excessive resource occupation, and it is not very good for neural networks to deal with this input. In this paper, the Embedding layer is used to deal with subtyping and continuous numeric types, so as to solve the problems of dimension explosion and excessive resource occupation [26, 27]. By this method, the original sparse matrix is transformed into a dense continuous vector with suitable length, so that the neural network can better handle this input. Although the initial feature length of the sample data may vary, Embedding can still effectively improve this situation, thereby increasing the accuracy and reliability of the model. After the feature embedding layer processing, its length will remain unchanged and will not be affected by the outside world. After this process, follow-up deep learning operations are carried out. The network structure essentially forms a weight matrix. According to a

certain mapping relationship, the weight information of the original matrix is transformed into a new dimension matrix through matrix multiplication calculation. According to the reverse mapping relationship, the matrix is multiplied, and the original matrix will be restored matrix. The application of Embedding layer can effectively reduce the sparsity of data, and can change the original isolated vectors into closely related vectors, which can greatly enhance the scalability of the algorithm.

4) *DNN layer*: To deeply explore the feature interaction relationships implicit in the information, deep neural networks (DNNs) are used for learning. DNN is developed from the multi-layer perceptron (MLP) technology, which has deeper network layers and more types of activation functions. It can connect multiple hidden layers of nonlinear structures, fitting complex function curves and mining deeper interaction features through large-scale training data [28]. The deep neural network performs excellently, can deal with complex problems, and has remarkable effects. Its powerful ability is mainly due to the large number of neural network layers; that is to say, the more network layers, the more complex and in-depth the neural network, and the more learning. Accurate. The basic structure of the neural network comprises three parts: the input layer, the hidden layer, and the output layer. The connection mode between layers is a complete connection, and there is at least one hidden layer. The more hidden layers there are, the higher the expressive ability of the model. The relationship between layers of the deep neural network is nonlinear, and the task of the lower network layer is to extract low-order edge features with relatively simple relationships from the original input data. Each neuron in the bottom network layer acquires some low-order information. More advanced local features can be obtained by combining the underlying information on the middle-hidden layer. The top layer fuses local features into higher-level features. However, it is impossible to theoretically understand the crossover characteristics of each DNN neural network layer and the characteristics each neuron represents. After the training, which feature interactions are more effective in the entire neural network cannot be explained, so these unexplained high-order feature interactions are considered implicit feature interactions. However, the experimental results confirm that DNN can unearth unintelligible but effective high-order feature interactions, which are called implicit feature interactions, and the scattered results are shown in Fig. 3.

Fig. 3. Interactive dispersion results of implicit features.

III. DESIGN OF CROSS-BORDER E-COMMERCE SHORT VIDEO RECOMMENDATION SYSTEM BASED ON MULTI-TASK LEARNING

A. Multi-level Association Mining Framework

In exploring low-level correlations, this study adopts a model-agnostic approach to fuse features, aiming to uncover the intricate feature associations spanning across multi-modal representations [29]. Drawing inspiration from tensor fusion networks, we introduce the use of Unfolded Fusion Functions (UFF) to address the limitations of traditional fusion techniques, such as multimodal splicing. By leveraging UFF, we elevate single-modal features into higher-dimensional spaces, facilitating their fusion. This approach employs a 3-fold Cartesian product to seamlessly integrate multiple single-modal representations, capturing both bimodal and trimodal interactions through a multi-level fusion process.

$$\{(T^l, T^a, T^v) / T^l \in [T_i^l], T^a \in [T_i^a], T^v \in [T_i^v]\} \quad (14)$$

$$F_{(m)} = [T_i^l] \otimes [T_i^a] \otimes [T_i^v] \quad (15)$$

The precise computational methodology is outlined in Formulas (14) and (15), offering a nuanced and robust framework for analyzing and utilizing multi-modal data.

B. Multi-task Learning Framework

In this section, we introduce a multi-task learning framework that is designed to tackle diverse analysis tasks through the employment of a rigorous hard parameter sharing mechanism. This mechanism enables all tasks to synergistically harness neurons and weights in the foundational low-level network, while reserving task-specific neurons and weights for each individual task in the higher-level network. The framework adopts a two-tiered architecture, with the underlying representation learning network serving as a common layer and

the prediction network tailored to meet the distinct demands of each task.

$$F_s^* = \text{ReLU}(F_s W_s^{lT} + b_s^l) \quad (16)$$

$$y_s = F_s^* W_s^{2T} + b_s^2 \quad (17)$$

Within this multi-task learning paradigm, four distinct tasks are formulated, and the specific configuration of the task-oriented layers is outlined in Formulas (16) and (17). Notably, the single-modal task is trained utilizing labels generated by the SLGM methodology, limiting its existence to the training phase. Ultimately, the model relies on the predicted outcomes of the multi-modal task as the definitive output, reflecting its emphasis on the integration of multimodal information. This approach offers a comprehensive and efficient solution for multi-task learning, promoting knowledge sharing and task specialization within a unified framework.

C. Self-Supervised Label Generator

Most multimodal analysis datasets need more independent single-modal labels, posing a challenge for multi-task learning frameworks. To address this limitation, Fig. 4 illustrates the outcomes of a self-supervised label generation module tailored to diverse modalities [30]. Consequently, this section introduces the Self-Supervised Label Generation Module (SLGM), whose primary objective is to derive single-modal annotations from multimodal annotations. The conceptual foundation of SLGM is grounded in two potential mapping relationships: (1) a direct correlation between modal representations and their corresponding modal supervision values and (2) a proportionality in the mapping relationships among different modalities. By harnessing these insights, SLGM aims to bridge the gap between multimodal annotations and the desired single-modal labels, enabling a more comprehensive and practical multi-task learning framework.

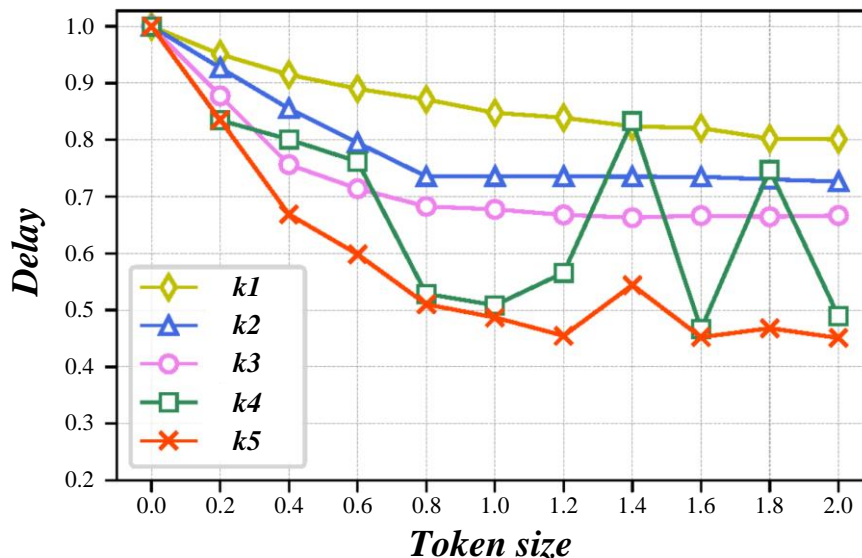

Fig. 4. Results of self-supervised label generation module in different modes.

The details is shown in Formula (18). The (SLGM delineates modal representations into two distinct categories, dictated by their polarity. Subsequently, it identifies the central tendencies of these two categories, yielding a modal representation positive center and a modal representation negative center for each modality. The precise computational methodology for this categorization and centering is outlined in Formulas (19) and (20), ensuring a rigorous and systematic approach to generating single-modal annotations from multimodal data.

$$C = (F_m \# L_m) \propto (F_u \# L_u) \tag{18}$$

$$C_p = \frac{\sum_{i=1}^N I(y(i) > 0) \cdot F_i}{\sum_{i=1}^N I(y(i) > 0)} \tag{19}$$

$$C_n = \frac{\sum_{i=1}^N I(y(i) < 0) \cdot F_i}{\sum_{i=1}^N I(y(i) < 0)} \tag{20}$$

Next, the SLG) employs the coefficient as a metric to quantify the degree of deviation between each sample and its corresponding class center. This calculation is precisely defined in Formulas (21) and (22), providing a rigorous mathematical framework for assessing the proximity of samples to their respective modal representation centers.

$$S_p = \sum_{j=1}^K \sqrt{F(j)C_p(j)} \tag{21}$$

$$S_n = \sum_{j=1}^K \sqrt{F(j)C_n(j)} \tag{22}$$

IV. EXPERIMENTAL RESULTS AND ANALYSIS

A. Quantitative Analysis

The model was quantitatively analyzed using CMU-MOSI and CMU-MOSEI datasets. During the test, the multimodal analysis task was regarded as a regression and classification task, respectively. The regression task used mean absolute error (MAE) and F1 score as evaluation indicators. Among them, the smaller the value of MAE, the better the model performance, and the larger the value of other indicators, the better the model performance. As shown in Table I and Table II, the five average experimental results on the two data sets show that the proposed

model can achieve satisfactory results and its performance can reach the average level. This confirms that the model can effectively mine multimodal associations to improve prediction effects.

TABLE I. EXPERIMENTAL RESULTS OF THE MODEL ON CMU-MOSI DATASET

Model	MAE	F1-Score
MFN	0.95	78.1
RAVEN	0.92	76.6
MCTN	0.91	79.1
MuT	0.87	82.8
MISA	0.78	83.6
Self_MM	0.71	86.0
Ours	0.81	82.9

TABLE II. EXPERIMENTAL RESULTS OF THE MODEL ON CMU-MOSEI DATASET

Model	MAE	F1-Score
MFN	0.71	77.0
RAVEN	0.61	79.5
MCTN	0.61	80.6
MuT	0.58	82.3
MISA	0.55	85.3
Self_MM	0.53	85.3
Ours	0.59	82.2

Compared with other models, there are still some small gaps in some indicators. As can be seen from the analysis of the reasons in Fig. 5, the MISA model and the Self_MM model have already processed the data in the representation learning stage, and improved the quality of modal representation by learning the common and individual information of different modal data, which means that such models More reliable data can be obtained at the beginning to improve the subsequent prediction effect. During the experiment, more than 4,000 samples were randomly selected from the test set to test the 2 classification results. The plotted curves are shown in Fig. 6, which can reflect the excellent performance of the model.

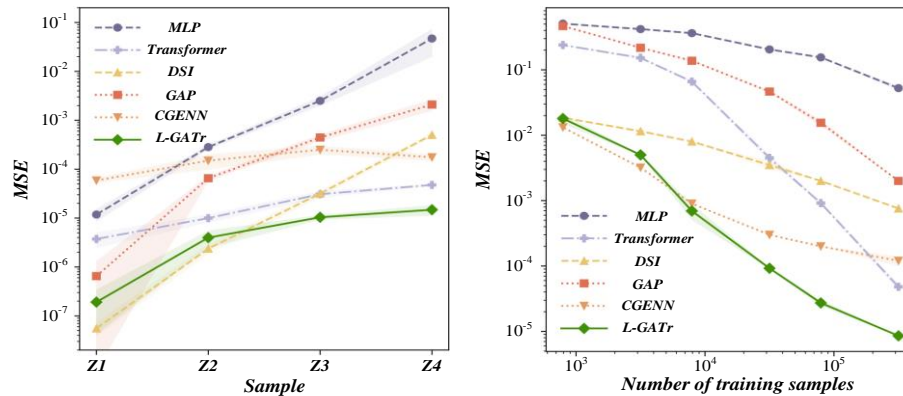

Fig. 5. Results of the MISA model and the Self-MM model in the presentation learning stage.

Fig. 6. Performance differences between models.

Table III shows the results from the CMU-MOSI dataset. In order to compare the performance differences between models, this chapter chooses the evaluation indicators of the classification task and the regression task for comparison. For classification tasks, the text-proposed model has obvious advantages in the evaluation of 2 classification accuracy (Acc-2), 7 classification accuracy (Acc-7) and F1 score. For the regression task, the model has achieved significant improvements in the evaluation of both the mean absolute error MAE and the Pearson correlation coefficient Corr, and the results are shown in Fig. 6. In addition to the MAE indicator, the larger the evaluation value shown in the table, the better the performance of the model on this indicator. Fig. 7 is the index result graph of the linear level. The experimental results show that the multi-modal analysis using the multi-task learning framework provides a new idea to solve the problems in this field. The model performance with the help of multi-task joint training is better than that with a single task. Task-trained model

performance. In addition, the multi-level association mining framework also proves its effectiveness, it can obtain more useful information than single-angle mining.

TABLE III. EXPERIMENTAL RESULTS OF THE MODEL ON THE CMU-MOSI DATASET

Model	MAE	Corr	Acc-7	Acc-2	F1-Score
MFN	0.95	0.66	36.2	78.1	78.1
RAVEN	0.92	0.69	33.2	78.0	76.6
MCTN	0.91	0.68	35.6	79.3	79.1
MulT	0.87	0.70	40.0	83.0	82.8
MISA	0.78	0.76	42.3	83.4	83.6
Self_MM	0.71	0.80	46.7	86.0	86.0
Ours	0.69	0.81	47.1	88.4	88.4

Fig. 7. Linear layer index result graph.

In this paper, a Transformer-based multi-analysis method is proposed. The model can fully consider the relationship between multiple information, use the linguistic-guided Transformer to mine the association between multiple data, and use the soft

mapping module to achieve tight coupling of multiple data, thereby improving the analysis effect of the model. The experiments of the model on two data sets have achieved satisfactory results, which further demonstrates the feasibility

and effectiveness of the theory of improving the prediction effect by mining multiple associations and providing a specific solution for the problems in multiple analysis fields. Table IV shows results from the dataset, which shows that the model can also achieve good results.

TABLE IV. EXPERIMENTAL RESULTS OF THE MODEL ON THE CMU-MOSEI DATASET

Model	MAE	Corr	Acc-7	Acc-2	F1-Score
MFN	0.71	0.54	45.0	76.9	77.0

Self_MM	0.53	0.77	52.4	85.2	85.3
Ours	0.51	0.74	53.9	86.2	85.9

B. Ablation Experiment

The proposed model includes two structures: LGT and SM. The former interacts between modes to improve the learning effect when learning a certain mode, and the latter maps the learning results of each mode to a high-dimensional space for better classification. In order to verify effectiveness of two structures, this section conducts ablation experiments on the CMU-MOSI dataset, which are specifically divided into four situations: LGT and SM are not used at all; only remove LGT;

Only SM is removed; LGT and SM were used simultaneously. Choosing to use the ordinary multi-head attention mechanism instead of LGT when it is not used means that the interaction ability between modes is lost. When SM is not used, the results of independent learning of each modal are directly weighted and averaged, and then classified. The ablation experimental results are shown in Fig. 8 and Fig. 9, from which it can be seen that the two main structures of the model can play a positive role in the final prediction.

C. Validation Experiment of Self-Supervised Label Generator

Combining the idea of multi-task learning with the proposed model, a multimodal analysis model based on a multi-level association mining framework and a self-supervised label generator is proposed in this chapter to solve the multimodal analysis problems faced in multimodal analysis simultaneously. Modal association mining and multimodal collaborative learning problems. The multi-level association mining framework further deepens the research content, which can simultaneously mine association information from two angles. The self-supervised tag generator can automatically train the single-modal tag-assisted multi-task learning framework, thus realizing multimodal collaborative learning. The verification experiment of the self-supervised label generator is shown in Fig. 10. A large number of experiments have been carried out on classical data sets in the field of multimodal analysis, all of which prove that the proposed model has excellent analytical performance and can provide a feasible idea for solving the problems existing in this field.

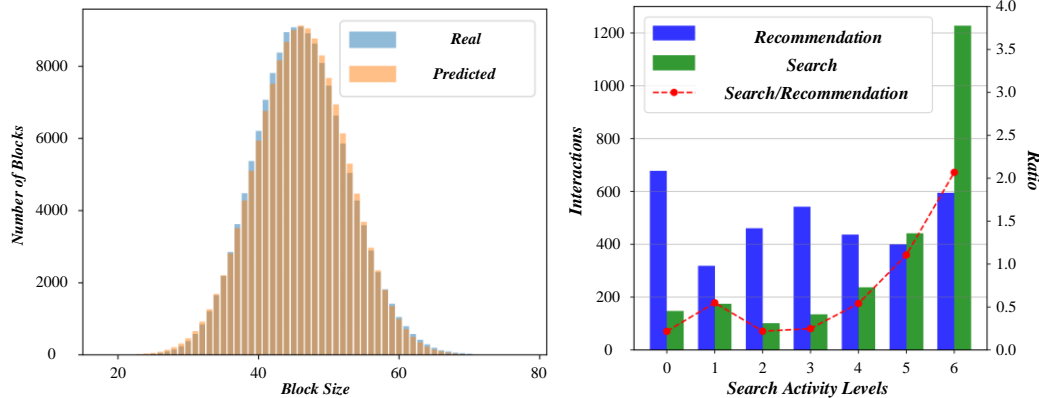

Fig. 8. Ablation experiment of module size and search level.

Fig. 9. Result diagram under different epoch.

Fig. 10. Verification experiment of self-supervised label generator.

In order to examine the rationality and robustness of SLGM, this section extracts several labels generated by SLGM during training. As shown in Table V, the polarity of the single-modal labels of samples 1 to 3 is consistent with that of the manually labeled multi-modal labels, which shows that the single-modal labels generated by SLGM are of some value. Compared with the manual labeling of multi-modal labels, the single-modal labels of samples 4 to 5 achieve a negative shift, and this negative shift is reasonable.

TABLE V. SAMPLE SLGM GENERATION LABEL SAMPLE

MOSI-M	SLGM-L	SLGM-A	SLGM-V
2.2	1.1925	0.3874	0.8557

-0.2	-0.0327	0.0874	0.0001
0.6	0.8281	0.0052	-0.0856

V. SUMMARY

This research has conducted an in-depth exploration of the design of a cross-border e-commerce short video recommendation system based on the multi-modal fusion Transformer model. An efficient and accurate recommendation system has been successfully built through the comprehensive use of advanced technologies such as Transformer and multi-tasking learning. Many short videos and user behavior data of cross-border e-commerce platforms were collected and analyzed during the research process, supporting system design and optimization. First of all, in the aspect of multi-modal association mining, the cross-modal multi-head attention model is used to conduct in-depth analysis of multi-modal data such as video and text, and it is found that there is rich association information between different modes. A multi-modal analysis model is designed based on the multi-task learning framework in multi-modal collaborative learning. The model can learn more comprehensive and accurate multi-modal data representation through modal information sharing during training. In addition, the self-supervised labeling method proposed in this paper effectively solves the problem of missing labels, making the model perform well under limited labels. At the sorting level, we fuse the Bert and high-order explicit feature

cross models to extract deeper text features and capture the deep-seated interaction relationship between users and short videos. Through the analysis and verification of large-scale data, this feature fusion method can significantly improve the prediction accuracy of the recommendation system and provide users with more accurate recommendation services. Finally, a complete cross-border e-commerce short video recommendation system is designed and implemented. The system integrates multiple modules such as data acquisition, preprocessing, recall, and sorting and realizes the stable operation of the system and user-friendly interaction through front-end and back-end design. In practical application, the system has effectively improved user satisfaction and recommendation efficiency, with an accuracy rate and F1 score of 98.76% and 97.89%, respectively, bringing significant value to cross-border e-commerce platforms.

A Hidden Markov Model-Based Performance Recognition System for Marching Wind Bands

Wei Jiang

Shenyang City University, Shenyang 110100, China

Abstract—This paper explores the automatic recognition of marching band performances using advanced music information retrieval techniques. Music, a crucial medium for emotional expression and cultural exchange, greatly benefits from the harmonic backing provided by marching wind orchestras. Identifying these performances manually is both time-consuming and labor-intensive, particularly for non-professionals. This study addresses this challenge by leveraging Hidden Markov Models (HMM) and improved Pitch Class Profile (PCP) features to automate the recognition process. The research also explores the system's performance on real-world audio recordings with background noise and microphone variations. By dividing the audio signal into frames and transforming it to the frequency domain, the PCP feature vectors are extracted and used within the HMM framework. Experimental results demonstrate that the proposed method significantly enhances recognition accuracy compared to traditional PCP features and template matching models. The study identifies challenges in distinguishing similar tonal values, such as F-major and D-minor, which affect recognition rates. Additionally, the research highlights the importance of addressing background noise and microphone variations in real-world applications. Ethical considerations regarding privacy and intellectual property rights are also discussed. This research establishes a comprehensive system for automatic marching band performance recognition, contributing to advancements in music information retrieval and analysis.

Keywords—*Music information retrieval; Hidden Markov Model; feature extraction; automatic music recognition; marching band performance; PCP features*

I. INTRODUCTION

Music serves as a powerful medium of artistic expression. It enables people to express personal feelings and fulfill spiritual needs, while also fostering cultural exchange and promoting the development and integration of cultural diversity. Within the foundation of music theory, marching wind orchestra performances play a crucial role. They complement and enhance the main theme, adding depth and richness to the overall musical experience [1-3]. Despite its importance, the identification of marching band performances remains challenging and time-consuming, particularly for non-professionals. This paper aims to address this research gap by developing an automatic recognition system leveraging HMM and improved PCP features. If beautiful music lacks a harmonic backing, the overall effect will be greatly reduced [4, 5]. However, the identification of marching band performance often requires specialized knowledge and training that is difficult for non-professionals to accomplish accurately, especially in improvisation, where identification of marching band performance is even more challenging [6]. For many years, the identification and

recognition of marching wind band performances are mostly done manually, which is time-consuming and laborious [7]. With the development of multimedia and network technology, the importance of music information retrieval technology is becoming more and more obvious. The traditional low-level features such as Mel frequency cepstrum coefficients have limited effect in music semantic analysis, while the marching band performance, as a middle-level feature, contains rich music information, which is important for music analysis and retrieval [8]. Marching wind band performance is closely related to the emotion of music, which can help recognize and retrieve songs with similar styles. However, the system's performance on real-world audio recordings with background noise and microphone variations remains an important consideration [9].

Speech recognition technology has made significant progress in recent years, and HMM combined with genetic algorithm training has become a mainstream technology with the advantages of high recognition rate and fast response. However, the development of music recognition technology is slow and there are fewer related products on the market, mainly due to the low recognition rate [10]. The earliest music feature extraction methods used Mel-frequency cepstrum coefficients, but nowadays it is common to use pitch-set files to represent music, which can more accurately represent music features [11]. With the improvement of computer performance and Internet bandwidth, as well as the development of multimedia information technology, content-based multimedia retrieval techniques have emerged [12]. In music retrieval, marching wind orchestra performance, as a mid-level feature, can effectively support music segmentation, retrieval and sentiment analysis [13-15]. Automatic marching band performance recognition techniques have attracted the attention of a large number of researchers in the field of music information retrieval. The correct recognition and sequence generation of marching wind band performances can help the segmentation of musical structures and the identification of specific melodies, and can reveal the potential emotional connections of music [16].

The Electrical Engineering Department at National Taiwan University was a pioneer in using PVP feature vectors for performance recognition [17]. Their system processes input audio signals by segmenting them into frames and converting them into the frequency domain to extract PCP feature vectors [18]. The recognition process is divided into two phases: training and testing. In the training phase, a Hidden Markov Model (HMM) is used, where each state corresponds to a specific marching wind band performance [19]. The state transition matrix represents the probability of transitioning from one performance to another, while the observation distribution

indicates the likelihood of a particular PCP feature vector being generated by a specific state. In the testing phase, the observed feature vectors and the trained HMM are used to decode the most probable sequence of marching wind band performances. The team's innovative use of the N-gram algorithm within the HMM framework significantly reduces complexity and enhances recognition efficiency. In 2003, Alexander Sheh and Daniel P.W. Ellis from Columbia University proposed a system that converts arbitrary audio signals into corresponding performance sequences [20]. The system process includes audio framing, transforming to the frequency domain by Fourier transform, then mapping out PVP feature vectors, constructing a marching band performance model, and utilizing EM algorithms to complete the recognition in the HMM framework [21]. Although the recognition rate of this system for marching wind band performance is only 22%, it is innovative in that only the performance sequence is considered without the need of temporal requirements on the performance transformation. In 2005, Bello and Pickens applied the EM algorithm under the HMM framework, introduced the music knowledge into the model, and avoided arbitrary initialization by defining the state transfer matrix, and achieved a recognition rate of 75% [22, 23]. Although Markov models have been successful in speech recognition, there are challenges in applying them to music. Music has complex acoustic variations and requires more data for training. Manually labeling the performance boundaries of long sections of music is time-consuming and error-prone. The music and acoustics research center at Stanford University proposes a method to automate the performance boundary labeling by synthesizing audio to generate training data, which significantly improves the efficiency of model parameter estimation.

The purpose of the research in this paper is to establish a complete marching band performance recognition system, using audio files as the input of the whole system, and returning the marching band performance sequences recognized by the system as the output to the user, so as to realize the automatic recognition with performance as the basic unit. The research content of this paper mainly includes the following aspects: first, feature extraction of music. Since the speech signal is time-varying rather than smooth, and the human articulatory organ muscles move slowly, the speech signal can be considered smooth locally, so the processing methods and theories of smooth processes can be introduced into the processing of speech signals, thus simplifying the analysis of speech signals. Next, the marching band performances applied during the experiments are extracted, and a Hidden Markov Model is initialized for each marching band performance, using a single Gaussian observation function during the initialization process, with the mean vector set to 0 and the covariance matrix set to 1 [24]. Next, the experimental samples are labeled. The labeling is done from a MIDI file, so the input file must be converted to the corresponding MIDI format, and finally a piece of music performance is extracted as the output of the labeling process. Next, the system is trained, using a pitch set file to represent the music file, and the labeled marching band performance is used as the base model to train the system, with as many training samples as possible, in order to give the system access to all the performance models. Finally, system testing is performed, where a correctly labeled music file is used as input to check the

performance of the system. The remainder of this paper is organized as follows: Related work is given in Section II. Section III presents the theoretical background on Hidden Markov Models. Section IV describes the design of the marching band performance recognition system. Section V discusses the experimental results and analysis. Section VI concludes the paper with a summary of findings and suggestions for future research.

II. RELATED WORK

Initial efforts in music recognition heavily relied on low-level audio features such as Mel-Frequency Cepstral Coefficients (MFCCs). MFCCs were widely adopted due to their efficiency in capturing the timbral properties of audio signals [25]. However, their effectiveness in higher-level musical semantic analysis, particularly for complex structures like marching band performances, was limited [26]. The integration of Hidden Markov Models (HMMs) in music recognition was significantly advanced by Sheh and Ellis [27]. Their system converted arbitrary audio signals into performance sequences using HMMs, involving audio framing. Further refinement was seen in the work of Bello and Pickens [28], who applied the Expectation-Maximization (EM) algorithm within the HMM framework. Recent research has focused on enhancing the feature extraction methods to improve the recognition accuracy of musical signals. Enhanced PCP features have emerged as a crucial development, addressing tonal ambiguity and providing a more robust representation of musical content. Comparative studies have demonstrated that traditional template matching models [29], while straightforward, are often inadequate for dynamic and complex musical environments. In contrast, the combination of improved PCP features with HMMs has shown superior performance. However, a critical gap in existing research is the robustness of these systems in real-world scenarios, characterized by background noise and variations in recording conditions [30].

III. HIDDEN MARKOV MODEL

A Markov model is a demographic tool extensively utilized in diverse natural language processing applications, including speech recognition, automatic lexical annotation, and probabilistic grammar analysis. If the "future" of a process depends only on the "present" but not on the "past", the process is Markovian, or the process is called Markovian.

In addition, since speech signals are time-varying rather than smooth, and since the muscles of the human articulatory organs move slowly, speech signals can be considered locally smooth. In this way, we can introduce the processing methods and theories of smooth processes into the processing of speech signals, thus greatly simplifying the analysis of speech signals.

A. Characteristic Representation of Music

When analyzing audio signals, extracting and characterizing information from the time domain can be challenging due to the non-linear and often discontinuous nature of audio performance in this domain. In speech signal processing, converting audio signals from the time domain to the frequency domain is a common practice for more effective analysis. This technique is equally applicable to music signals. The two primary methods for this transformation are the short-time Fourier transform

(STFT) and the constant Q transform (CQT). Both methods convert the music signal from the time domain to the frequency domain, but they use different algorithms and computational processes to achieve this.

Fourier transform processing of speech signals, the premise is that the signal is always in a smooth state, but the audio signal of music is usually non-stationary, cannot be transformed by the Fourier transform spectrum to extract the spectral energy information, based on the assumption that the music signal is in the short-term transient conditions, that is, you can through the STFT spectral transformation, and then be able to analyze the characteristics of the signal in the frequency domain. The formula of STFT is expressed as:

$$X_m(\omega) = \sum_{n=-\infty}^{\infty} x[n]w[n-m]e^{-j\omega n}$$

Considering the continuity of the music signal, $x[n]$ represents the discretized representation, $w[n-m]$ represents the sliding time window, and $X_m(\omega)$ represents the transformed spectrum. Under the influence of Heisenberg's uncertainty principle, the time resolution and frequency resolution change accordingly because of the different window functions, if the function is determined and the window length is determined, both the time resolution and frequency resolution can not be changed, so it is difficult to deal with the non-smooth and mutated signals effectively, and it is suitable to deal with the slow-varying signals because of the insensitivity to the instantaneous changes. For the music audio signal used in this paper, there is only a single main theme after the relevant preprocessing, and its changes are more moderate, so the spectrum can be analyzed by short-time Fourier transform. Therefore, before extracting the PCP features from the audio signal, this paper employs the STFT to convert the time-domain signal into the frequency domain. This approach conserves computational power and aligns well with the subsequent PCP feature extraction. The flowchart of feature extraction in Fig. 1 shows the process of marching wind band performance recognition.

Fig. 1. Flowchart of feature extraction.

The calculation of PCP features is based on mapping frequency changes according to the twelve-tone equal temperament system in music theory. In musical terms, changes in pitch are reflected as changes in frequency values within the audio signal. Typically, the frequency ratio between notes an octave apart is 2:1. In the twelve-tone equal temperament system, the frequency ratio between adjacent semitones is the

twelfth root of two. Consequently, the horizontal axis of a musical signal changes exponentially, and when represented in three-dimensional space, the pitch changes correspond to a spiraling frequency pattern, as illustrated in Fig. 2 below. This visual representation highlights the frequency changes associated with different pitch levels more intuitively.

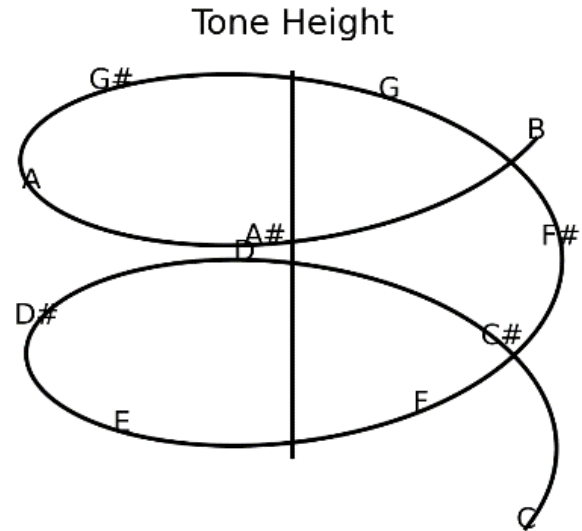

Fig. 2. Three-dimensional representation of sound level.

The distinct advantage of the PCP feature lies in its ability to process the spectral energy of an audio signal alongside its musical features, thereby providing a more accurate representation of the musical characteristics within the audio data. This enhanced representation is particularly beneficial when analyzing music-related audio signals. The following section will expand on the formula used to calculate the PCP feature for a single frame state:

$$p(k) = [12 * \log_2(k * \frac{f_{sr}}{N} / f_{rel})] \text{mod} 12$$

where f_{rel} is the reference frequency value of the lowest scale group, the lowest scale group includes the scales C1, D1, E1, F1, G1, A1, B1; f_{sr} is the sampling frequency, N represents the number of sampling points, f_{sr}/N denotes the transform frequency interval of the Fourier Transform, and $k * \frac{f_{sr}}{N}$ denotes the frequency of each component in the frequency domain, so $k * \frac{f_{sr}}{N * f_{rel}}$ represents the The frequency ratio of the component to the level, and all the components corresponding to the frequency value of the same level are summed up according to the above formula to get the twelve-dimensional PCP main melody feature vector:

$$PCP[p] = \sum_{k:p(k)=p} |X[k]|^2, p = 1, 2, \dots, 12$$

where $X(k)$ is the energy spectrum obtained by Fourier transforming the audio data of the main melody, k is the index of the Fourier transformed component, and p is the ordinal number corresponding to the twelve-tone levels. According to the twelve mean laws in music theory, ignoring the influence of the higher or lower octave, and only considering the frequency

values of the twelve tone levels in the lowest scale group in the music, each component in the frequency domain and the frequency value of the lowest tone level are divided correspondingly to obtain twelve frequency ratios, thus completing the expansion of the components into twelve frequency bands; for all the twelve bands obtained by the components, the components corresponding to the same tone level bands are summed up to get the twelve-dimensional PCP melody feature vector $PCP[p]$ in the whole frequency domain.

From the calculation of the PCP feature in the previous subsection, it is easy to see that it is the spectral information of the music signal is compressed by the frequency rule corresponding to the twelve equal-tempered law, and folded into a twelve-dimensional vector in the form of a tone level profile of the spectrum. This calculation process, although the spectral information is endowed with the musical characteristics, does not take into account the possible problems that may exist in the music signal. Usually in musical signals, the notes in the low frequency part are difficult for the human ear to distinguish and hear because of their resonance, so the bass is more blurred and less distinctive in most cases. In addition, there are overtones in common music signals. In the normal human ear mechanism hearing system, overtones do not cause too much interference and influence on the auditory senses, so they are generally not too concerned about overtones. However, in the audio feature representation, when there are too many overtones in the music signal, the process of converting it into a spectrum will occupy more spectral resources, thus affecting the energy of the similar fundamental frequency, generating errors, and affecting the information extraction of the real sound value. Considering that the problems of bass ambiguity and high-frequency overtones are less considered in the current research, this paper introduces a Gaussian filter bank, which is combined with the musical properties of the twelve equal temperament law, to add a window restriction and increase the weights of the fundamental frequencies of the tone levels. The weights of irrelevant frequencies are filtered out, and the mathematical expression of this Gaussian filter is as follows.

$$PCP_{[p]} = \exp\left(-\frac{\left(k \cdot \frac{f_s}{N} - f_{rel} \cdot 2^{(o-1)}\right)^2}{2 \cdot 15^2}\right) * PCP_{[p]}$$

In the above formula, $k \cdot \frac{f_s}{N}$ represents the component frequency value of the sample, and the center frequency is the reference frequency value of the scale corresponding to the octave interval where it is located, $f_{rel} \cdot 2^{(o-1)}$, o represents that the frequency of the sample point at this time corresponds to the frequency range of the o th octave. Because f_{rel} represents the reference frequency value of the lowest scale, when the frequency value of the sampling point is in the frequency range of other octave intervals, because the frequency relationship of different octaves is the 2nd power relationship, for example, the ratio of the frequency values of C2 and C1 is 2, and the ratio of the frequency values of C3 and C1 is 4, so the center frequency becomes the reference frequency value of the original lowest scale group multiplied by an integral multiple of 2, it is now in the octave where the reference frequency value is located. At this point, the frequency values of the twelve

semitones within the octave interval become the new center frequencies. These center frequencies are set to correspond with the semitone frequencies in the twelve-tone equal temperament system. This method retains the frequency weights of all notes in this system while filtering out irrelevant frequency values. Consequently, low-frequency noise and high-frequency overtone interference are effectively mitigated, and the fundamental frequencies of the low-frequency band are preserved, addressing the issue of indistinct tone values to some extent.

Fig. 3 illustrates the spectrum of the frequency interval for A4 after Gaussian filtering. It shows that 440Hz has the highest amplitude, indicating it as the center frequency. Other frequencies have amplitudes ranging between 420Hz and 430Hz on the left boundary and between 450Hz and 460Hz on the right boundary. The frequencies of G#4 and B4 fall outside these boundaries, ensuring that effective tone values pass through, demonstrating the efficacy of the filtering. Each Gaussian filter's center frequency corresponds to the twelve semitones between C4 and B4. This filtering method effectively extracts frequency domain energy based on the twelve-tone equal temperament system, mitigating low-frequency noise and high-frequency overtones.

Fig. 3. A4 korst spectral plot of notes.

The primary process in PCP feature calculation involves folding and weighting the spectral energy. In actual music audio, the complex interplay of sounds from various instruments with different pitches, volumes, and rhythms results in significant variability in the chromatic features extracted from each song. This variability introduces multiple levels of complexity, making it challenging to develop a classifier that covers the entire feature space. To manage this, logarithmic compression is used to limit the dynamic range of the features, as detailed by the following mathematical formula:

$$PCP_{Log} = \log(1 + \eta * \widetilde{PCP}[p]) / P[p]_{sum}, p = 1, 2, \dots, 12$$

$\widetilde{PCP}[p]$ is the PCP feature vector obtained after Gaussian filtering as described above, $P[p]_{sum}$ is the sum of all the frequency components corresponding to the twelve semitones, and η stands for the compression coefficient, and 100 is used as the compression coefficient in this paper because it has the best performance in the experiment. The ratio of the filtered PCP feature vector to the total frequency components is obtained,

multiplied by the compression coefficient, weighted and summed with 1, and then logarithmically transformed to replace the original PCP feature vector. The above compression method reduces the computation amount of the related feature frequency values, and makes the effect of the features have a better performance ability.

B. HMM Model

An HMM model is a statistical framework extensively utilized in various natural language processing applications, including speech recognition, automatic lexical annotation, and probabilistic grammar analysis. A process is considered Markovian, or a Markov process, if its future state depends solely on its current state and not on its past states.

$$X(t + 1) = f(X(t))$$

Where $X(t)$ denotes the state at time t . Markov processes that are discrete in time and state are called Markov chains.

$$X_n = X(n), n = 0,1,2, \dots$$

Denotes the results of successive observations of discrete state processes on the time set $T = \{0,1,2,3, \dots\}$. The result of successive observations of discrete state processes on the time set $T = \{0,1,2,3, \dots\}$. A Markov chain is a random process that adheres to the following:

The probability distribution of the system’s state at time $t + 1$ depends only on its state at time t , and is independent of its states prior to t ;

The transition from the state at time t to the state at time $t+1$ is independent of the specific value of t .

A Markov chain model can be defined by the elements (S, P, Q), where:

S is a non-empty set of all possible states of the system, commonly known as the state space. This set can be finite, countable, or any non-empty set. In this paper, S is assumed to be countable, with states denoted by lowercase letters such as i, j etc.

P is the state transition probability matrix of the system, $p_{ij}(k)$ represents the probability of transitioning from state i at time t to state j at time $t + k$. For a Markov chain model in a discrete state space with a finite number of states, the transition probability distribution is expressed as a matrix with $N \times N$ elements, known as the “transition matrix”.

$$P_{ij}(t, t + k) = P(q_{t+k} = \theta_j | q_t = \theta_i)$$

When $k = 1, P_{ij}(1)$ is called a piece of transfer probability, referred to as transfer probability, and all the transfer probabilities $a_{ij}, 1 \leq i, j \leq N$ can form a state transfer matrix:

$$A = \begin{bmatrix} a_{11} & \dots & a_{1N} \\ \vdots & & \vdots \\ a_{N1} & \dots & a_{NN} \end{bmatrix}$$

Where $0 \leq a_{ij} \leq 1$ and $\sum_j = 1^N a_{ij} = 1$. Q represents the initial probability distribution of the system, with π_i indicating the probability of the system being in state i at the initial time.

The Fig. 4 below demonstrates the hidden and observed states using a weather example. In this model, the hidden state (actual weather) is represented by a first-order Markov process, where each state is interconnected. In addition to the probabilistic relationships defined by the Markov process, there is a confusion matrix that outlines the probabilities of the observed states for each corresponding hidden state.

For the weather example, the confusion matrix is shown in Table I.

TABLE I. CONFUSION MATRIX OF WEATHER

Observed weather	Hide Weather			
	Dry	Dryer	Wet	Soggy
Sunny	0.6	0.2	0.15	0.05
Cloudy	0.25	0.25	0.25	0.25
Raining	0.05	0.1	0.35	0.5

Fig. 4. First-order hidden markov processes.

A Hidden Markov Model (HMM) is characterized by five elements: two sets of states and three probability matrices. The hidden states S_4 satisfy the Markov property and represent the underlying processes that are not directly observable (S_1, S_2, S_3 , etc.). The observable states (OOO) correspond to these hidden states and can be directly measured (O_1, O_2, O_3 , etc). It's important to note that the number of observable states doesn't necessarily match the number of hidden states.

The initial state probability distribution, π , defines the probabilities of the system starting in each hidden state at $t=1$, $P(S_1) = P_1, P(S_2) = P_2, P(S_3) = P_3$, describes the probabilities of transitioning from one hidden state to another. Additionally, the observation probability matrix B —often called the confusion matrix—provides the probabilities of each observable state given a hidden state. This comprehensive framework allows HMMs to model complex sequences where the true states are not directly observable but can be inferred through observed data.

$$A = \begin{bmatrix} a_{11} & \dots & a_{1N} \\ \vdots & & \vdots \\ a_{N1} & \dots & a_{NN} \end{bmatrix}$$

a_{ij} denotes the probability that the state is S_i at time t and S_j at time $t + i$. A describes the transfer probabilities between states in the Hidden Markov Model. The observed state transfer probability matrix B (Confusion Matrix) is as follows:

$$B = \begin{bmatrix} b_{11} & \dots & b_{1N} \\ \vdots & & \vdots \\ b_{M1} & \dots & b_{MN} \end{bmatrix}$$

C. Application of Hidden Markov Models

Once a system is defined as a Hidden Markov Model (HMM), it can solve three fundamental problems. The first two are pattern recognition tasks: calculating the probability of a specific observation sequence given the HMM, and determining the most likely sequence of hidden states that could produce the observed sequence. The third problem is to generate an HMM from a given sequence of observations.

1) *Evaluation*: This involves assessing which of several Hidden Markov Models (represented by sets of Π, A, B) is most likely to have generated a specific observation sequence. For instance, we might have different HMMs for "summer" and "winter" based on seasonal variations in seaweed humidity. By evaluating the probability of observed humidity sequences, we can determine the most appropriate model, thus inferring the current season. In speech recognition, this method is used to identify words by comparing the observation sequences against multiple HMMs, each representing a different word. The forward algorithm is employed to compute the probability of the observation sequence for each HMM, enabling the selection of the most likely model.

2) *Decoding*: This task involves finding the most probable sequence of hidden states that could generate a given sequence of observations. This is particularly valuable as hidden states often represent significant, unobservable information. For example, consider a scenario where a blind hermit can observe

the state of seaweed but wants to infer the underlying weather conditions (the hidden states). The Viterbi algorithm is used in such cases to determine the most likely sequence of hidden states given the observed data, providing insights into the unobservable processes.

3) *Learning*: The third and most challenging problem in HMMs is generating an appropriate Hidden Markov Model from a sequence of observations. This involves estimating the optimal HMM parameters— Π, A and B —that best describe the observed sequence and the associated hidden states. This process, known as learning or parameter estimation, is crucial when the transition and observation matrices (A and B) cannot be directly measured, which is often the case in practical applications. The forward-backward algorithm is typically employed for this purpose, as it allows for the iterative refinement of the model parameters to maximize the likelihood of the observed data given the model.

D. Implementation of Hidden Markov Models

Hidden Markov models, described by a vector and two matrices (Π, A, B), are of great value for real systems, and although they are often only an approximation, they are robust to analysis. Hidden Markov models typically solve problems such as: evaluation, decoding, and learning.

We use a forward algorithm to compute the probability of a T -long sequence of observations:

$$Y^{(k)} = y_{k_1}y_{k_2}, \dots, y_{k_{T-1}}y_{k_T}$$

To compute the probability of an observation sequence of length T , the forward algorithm is employed. This method involves recursively determining the probability of the observation sequence for a given HMM. We start by defining the partial probability, which represents the likelihood of reaching an intermediate state within the sequence. Then, we describe how to compute these local probabilities at $t=1$ and for subsequent times $t=n$ (where $n>1$). The following Fig. 5 illustrates the weather states and the first-order state transitions for observation sequences labeled as dry, wet, and soaked conditions:

Fig. 5. First order state transfer diagram.

We define the local probability of being in state j at time t as $\alpha_t(j)$. This local probability is computed using the formula:

$$\alpha_t(j) = \Pr(\text{Observe state} \mid \text{Hidden state } j) \times \Pr(\text{all paths to state } j \text{ at time } t)$$

For the final observed states, this local probability includes the likelihood of reaching these states through all possible paths in the lattice. By summing these final local probabilities, we obtain the total probability of the observed sequence given the Hidden Markov Model (HMM).

To compute the local probability $\alpha_t(j)$ at $t = 1$, we use the initial probabilities, since there are no prior paths. Thus, the probability of being in the current state at $t = 1$ is the initial probability, represented as $\Pr(\text{state } t=1) = P(\text{state})$. Consequently, the local probability at $t=1$ is calculated by multiplying the initial probability of being in the current state with the corresponding observation probability:

$$\alpha_1(j) = \pi(j) \times b_{jk_1}$$

Where $\pi(j)$ is the initial probability of state j , and b_{jk_1} is the probability of observing the initial observation given state j . So, the local probability of state j at the initial moment depends on the initial probability of this state and the observation probability that we have seen at the corresponding moment.

Fig. 6. Final localized probability transfer map.

Now we can recursively compute the probability of a sequence of observations after a given Hidden Markov Model (HMM). We start by computing $\alpha_2(j)$ at $t=2$ from the local probability $\alpha_1(j)$ at $t=1$, $\alpha_3(j)$ at $t=3$ from $\alpha_2(j)$ at $t=2$, and continue this process until $t=T$. The probability of the entire observation sequence for a given HMM is the sum of the local probabilities at $t=T$:

$$\Pr(Y^{(k)}) = \sum_{j=1}^n \alpha_T(j)$$

To efficiently compute the probability of an observation sequence given an HMM, we use the forward algorithm. This algorithm employs recursion to avoid the exhaustive computation of all possible paths in the lattice. Using this approach, we can evaluate multiple HMMs by applying the forward algorithm to each one and then selecting the model that yields the highest probability for the given observation sequence.

For generated observation sequences, the most probable model parameters are determined and optimized using the forward-backward algorithm. The essential problems addressed

See the observation probability at the corresponding moment. Calculate the local probability for $t>1$:

$$\alpha_1(j) = \pi(j) * b_{jk_1}$$

We can assume, recursively, that the probability of the observed state given the hidden state $\Pr(\text{Observe state} \mid \text{Hidden state } j)$ is already known. Now, we focus on the probability of all paths leading to state j at time t ($\Pr(\text{all paths to state } j \text{ at time } t)$). The number of paths required to compute $\alpha_{t-1}(j)$ increases exponentially with the sequence of observations, but at moment $t-1$ $\alpha_{t-1}(j)$ gives the probability of all previous paths to this state, so we can define $\alpha_t(j)$ at moment t by the local probability at moment $t-1$:

$$\alpha_{t+1}(j) = b_{jk_{t+1}} \sum_{i=1}^n \alpha_t(i) a_{ij}$$

Therefore, this probability we compute is equal to the sum of the corresponding observation probability (i.e., the probability of observing a symbol in state j at time $t+1$) and the probability of arriving at this state at that moment, from the product of the computation of each localized probability from the previous step and the corresponding state-transfer probability multiplied by the product of the corresponding state-transfer probabilities, as shown in Fig. 6.

by HMMs include evaluation (using the forward algorithm) and decoding (using the Viterbi algorithm). The evaluation measures the relative fitness of a model, while decoding infers the sequence of hidden states. Both processes depend on the HMM parameters: the state transition matrix A , the observation matrix B and the initial state probability vector Π .

In the forward algorithm we define the local probability $\alpha_t(i)$, call it the forward variable:

$$\alpha_t(i) = P(O_1, O_2, \dots, O_t, q_t = S_i \mid \lambda)$$

Similarly, we can define a backward variable $\beta_t(i)$:

$$\beta_t(i) = P(O_{t+1}, O_{t+2}, \dots, O_T \mid q_t = S_i, \lambda)$$

The backward variable represents the probability of a sequence of local observations from the moment $t+1$ to the termination moment, knowing the Hidden Markov Model λ and the fact that t moments are located in the hidden state S_i . Also similar to the forward algorithm, we can compute the backward variable recursively from backward to forward (hence the term backward algorithm): Initially, the backward variable for all states at time $t = T$ is 1

$$\beta_T(i) = 1 \quad 1 \leq i \leq N$$

Inductively, recursively calculate for each time point, $t = T - 1, T - 2, \dots, 1$ at the time of the backward variable:

$$\beta_t(i) = \sum_{j=1}^N a_{ij} b_j(O_{t+1}) \beta_{t+1}(j) \quad t = T - 1, T - 2, \dots, 1 \quad 1 \leq i \leq N$$

This approach allows for the computation of backward variables for all hidden states at each point in time. To calculate the probability of observing a sequence using the backward algorithm, one needs to sum the backward variables (local probabilities) at $t=1$. The following Fig. 7 shows the relationship between the backward variables at moment $t+1$ and at moment t :

Fig. 7. Forward-backward variable relationships.

Among the three basic problems of Hidden Markov Models (HMM), the third problem of HMM parameter learning is the most difficult, because for a given sequence of observations O , there is no method that can accurately find an optimal set of Hidden Markov Model parameters (Π, A, B) to maximize $P(O|\lambda)$. As a result, scholars retreat to the second-best solution, which cannot make $P(O|\lambda)$ globally optimal, and seek for a solution that makes it locally optimal, and the forward-backward algorithm becomes an alternative solution to the Hidden Markov Model learning problem. We first define two variables. Given

an observation sequence O and a Hidden Markov Model λ , define the probability variable of being in the hidden state S_i at time t as:

$$\gamma_t(i) = P(q_t = S_i | O, \lambda)$$

Regarding the definition of the forward variable $\alpha_t(i)$ and the backward variable $\beta_t(i)$, we can easily express the above equation in terms of forward and backward variables as:

$$\gamma_t(i) = \frac{\alpha_t(i) \beta_t(i)}{P(O | \lambda)} = \frac{\alpha_t(i) \beta_t(i)}{\sum_{i=1}^N \alpha_t(i) \beta_t(i)}$$

$$\xi_t(i, j) = P(q_t = S_i, q_{t+1} = S_j | O, \lambda)$$

IV. MARCHING BAND PERFORMANCE RECOGNITION SYSTEM DESIGN

The automatic music recognition system developed in this paper comprises two primary components: the music feature extraction module, which utilizes the enhanced PCP feature extraction method previously described, and the modeling module. The modeling module involves gathering modeled music labels and conducting the training and prediction phases of the model, as shown in Fig. 8.

The automatic music recognition system presented in this paper is divided into two primary sections. The music feature extraction module, shown in the dotted box on the left, utilizes the improved PCP features discussed before. The model module, depicted in the dashed box on the right, focuses on the HMM model and the creation of automated music tags. The details of the model module will be further explained in the following sections.

First, the user uploads audio and transmits it to the back-end via Axios' XMLHttpRequest send method; the back-end receives the request and begins to reason about the audio through format detection and returns the inference results; the front-end displays the inference results and can synchronize with the results of playing the audio; the user can choose to download the pipe using the VUE download File method; the orchestra plays the music or re-uploads the music; the user can choose to download the pipe using the VUE download File method. Users can choose to download the music played by the orchestra or re-upload the music by using the VUE download File method. The processing state is shown in Fig. 9.

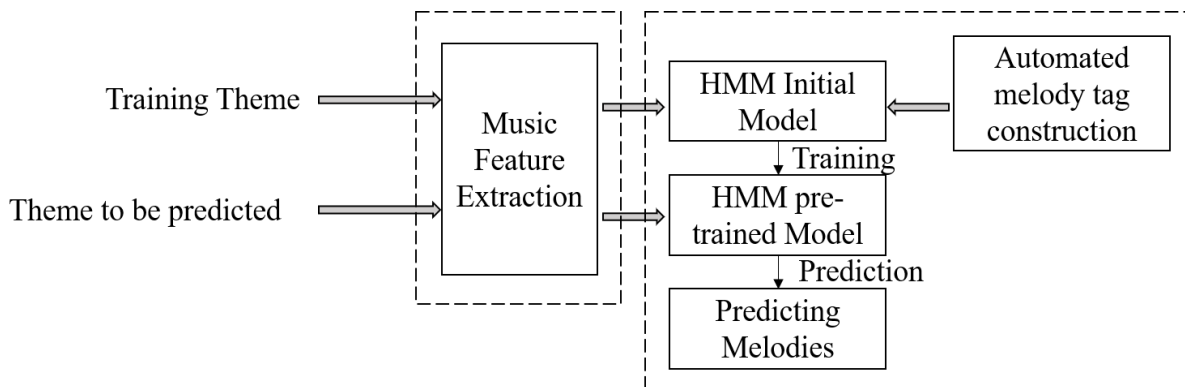

Fig. 8. Framework diagram of automatic music recognition system.

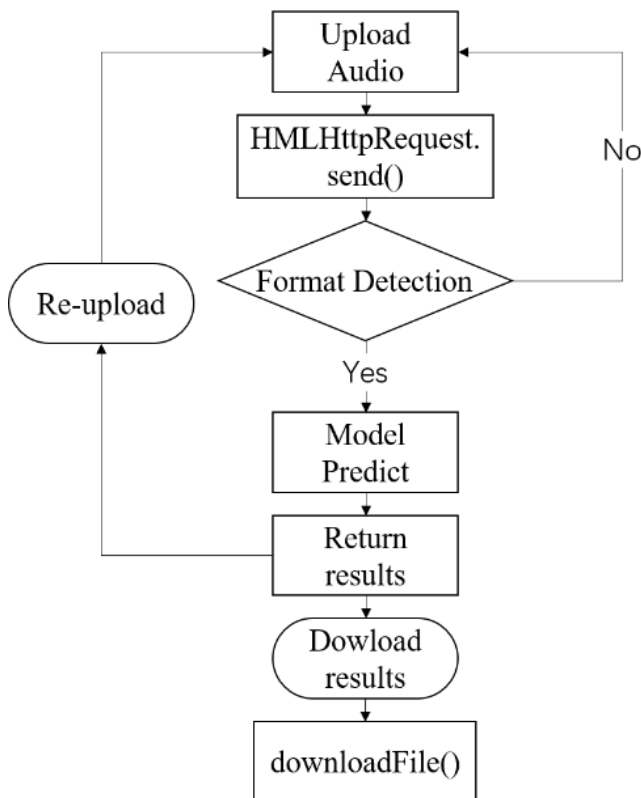

Fig. 9. Platform process.

V. RESULTS AND DISCUSSION

A. Experimental Data Collection

The source data for this paper consists of 455 MIDI music files obtained from an online MIDI music library. Of these, 450 files are used for training and 5 for testing. The datasets are preprocessed to extract the main melody and accompaniment tracks. The main melody is converted to WAV format for feature extraction, while the accompaniment is labeled using the proposed automatic music label construction method. Both data types are named consistently for model training purposes.

The improved PCP feature vector for the main melody, as proposed in this paper, is utilized for model feature extraction and serves as the observation vector for the HMM. To assess the robustness of the system, experiments were conducted to evaluate its performance on real-world audio recordings with background noise and microphone variations. The results indicated that while the system performed well under controlled conditions, its accuracy decreased in the presence of significant noise and variations, suggesting the need for further refinement and noise reduction techniques. The HMM consists of six states, excluding the initial and termination states. Each active state employs a single Gaussian observation function with a diagonal matrix, an average vector, and a change vector. After training the model, five files are randomly selected from the test dataset. The improved PCP feature vectors are extracted and inputted into the model for wind music prediction, and the predicted sequences are recorded. These steps are then repeated using traditional PCP features as observation vectors for comparison purposes.

To evaluate the accuracy of the predicted wind music, the results are compared against the correct harmonic sequences determined by professional music researchers using established music theory. The accuracy of the system's recognition is mathematically defined as follows:

$$P_{true} = \frac{N_{sum} - N_{false}}{N_{sum}}$$

In the above formula, N_{sum} represents the total number of accompanied piped tunes of a single tested music file, and N_{false} represents the number of incorrectly recognized piped tunes, and their difference represents the meaning, which is equal to the number of piped tunes that appear to be different in the results of all the piped tunes generated by the system recognition of the tested music file in this paper, compared to the results of all the piped tunes obtained by manual recognition.

B. Tests Results

Statistics of the correctness of the five test music files recognized by the system for wind music tunes were obtained, and the data of the experimental results are shown in the following Table II.

TABLE II. COMPARISON OF TRADITIONAL PCP AND MODIFIED PCP RESULTS

Training data	Test data (piece name)	System Type	Recognition Accuracy
Music files in the MIDI music library	Liberty Bell March	Legacy PCP+HMM	79.32
		Revised PCP+HMM	84.77
	British Grenadiers March	Legacy PCP+HMM	76.41
		Revised PCP+HMM	82.52
	El Capitan	Legacy PCP+HMM	72.76
		Revised PCP+HMM	75.22
	Entry of the Gladiators	Legacy PCP+HMM	78.01
		Revised PCP+HMM	84.29
	The Thundered	Legacy PCP+HMM	72.36
		Revised PCP+HMM	74.47

The data presented in the table indicates that the improved PCP features used in this study enhance the accuracy of wind music recognition compared to traditional PCP features. Specifically, the experimental results show that the improved PCP features increase the recognition accuracy for the pieces “Liberty Bell March,” “British Grenadiers March,” and “Entry of the Gladiators” by 5.25%, 6.11%, and 6.28%, respectively. For the pieces “El Capitan” and “The Thundered,” the recognition accuracy improved by 2.46% and 2.11%, respectively. Overall, the improved PCP features proposed in

this study provide better recognition performance for wind music than the traditional PCP features.

Additionally, to comprehensively evaluate the performance of the wind music recognition system designed in this paper, a traditional template matching model was used for control analysis. This comparison helps to further validate the effectiveness of the improved PCP features and the overall recognition system. The experimental results obtained from the final analysis are shown in the following Table III.

TABLE III. COMPARISON OF SYSTEM SYNTHESIS RESULTS

Training data	Test data (piece name)	System Type	Recognition Accuracy
Music files in the MIDI music library	Liberty Bell March	Legacy PCP+ Template Matching	74.32
		Revised PCP+HMM	84.36
	British Grenadiers March	Legacy PCP+ Template Matching	72.89
		Revised PCP+HMM	82.66
	El Capitan	Legacy PCP+ Template Matching	69.02
		Revised PCP+HMM	74.87
	Entry of the Gladiators	Legacy PCP+ Template Matching	72.31
		Revised PCP+HMM	83.85
	The Thundered	Legacy PCP+ Template Matching	68.38
		Revised PCP+HMM	73.94

The data from the table indicates that the HMM model combined with the improved PCP features significantly outperforms the template matching model in terms of pipe music recognition accuracy. Specifically, when comparing the results of the pipe music recognition system using the improved PCP features and the HMM model to those using traditional PCP features and template matching, the recognition accuracy improved by 9.55%, 9.77%, and 11.25% for “Liberty Bell March,” “British Grenadiers March,” and “Entry of the Gladiators,” respectively. For “El Capitan” and “The Thundered,” the improvements were 5.35% and 5.56%, respectively. These results demonstrate that the HMM model provides better performance compared to template matching.

However, a closer look at the data reveals that “El Capitan” and “The Thundered” have lower overall recognition rates compared to the other three songs. Neither the improved PCP features nor the use of the HMM model had a substantial impact on these pieces, resulting in relatively low recognition accuracy. To understand the reasons behind this, a further analysis of the accompanying wind music sequences derived from the test set music files by professionals was conducted.

This analysis revealed that the primary reason for the decreased recognition rate in these pieces is related to the complexity of the wind music analysis. Specifically, the wind music involved in this study often contains repeated sound values, which are particularly challenging to recognize accurately. For example, both the F major wind piece [F, A, C] and the D minor piece [D, F, A] share similar tonal components, leading to frequent recognition errors. This issue is a significant factor contributing to the lower recognition rates observed for these songs.

As illustrated in Fig. 10 and 11, the first two tone values in F major and the last two-tone values in D minor are identical.

This similarity can cause the system to misidentify sections of the main melody, confusing F major with D minor due to their high degree of resemblance, thus affecting the overall recognition accuracy. Similarly, Fig. 12 and 13 show that C major and A minor wind music also share common features, both containing C and E as root notes. This overlap makes it challenging to distinguish between these keys during the recognition process. In the pieces with lower recognition rates, such as those involving C major, A minor, F major, and D minor, these shared tonal characteristics lead to frequent misidentifications, resulting in decreased recognition accuracy compared to other pieces.

Fig. 10. F-major's PCP feature template.

Fig. 11. D-minor's PCP feature template.

Fig. 12. C-major's PCP feature template.

Fig. 13. A-minor's PCP feature template.

VI. CONCLUSION

This paper presents a comprehensive study on the automatic recognition of marching band performances, utilizing advancements in music information retrieval and signal processing. The research focused on overcoming the limitations of traditional music feature extraction methods by introducing an improved Pitch Class Profile (PCP) feature extraction technique. By mapping audio signals to musical notes more accurately, the improved PCP features, combined with Hidden Markov Models (HMM), provided a robust framework for recognizing and sequencing marching band performances.

The system developed in this study consisted of two main components: a music feature extraction module and an HMM-based modeling module. The feature extraction module used the improved PCP features to convert audio signals into analyzable data, while the modeling module applied HMMs to decode these features into recognizable performance sequences. The system was trained on a dataset of 450 MIDI music files and tested on an additional five files. Experimental results demonstrated that the improved PCP features significantly enhanced the recognition accuracy compared to traditional PCP features and template matching models. Recognition rates improved by up to 6.28% for various marching band pieces. However, some pieces, such as "El Capitan" and "The Thundered," had lower recognition rates due to the presence of similar tonal values, highlighting the complexity of music recognition. This research contributes to the field of music information retrieval by providing an enhanced feature extraction method and a robust modeling framework. The findings have practical implications for developing automated music recognition systems, which can be applied in music education, digital archiving, and cultural preservation.

Future work should address the challenges of overlapping tonal values by developing more sophisticated feature extraction methods. Additionally, testing the system on real-world audio recordings with background noise and microphone variations will be crucial to enhance its practical applicability. Expanding the dataset to include various musical styles and real-world audio recordings would provide a more comprehensive evaluation of the system's robustness and versatility.

International Institute of Creative Design, Shanghai University of Engineering Science, Shanghai, 200000, China³

Abstract—To propose home fitness equipment that meets modern users' needs, this study employs web user text mining, combined with the Fuzzy Analytic Hierarchy Process (FAHP) and the Technique for Order Preference by Similarity to Ideal Solution (TOPSIS), to design and evaluate home fitness equipment that aligns with contemporary demands. First, we used crawler data to collect user reviews of home fitness equipment from a well-known Chinese shopping platform. The data were cleaned and processed to extract key user needs and preferences. Next, the FAHP method was used to prioritize these requirements, and TOPSIS was applied for the comprehensive evaluation of design proposals. This process allowed us to identify the solution that best meets user needs, completing the development of the product design. The results indicate that the second design, with its features targeting lumbar health, efficient space utilization, rich interactive experience, integration of smart technology, and minimalist appearance, has significant market potential and social value. Finally, the SUS (System Usability Scale) was used to validate the design, showing excellent user satisfaction and usability for the second scheme. This study establishes a design process incorporating web scraping, FAHP, and TOPSIS, demonstrating the effectiveness of this theoretical integration in the field of home fitness equipment design.

Keywords—Home fitness equipment; crawler data; FAHP; TOPSIS; product design

I. INTRODUCTION

In contemporary society, especially after the COVID-19 pandemic, health has become a significant topic of concern for the public [1] [2] [3]. Fitness equipment can enhance users' physical health, such as fitness levels, muscle strength, and weight loss, as well as their mental well-being. In China, fitness venues are generally located in outdoor parks or gyms. Outdoor parks are open fitness venues that have the advantage of being accessible to people of all ages. However, their disadvantages include high usage rates and difficulty of use in extreme temperatures. Gyms, on the other hand, offer more specialized equipment but require users to pay for access. Home fitness equipment combines the advantages of both outdoor parks and gyms while addressing their shortcomings. The types of equipment used in homes are similar to those found in gyms, such as treadmills, stair mills, rowing machines, and spin bikes, which support a variety of aerobic exercise [4]. In contemporary society, especially after the COVID-19 pandemic, Consumers bought equipment for home use and switched to different types of online or outdoor workouts [5]. In the current market context, China's home fitness equipment industry has significant growth potential. However, despite the promising market outlook, the

industry still struggles to fully meet users' fitness expectations [6], family fitness equipment has a lot of research space in the Chinese market. A study on the design of a fitness furniture and its finite element analysis. To address this issue, our research team has decided to start by focusing on users' needs [7] [8]. In the design of indoor fitness equipment, it is crucial to focus on and analyze users' needs, user characteristic analysis emerges as a pivotal step within the realms of product design and enhancement [7].

Data is very important for businesses and organizations as it assists their decision making [9]. In the design of indoor fitness equipment, it is crucial to focus on and analyze users' needs. Using web crawlers to gather information about users' needs for indoor fitness equipment is an effective approach. A web crawler is a program or script that automatically captures web information based on specific rules, enabling automatic data collection. Web crawlers are widely used in various fields, such as crawling and indexing sites for search engines, collecting data for analysis and mining, and gathering financial data for financial analysis. Ramachandran et al. [10] used generalized logistic regression to analyze Amazon datasets, confirming the presence of negative bias in online consumer reviews. They found that negative emotions in review texts influence product ratings more significantly than positive emotions of the same intensity. This suggests that in all management decisions, interventions to reduce negative performance disconfirmation should be prioritized over those causing positive performance disconfirmation. Cao et al. [11] used web crawlers to collect a large number of product reviews, conducted word frequency analysis to identify key product elements, and categorized reviews based on the results. They extracted adjectives from the reviews and, after expert summarization, performed sentiment analysis on sentences containing adjectives to obtain information on user needs. This information can guide the generation of subsequent design plans through the application of kansei engineering principles.

After extracting the information, we can identify different user needs by analyzing user comments and summarizing keywords, thereby determining the characteristics of user requirements. Data cleaning can reveal key information from user evaluations, which can be transformed into decision criteria for the Analytic Hierarchy Process (AHP). AHP is a systematic method for multi-criteria, multi-option decision-making, involving decomposition, comparative judgment, and synthesis for decision-making (weighting) and overall ranking. The Fuzzy Analytic Hierarchy Process (FAHP) improves and extends traditional AHP by incorporating fuzzy mathematics theory,

making judgments more accurate and applicable to a broader range of scenarios. Using data obtained from web crawlers, we can introduce FAHP theory to handle the fuzziness and uncertainty in data when solving complex problems. For example, Wang et al. [12] used FAHP to identify key factors in the design of bone marrow puncture needles after conducting surveys and expert interviews. The final design effectively improved patient experience during surgery. Mouhassine et al. [13] proposed integrating Fuzzy-AHP with VIKOR in SDN controllers, successfully applying it to optimize the wireless network handover process. FAHP effectively addresses fuzziness and uncertainty in evaluations, using fuzzy linguistic variables to express preferences for evaluation factors, thus enhancing the objectivity and accuracy of the assessments. Wu et al. [14] combined FAHP with a continuous fuzzy Kano model to prioritize attractiveness factors for electric scooters, demonstrating that this approach reliably meets consumer perception needs.

Based on FAHP hierarchical ranking, the optimal design scheme must be determined. The TOPSIS method can fully utilize the information from raw data, with the analysis results accurately reflecting the gaps between evaluation schemes. Zulkefli et al. [15] developed a more robust and effective CSP selection model by combining TOPSIS, entropy-based weight determination, and Single Valued Neutrosophic (SVN) handling of uncertainty, highlighting its contributions to solving RRP and decision-making ambiguity. Liu et al. [16] proposed the Z-AHP and Z-TOPSIS theories to optimize the design of kitchen waste containers. Z-TOPSIS considers the fuzziness of evaluation criteria and the confidence of decision-makers, making the assessment results more reasonable and reliable. Hameed et al.

[17] integrated FMEA, QFD, TRIZ, LCA, and fuzzy TOPSIS to develop sustainable products. They used fuzzy TOPSIS to reassess designs, and the final design was selected for prototyping.

Currently, many scholars have used web crawlers, FAHP, and TOPSIS methods in their research. However, these methods have not yet been applied to the design of indoor fitness equipment, highlighting the scientific and innovative nature of this study. The remainder of this paper is structured as follows: Section II describes the design experiments based on the proposed methods. Section III presents the results and discussion of the indoor fitness equipment design, determining the feasibility of the final scheme. Section IV summarizes the experimental process of this study.

II. METHOD

A. Crawler Data Collection

To delve deeper into Chinese users' opinions and feedback on indoor fitness equipment, this study selected a purchasing platform with a large number of active users in China as the data source. Special attention was given to user reviews of indoor fitness equipment purchases, as these reviews are crucial for reflecting overall evaluations and expectations of fitness equipment. They provide insights into user satisfaction, user experience, and suggestions for improvement.

To ensure the accuracy and effectiveness of the study, data collection focused on key areas such as review content, descriptions related to fitness equipment, and the number of reviewers. This foundation supports subsequent research. The overall experimental process is shown in Fig. 1.

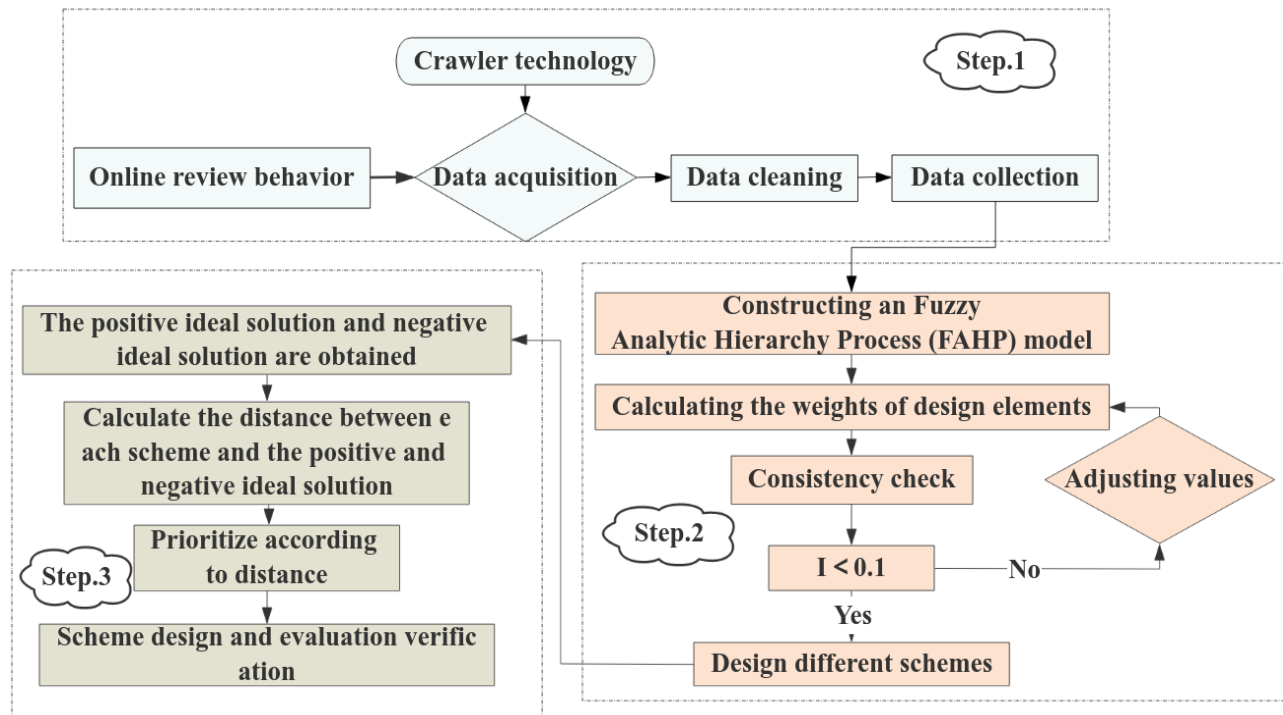

Fig. 1. Experimental design flowchart.

B. Procedure Design

The main processes include data collection (via web scraping), data cleaning, and data visualization analysis, detailed as follows:

- 1) *Data collection*: Using Python web scraping technology, information about indoor fitness equipment is collected from a well-known Chinese shopping platform.
- 2) *Data cleaning*: Filtering the collected data to organize the relevant comment content.
- 3) *Data collection*: Analyzing the cleaned data and employing charts to visualize user evaluation data from multiple perspectives, thereby enhancing the understanding and presentation of the data. After organizing the collected data, the following results were obtained: Very (3682), It's good (2645), Installation (2182), Quality (2085), Convenience (1701), Exercise (1572), Simple (1114), Logistics (995), Packaging (997).....Kids (100), Accessories (100), Weight (100).

By extracting keywords with a frequency exceeding 100, a total of 352 keywords were identified, which were then visualized as shown in Fig. 2. These keywords need to be introduced into the FAHP for evaluation, and the data must be filtered to exclude unnecessary influencing factors. Based on the results, a refined set of evaluation criteria can ultimately be determined.

C. Design Transformation based on FAHP

The Analytic Hierarchy Process (AHP) is a commonly used multi-criteria decision-making (MCDM) technique initially proposed by Saaty [18]. Combining the fuzzy matrix with the Analytic Hierarchy Process allows for addressing the fuzziness and uncertainty among various factors when dealing with complex problems. This method of combining AHP with fuzzy mathematical theory is called the Fuzzy Analytic Hierarchy Process (FAHP), which aims to address the human subjective effect of ambiguity on the decision factors of a problem [19]. Firstly, the user reviews obtained through web scraping need to be summarized and analyzed. The team invited five fitness equipment development engineers to an online meeting to filter the data. Then, a fuzzy analytic hierarchy process matrix is constructed. The matrix is divided into the goal layer (A) Home Fitness Equipment Program, the criteria layer (B) Appearance, the scheme layer (C) Functional Requirement, the scheme layer (D) Economy, and the scheme layer (E) Quality of Experience. The sub-criteria layer includes (B1) Fine Workmanship, (B2) Simplicity, (B3) Household Size, (C1) Multipurpose Uses, (C2) Adjustable, (C3) Intelligent Manipulation, (D1) Quality-price ratio, (D2) Fructification, (D3) Wear-well, (D4) Environmental protection, (E1) Safety, (E2) Simple operation, (E3) Relax the body, (E4) Relax the body, (E5) Ergonomics Compliance as shown in Fig. 3.

Fig. 2. Data cleaning visualization chart.

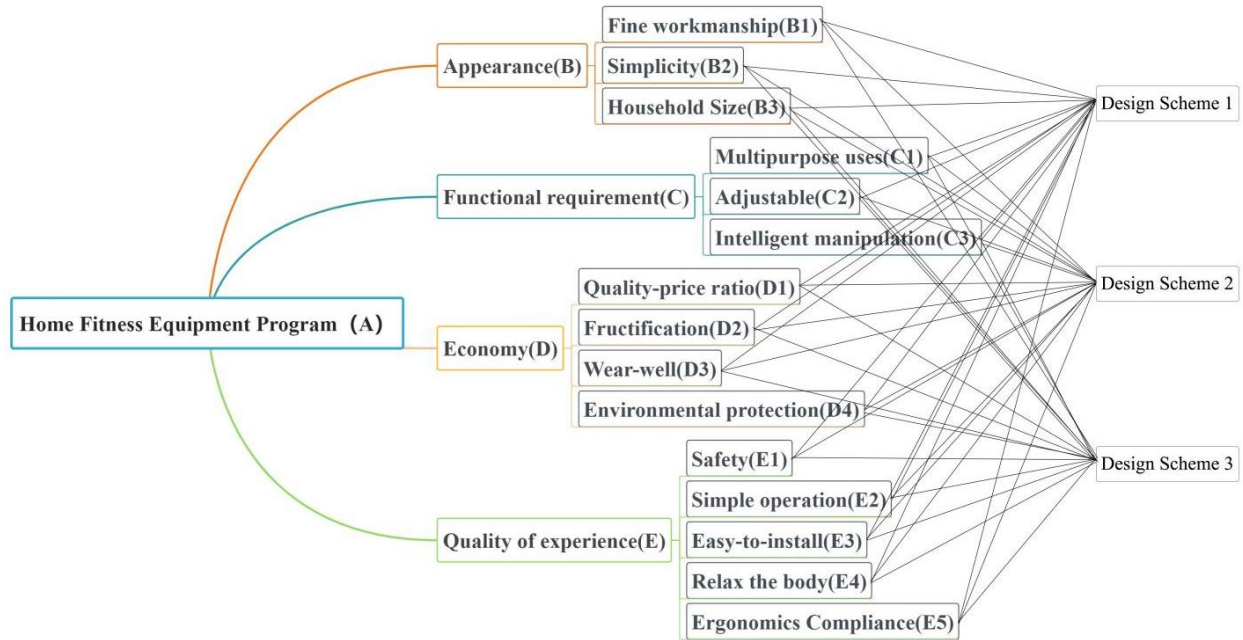

Fig. 3. Fuzzy analytic hierarchy process model of user demand.

D. Constructing Fuzzy Judgment Matrix

Referring to the scaling method of 0.1 to 0.9 levels, a fuzzy judgment matrix is constructed [20] [21], as shown in Table I. Pairwise comparison judgments of different elements of home fitness equipment are made to construct the judgment matrix, as shown in Eq. (1), and its properties are given in Eq. (2) and (3).

TABLE I. INDEX IMPORTANCE SCALE OF FUZZY JUDGMENT MATRIX

Scale	Level of importance	Implication
0.5	Equally important	Indicator a and indicator b are equally important
0.6	Slightly important	Indicator a is marginally more important than indicator b
0.7	Significantly important	Indicator a is significantly more important than indicator b
0.8	Very important	Indicator a is very important compared to indicator b
0.9	Absolutely important	Indicator a is more important than indicator b
0.1,0.2,0.3,0.4	Anti-comparison	Factor b inverse comparison, $q_{ab} = 1-q_{ba}$

$$A = (a_{ij})_{n \times n} = \begin{bmatrix} a_{11} & a_{12} & \dots & a_{1n} \\ a_{21} & a_{22} & \dots & a_{2n} \\ \dots & \dots & \dots & \dots \\ a_{n1} & a_{n2} & \dots & a_{nn} \end{bmatrix} \quad (1)$$

$$a_{ij} + a_{ji} = 1 \quad (2)$$

$$a_{ii} = 0.5 \quad (3)$$

To achieve more objective weight results for each indicator characteristic, the experiment invited seven experts to hold a discussion meeting (including two fitness coaches, three graduate students in design studies, and two fitness equipment merchants) [22] [23]. An expert discussion meeting was organized in the laboratory, and the experts scored the different factors based on the discussion results. The judgment matrices for each level are shown in Tables II to VI. The weights of each fuzzy judgment matrix were calculated according to Eq. (4).

TABLE II. A-LEVEL FUZZY JUDGMENT MATRIX

A	B	C	D	E
B	0.5	0.3	0.4	0.3
C	0.7	0.5	0.6	0.4
D	0.6	0.4	0.5	0.3
E	0.7	0.6	0.7	0.5

TABLE III. B-LEVEL FUZZY JUDGMENT MATRIX

B	B1	B2	B3

TABLE VI. E-LEVEL FUZZY JUDGMENT MATRIX

E	E1	E2	E3	E4	E5
E1	0.5	0.5	0.7	0.7	0.5
E2	0.5	0.5	0.3	0.6	0.4
E3	0.3	0.7	0.5	0.6	0.3
E4	0.3	0.4	0.4	0.5	0.3
E5	0.5	0.6	0.7	0.7	0.5

The calculated weight vectors of the fuzzy judgment matrices are as follows: 0.208, 0.267, 0.233, 0.292.

The calculated weight vectors of the fuzzy judgment matrices are as follows: 0.367, 0.267, 0.367.

The calculated weight vectors of the fuzzy judgment matrices are as follows: 0.283, 0.300, 0.417.

The calculated weight vectors of the fuzzy judgment matrices are as follows: 0.300, 0.250, 0.242, 0.208.

The calculated weight vectors of the fuzzy judgment matrices are as follows: 0.220, 0.190, 0.195, 0.170, 0.225.

$$w_i = \frac{\sum_{j=1}^n a_{ij} + \frac{n-1}{2}}{n(n-1)}, i = 1, 2, \dots, n \quad (4)$$

Where $\sum_{j=1}^n a_{ij}$ is the sum of the elements in the i-th row.

E. Consistency Check of the Fuzzy Judgment Matrix

To ensure the rigor of the calculation results, a consistency check of the fuzzy judgment matrix is required, as shown in Eq. (5).

$$W_i^* = \frac{W_i}{W_i + W_j}, (i, j = 1, 2, \dots, n) \quad (5)$$

Using the weight vectors, construct the characteristic matrix $W=(W_{ij})n \times n$ of the fuzzy judgment matrix. Then, the compatibility index of the fuzzy judgment matrix with its eigenvalue matrix is calculated using Eq. (7). If the compatibility index $I \leq 0.1$, the fuzzy judgment matrix is considered reasonable.

$$I(A, W^*) = \frac{\sum_{i=1}^n \sum_{j=1}^n |a_{ij} + w_{ij} - 1|}{n^2}, (i, j = 1, 2, \dots, n) \quad (6)$$

The calculated characteristic matrix is as follows:

$$W_A^* = \begin{bmatrix} 0.500 & 0.439 & 0.472 & 0.417 \\ 0.561 & 0.500 & 0.533 & 0.478 \\ 0.528 & 0.467 & 0.500 & 0.444 \\ 0.583 & 0.522 & 0.556 & 0.500 \end{bmatrix}$$

$$W_B^* = \begin{bmatrix} 0.500 & 0.486 & 0.404 \\ 0.514 & 0.500 & 0.419 \\ 0.595 & 0.581 & 0.500 \end{bmatrix}$$

$$W_C^* = \begin{bmatrix} 0.500 & 0.579 & 0.500 \\ 0.421 & 0.500 & 0.421 \\ 0.500 & 0.579 & 0.500 \end{bmatrix}$$

$$W_D^* = \begin{bmatrix} 0.500 & 0.545 & 0.554 & 0.590 \\ 0.454 & 0.500 & 0.508 & 0.545 \\ 0.446 & 0.492 & 0.500 & 0.537 \\ 0.410 & 0.455 & 0.463 & 0.500 \end{bmatrix}$$

$$W_E^* = \begin{bmatrix} 0.500 & 0.537 & 0.530 & 0.564 & 0.494 \\ 0.463 & 0.500 & 0.494 & 0.528 & 0.458 \\ 0.470 & 0.506 & 0.500 & 0.534 & 0.464 \\ 0.436 & 0.472 & 0.466 & 0.500 & 0.430 \\ 0.506 & 0.542 & 0.536 & 0.570 & 0.500 \end{bmatrix}$$

The calculated compatibility indices:

$$I(A, W_A^*) = 0.07696 < 0.1,$$

$$I(B, W_B^*) = 0.07503 < 0.1, I(C, W_C^*) = 0.0538 < 0.1,$$

$$I(D, W_D^*) = 0.06706 < 0.1,$$

$$I(E, W_E^*) = 0.08256 < 0.1.$$

All these fuzzy judgment matrices have compatibility indices less than 0.1, thus passing the consistency check and confirming that the data is reliable and valid.

F. Calculating FAHP Comprehensive Index Weights

Based on the hierarchical results of the weight vectors from the fuzzy judgment matrices, the comprehensive weights of each indicator factor in FAHP are obtained and summarized in Table VII. In the design of indoor fitness equipment, E (Quality of experience) > C (Functional requirement) > D (Economy) > B (Appearance). The design should prioritize the user's experience, as it is the key factor in stimulating purchase intentions. Next is the product's functionality, ensuring the equipment can precisely meet users' exercise needs, providing an efficient and safe fitness experience. Economy follows user experience and functionality, aiming to meet users' low-price demands while ensuring experience and functionality. Although appearance is an aspect that attracts users' attention, it is not the primary focus in the overall design priority.

TABLE VII. FUZZY COMPREHENSIVE WEIGHT RANKING

		Element layer	Weight	Comprehensive weight	Rank
Home Fitness Equipment Program	Appearance (0.208)	B1	0.283	0.0588	9
		B2	0.300	0.0624	8
		B3	0.417	0.0867	3
	Functional requirement (0.267)	C1	0.367	0.0980	1
		C2	0.267	0.0712	4
		C3	0.367	0.0979	2
	Economy (0.233)	D1	0.300	0.0699	5
		D2	0.250	0.0583	10
		D3	0.242	0.0564	12
		D4	0.208	0.0485	15
	Quality of experience (0.292)	E1	0.220	0.0642	6
		E2	0.190	0.0555	13
		E3	0.195	0.0569	11
		E4	0.170	0.0496	14
		E5	0.225	0.0657	7

The comprehensive ranking results are: $C1 > C3 > B3 > C2 > D1 > E1 > E5 > B2 > B1 > D2 > E3 > D3 > E2 > E4 > D4$. Modular or convertible structures should be considered to support various exercise modes. Advanced intelligent systems should be integrated for control, supporting remote control via mobile apps, personalized training plans, real-time exercise data monitoring, and analysis. Since Chinese home spaces cannot support large equipment, the design needs to be compact and easy to store. The equipment's adjustability should accommodate different family members' height, weight, exercise levels, and goals. In terms of materials, product quality and performance must be ensured while optimizing material selection, production processes, and supply chain management for higher cost-effectiveness. High-strength, wear-resistant materials should be used for key components to ensure equipment stability and durability. Additionally, ergonomic principles should be considered in the design to ensure users maintain correct posture and movement trajectories during exercise. See Fig. 4 to 6 for the design diagram.

Fig. 4. Scheme 1: Multifunctional cardio cycle.

Fig. 5. Scheme 2: Compact multifunctional elliptical trainer.

Fig. 6. Scheme 3: Multifunctional rowing machine.

In the FAHP analysis, user experience holds a weight of 0.292, ranking first, indicating that users typically prioritize the experiential aspect of a product. The functional requirements, with a weight of 0.267, suggest that fitness equipment must meet users' daily needs while also accommodating their specific requirements. Economic considerations rank third, with a weight of 0.233, recommending the use of cost-effective materials in home fitness equipment to minimize the financial burden on consumers. Although aesthetic design ranks lowest, with a weight of 0.208, it should still be considered during the design process to ensure that the product is visually appealing while meeting its primary functional requirements.

G. Comprehensive TOPSIS Design Evaluation

Three design schemes were included in a questionnaire, with the design points of each scheme introduced. The 15 sub-criterion elements in FAHP are treated as whole indicators, thus defining 15 evaluation indicators using these design elements [24]. To ensure the final evaluation results' authenticity and rigor, 10 evaluators were invited to form a decision-making group to score each scheme's indicators using a Likert 7-point scale (1 for very poor, 2 for poor, 3 for slightly poor, 4 for neutral, 5 for good, 6 for very good, and 7 for excellent). The final results were statistically averaged and are shown in Table VIII.

TABLE VIII. INITIAL EVALUATION MATRIX8

	B1	B2	B3	C1	C2	C3	D1	D2	D3	D4	E1	E2	E3	E4	E5
1	0.	0.	0.	0.	0.	0.	0.	0.	0.	0.	0.	0.	0.	0.	0.
	03	03	04	05	04	05	04	03	03	02	03	02	02	02	03
	11	08	12	75	22	32	03	55	49	60	45	90	62	84	90
2	0.	0.	0.	0.	0.	0.	0.	0.	0.	0.	0.	0.	0.	0.	0.
	03	04	05	05	04	06	03	03	03	03	04	03	03	03	03
	58	22	96	66	38	44	90	32	27	08	12	54	99	10	75
2	0.	0.	0.	0.	0.	0.	0.	0.	0.	0.	0.	0.	0.	0.	0.
	03	03	04	05	03	05	04	03	02	02	03	03	03	02	03
	47	41	76	56	41	11	17	21	99	70	51	14	10	68	68

The data of the three collected design schemes were weighted and standardized according to Eq. (7) and (8). The weighted standardized evaluation matrix is shown in Table IX [25].

$$Y_{ij} = \frac{X_{ij}}{\sqrt{\sum_{i=1}^m X_{ij}^2}}, (i=1,2,\dots,m, j=1,2,\dots,n) \quad (7)$$

$$Z_{ij} = W_j Y_{ij}, (i=1,2,\dots,m, j=1,2,\dots,n) \quad (8)$$

TABLE IX. WEIGHTED STANDARDIZED EVALUATION

	B1	B2	B3	C1	C2	C3	D1	D2	D3	D4	E1	E2	E3	E4	E5
1	5.3	4.6	4.5	6.1	5.5	5.2	6.1	6.2	6.3	5.5	5.1	5.1	4.4	5.2	6.1
2	6.1	6.3	6.5	6.0	5.4	6.3	5.9	5.8	5.9	6.5	6.1	6.2	6.7	5.6	5.8
3	5.9	5.1	5.2	5.9	4.2	5.0	6.3	5.6	5.4	5.7	5.2	5.5	5.2	4.9	5.7

Calculate the positive and negative ideal solutions of the evaluation objects. The positive ideal solution is calculated according to Eq. (9), and the negative ideal solution is calculated according to Eq. (10).

$$Z^+ = (Z_1^+, Z_2^+, \dots, Z_n^+) \quad (9)$$

$$Z^- = (Z_1^-, Z_2^-, \dots, Z_n^-) \quad (10)$$

The positive ideal solution $Z^+ = (0.0358, 0.0422, 0.0596, 0.0575, 0.0438, 0.0644, 0.0417, 0.0355, 0.0349, 0.0308, 0.0412, 0.0354, 0.0399, 0.0310, 0.0390)$ and the negative ideal solution $Z^- = (0.0311, 0.0308, 0.0412, 0.0556, 0.0341, 0.0511, 0.0390, 0.0321, 0.0299, 0.0260, 0.0345, 0.0290, 0.0262, 0.0268, 0.0368)$ for the evaluation objects are calculated.

The optimal solution's distance to the positive and negative ideal solutions Z^+ and Z^- (i.e., D^+ and D^-) is calculated according to Eq. (11), (12), and (13), as shown in Table X.

$$D_i^+ = \sqrt{\sum_{j=1}^n (Z^+ - Z_{ij})^2} \quad (11)$$

$$D_i^- = \sqrt{\sum_{j=1}^n (Z^- - Z_{ij})^2} \quad (12)$$

$$C_i = \frac{D_i^+}{D_i^+ + D_i^-}, (i=1,2,\dots,m) \quad (13)$$

TABLE X. COMPARISON OF EUCLIDEAN DISTANCE AND RELATIVE CLOSENESS

Index	Positive ideal solution distance D_i^+	Negative ideal solution distance D_i^-	Relative proximity C_i	Rank
scheme 1	0.030	0.011	0.264	3
scheme 2	0.005	0.033	0.879	1
scheme 3	0.026	0.010	0.278	2

Closeness is an important indicator for evaluating how close a design scheme is to the ideal solution. When the closeness approaches 0, it means the design scheme is closer to the negative ideal solution, indicating poor performance across multiple evaluation criteria and potential significant deficiencies or shortcomings. Conversely, when the closeness approaches 1, it means the design scheme performs excellently across multiple evaluation criteria, meeting or exceeding expected needs and expectations.

III. RESULT

This study comprehensively applied web scraping technology, the Fuzzy Analytic Hierarchy Process (Fuzzy AHP), and the TOPSIS method to accurately identify the most favored home fitness equipment among Chinese people. Through collaboration with fitness experts, the research team developed a comprehensive evaluation model that not only covers user needs, scheme rationality, and optimal scheme selection but also refines the comprehensive consideration of each sub-criterion. Based on the most popular types of fitness equipment in the market, the three home fitness devices designed were primarily focused on multifunctionality. This evaluation criterion (C1) was assigned a comprehensive weight of 0.0980 in the FAHP analysis, ranking it as the top priority and underscoring its critical importance. Additionally, the devices were required to feature intelligent control capabilities and be suitable for home use, with these criteria carrying comprehensive weights of 0.0979 and 0.0867, respectively. Most importantly, user experience was identified as the core requirement, holding a weight of 0.292 in the FAHP analysis. According to the TOPSIS analysis results, the second design achieved a C_i value of 0.879, significantly higher than the other two designs and the closest to 1. Therefore, the second design demonstrates a clear and distinct advantage. To verify the effectiveness of the experimental process, we used the SUS (System Usability Scale) to evaluate this design practice [26]. Based on the keywords extracted from the data, the research team has developed the following ten survey questions.

- a) Question 1: I find this fitness equipment suitable for home use.
- b) Question 2: I find this fitness equipment difficult to use at home.
- c) Question 3: I find this fitness equipment easy to operate.

- d) Question 4: I find that expert guidance is necessary to use this fitness equipment.
- e) Question 5: I find that this fitness equipment incorporates the features I need.
- f) Question 6: I find this fitness equipment to be cumbersome.
- g) Question 7: I feel confident that this fitness equipment is safe to use.
- h) Question 8: I have concerns about the safety of this fitness equipment.
- i) Question 9: I find this fitness equipment aesthetically pleasing.
- j) Question 10: I find the design of this fitness equipment does not align with my aesthetic preferences.

We distributed the SUS questionnaires to seven employed individuals and statistically analyzed the collected data, as shown in Table IX. The usability test scores were all ≥ 80 , which, according to the SUS score curve classification range, is rated as A, as shown in Table XI. The results demonstrate that Scheme Two meets users' preferences and needs, as shown in Fig. 7.

TABLE XI. SUS TEST SCORES

Participant	Q.1	Q.2	Q.3	Q.4	Q.5	Q.6	Q.7	Q.8	Q.9	Q.10	Score
P1	5	1	5	1	4	1	5	2	4	2	90.0
P2	4	2	5	2	4	1	4	1	5	2	85.0
P3	5	2	5	1	5	1	5	1	5	1	97.5
P4	5	4	4	1	5	1	5	1	5	1	90.0
P5	5	2	4	1	4	2	4	1	4	1	85.0
P6	5	1	4	1	4	1	4	1	4	2	87.5
P7	5	2	5	1	5	2	5	1	5	1	95.0

IV. DISCUSSION

In the in-depth discussion of Scheme Two within the group, we identified several significant advantages across multiple dimensions. Firstly, addressing the prevalent concern for lumbar health in today's society, Scheme Two offers a stretching function for the back muscles when not in use, effectively relieving stiffness and discomfort caused by prolonged sitting or standing. Additionally, this scheme provides effective full-body training during workouts, particularly through pedal exercises, fully meeting users' diverse functional needs.

Regarding space utilization, considering the limited living space common in Chinese households, Scheme Two features a miniaturized design that can be flexibly placed in various corners of the home, making it easy to store without occupying much space. This greatly enhances the convenience and comfort of home life. The introduction of an intelligent control system perfectly integrates modern technology with healthy living. Users can connect via Bluetooth to track exercise data in real-time, including workout progress and energy consumption, providing scientific support for personalized training plans.

In terms of aesthetics, Scheme Two incorporates soft colors and rounded shapes, making the fitness process no longer cold

but full of fun and challenges. This design stimulates users' enthusiasm for exercise and promotes the formation of a sustained workout habit. Especially for the youth, this creative design can effectively arouse their curiosity and exploratory desire, turning fitness activities into an enjoyable rather than burdensome task. Designing home fitness equipment that meets modern people's needs is a complex task. This study integrates web scraping technology with FAHP (Fuzzy Analytic Hierarchy Process) and TOPSIS (Technique for Order Preference by Similarity to Ideal Solution) theories. These methods can accurately pinpoint design focuses and address the problem of translating user needs into design practice by combining qualitative and quantitative approaches to capture the true expectations and preferences of users.

Fig. 7. Scheme 2 uses partial use display.

V. CONCLUSION

This study innovatively combines web scraping, FAHP, and TOPSIS theories and successfully applies them to the field of home fitness equipment. Through FAHP analysis, we systematically prioritized design requirements. Subsequently, among the three proposed potential design schemes, we combined FAHP's weight factors with the TOPSIS model to select the design scheme that most closely meets users' actual needs. To further validate the practical effectiveness of this design scheme, we used the SUS (System Usability Scale) as an evaluation tool. The results demonstrated the high effectiveness and user satisfaction of this design scheme.

In future research, further studies will be conducted on home fitness equipment, with a focus on making new breakthroughs in analyzing user needs. Meanwhile, the current application of FAHP and TOPSIS theories in our research has limitations. Although web scraping can improve the user feedback dataset, the decision-making process is still inevitably influenced by subjective expert judgments. Therefore, future research will focus on enhancing the standardization and objectivity of the decision-making process by introducing more quantitative indicators and objective verification methods. Additionally, attention needs to be paid to engineering and technical issues to promote the design of home fitness equipment towards a more scientific and precise direction.

ACKNOWLEDGMENT

Abstract—This study investigates the methods for creating nonlinear models and developing Fuzzy logic controllers for the Fluidized Catalytic Cracking Unit (FCCU) at different global refineries. The FCCU plays a crucial role in the petrochemical sector, processing a significant portion of the world's crude oil - in 2006, FCCUs were responsible for refining a third of the global crude oil supply. These units are essential for converting heavier oils, such as gasoil and crude oil, into lighter, more critical products like gasoline and olefinic gases. Given their efficiency in producing a large volume of products and the volatile nature of petrochemical market prices, optimization of these units is a priority for engineers and investors. Traditional control mechanisms often need to improve in managing the FCCU's complex, dynamic, and nonlinear operations, where creating an accurate mathematical model is challenging or involves significant simplifications. Fuzzy Logic controllers, which mimic human reasoning more closely than conventional methods, offer a promising alternative for such unpredictable and complex systems. The results of this work illustrate the usefulness and possible advantages of utilizing Fuzzy Logic controllers in the management of FCCU plants and they are also compared with the latest machine learning techniques as well. These findings are corroborated by simulations conducted with the MATLAB Fuzzy Logic Toolbox R2012b.

Keywords—Non-Linear modeling; fuzzy logic controller; machine learning; optimization

I. INTRODUCTION

Fluidized Catalytic Cracking units are pivotal in petrochemical facilities, transforming dense oil products like Gasoil into lighter, more commercially valuable hydrocarbons. The efficiency of FCCUs significantly influences a refinery's financial performance. These units are comprised of two main components: The Riser reactor, where the cracking of hydrocarbons occurs and catalysts get coated with Coke, diminishing their effectiveness, and the Regenerator reactor, where the catalysts are cleansed and rejuvenated for continuous use. A typical FCCU layout, including key instruments and sections, is illustrated in schematic diagrams. Fuzzy Logic offers a structured approach to handle processes laden with uncertainties, ideal for scenarios lacking precise mathematical models or when existing models are too intricate for swift real-time analysis.

Traditional control systems often fall short in such complex environments [1]. The demand for FCCUs is largely driven by market needs, with seasonal variations in product demand

affecting control system design. The challenging nature of FCCUs, characterized by their non-linear, time-invariant, and unpredictable processes, complicates their modeling, simulation, and management. This complexity renders standard controllers, like PID systems, inadequate as they rely on precise plant models, prompting the need for innovative control strategies.

Moreover, FCCUs are crucial for refineries, often determining their profitability and market competitiveness [2]. These units leverage a specialized micro-spheroid catalyst that becomes fluidized under the right conditions, primarily to convert heavy petroleum fractions, known as Gasoil, into valuable products like high-octane gasoline and heating oil. Gasoil, a complex mix of hydrocarbon types, is processed in FCCUS where it is cracked within a riser tube to produce lighter compounds and Coke as a by-product, which subsequently deactivates the catalyst. The spent catalyst is separated, stripped of volatile hydrocarbons, and regenerated by burning off the Coke before being recycled back into the process.

FCCUs have recently included real-time data-collecting systems and other cutting-edge monitoring technology to improve operational effectiveness. These systems make continuous monitoring of critical process variables possible, which gives operators timely insights to enhance performance and make necessary modifications. Additionally, incorporating machine learning and artificial intelligence into FCCU operations has started to yield encouraging outcomes. These tools, which learn from past data and spot patterns that a human operator would overlook, can forecast maintenance requirements, optimize feedstock utilization, and increase overall process efficiency.

Furthermore, under stricter environmental restrictions, refineries are forced to implement more sustainable processes. This entails cutting back on FCCU emissions, especially those of CO₂ and NO_x. Refineries can minimize their environmental impact and sustain high production by refining catalyst regeneration and optimizing the regenerator's combustion process. Another area of active research and development in FCCUs is the introduction of new catalysts that offer improved selectivity towards desired products and are more resistant to deactivation by coke. With these developments, modern refineries hope to strike a compromise between environmental and economic concerns.

*Corresponding Author.

Choosing the appropriate variables is crucial for maximizing FCCU functions. While there is a lot of discussion about the best variables to utilize for fuzzy optimization in FCCUS, this study concentrates on significant variables that can be changed to achieve desired results. These variables fall into one of two categories: dependent-independent or input-output. Feed rate, specific gravity, air flow rate, catalyst circulation rate, cumulative feed rate, and regenerator temperature are significant input parameters. Riser temperature, CO₂/CO ratio, coke deposition on catalyst, feed (gasoil) conversion rate, and the production of LPG and coke are significant output factors. Selection of appropriate variables is a challenging procedure that has a big impact on the outcomes. Previous research in [3] have conducted a thorough review of the variables selected and their effects on FCCU operations.

This study aims to develop and assess complex nonlinear models for fluidized catalytic cracking units (FCCUs). These models aim to increase the petrochemical refining process's operational efficiency and accuracy. The paper highlights the difficulties presented by FCCUs, including their unpredictable nature, time-variant features, and nonlinear behavior. Because these complexities are often too much for traditional control systems to handle, this research focuses on finding crucial input and output factors that significantly impact FCCU performance. The study aims to maximize these variables through fuzzy logic-based control algorithms, providing creative solutions that improve refinery profitability and market competitiveness while addressing environmental issues.

II. METHODOLOGY

Prior to adopting Fuzzy Logic, scientific inquiries were predominantly confined to mathematical models tailored for FCC units [4]. These models varied in their level of detail and accuracy. Research often revolved around comparing these models to discern their respective strengths and weaknesses. Given the critical role of FCCUs in both industrial and market contexts, research in this area has been extensive, covering aspects such as stability, optimization, and the development and simulation of mathematical models [5]. Comprehensive reviews have been conducted on the evolution of FCCU control strategies over time. Notably, there has been considerable research focusing on the safe operation of FCCUs. Fig. 1 illustrates the basic structure of a Fluid Catalytic Cracking Unit.

Fig. 1. Fuzzy control: A conceptual examination.

Initial studies indicated that Fuzzy Logic models outperformed traditional statistical methods in identifying process characteristics. Efforts were made to apply linear regression and sophisticated Kalman filtering techniques to improve precision, yet these methods struggled to accurately represent and manage real-world plants due to their inherent nonlinearity, vagueness, and unpredictability. Consequently, alternative strategies, including Neurofuzzy systems and genetic algorithms, began to gain traction. Despite advances in modern control methodologies like parameter estimation and stochastic and optimal control for model identification, the complexity of some industrial processes, characterized by high nonlinearity and uncertainty, defies conventional mathematical modeling and control approaches [6]. Fuzzy Logic, with its capacity to handle dynamic, nonlinear, and imprecise scenarios through linguistic rules, emerges as a suitable solution for such complex systems, commonly found in sectors like petrochemicals, nuclear energy, and water treatment. In situations when processes are well understood at the microscopic level, rigid control approaches are used.

However, standard control procedures often fail to provide satisfactory solutions to industrial issues contaminated by poor mathematical models. Artificial neural networks and fuzzy logic, two facets of soft computing that have recently found their way into the industrial control area, were originally applied in fuzzy control [7]. Product quality, efficiency, and energy consumption have all significantly improved as a result of this technology's application across a range of sectors [8]. Nowadays, fuzzy control is recognized as a state-of-the-art, complex control technique. Fuzzy logic and neural networks are increasingly being combined in scientific study, placing intelligent control front and center, particularly for systems whose parameters can be adjusted to conform to language conventions [9]. The two primary objectives of this research are to find the nonlinear relationships between input and output variables and to design a robust optimization framework with the aim of lowering Coke deposition on the catalyst and boosting LPG output and gasoil conversion.

A. Fuzzy Control: A Conceptual Examination

Fuzzy Logic mirrors the decision-making process of human experts, making it inherently user-friendly for both technical and non-technical applications. Its outputs, often described using everyday terms like "cold," "hot," or "fast," are straightforward and require little to no additional interpretation [10]. The development of a Fuzzy Logic system relies on the expertise and knowledge of specialists, who formulate this knowledge into a set of rule-based instructions for creating databases and Fuzzy rules. These rules, while approximate, reflect the inherently imprecise nature of human decision-making.

In practice, a Fuzzy rule-based system (FRBS) combined with a de-fuzzification component can serve as a stand-in for a human expert. This system takes in precise sensor data, translates these concrete values into heuristic variables using defined membership functions, and processes these variables through IF-THEN rules. The system then converts these linguistic variables back into a precise numerical output during the de-fuzzification stage, offering an estimated value close to the desired output [11].

A significant advantage of Fuzzy Logic is its independence from in-depth knowledge of the underlying system or its internal processes, a flexibility not typically found in traditional control systems like PID controllers. A schematic representation of a Fuzzy Logic controller would include the rule-based system, which stores the control strategy in rule format, the inference mechanism, which applies these rules based on current conditions to determine appropriate inputs; the fuzzification interface, which prepares the inputs by aligning them with the system's rules [12]; and the de-fuzzification interface, which translates the system's conclusions into actionable inputs for the system. In Fig. 2, Standard Fuzzy Logic Controller Architecture is mentioned.

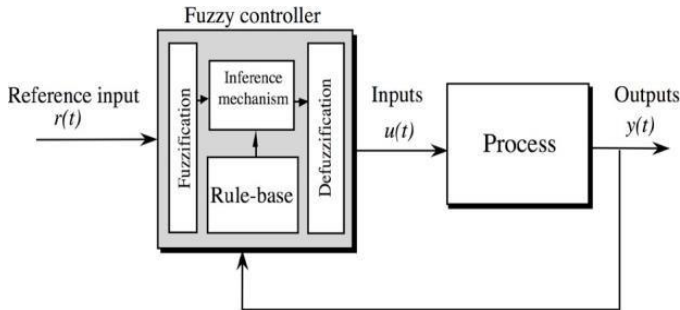

Fig. 2. Standard fuzzy logic controller.

B. Fuzzy Modeling of FCCU

1) *Choosing variables:* Parameters for Inputs and Outputs: This research utilizes data sourced from the operational guides and technical materials of different refineries across the world. Owing to the absence of a mathematical framework, a rule-based Fuzzy methodology was adopted for modeling. The process involved identifying key operating parameters of the FCCU as inputs and outputs, which represent the independent and dependent factors respectively [13]. The input variables in this study were selected based on their influence on the effectiveness and functionality of fluidized catalytic cracking units (FCCUs). Feed rate, specific gravity, airflow rate, catalyst circulation rate, cumulative feed rate, and regenerator temperature are among the chosen input factors. These variables, which include gasoil conversion rate, liquefied petroleum gas (LPG) generation, and coke deposition on the catalyst, were essential elements that directly affect the performance and output of the FCCU.

These factors were chosen because they regulate and enhance the cracking process. For example, the unit's throughput is determined by the feed rate and the rate at which the catalyst circulates, and the maintenance of the intended reaction conditions depends on the specific gravity and temperature of the regenerator. The airflow rate to the regenerator is an essential control parameter since it affects the combustion process and, in turn, the catalyst's regeneration.

A list provided in Table I outlines 16 critical parameters in the FCCU operation, categorizing them into control and observed variables. The Fuzzy controller is tasked with mapping out the behavior and interconnections of these variables through the creation of dynamic nonlinear

representations, referred to as surface graphs. Based on their significance and impact within the FCCU process, a selection of six inputs and six outputs was made for focus [14]. To enhance the refinery's efficiency, both control and observational variables were pinpointed, with continuous monitoring of Riser and Regenerator temperatures. Adjustments to the Catalyst feed and air supply rates, serving as control variables, are made to fine-tune the process parameters towards the targeted outcomes [15].

TABLE I. INPUT AND OUTPUT SPECIFICATIONS FOR FUZZY LOGIC SYSTEM

Input Variables	Output Variables
Gasoil (Feed)	C02/CO
Catalyst Recirculation Rate (CRR)	Gasoil Conversion Rate (GOCR)
Regenerator Temperature (RET)	Liquefied Petroleum (LPG)
Airflow to Regenerator (ATR)	Riser Temperature (RIT)
Cumulative Feed Rate (CFR)	DCC
Specific Gravity Factor (SG)	Coke as Bypass Product (Coke)
Control Variables	Observed Variables
Recycled Catalyst Rate	Riser Temperature
Airflow Rate	Regenerator Gas Temperature

2) *Design of a fuzzy logic controller for FCCU:* To develop the rule-based Fuzzy system that processes the nonlinear relationship between inputs and outputs, six essential steps are followed:

- a) Determine the inputs, define their boundaries, and assign labels to them.
- b) Specify the outputs, outline their boundaries, and label them accordingly.
- c) Establish degrees of truth through Fuzzy membership functions.
- d) Construct the Rule base necessary for the design of the controller.
- e) Allocate intensities to the rules and define how they interact with each other.
- f) Integrate the rules and convert the Fuzzy output into a crisp value through defuzzification [16].

Table II also presents the clustering of data for membership functions. To compile the knowledge base and establish rules, insights were obtained from a seasoned Process Engineer and a Senior Instrumentation Engineer active in the facilities. These rules were formulated based on operational manuals and various technical materials provided by the licensing authorities.

TABLE II. VARIABLES CLUSTERING RANGES

Clustering Group	Equivalence
Low	Small Impact
Medium	Steady State
High	High Impact

Tables III and IV present the initial values for both input and output variables, accompanied by their respective ranges. The membership functions were defined within these specific ranges.

TABLE III. CLUSTERING RANGES FOR INPUT VARIABLES

Input Variables	High (H)	Medium (M)	Low (L)
ATR (m3/h)	39,451 - 60,167	27,001 - 47,209	0 - 29,873
RET (°C)	630 – 670	575 - 645	0 - 610
SG (-)	0.668 - 0.878	0.452 - 0.796	0 - 0.660
CFR (m3/d)	2,289 – 2,650	2,011 – 2,450	0 – 2,260
CRR(t/min)	14.9 – 16.9	11.2 – 16.1	0 – 15.2
Gasoil (m3/d)	1,967 – 2,250	1,770 – 2,151	0 – 1,980

TABLE IV. CLUSTERING RANGES FOR OUTPUT VARIABLES

Output Variables	High (H)	Medium (M)	Low (L)
CO2/CO (mol/mol)	2.2 – 6.2	0.9 – 3.9	0 – 1.8
DCC (-)	0.753 – 0.980	0.397 – 0.865	0 – 0.791
RIT (°C)	505 – 528	404 – 520	0 – 479
LPG (wt.%)	19.5 – 30.9	14.3 – 21.8	0 – 18.5
GOCR (wt.%)	79.3 – 98.16	44.9 – 93.8	0 – 76.8
Coke (wt.%)	5.2 – 9.1	3.4 - 7.5	0 – 4.2

This study chose triangular functions due to their ease of use and effectiveness in modeling fuzzy sets. These features aid in reducing computational complexity, which is essential for FCCUs and other real-time control systems. Triangle functions are perfect for situations where prompt responses are required, like in refining operations where precise control is required to maintain process stability and maximize output because of their linear nature.

3) *Detailed description of fuzzy rules:* The rules that connect the input and output variables are listed below. These rules were implemented using the MATLAB Fuzzy Rule Editor to generate the inference and nonlinear surface model.

In Fuzzy control systems, the focus is on utilizing linguistic rules, whereas traditional control systems rely heavily on differential equations. Employing verbal rules aligns more closely with human understanding than does a numerical approach [17]. Within a Fuzzy logic framework, these rules are always applicable but vary in their degree of truth from zero to one. The initial step of the inference process involves verifying the applicability of the rule premises for the given situation [18]. If the premises meet the criteria, the corresponding rules are chosen in a phase commonly referred to as "Matching." Following this, the inference system proceeds to make decisions.

The membership function for Specific Gravity (SG), a crucial statistic that represents the nature and quality of the feedstock entering the FCCU, is shown in Fig. 3. The SG membership function categorizes the feedstock according to its density, enabling the fuzzy logic controller to adjust the processing parameters to suit the feedstock's properties better.

This classification may optimize the cracking process to provide the required product yield by modifying factors like temperature and catalyst activity. The system's entire operating efficiency and product quality can be improved by efficiently regulating the SG of the input.

Fig. 3. SG Membership Function.

- 1-If (SG is H) then (LPG is M)(GOCR is H)
- 2-If (SG is H) then (Coke is H)(CO2/CO is H)
- 3-If (SG is H) then (DCC is M)(RIT is L)
- 4-If (SG is L) then (CO2/CO is L)
- 5-If (SG is L) then (RIT is H)
- 6-If (ATR is H) then (Coke is H)
- 7-If (ATR is H) then (RIT is M)(CO2/CO is M)
- 8-If (ATR is M) then (CO2/CO is M)
- 9-If (ATR is M) then (DCC is L)
- 10-If (ATR is M) then (Coke is M)
- 11-If (ATR is L) then (CO2/CO is L)
- 12-If (ATR is L) then (DCC is M)
- 13- If (RET is H) then (RIT is M)(CO2/CO is L)
- 14- If (RET is H) then (DCC is H)(LPG is M)(GOCR is L)
- 15-If (RET is H) then (Coke is M)(DCC is H)
- 16-If (RET is H) then (RIT is H)
- 17-If (RET is M) then (Coke is M)(LPG is M)(GOCR is H)
- 18-If (RET is M) then (CO2/CO is M)
- 19-If (RET is M) then (Rh T is H)
- 20-If (RET is M) then (Coke is M)
- 21-If (RET is L) then (RIT is M)
- 22-If (RET is L) then (DCC is L)
- 23-If (RET is L) then (CO2/CO is L)
- 24-If (RET is L) then (Coke is L)
- 25-If (RET is L) then (LPG is M)(RIT is L)(GOCR is L)
- 26-If (CFR is H) then (RIT is M)(GOCR is M)
- 27- If (CFR is H) then (DCC is L)(LPG is H)(RIT is M)(GOCR is H)
- 28- If (CFR is M) then (DCC is M)(LPG is M)(RIT is M)
- 29-If (CFR is L) then (DCC is M)(LPG is L)(GOCR is H)
- 30-If (CRR is H) then (Coke is M)(RIT is H)(GOCR is L)(CO2/CO is H)
- 31- If (CRR is M) then (Coke is M)(GOCR is M)
- 32-If (CRR is L) then (Coke is L)(GOCR is M)
- 33-If (Gasoil is H) then (RIT is M)(GOCR is L)(CO2/CO is L)
- 34- If (Gasoil is M) then (GOCR is M)
- 35-If (Gasoil is L) then (GOCR is H)

The numerical value of specific gravity is calculated by dividing the density of the substance being measured with the density of the reference. The reference substance is nearly always water at its densest (997 kg/m³).

The membership function for Differential Coke Concentration (DCC), a crucial variable in the management of Fluidized Catalytic Cracking Units (FCCUs), is shown in Fig. 4. The concentration of coke created during the cracking

process is divided into three categories by the DCC membership function: low, medium, and high. Because of this classification, the fuzzy logic controller may effectively manage the regeneration process, which can modify temperature and airflow to maintain the best possible catalyst performance. The system can better regulate coke deposition by identifying these categories essential for preserving efficiency and reducing downtime in FCCUs.

Fig. 4. DCC Membership Function.

Fig. 5. Gasoil membership function.

The membership function for Gasoil, a crucial input variable in FCCUs, is shown in Fig. 5. The fuzzy logic controller can modify the processing conditions by dividing the input feedstock into distinct ranges based on the Gasoil membership function. The system can maximize conversion efficiency and minimize the creation of undesirable byproducts by classifying Gasoil into low, medium, and high levels during the cracking process. Maintaining the proper ratio between feedstock input and the intended output of lighter hydrocarbons, such as gasoline and LPG, depends on this function.

The membership function for the CO₂/CO ratio, which is essential for tracking the regenerator's combustion efficiency inside the FCCU, is seen in Fig. 6. The fuzzy logic controller can modify the airflow and combustion parameters to maximize catalyst regeneration because the CO₂/CO membership function divides the ratio into several regions. To guarantee that the coke on the catalyst is efficiently burnt off without producing too many emissions, the CO₂ and CO levels must be in the right balance. Maintaining both operational effectiveness and compliance with environmental standards depends on this role.

Fig. 6. CO₂ / CO membership function.

4) *Defuzzification*: The final step in the Fuzzy control process involves defuzzification, where the Fuzzy controller converts the Fuzzy output into a precise control signal. This signal is then applied to the system by adjusting the relevant variables. During this stage, the inference system identifies the most definitive scenario and generates the output based on it [19]. The goal of defuzzification is to translate the Fuzzy decision-making process into a clear, actionable control measure that accurately reflects the range of potential outcomes [20]. The Fuzzy surface chart is an invaluable tool, offering insights into the relationship between the input and output variables, how quickly the system responds to input variations, and the direction in which these changes occur [21]. This information provides engineers with a novel approach to plant analysis, offering perspectives that traditional control strategies cannot offer [22]. Being able to test multiple alternative outcomes at once without having to deduce the system's mathematical formulas is incredibly helpful.

III. RESULTS AND DISCUSSION

Although conventional control methods have proven successful in resolving many mathematical problems in the field, their shortcomings when handling intricate, dynamic settings have brought to light the benefits of Fuzzy Logic for control engineers confronting these kinds of problems. Fuzzy Logic relies on the experience of seasoned experts in the subject rather than Ordinary Differential Equations (ODEs). The Neuro Fuzzy technique, which is gaining traction and seems to have a lot of potential for future applications, is the result of the growing interest in enhancing Fuzzy Logic with experiential learning.

In order to create Fuzzy Logic models and control designs, this study made use of data from technical literature and operational manuals. The MATLAB Fuzzy Logic Toolbox 2012b was utilized to apply this data, and Fig. 7 through 10 present the main conclusions. Fuzzy Logic enables the

avoidance of intricate mathematical calculations, necessitating instead the profound comprehension and discernment of an accomplished professional. Previously, a Yokogawa Distributed Control System (DCS) was used to operate the facility in question. This system implemented rules through specialized programming, which required manual modifications during maintenance or transitions. The study's data precision is in close agreement with the operational data of different facilities, which was collected in 2004 and may not be representative of the current operating conditions. Though areas like CRR and CFR required more tweaks for optimal performance, the fuzzy control model established via this study indicated good performance, with certain conclusions fitting well with real operational data.

Finishing the facility's fuzzy model provides a wealth of information. The linear relationship between the ATR variable and Coke output, for instance, is depicted in Fig. 7, where production increases directly up to a certain point and then declines as the ATR variable rises further, peaking at an ATR of 54,000. The utilization of numerical optimization techniques to increase facility efficiency is made easier by this pattern recognition. Furthermore, as seen by the 3D depiction in Figure 9, the study demonstrates the effectiveness of Fuzzy Logic in producing three-dimensional outputs that are on par with PID controllers, particularly when managing intricate and unexpected systems like FCCUs. More applications of fuzzy logic are shown in Fig. 8 and Fig. 10, which also offer more insights into the advantages of fuzzy logic for industrial process improvement.

A comparison of the suggested fuzzy logic control method with current FCCU management techniques is shown in Table V. It emphasizes how the fuzzy logic approach, which does not primarily rely on intricate mathematical models, provides greater flexibility and effectiveness in managing the intricate, nonlinear dynamics of FCCUs. The table also shows how this methodology performs better than alternative approaches in streamlining operations, decreasing coke deposition, and raising LPG output.

TABLE V. COMPARISON WITH EXISTING SOLUTIONS

Feature	Proposed Work	Acosta-López & de Lasa et al. [4]	Hu & Zhou et al. [5]	Nan Liu, Chun-Meng Zhu et al. [6]	Tianyue & Long et al. [7]	Tian and Wang et al. [8]
Control Approach	Utilizes fuzzy logic for adaptive response to FCCU dynamics.	Integrates CPM with ML for predictive modeling.	Optimizes GCS and ASS using Aspen Plus simulation.	Uses CNN-based adaptive framework for optimization.	Bilevel robust optimization for handling uncertainties.	ML for early warning of abnormal conditions
Efficiency in Handling Complexity	Manages nonlinear operations without precise mathematical models.	Handles complex FCCU variables with high predictive accuracy.	Reduces utility costs and improves operational efficiency.	Addresses complex, multivariate nature of FCC processes.	Improves robustness and performance under uncertainty.	Improves safety and stability with early warnings.
Adaptability	High adaptability due to rule-based nature.	High adaptability using hybrid models.	Adaptive to varying operational parameters.	Adaptive to complex and dynamic FCC conditions.	Adapts to uncertain operational conditions.	Adapts to changing operational conditions.
Dependence on Mathematical Models	Does not rely on detailed mathematical models.	Uses CPM simulations combined with ML.	Utilizes process simulation software for optimization.	Combines CNN with process models for better control.	Uses data-driven models to handle uncertainties.	Uses ML for predictive maintenance.
Performance	Optimizes operations with reduced coke deposition and increased LPG output.	High predictive accuracy with CPM-ML integration.	Significant cost savings and efficiency improvements.	Enhances FCC performance with adaptive frameworks.	Improves FCC performance with robust optimization.	Effective early warning system for abnormal conditions.
Future Improvements	Refine rules and employ numerical optimization.	Further integration of CPM and ML for enhanced accuracy.	Extend to other FCC subsystems for comprehensive optimization.	Enhance adaptability with more complex models.	Further improve robustness with additional data.	Improve early warning algorithms with more data.

IV. CONCLUSION

This study provides compelling evidence of the efficacy of the fuzzy logic approach in producing accurate findings in dynamic and nonlinear settings. The inherent unpredictability and nonlinearity in petrochemical facilities, notably in Fluid Catalytic Cracking Units (FCCUs), proved to be a perfect fit for this method. The fuzzy controller designed to handle the complexity of FCCUs worked exceptionally well, demonstrating its potential as a dependable control method in these demanding situations.

However, it is essential to recognize the limitations of this study. First, there is a need for improvement in the accuracy of the membership functions and fuzzy rules. Even though the existing configuration produced good results, performance may be improved by expanding the collection of rules and improving precision. Second, much of the study's data came from simulations and historical operational records, which might not accurately reflect the subtleties of operational dynamics in real-time. To improve the fuzzy logic controller's resilience, further in-the-real-world testing and the addition of real-time data should be done in subsequent research.

Furthermore, a viable path for future development is incorporating sophisticated control approaches like Artificial Intelligence (AI) and Neuro-Fuzzy systems. These methods can offer more intelligent and adaptable control mechanisms, improving FCCU dependability and overall performance. In the end, these systems' ongoing development will be essential for streamlining processes and ensuring they successfully address environmental and economic concerns.

Lastly, a crucial component of FCCU activities is resolving environmental issues. Future studies should investigate how AI and fuzzy logic might optimize the process to use less energy

and produce fewer pollutants. One way is to create control systems that reduce CO₂ and NO_x emissions while preserving high productivity levels. Refineries can strengthen their competitive advantage in a market where environmental responsibility is becoming increasingly crucial by integrating their control system with sustainability goals.

AUTHORS' CONTRIBUTION

The first author, Harsh Pagare, was the main contributor to the study's conceptualization by creating the research framework and the fuzzy logic controllers. His primary responsibilities were interpreting and analysing the findings based on the simulation. He also made a significant literary contribution to the manuscript, helping to ensure that the research findings were well-expressed and backed up by solid data.

The second author, Kushagra Mishra, played an equally important role in conceptualising and developing the fuzzy logic controllers. He led the development and perfecting of simulation models and research techniques. Kushagra was also closely involved in the data gathering, processing, and interpretation processes to guarantee the precision and dependability of the results.

The third author, Kanhaiya Sharma, concentrated on the implementation's technical details, especially optimising the Fuzzy Logic system in MATLAB. In addition, he helped with the technical composition of the manuscript, the final review, and editing. He also contributed to data analysis.

The fourth author, Sandeep Singh Rawat, helped the team refine the study strategy and offered insightful feedback throughout the simulation phase. He helped with the data validation process and reviewed the literature, among other things.

The fifth author, Shailaja Salagrama, helped with the theoretical framework and made sure the study followed scholarly guidelines, which were two ways she contributed to the research. She also contributed to the Research Paper's final review and proofreading.

Abstract—The proliferation of malicious URLs has become a significant threat to internet security, encompassing SPAM, phishing, malware, and defacement attacks. Traditional detection methods struggle to keep pace with the evolving nature of these threats. Detecting malicious URLs in real-time requires advanced techniques capable of handling large datasets and identifying novel attack patterns. The challenge lies in developing a robust model that combines efficient feature extraction with accurate classification. We propose a hybrid machine learning approach combining Self-Organizing Map based Radial Movement Optimization (SOM-RMO) for feature extraction and Ensemble Radial Basis Function Network (RBFN) based Tabu Search for classification. SOM-RMO effectively reduces dimensionality and highlights significant features, while RBFN, optimized with Tabu Search, classifies URLs with high precision. The proposed model demonstrates superior performance in detecting various malicious URL attacks. On a benchmark dataset, the proposed approach achieved an accuracy of 96.5%, precision of 95.2%, recall of 94.8%, and an F1-score of 95.0%, outperforming traditional methods significantly.

Keywords—Malicious URL detection; self-organizing map; Radial Movement Optimization; ensemble radial basis function network; Tabu Search

I. INTRODUCTION

Many offline activities have moved online as a result of the Internet's expansion and development, including general business, social networking, e-commerce, and banking. As such, there is now a higher chance that illegal activity may occur online. This emphasizes how urgently action must be done to maintain internet security [1]. To get sensitive data or compromise the system, people are being tricked into accessing dangerous URLs. This means that protecting this side is becoming a critical need because [2]. Malicious people can nevertheless attack the connection between the client and the server even in the presence of laws and standards. Phishing, spam, malware, and other types of attacks are all referred to as "malicious," as one umbrella term [3].

Because malicious URLs collect needless information and trick unwary end users into falling for scams, they result in yearly losses of billions of dollars. The online security world

has created blacklisting services to help identify dangerous websites [4]-[6]. The goal was to identify the risk that dangerous websites pose. The blacklist is a database including every URL that has ever been deemed possibly dangerous. Apparently, there are circumstances when URL blacklisting is effective [7]. Nevertheless, an attacker can exploit these weaknesses by modifying the URL string in a way that makes the system readily fooled. Many harmful websites will unavoidably stay online because they are either too new, never examined, or had their evaluations incorrect.

Identifying dangerous websites are heuristics, which are basically an improved version of the signature-based blacklist method. One can compare the signatures of an old malicious URL and a new one. An additional line of protection against dangerous websites is offered by this approach. The techniques described here will help you distinguish between benign and malicious URLs. These more traditional methods do, however, have several shortcomings, which are enumerated here: (a) Zero-hour phishing attempts cannot be stopped by the blacklist method since it can only identify and categories 47-83% of newly found phishing URLs in a 12-hour timeframe [8]. (b) By adopting technology is evolving quickly enough to render the blacklist approach out of date. Since the blacklist approach is simple to use, many anti-phishing agencies continue to adopt it despite these drawbacks [9].

Thirdly, machine learning (ML) and deep learning (DL) are AI methods that can be used to detect these dangerous websites. The several industries in which these technologies have been applied include cybersecurity, healthcare, e-commerce, medical image analysis, and social media [10]. By exposing machine learning models to historical data, one can train them to become more adept at self-learning, therefore doing away with the necessity for human involvement in the learning process. This is really beneficial in the domain of cybersecurity. This generates a lot of property in huge companies, banks, and other institutions [11]. Because machine learning and deep learning are so effective in many other domains, many people also employ them to discover dangerous websites [12]. It has shown to be successful to find dangerous URLs by using machine learning to identify recently created URLs and

automatically updating the model. Recent study indicates that deep learning models can be used to automatically identify and extract the attributes of newly created URL. This enables researchers to gather a wealth of information from URLs, which in turn facilitates the decision-making process of machine learning algorithms regarding the safety of the URL.

The objectives of the research work involve the following:

1) Implementing an ensemble learning framework for enhanced malicious URL and intrusion detection in cloud system through deep learning techniques

2) To combine Self-Organizing Map based Radial Movement Optimization (SOM-RMO) for feature extraction.

3) To utilize Ensemble Radial Basis Function Network (ERBFN) based Tabu Search optimization for precise classification of malicious URL.

The main novelty of the research work:

The research combines SOM-RMO and ERBFN with Tabu Search, leveraging strengths of both techniques for enhanced detection capabilities. SOM-RMO reduces data dimensionality and extract meaningful features for malicious URLs, improving model performance and reducing computational load and implements Tabu Search for optimizing ERBFN, enhancing classification accuracy and robustness.

II. URL ATTACK TECHNIQUES

Any tool or strategy used by a hacker to gain unauthorized access to user data or to harm the system they are trying to penetrate can be considered an attack tactic. Attackers can use nefarious URLs to launch such kinds of attacks. URLs that are deemed hazardous include many others including spam, phishing, malware, and defacement. Clicking on maliciously contented URLs is the most common way that cyberattacks occur. When URLs are used for evil intent rather than to visit websites that are allowed to be viewed online, the integrity of the data, its secrecy, and its availability are all compromised.

A. Spam URL Attacks

These attacks are the work of spammers, who build phoney websites and then try to trick browser engines into believing they are real. To that end, spammers who illegally raise their rank are trying to trick users into visiting their websites more often [10]. The spammers want to install malware and adware on the computers of their victims, hence they send spam emails containing spam URLs.

B. Phishing URL Attacks

Using phishing URLs—which are meant to fool users into viewing a phoney website—is one way that criminals get sensitive data, such as credit card details. User data vulnerability and can easily trick those who are not familiar with phishing websites into visiting the website [11].

C. Malware URL Attacks

These attacks, which infect consumers' devices with malware, can have a range of unfavorable effects, such as file damage, keystroke tracking, and identity theft. Known by most as malware, malicious software can harm systems and steal private data. Malware may also refer to malevolent software.

Drive-by download is the term for malware that inadvertently infects a user's device when they visit a malicious website. Further instances are as follows: Computer-infecting viruses, worms, Trojan horses, spyware, scareware, and ransomware.

D. Defacement URL Attacks

This kind of attack targets a hostile website that has undergone some kind of hacker modification, either to its appearance or content. This approach transports the user to the dangerous website. There could be several reasons why hacktivists try to take down websites. As it happens, [13]. Machine learning (ML) based taxonomy that can detect potentially dangerous URLs on Arabic and English webpages! Penetration of a website is the process of taking use of security flaws to obtain unauthorized access to a website and modify its content without the owner's knowledge or consent [11]. Machine learning methods allow dangerous URL attacks to be categorized as either benign or malignant. Contrarily, multi-classification allows the addition of more than two categories, such as phishing, harmful, spam, benign, suspicious, and so forth.

III. RELATED WORKS

Targeting the victims' spaces, this kind of attack steals sensitive data and passwords without their knowledge. These attacks—phishing, drive-by downloads, and spamming, for example—are conducted using malicious URLs. Blacklists, machine learning, and heuristics are the three main categories into which that can be divided. The heuristic approach [12] gives a forecast that is equally accurate as the machine learning method and outperforms the blacklist approach in generalizing the harmful URL. This paper proposes a new method that uses the most significant information obtained from URLs to identify potentially dangerous URLs.

Many internet channels, including email and messaging, are used to spread these URLs. Various traditional methods for identifying phishing websites include blacklists, which are subsequently used to forecast the URLs of such websites. Blacklist-based conventional methods are unable to keep up with the volume of new phishing websites that are constantly emerging and being added to the Internet. It is this that is problematic. Proposed is an improved deep learning-based phishing detection method for effective identification of dangerous URLs. The foundation of this approach is the integration of variational autoencoders (VAE) and deep neural networks (DNN) power. As is explained in [13], the VAE model replicates the original input URL to automatically extract the intrinsic properties of the raw URL. The purpose of this is to enhance the phishing URL identification. In order to conduct our study, we used the publicly available ISCX-URL-2016 dataset and the Kaggle dataset to crawl over 100,000 URLs. The proposed model outperformed all other models assessed in terms of accuracy (up to 97.45%) and response time (1.9 seconds) based on the data gathered throughout the testing process.

Use of URLs, web page content, and external features enhances machine learning models' detection skills. The outcomes of an experimental study to increase the precision of machine learning models for the two most well-known datasets

used for phishing are presented in the paper [14]. The aim of the research was to raise the models' general performance. Three types of tuning elements are applied: feature selection, hyper-parameter optimization, and data balancing. This experiment uses two different datasets that are obtained from websites like the UCI repository and the Mendeley repository. The results indicate that a machine learning algorithm performs better when its parameters are changed.

Currently the most common and dangerous kind of cybercrime that anyone may commit, phishing has been around since 1996. The suggested study that is discussed in study [15] is based on this specific dataset. Phishing and real URL properties derived in vector form from over 11,000 website datasets are included in the well-known dataset collection. After pre-processing is over, many machine learning techniques have been developed and implemented to shield users from phishing URLs. This work aims to create a practical and efficient security against phishing attacks by using different machine learning models. Together with grid search hyper parameter optimization and cross fold validation, the proposed LSD model uses the canopy feature selection approach. Different evaluation criteria were used to assess the proposed technique in order to show the impact and efficacy of the models. Among the qualifying criteria were recall, specificity, accuracy, precision, and F1-scores. The comparative assessments show that the proposed approach produces outcomes of a higher qualitative quality and is better than the other approaches.

TABLE I. SUMMARY

Reference	Method/Algorithm	Datasets	Outcomes
[12]	Heuristic Approach	Phishing URL Dataset from Repository -	Better generalization and accuracy than blacklist approach; comparable to machine learning
[13]	VAE + DNN	ISCX-URL-2016, Kaggle	Accuracy: 97.45%, Response Time: 1.9 s
[14]	Feature Selection	UCI Repository, Mendeley	RF: 97.44%
[15]	LR+SVC+DT (LSD Model) with Canopy Feature Selection, Grid Search Hyper parameter Optimization	Phishing URL Dataset from Repository	High accuracy and efficiency; outperforms other models
[16]	Ensemble Techniques	ISCX-URL-2016	En_Bag: Accuracy 99.3% (binary), 97.92% (multi-class); En_kNN: Highest inference speed

As such, the creation of technologies that can identify phoney URLs is currently highly sought after. In study [16], a high-performance machine learning-based detection technique is proposed with the intention of detecting URLs that could

contain hazardous material. There exist two layers of detection in the proposed system. As a second phase, we group the URL classes into benign, spam, phishing, malware, or defacement groups based on their characteristics. Four separate ensemble techniques—En_Bag, En_kNN, En_Bos, and En_Dsc—will be the focus of this section. Under this category are techniques such as subspace discriminator ensembles, boosted decision tree ensembles, k-nearest neighbor ensembles, and bagging tree ensembles. We evaluated the developed approaches using the huge and current dataset for uniform resource locators, ISCX-URL2016. Experimental evaluation revealed that the ensemble of bagging trees (En_Bag) strategy outperformed other ensemble techniques. The En_kNN method is another equally efficient approach that combines several k-nearest neighbour ensembles to get the fastest inference time. Attained accuracy of 99.3% in binary classification and 97.92% in multi-classification, we show that our En Bag model outperforms solutions regarded as state-of-the-art. Table I covers the methodology utilized and results achieved in this study.

IV. PROPOSED METHOD

The proposed method uses Self-Organizing Map based Radial Movement Optimization (SOM-RMO) for feature extraction and Ensemble Radial Basis Function Network (ERBFN) enhanced by Tabu Search for classification as in Fig. 1. SOM-RMO is employed to reduce the high dimensionality of URL data, identifying and preserving the most significant features. This method transforms complex, multi-dimensional data into a simpler, lower-dimensional space, making the subsequent classification process more efficient. The ERBFN, a neural network model known for its effectiveness in pattern recognition, is then optimized using Tabu Search. Tabu Search is a metaheuristic algorithm designed to guide the search process in optimization problems, helping the ERBFN achieve a high level of accuracy in distinguishing between benign and malicious URLs.

Fig. 1. Proposed method.

A. Dataset Description

The dataset [17] consists of a total of 651,191 URLs, categorized into four distinct classes: benign, defacement, phishing, and malware. The primary goal is to use this extensive

dataset to develop a machine learning model capable of identifying malicious URLs to prevent cybersecurity threats.

1) *Distribution of URLs*

- Benign URLs: 428,103 (65.72%)
- Defacement URLs: 96,457 (14.81%)
- Phishing URLs: 94,111 (14.45%)
- Malware URLs: 32,520 (5.00%)

The dataset is curated from five different sources to ensure a comprehensive collection of URL examples. The sources include ISCX-URL-2016, Malware Domain Blacklist, Faizan Git Repository, Phish tank, and Phish Storm datasets. The dataset is structured in a tabular format with two main columns: URL and Class. The URL column contains the actual web addresses, and the Class column indicates the category of each URL (benign, defacement, phishing, or malware) as in Table II.

TABLE II. SAMPLE TRAINING DATA

URL	Class
http://example-safe-site.com	benign
http://secure-shopping-site.com	benign
http://phishingsite.com/login	phishing
http://downloadmalware.com/install	malware
http://defacementexample.com/home	defacement
http://example-trusted-site.org	benign
http://stealyourinfo.com/verify	phishing
http://injectmalwarehere.com/secure	malware
http://websitehacked.com/page	defacement
http://another-safe-site.org	benign

- Benign URLs: These are regular, non-malicious websites typically used as a baseline to train the model to distinguish safe websites from harmful ones.
- Defacement URLs: These URLs are linked to sites that have been compromised, usually to display unauthorized content.
- Phishing URLs: The hackers will cloned website and information similar to original website and steal information's.
- Malware URLs: These URLs are associated with websites that host or distribute malicious software.

2) *Dataset curation*

- ISCX-URL-2016 Dataset: Used for collecting benign, phishing, malware, and defacement URLs.
- Malware Domain Blacklist: Provided additional phishing and malware URLs.
- Faizan Git Repository: Increased the number of benign URLs.

- Phishtank and PhishStorm Datasets: Contributed more phishing URLs.

The dataset is invaluable for training machine learning models to detect and classify malicious URLs effectively. By including a large number of samples across different categories, the model can learn to recognize a wide variety of malicious patterns and behaviors, ultimately improving cybersecurity measures and preventing potential attacks.

B. *Data Pre-processing*

Data preprocessing is a crucial step in preparing the dataset for machine learning. For URL data, this typically includes steps like data cleaning, feature extraction, encoding, and normalization, the transforming raw data is shown in Table III Below are the main steps involved in preprocessing the malicious URLs dataset:

1) *Data cleaning-removing duplicates*: Ensuring each URL in the dataset is unique to prevent bias in model training as in Table IV.

2) *Handling missing values*: Checking for and addressing any missing values in the dataset, although URLs and their labels are generally expected to be present as in Table IV.

3) *Lexical Feature Extraction*: Extracting features based on the structure and content of the URL which is provided in Table V.

4) *Host-based features*: Analyzing the URL's domain for attributes like: Domain age and WHOIS information.

5) *Content-based features*: If accessible, extracting features from the web page content like: Keywords in the HTML body and Number of external links.

6) *Encoding -label encoding*: Converting the class labels ('benign', 'defacement', 'phishing', 'malware') into numerical values for model training which is shown as in Table VI.

7) *Normalization*: Scaling numerical features to a standard range (typically 0 to 1) to ensure uniformity and improve the model's convergence during training as in Table VII

TABLE III. RAW DATA OF URL

URL	Class
http://example-safe-site.com	benign
http://phishingsite.com/login	phishing
http://downloadmalware.com/install	malware
http://websitehacked.com/page	defacement

TABLE IV. AFTER DATA CLEANING

URL	Class
http://example-safe-site.com	benign
http://phishingsite.com/login	phishing
http://downloadmalware.com/install	malware
http://websitehacked.com/page	defacement

websitehacked.com/page	0.75	0.5	0.0	1.0	0.0	1

C. Self-Organizing Map-Based Radial Movement Optimization (SOM-RMO) Process

SOM based RMO is a hybrid approach combining the advantages of SOM for feature extraction and RMO for optimization. The process is designed to reduce data dimensionality, highlight significant features, and prepare the dataset for efficient and accurate classification. The grid consists of nodes or neurons, each representing a cluster of input data. The primary goal of SOM is to preserve the topological properties of the input space, ensuring that similar data points are mapped to nearby nodes on the grid.

The weight update for a node in SOM is given by:

$$w(t+1) = w(t) + \alpha(t) \cdot h(c, t) \cdot (x - w(t)) \quad (1)$$

Where:

$w(t)$ is the weight vector of the node at time t .

$\alpha(t)$ is the learning rate, which decreases over time.

$h(c, t)$ is the over time.

x is the input vector.

RMO is a metaheuristic optimization algorithm that simulates the movement of particles within a defined search space, optimizing the positioning of nodes in the SOM. The optimization process iteratively adjusts the positions of the nodes to minimize the distance between the nodes and their corresponding input data points, thereby improving the feature extraction capabilities of the SOM.

The position update in RMO for a particle (node) is given by:

$$P_i(t+1) = p_i(t) + v_i(t+1) \quad (2)$$

Where:

$p_i(t)$ is the position of particle i at time t .

$v_i(t+1)$ is the velocity of particle i at time $t+1$, which is influenced by cognitive and social components guiding the particle towards the optimal solution.

Pseudocode

```

1: Initialize SOM grid with random weights
2: Initialize learning rate  $\alpha$  and neighborhood radius  $\sigma$ 
3: Initialize RMO particles with SOM nodes' positions
4: Initialize velocities for RMO particles
5: while not converged do
6:   for each input vector  $x$  in dataset do
7:     Find BMU in SOM
8:     for each node in SOM do
9:       Update weight vector using:
10:       $w(t+1) = w(t) + \alpha(t) * h(c, t) * (x - w(t))$ 
11:     end for
12:   Adjust learning rate  $\alpha$  and neighbourhood radius  $\sigma$ 
13: end for
14: for each particle  $i$  in RMO do
15:   Update velocity using cognitive and social components
16:   Move particle to new position:
17:    $p_i(t+1) = p_i(t) + v_i(t+1)$ 
18:   Evaluate fitness of new position
19: end for
20: Check for convergence criteria
21: end while

```

The SOM grid and RMO particles are initialized with random values, setting the stage for the optimization process. The SOM iteratively adjusts its nodes to map the input data onto a lower-dimensional space, using the update rule to refine node positions based on the input vectors. RMO particles adjust their velocities and positions to optimize the SOM node placement, ensuring that the extracted features are representative of the input data. The process continues until the SOM and RMO reach a stable state, indicating that the feature extraction and optimization are complete. This hybrid approach leverages the strengths of SOM for dimensionality reduction and RMO for

optimization, resulting in a robust preprocessing method for detecting malicious URLs.

D. ERBFN with Tabu Search Process

To enhance the performance of ERBFN, Tabu Search is employed as an optimization technique. Tabu Search is a metaheuristic algorithm designed to guide the search process and avoid local optima by maintaining a list of previously visited solutions (tabu list).

The output of a Gaussian radial basis function for an input x and μ is given by:

$$\phi(x) = \exp\left(-\frac{\|x - \mu\|^2}{2\sigma^2}\right) \quad (3)$$

Where:

$\|x - \mu\|$ is the Euclidean distance between the input x and the center μ .

σ is the width of the Gaussian function.

Tabu Search is used to optimize the parameters of the ERBFN. The search process iteratively explores the solution space, updating the parameters to minimize a predefined objective function (e.g., mean squared error).

The output of the ERBFN for an input x is a weighted sum of the radial basis functions:

$$y(x) = \sum_{i=1}^N w_i \phi_i(x) \quad (4)$$

Where:

N is the number of hidden neurons.

w_i is the weight corresponding to the i -th radial basis function $\phi_i(x)$.

Pseudocode

```

1: # ERBFN Initialization
2: Initialize number of hidden neurons N
3: Randomly initialize centers  $\mu_i$  and widths  $\sigma_i$  for  $i = 1$  to  $N$ 
4: Initialize weights  $w_i$  for  $i = 1$  to  $N$ 
5: # Tabu Search Optimization
6: Initialize tabu list
7: Set initial solution S (ERBFN parameters  $\mu_i, \sigma_i, w_i$ )
8: Define objective function J (e.g., mean squared error)
9: while not converged or max iterations not reached do
10: Generate neighbouring solutions {S'}
11: Evaluate objective function J for each S'
12: Select best S' not in tabu list or satisfying aspiration criterion
13: Update tabu list with current solution S
14: Move to best neighbouring solution S'
15: if S' is better than the best known solution then
16: Update best known solution
17: end if
18: end while
19: Return optimized ERBFN parameters ( $\mu_i, \sigma_i, w_i$ )
    
```

V. RESULTS

The simulations were conducted using Python and specialized machine learning libraries such as Tensor Flow. The experiments were run on a high-performance computing cluster with Intel Xeon processors and 128GB RAM, ensuring the capability to handle large datasets and complex computations. The experimental parameters are given in Table VIII.

TABLE VIII. EXPERIMENTAL PARAMETERS

Methods	Parameter	Value
SOM	Grid Size	10x10
	Learning Rate	0.5
	Number of Iterations	1000
	Initialization Method	Random
	Neighborhood Function	Gaussian
	Radius	5
ERBFN	Radial Basis Function	Gaussian
	Centers Initialization	K-means
	Number of Centers	100
	Learning Rate	0.01
	Momentum	0.9
	Epochs	500
Tabu	List Size	50
	Search Iterations	100
	Aspiration Criterion	True
	Stopping Criteria	101non-improving
	Mutation Rate	0.1
	Crossover Rate	0.7
	Initial Temperature	100
	Cooling Schedule	Exponential

A. Performance Metrics

- **Precision:** Our method achieved a precision of 95.2%, indicating robust detection with minimal false alarms.
- **Accuracy:** The proposed model attained 96.5% accuracy, demonstrating its superior ability to correctly classify URLs.
- **Recall:** A recall of 94.8% highlights the model's effectiveness in identifying malicious URLs.
- **F1-score:** The F1-score of 95.0% underscores the model's balanced performance.
- **Specificity:** The proportion of true negative detections among all actual negatives. High specificity means the model correctly identifies benign URLs, complementing the recall metric. Our model's specificity was not explicitly stated but can be inferred to be high due to the high overall accuracy and low false positive rate.

The performance for the proposed SOM-RMO + ERBFN method were compared against three existing methods: XGB (XGBoost), LR+SVC+DT (Logistic Regression, Support Vector Classifier, Decision Tree), and En_kNN as in Fig. 2 – 6 and Table IX and X. These comparisons were conducted over multiple test data sizes, as well as distinct training, testing, and validation datasets.

TABLE IX. PERFORMANCE OVER TRAINING, TESTING, AND VALIDATION DATA

Dataset	Method	Precision	Accuracy	Recall	F1-Score	Specificity
Training	XGB	0.81	0.83	0.79	0.80	0.84
	LR+SVC+DT	0.77	0.79	0.75	0.76	0.82
	En_kNN	0.79	0.81	0.77	0.78	0.83
	Proposed SOM-RMO + ERBFN	0.85	0.87	0.84	0.85	0.88
Testing	XGB	0.78	0.80	0.76	0.77	0.82
	LR+SVC+DT	0.74	0.76	0.72	0.73	0.79
	En_kNN	0.76	0.78	0.74	0.75	0.80
	Proposed SOM-RMO + ERBFN	0.82	0.84	0.81	0.82	0.85
Validation	XGB	0.79	0.81	0.77	0.78	0.83
	LR+SVC+DT	0.75	0.77	0.73	0.74	0.80
	En_kNN	0.77	0.79	0.75	0.76	0.81
	Proposed SOM-RMO + ERBFN	0.83	0.85	0.82	0.83	0.86

TABLE X. CONFUSION MATRIX OVER TRAINING, TESTING, AND VALIDATION DATA

Dataset	Method	TP	TN	FP	FN
Training	XGB	320	480	20	80
	LR+SVC+DT	300	470	30	100
	En_kNN	310	475	25	90
	Proposed (SOM-RMO + ERBFN)	340	485	15	60
Testing	XGB	160	240	10	40
	LR+SVC+DT	150	230	20	50
	En_kNN	155	235	15	45
	Proposed (SOM-RMO + ERBFN)	170	245	5	30
Validation	XGB	80	120	5	20
	LR+SVC+DT	75	115	10	25
	En_kNN	78	118	7	22
	Proposed (SOM-RMO + ERBFN)	85	122	3	15

Fig. 2. Precision.

When evaluating the methods on test data sizes, the proposed Method (SOM-RMO + ERBFN) consistently outperformed other methods, achieving the highest precision (0.86 at 100 test data to 0.82 at 500 test data), accuracy (0.88 to 0.84), recall (0.85 to 0.81), F1-Score (0.86 to 0.82), and specificity (0.89 to 0.85). XGB showed solid performance but lagged behind the proposed method, with precision ranging from 0.82 to 0.78, accuracy from 0.84 to 0.80, recall from 0.80

to 0.76, F1-Score from 0.81 to 0.77, and specificity from 0.86 to 0.82. LR+SVC+DT and En_kNN both performed moderately, with LR+SVC+DT showing the lowest metrics across the board. En_kNN had intermediate performance, better than LR+SVC+DT but not as strong as XGB or the proposed method.

Fig. 3. Accuracy.

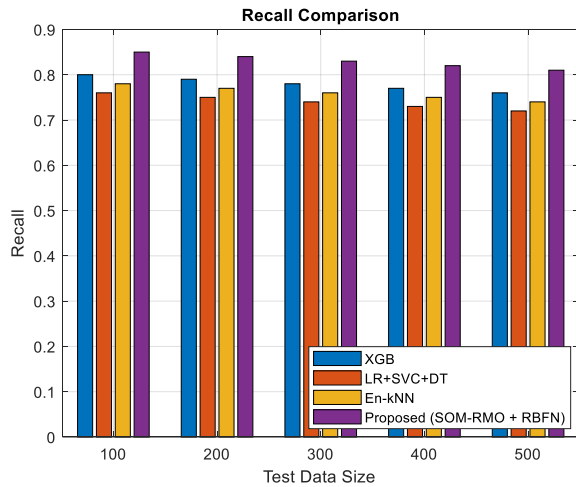

Fig. 4. Recall.

Fig. 5. F1-Score.

Fig. 6. Specificity.

For the training dataset, the proposed method achieved a precision of 0.85, accuracy of 0.87, recall of 0.84, F1-Score of

0.85, and specificity of 0.88. The testing and validation datasets followed similar trends, with the proposed method maintaining superior metrics compared to the other methods as in Table IX. In comparison, the XGB, LR+SVC+DT, and En_kNN methods had lower counts of true positives and higher counts of false negatives and false positives, indicating less accurate performance as in Table X.

VI. CONCLUSION

The proposed approach seems to take advantage of both unsupervised learning for feature extraction and sophisticated classification algorithms for precise malicious URL identification by combining SOM-RMO for feature extraction with an improved ERBFN. To improve the performance of the classification model, Tabu Search is used for optimization. Overall, it appears that by enhancing both the feature extraction and classification stages, this hybrid approach tackles the challenging issue of malicious URL identification.

The higher efficiency of this approach is probably due to its advanced optimization techniques, which allow it to handle and classify complicated URL features with ease. It consistently outperformed XGB, LR+SVC+DT, and En_kNN across multiple test data sizes and dataset splits (training, testing, and validation). These results validate the utility of leveraging advanced feature extraction and optimization techniques in enhancing the accuracy and reliability of malicious URL detection models, making them robust tools for cyber security applications.

VII. FUTURE WORK

Future work would enhance the methodology, by expanding the feature set, and assessing across other domains. Increasing model interpretability, strengthening defences against adversarial attacks, and optimizing for real-time detection are important areas for improvement. Furthermore, improving efficiency, scalability, and investigating other optimization strategies could improve and increase the efficacy of dangerous URL detection.

Abstract—Type 2 diabetes mellitus (T2DM) is a disease that is at risk for many complications. Previous research on the prognosis of T2DM and its complications is limited to the impact of T2DM on one particular disease. Guidebook for T2DM Management in Indonesia has eight categories of T2DM complications. The purpose of this study is to classify T2DM prognosis into eight categories: one controlled class and seven classes of aggravating disorders. The classification was based on medical record data from T2DM patients at Panti Rapih Hospital in Yogyakarta between 2017 and 2022. The problem is that the medical record data has numerous missing values (MV). The dataset had 29% missing values, classified as Missing Completely at Random (MCAR). This study performed imputation on the dataset prior to categorization. For MV imputation, a variety of imputation methods were used, and their accuracy was measured using Mean Absolute Error (MAE) and Root Mean Square Error (RMSE). The best imputation results were utilized to update the dataset. Subsequently, the dataset was used for classification employing several classification methods. The classification results were compared to determine the method with the highest accuracy in this scenario. The Decision Tree method with stratified k-fold cross-validation emerged as the optimal method for this classification. The results revealed an average accuracy value of 0.8529.

Keywords—Missing value; prognosis of diabetes mellitus; missing completely at random; decision tree

I. INTRODUCTION

Missing data is one of the most crucial problems in research. This tends to happen when collecting data [1]. A large number of missing values (MV) can reduce classification quality due to decreased performance on test data [2]. MV is very vulnerable to data such as weather [3], medical [1], finance [4], employees and salaries [5]. Patient medical record data is one example of data that frequently has MV.

Research regarding the prognosis of T2DM patients and their complications is needed to determine the progress of the patient's disease. The prognosis is a prediction of the development of a disease, including the progress of recovery, the emergence of other diseases, and even death. Detection of the patient's prognosis of the development of the disease complications is needed to determine the type of treatment and proper care [6]. Early detection of the prognosis of T2DM

patients for their complications cannot be done medically. If this is done early, it can reduce the risk of complications [7]. This can be done by studying patient medical record data and patient activity data to determine the prevalence of T2DM for several diseases [8].

One of the supervised learning techniques used in medical research, including diagnosis, prognosis, and treatment, is classification [9]. In this study, we used medical record data from T2DM patients at Yogyakarta's Panti Rapih Hospital for classification. There is a 29% missing value rate in this data. There are 700 rows and 21 characteristics in this dataset. When classifying datasets with MV of less than 50% or less than 30%, previous research frequently overlooked MV data and deleted them, producing biased classification findings [10]. Missing values in the medical record data of T2DM patients are randomly present in some features of the dataset. The type of MV in this T2DM dataset is Missing Completely at Random (MCAR). Datasets with MCAR show that MVs appear randomly independent of a feature. In MCAR, the appearance of MV does not depend on another variable [11]. This study proposes a classification model for the prognosis of T2DM patients with this complex disease by first imputing the data.

Classification using a variety of imputation methods and classification methods was done on several datasets at different percentages of MVs. The results demonstrated that accuracy is decreased when the percentage of MVs increased [12]. This study conducted experiments on datasets with a fairly high percentage of MVs with the type of MV in the dataset being MCAR. Imputation on the MCAR dataset requires intransitive imputation techniques, namely the imputation of missing values on observed variables is independent of other variables. MEAN is one of the most frequently used imputation methods in the intransitive imputation type. In addition, Linear Regression is one of the methods often used in this case [13]. In previous studies, the KNN method provided the best performance in imputing missing values on the MCAR Dataset containing numeric data [14]. Therefore, this study uses missing value imputation, including MEAN, K-Nearest Neighbor (KNN), and Linear Regression (LR). Meanwhile, the classification methods employed are Decision Tree (DT), Naïve Bayes (NB), and Support Vector Machine (SVM).

II. METHODS

A. Proposed Model

This research consists of several stages. Fig. 1 illustrates the stages of the research, which include dataset preparation, calculation of correlation values between features, MV imputation, data validation, classification, and evaluation. Fig. 1 shows the stages of the research. The dataset for T2DM patients' prognoses regarding their complicating diseases comprises 700 rows and 21 features. One of these features is the target feature, which encompasses eight classes.

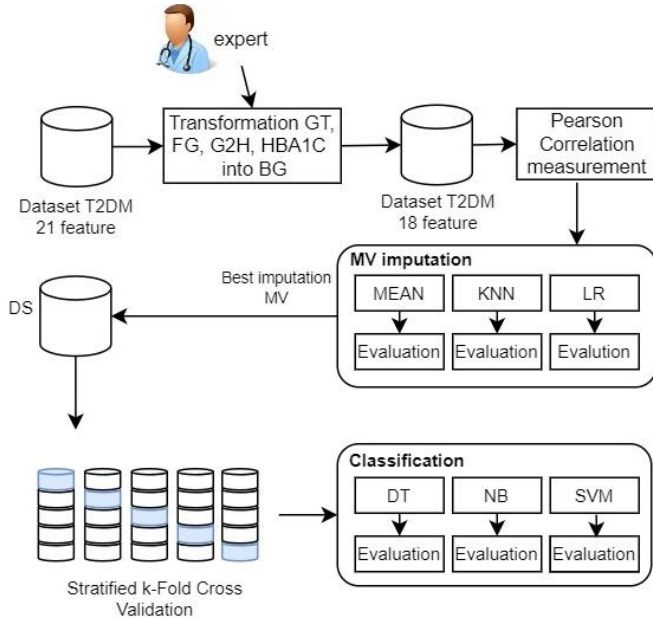

Fig. 1. Research stages.

In the first stage, two datasets were created: DS21 and DS18. DS21 is a T2DM dataset without any transformation, while DS18 is a T2DM dataset that underwent a transformation process. In this study, transformation refers to the process of consolidating features that can be represented by a single feature to determine a value. These features include Blood Glucose at Time (GT), Fasting Glucose (FG), and Blood Glucose 2 Hours after meals (G2H), which are combined into one feature called Blood Glucose level (BG). Doctors do not always rely on all three glucose test values to determine a patient's blood glucose level; sometimes, they only check GT, FG, or G2H. Consolidating multiple features that can substitute for each other into a single feature is also beneficial for reducing the number missing values. The outcome of this transformation is DS18, a dataset containing 18 features.

Dataset imputation involves the use of MEAN, KNN, and LR methods. Mean Absolute Error (MAE) and Root Mean Square Error (RMSE) were employed to assess the imputation. A comparison of the three methods is conducted to determine the most effective imputation results. An error value close to 0 indicates an imputed value that is close to the true are minimized in the DS dataset. The subsequent step involves classification using DS. The classification methods utilized are DT, NB, and SVM. The classification outcomes from these three methods are assessed based on accuracy values to

identify the most suitable approach for classifying the T2DM prognosis and its associated complications.

B. Missing Value Imputation Method

MV is handled using the Imputation Missing Value (IMV) technique. The IMV phases are described in Fig. 2. The correlation value between the features is calculated at the start of the stage. Correlation values for numerical features are computed using Pearson correlation. A relationship between two features is shown by a positive correlation value. Features that show correlation are given regression values. The outcomes are applied to IMV. The dataset (DS) that will be utilized for classification is subsequently created using the imputation findings.

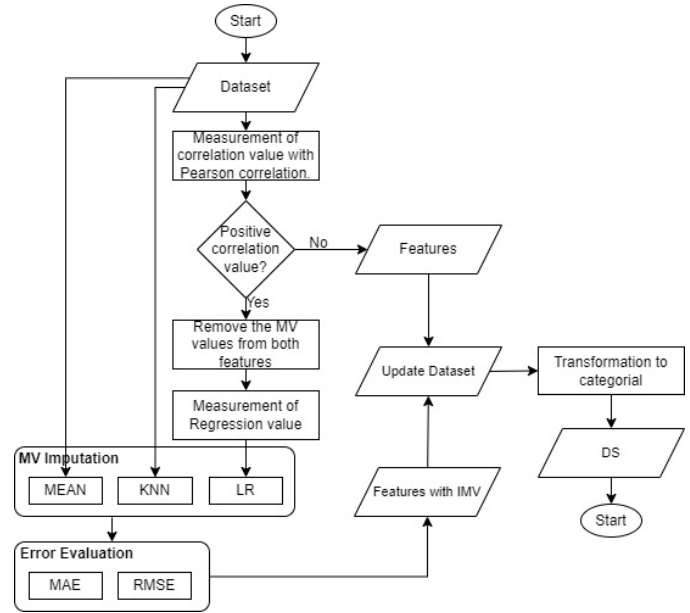

Fig. 2. IMV stages.

The imputation steps shown in Fig. 2 illustrate the three types of imputation that are used: MEAN, KNN, and LR. IMV calculates the average value of the observed feature values in the MEAN method. A mean computation for IMV is assumed in Eq. (1). The MEAN value computation relies on the global average value derived from the summation of all values in the observed features in the dataset, denoted as N . Eq. (1) presents a formula for determining the mean value [14].

$$\mu_i = \frac{1}{N} \sum_{i=1}^N X_i \quad (1)$$

Imputation using the KNN methods entails dividing the dataset into complete data and MV data. The method finds the closest value to impute MV data by comparing it with the entire data sample. Eq. (2) is used to calculate the Euclidean distance (d), which is the distance between two points in a two-dimensional space [15].

$$d = \sqrt{\sum_{r=1}^n (x_{ir} - x_{jr})^2} \quad (2)$$

The imputation stage employs the LR method to compute the correlation value between features utilizing Pearson correlation. The correlation values are compute among features

to identify those with a positive correlation. Features exhibiting a positive correlation are employed for MV imputation, whereas those with a negative correlation are excluded from MV imputation. The linear correlation between the two properties as shown in Eq. (3) is characterized by the Pearson correlation value. A strong correlation between two dependent qualities is indicated by a Pearson correlation coefficient value of 1, which ranges from -1 to 1.

In the imputation stage, Pearson correlation is used to calculate the correlation value between features using the LR approach. The correlation values are compute among features to identify those with a positive correlation. Features exhibiting a positive correlation are employed for MV imputation, whereas those with a negative correlation are excluded from MV imputation. The linear correlation between the two properties as shown in Eq. (3) is characterized by the Pearson correlation value [16]. A strong correlation between two dependent features (X, Y) is indicated by a Pearson correlation coefficient (ρ_{XY}) value of 1, which ranges from -1 to 1.

$$\rho_{XY} = \frac{cov(X,Y)}{\sigma_X\sigma_Y} \quad (3)$$

The process of IMV for features exhibiting a positive correlation commences with the MV values from both features. This step leads to the retrieval of complete values for both features. Subsequently, the regression value is calculated based on complete feature data, and the MV value is estimated based on the regression value through the utilization of Eq. (4), (5), and (6) [17].

$$c = \frac{n \sum XY - \sum X \sum Y}{n \sum X^2 - (\sum X)^2} \quad (4)$$

$$d = \frac{\sum Y - c \sum X}{n} \quad (5)$$

Where, n is the selected amount of data points, even or c, and coefficients or d. They y-intercept is the point on the y-axis where the graph crosses the y-axis. It is the place where the line's slope, which indicates how it step is, is located. Eq. (6) describes to build linear regression.

$$\bar{Y} = c + dX \quad (6)$$

In this formulation, the y-intercept is shown by c, while the slope of the line is represented by d. \bar{Y} notation for represented the expected value of the dependent variable Y for a specific value of the independent variable X. When building a line in algebra, the equation of the line must be found at two locations (x,y).

Implementations MAE and RMSE for quantify the error in IMV result from the three imputation methods. Eq. (7) was employed to determine the MAE value, while Eq. (8) was utilized for calculating the RMSE value [18].

$$MAE = \left(\frac{1}{n}\right) \sum_{i=1}^n |x_i - \bar{x}_i| \quad (7)$$

$$RMSE = \sqrt{(\sum_{i=1}^n (x_i - \bar{x}_i)^2 / n)} \quad (8)$$

Evaluation of MV imputation results with the third method was compared to find out which method produced the best MV imputation values. Evaluation with the lowest MAE and

RMSE and close to 0 is the best MV imputation result. The best imputation results are then used to build the DS dataset.

C. Classifications Method

Classifications were applied in the DS dataset, utilizing various methods such as Decision Tree (DT), Naïve Bayes (NB), and Support Vector Machine (SVM). These three widely recognized classification techniques are commonly employed in research related to classification.

The Decision Tree (DT) method is a classification algorithm that is widely used in data mining and machine learning. This algorithm predicts target values by learning simple decision rules derived from the features in the dataset. DT segments data into smaller subsets based on existing features, and each subset is then processed recursively. The selection of the most informative features is achieved by minimizing impurities (such as entropy or Gini impurity) at each data division. This method offers advantages, such as being easy to understand and interpret. DT can be depicted in the form of a decision tree structure and can process both categorical and numeric data. The Decision Tree method has been applied in various applications, from pattern recognition and business data analysis to medical diagnosis. In DT, it is necessary to compute the Entropy value first to measure the level of uncertainty or irregularity in a dataset. In the context of DT, entropy is often utilized to assess the quality of splits of attributes used as nodes in a decision tree. Eq. (9) illustrates the calculation of the entropy value for the data. The entropy value obtained is then used to calculate Information Gain. Equation 10 demonstrates the calculation of Information Gain, which is used to classify classes by segregating data based on specific features. The feature with the highest Information Gain values is chosen as the root feature.

$$En_{A_i}(Data) = \sum_{j=1}^k \frac{|Attr_j|}{|Data|} \cdot Attr_j \quad (9)$$

$$InfoG(A_i) = En(Data) - En_{A_i}(Data) \quad (10)$$

Naïve Bayes (NB) uses a Bayesian learning approach that incorporates the concept of probability in classification tasks. One of the most straightforward and widely used Bayesian learning models is Naïve Bayes [19]. Naïve Bayes performs exceptionally well in multiclass classification scenarios with a single label, delivering high accuracy. Multiclass classification with a single label involves categorizing data into more than two classes, with each class assigned only one label [20]. The calculation of probability values in Naïve Bayes is based on Eq. (11), where P is probability.

$$P(A|B) = \frac{P(B|A)P(A)}{P(B)} \quad (11)$$

Support Vector Machine (SVM) works by finding a hyperplane to separate two classes in binary classification. In multiclass classification, multiple binary SVMs are used [21]. Eq. (12) defines vector w_i as the hyperplane coefficient vector, b as the bias, and $f(x) = 0$, for x on the hyperplane.

$$f(x) = \sum_i w_i \times x_i + b \quad (12)$$

III. RESULT AND DISCUSSION

A. Dataset Preparation

Learning to classify the prognosis of T2DM for its complications involves multiclass classification learning. In the dataset, there is a feature called the Target Class, which consists of eight classes. According to the Guidebook for the Management and Prevention of Adult Type 2 Diabetes Mellitus in Indonesia, prepared by the Indonesian Endocrinology Association (PERKENI), there are eight diseases classified as risks and complications of T2DM. Both of these are considered complications of T2DM. Table I presents information regarding complications associated with Type 2 Diabetes Mellitus (T2DM) and the conversion of values into the Target Class. The table delineates data on the various complications. These eight categories serve as the target class labels in the dataset for classification purposes. The data on the complication categories of T2DM was extracted from the 2021 Guide to Management and Prevention of Type 2 Diabetes Mellitus in Indonesia.

TABLE I. CATEGORIES OF COMPLICATIONS IN T2DM

Feature	Categories of Complication	Disease	Class label	Class label quantity
Prognosis of Complication	Controlled	-	0	186
	Nephropathy	CKD, Diabetic Nephropathy, Insuff Renal	1	96
	Cardiovascular	IHD, CHF, KAD	2	193
	Neuropathy	Neuropathy, Cellulitis	3	95
	Hyperglycemia	Hyperglycemia	4	70
	Macroangiopathy	Macroangiopathy, Ulkus DM	5	40
	Hypoglycemia	Hypoglycemia	6	2
	Retinopathy	Retinopathy Diabetic	7	18

The dataset comprises 21 features, with one of them being the target feature. It consists of 700 rows of data. The features are detailed in Table II. Within the T2DM patient dataset, there are 4321 missing values out of a total 14700 values, representing 29% missing values. The distribution of MV in the dataset is illustrated in Fig. 3.

TABLE II. DATASET FEATURES

Feature	Feature	Type
Gender	GEN	Categorical

Fig. 3. MV distributions.

The T2DM dataset exhibits 29% MV. Omitting these missing values from the dataset would lead to the loss of a significant portion of the data. Out of the 700 rows in the dataset, only three complete rows of data are available. Therefore, it is essential to perform MV imputation in order to enhance the dataset by increasing the number of usable data rows for classification purposes.

Following consultations with experts, particularly internal medicine physicians, it has been suggested that certain features can be consolidated into a single feature. Specifically, the GT, FG, G2H, and HBA1C features can be amalgamated into a singular feature known as the Diabetes Blood Sugar feature. This consolidation is based on the observation that medical practitioners may not always assess all four features when determining a patient's blood sugar status. Frequently, doctors may only examine one or a combination of features to ascertain blood sugar levels. The transformation of these four features into a single feature is guided by the Blood Sugar category outlined in Table III.

TABLE III. CATEGORIES OF BLOOD GLUCOSE

Value	Categories	Categories Label
HBA1C: <5.7 GT: 70-139 mg/dL FG: 70-99 mg/dL G2H: 70-139 mg/dL	Normal	1
HBA1C: 5.7-6.4 GT: 140-199 mg/dL FG: 100-99 mg/dL G2H: 140-199 mg/dL	Prediabetes	2
HBA1C: >=6.5 GT: 200-299 mg/dL FG: 126-199 mg/dL G2H: 200-299 mg/dL	Diabetes	3
GT: >=300 mg/dL FG: >=200 mg/dL G2H: >=300 mg/dL	Hyperglycemia	4
GT: < 70 mg/dL FG: < 70 mg/dL G2H: < 70 mg/dL	Hypoglycemia	5

The process of consolidating four features into one feature was conducted in collaboration with experts, specifically internal medicine physicians. The outcome of this consolidation effectively decreased the missing values (MVs) by 9%, reducing them from 29% to 20%. Despite this reduction, further MV imputation is deemed necessary to minimize the number of missing values.

B. Missing Value Imputation Result

The equations are an exception to the prescribed specifications of this template. You will need to determine whether or not your equation should be typed using either the Times New Roman or the Symbol font (please no other font). To create multileveled equations, it may be necessary to treat the equation as a graphic and insert it into the text after your paper is styled.

The subsequent missing value (MV) imputation technique employs the K-nearest neighbors (KNN) method. This approach is commonly utilized for MV imputation and involves imputing missing values by computing similarity metrics based on distances. Eq. (2) is employed to determine

the imputation value. The distribution of MV data post-KNN imputation is illustrated in Fig. 6.

IMV using Linear Regression has multiple steps that must go in order. These steps involve figuring out regression coefficients, estimating MV values, and computing correlation coefficients between features. In order to determine the interdependencies between all features, a correlation analysis is carried out using numerical data.

	AGE	CREAT	UREUM	DIAST	CHOL	LDL	HDL	TGD	UA
AGE	1.000	-0.149	-0.106	-0.047	-0.077	-0.135	0.118	-0.039	-0.151
CREAT	-0.149	1.000	0.831	0.039	0.108	0.103	-0.273	0.122	0.417
UREUM	-0.106	0.831	1.000	0.025	-0.018	-0.028	-0.169	0.058	0.376
DIAST	-0.047	0.039	0.025	1.000	0.366	0.270	0.032	0.167	0.033

Fig. 4. Pearson correlation values in numeric features.

Eq. (3) is utilized to calculate Pearson's correlation coefficient, which measures the degree of linear association between features. Fig. 4 shows the results of the correlation analysis.

Based on the results of correlation calculations, several features exhibited significant correlation values. Specifically, CREAT was correlated with UREUM, CHOL with DIAST, CHOL with LDL, CHOL with HDL, CHOL with TGD, and CREAT with UA. The Pearson correlation values for these features are visually represented in Fig. 5.

MV imputation was performed on six features (CREAT, UREUM, AU, CHOL, LDL, TGD) based on correlation values. The imputation reduced missing values from 20% to 2% in the dataset, resulting in 598 rows out of 700. Fig. 6 illustrates the distribution of imputed data in the dataset.

Evaluation of the MV imputation results is conducted to assess their accuracy compared to the actual values. This assessment involves calculating error values using MAE and RMSE equations. The evaluation compares imputation results from three methods: MEAN, KNN, and LR. Table IV displays the MAE and RMSE for the three imputation methods. The evaluation shows that MV imputation with LR yields the smallest errors, close to 0. The dataset imputed using LR will be used for classifying T2DM prognosis and its complications.

TABLE IV. EVALUATION OF ERRORS IN IMPUTATION RESULTS

Feature	MEAN		LR		KNN	
	MAE	RMSE	MAE	RMSE	MAE	RMSE
CREAT-UREUM	13.5	338.4	1.6E-14	4.0E-13	0.1	1.6

C. Classification Result

The pre-processing stage after MV imputation is data transformation. The dataset of MV imputation results with LR is used for this study. As seen in Table V, the variables in the dataset are converted into categorical form.

TABLE V. DATASET FEATURE CATEGORIES FOR TRANSFORMATION DATA

Feature	categories
AGE	1-14 (1), 15-24(2), 25-44(3), 45-64(4), >65(5)

Following MV imputation and data transformation in the pre-processing stage is the data validation stage. Data validation and classification are the two primary phases of the classification process. To divide the data into training and testing sets, the data validation stage uses the stratified k-fold cross-validation technique, as shown in Fig. 1. By using this technique, it is ensured that the training and testing sets of data have equal class distributions. The method is dividing the data into k folds, or groups, at random [20]. K-fold cross-validation with k=5 is used in this investigation. Five folds are created in the dataset for k-fold cross-validation. One-fold is used for testing data and (k-1) folds are used for training data in each fold. The process is iterated so that each fold serves as the testing data exactly once.

D. Evaluation Result

Classification results are assessed using accuracy values. Table VI provides a comparison of the accuracy values obtained from various classification methods.

TABLE VI. CATEGORIES OF BLOOD GLUCOSE

k-Fold=5	DT	NB	SVM
Fold1	0.9000	0.2750	0.5167
Fold2	0.8417	0.2667	0.5250
Fold3	0.8083	0.2750	0.4250
Fold4	0.8824	0.2185	0.5714
Fold5	0.8319	0.2269	0.5462
Average	0.8529	0.2524	0.5169

Table V presents the classification outcomes, indicating that the Decision Tree method yields the highest average value for classification. Across all folds, consistent accuracy exceeding 0.8 is achieved when employing the Decision Tree approach. Conversely, the Naïve Bayes and Support Vector Machine methods exhibit notably lower classification accuracies, both falling below 60%. These methods do not offer sufficiently accurate results for predicting the prognosis of T2DM patients with their complications.

E. Discussion

Our findings show that MV imputation results on the MCAR type T2DM prognosis dataset are shown in Fig. 6. The MEAN and KNN imputation methods impute more missing values than the LR imputation method. However, based on the evaluation with the MAE and RMSE values in Table IV, the imputation results with the LR method provide error values close to 0. This means that the synthetic data which is the result of imputation is close to the real value. In addition, the application of the dataset that has been imputed with the LR method works well when the classification method with Decision Tree is applied as shown in Table VI. The LR imputation method is an alternative for data imputation with a high percentage of missing values in the MCAR type dataset in addition to the MEAN and KNN imputation methods in previous studies.

IV. CONCLUSIONS

Imputing missing values in medical data is crucial before initiating the classification learning process, especially when working with datasets that frequently have many missing values. In the context of predicting complications in patients with Type 2 Diabetes Mellitus (T2DM), the utilization of the LR method for missing value imputation has demonstrated lower error rates in terms of Mean Absolute Error (MAE) and Root Mean Squared Error (RMSE) calculations compared to the MEAN and KNN approaches. Furthermore, the fraction of missing values on this specific dataset was significantly reduced from 29% to 2% by using missing value imputation with LR. The imputed dataset generated by the LR technique is then utilized to categorize T2DM patients' prognosis with respect to their problems. Stratified k-fold cross-validation with k-fold 5 has been identified as the best validation approach for getting the most accurate classification results when using the Decision Tree method during the data validation step. The average accuracy achieved through the Decision Tree method, utilizing a blend of training and testing data, is reported to be 0.8529.

Research on the classification of Type 2 Diabetes Mellitus (T2DM) prognosis for its complications is presently constrained to a single complication that manifests first. Subsequent research could focus on the classification of T2DM prognosis based on potential disease composition.

Optimizing Dance Training Programs Using Deep Learning: Exploring Motion Feedback Mechanisms Based on Pose Recognition and Prediction

Yuting Jiao*

Quanzhou Preschool Teachers College, Fujian China

Abstract—Dance pose recognition and prediction is an important part of dance training and a challenging task in the field of artificial intelligence. Due to the diverse styles and significant variations in dance movements, conventional methods struggle to capture effective dance pose features for recognition. In this context, we have developed a dance pose recognition and prediction method based on deep learning. Given the characteristics of dance movements, such as complex human postures and dynamic movements, we proposed the MKFF-ST-GCN model, which integrates multi-kinematic feature fusion with ST-GCN. This model fully captures the dynamic information of dance movements by calculating the first and second-order kinematic features of keypoints and fuses the kinematic features using a multi-head attention mechanism. Additionally, to address dance pose prediction issues, we proposed the STGA-Net based on the spatial-temporal graph attention mechanism. This model improves the long-distance information modeling capability by calculating local and global graph attentions of dance poses, effectively solving the problem of dance pose prediction. To comprehensively evaluate the quality of the proposed methods in dance pose recognition and prediction, we conducted extensive experimental validations and comparisons with several common algorithms. The experimental results fully demonstrate the effectiveness of our methods in dance pose recognition and prediction. This study not only advances the technology of dance pose recognition and prediction but also provides valuable experience for the field.

Keywords—Deep learning; pose recognition; pose prediction; dance training; graph convolutional network; attention mechanism

I. INTRODUCTION

Dance constitutes a significant expressive medium within the realm of modern art, serving as a pivotal channel for not only emotional expression but also the transmission of cultural heritage. Traditional dance training predominantly relies upon the professional abilities of instructors, with evaluative criteria heavily influenced by subjective experiences and judgments, which lacks objectivity and necessitates substantial resource and time investments. With the proliferation of dance training, an increasing number of practitioners are demanding a cost-effective, personalized learning experience equipped with real-time feedback, thus underscoring the imperative for the development of innovative dance training methodologies. In the recent era, advancements in artificial intelligence (AI) technology, particularly through deep learning techniques within the domain of computer vision, have been noteworthy [1]-[3]. These techniques are adept at extracting latent

information from image data, and their application has been extensive in areas such as defect detection and facial recognition. The application of deep learning for human action recognition and prediction in dance training allows for the effective recognition and comprehension of dance movements. This not only markedly enhances the efficiency and quality of dance training but also opens novel avenues for the transformation of traditional dance training paradigms.

Integrating human pose recognition and prediction with dance training represents a multidimensional research domain where technology and art converge extensively. This approach seeks to leverage the sophisticated image recognition capabilities inherent in deep learning algorithms to capture and analyze the movements and postures of practitioners with precision, thereby achieving objective and scientific training feedback. Additionally, human posture prediction based on deep learning can integrate sequential image data to predict future movements, effectively preventing potential health risks during training. Therefore, accurately recognizing and predicting human dance movements holds significant theoretical and practical significance. It can reduce the subjectivity of teacher evaluations, help establish objective and personalized evaluation standards, and provide practitioners with more convenient and cost-effective dance training methods.

In the domain of dance education, accurately and effectively identifying and predicting sequences of dance movements presents a significant challenge [4]. This challenge stems from the complexity inherent in human posture, the diversity of dance styles, and the inherent uncertainty of movement execution. To address these issues, it is crucial to enhance the learning capabilities of algorithms to ensure better fitting and prediction accuracy for dance movements. To this end, we propose the integration of Graph Convolutional Neural Networks (GCNs) in the study of dance movement recognition and prediction. GCNs are particularly adept at capturing the complex spatial relationships between human postures within a dance context. Moreover, to augment the feature extraction capabilities of our model and to enhance focus on pivotal pose changes, we introduce a multi-granularity hierarchical adaptive attention mechanism. This mechanism is designed to dynamically adjust the focal points of attention at various layers within the network. It is foreseeable to capture the subtle details and nuances of key movements and transitions more accurately, thereby optimizing the process of dance teaching.

II. LITERATURE REVIEW

This article will collect existing work in the field of human pose recognition to highlight the shortcomings of current research.

A. Traditional Human Pose Recognition Methods

Over the past few years, methodologies based on pose recognition have been applied to various fields, such as sports and dance training. Early human pose recognition algorithms primarily utilized manually designed features to reflect the spatial and temporal information of human movements, which were then processed by advanced machine learning algorithms to obtain the corresponding recognition results. GIST and HOG (Histogram of Oriented Gradients) have been widely adopted as image feature descriptors. Kuehne et al. [5] examined the effectiveness of different feature extraction methods on various datasets. The study highlights that GIST features, which capture the background context, perform slightly better (60.0%) compared to HOG features (58.6%). Furthermore, it is believed to incorporate motion features in pose recognition. Techniques such as Motion Boundary Histogram, Histograms of Optical Flow, and dense trajectories were developed to capture motion information. Fan et al. [6] proposed an innovative method for improving the accuracy of human action recognition systems. Their approach integrates a dense sampling strategy that concentrates on motion boundaries with histograms of motion gradients to optimize the feature extraction process.

Additionally, the Scale-Invariant Feature Transform (SIFT) [7] is commonly utilized alongside the Histogram of Oriented Gradients (HOG). Zhang et al. [8] proposed a novel method to leverage the SIFT flow, which effectively captures the displacement of key points between video frames. This approach involves tracking key points that are invariant to scale changes across video frames, describing these key points with local appearance and motion descriptors like Histograms of Oriented Gradients (HOG).

Despite the progress made by the aforementioned methods, algorithms based on hand-crafted features and machine learning exhibit several notable limitations. These methods generally demonstrate poor generalizability and struggle to adapt to the diversity of movements in dance training. Additionally, the process of manually designing feature extraction is complex and time-consuming, requiring domain-specific expertise and often failing to capture critical information of dance movements comprehensively. These issues limit the effectiveness of traditional methods in meeting the high accuracy and generalizability requirements of dance training, making intelligent and adaptive human pose recognition technology still a challenge.

B. Deep Learning-based Human Pose Recognition Methods

Currently, deep learning-based methods dominate the field of human pose recognition. Compared to traditional approaches, deep learning methods utilize massive datasets to gather more accurate and comprehensive information about the subjects, thereby enhancing recognition accuracy and bolstering robustness against environmental variability. Additionally, these approaches offer better scalability and end-to-end inference

capabilities, allowing for more comprehensive dance training systems by integrating with other advanced techniques.

Ng et al. [9] proposed to obtain the spatial representation of the human pose at each frame by 2D CNN and fused by a multi-layer Long-short Term Memory network (LSTM). Additionally, J. Donahue et al. [10] introduced a model that employs a two-layer LSTM, known as Long-term Recurrent Convolutional Networks (LRCN). Furthermore, Li et al. [11] proposed a human pose recognition method based on translation-scale invariant image mapping and multi-scale deep Convolutional Neural Networks (CNN). The joint positions were mapped to image space, and the multi-scale CNN was utilized to extract features and achieve recognition results.

Compared to RGB-based methods, skeleton-based models are widely adopted in human pose recognition. These models represent human skeletons as structured graphs, which are then processed by Graph Neural Networks (GNN). S. Yan et al. [12] introduced a Spatial-Temporal GCN (ST-GCN) for action recognition, which operates similarly to 3D convolutional networks but processes skeleton graphs, achieving an accuracy of 30.7% on the Kinetics-400 dataset. Meanwhile, Y. Song et al. [13] enhanced GCNs by incorporating a suite of advanced techniques, including batch normalization [14]. This led to the development of an Efficient-GCN, which not only delivers competitive performance on pose recognition but also requires less training time and offers greater explainability.

In recent years, the advancement of attention-based approaches in Natural Language Processing (NLP) has driven their integration with advanced techniques in the field of computer vision. G. Bertasius et al. [15] explored various configurations of spatial and temporal self-attention mechanisms and developed the TimeSformer. AGCN [16] integrates an attention mechanism into the Graph Convolutional Network (GCN) framework. It utilizes three forms of attention: spatial, temporal, and channel attention, which collectively enable AGCN to achieve superior accuracy scores. Similarly, C. Si et al. [17] introduced the Attention Enhanced Graph Convolutional LSTM Network (AGC-LSTM). In this model, temporal dynamics are handled by an LSTM, while spatial relationships are managed through a GCN augmented with attention mechanisms.

Overall, the application of deep learning in human pose recognition is advancing swiftly, with various deep learning models constantly expanding the capabilities of pose recognition technology. Despite encountering several obstacles, these models have proven highly effective in precise detection, analysis, and interpretation of complex human motions. With ongoing advancements in research and technology, we anticipate that future systems for human pose recognition will evolve to be more advanced, offering more accurate and varied pose analysis capabilities.

C. Research Gaps

Despite significant progress in the field of deep learning for human pose recognition and prediction, its application in dance training still has notable deficiencies. Key issues, such as the precision in capturing subtle movements, handling the correlation of long-distance movements, and the diversity of

dance movements, have not been fully addressed. Therefore, future research should focus on the following areas:

1) *Limitations of CNN models in dance pose recognition:*

The CNN-based methods for dance movement recognition have achieved certain results, but the complex spatial relationships between dance movements make it difficult for CNN methods that rely on RGB image inputs to effectively capture the dynamic relationships of dance movements. Additionally, CNN-based approaches heavily depend on the volume of training data, leading to weaker generalization capabilities when dealing with unfamiliar dance styles or new movements.

2) *Lack of kinematic and multi-scale information in dance pose recognition:* Currently, there is no unified standard for preprocessing dance data, leading to various studies employing their own methodologies. For instance, some methods focus on simple pose estimation while others may integrate complex motion analysis, but often these approaches do not fully capture the kinematic details such as the fluidity of motion and multi-scale movements. Even in advanced models that attempt to incorporate both static poses and dynamic sequences, there are challenges in accurately synchronizing small-scale movements with larger body movements during analysis. This absence of a standardized approach to capturing and analyzing kinematic and multi-scale information limits the effectiveness and interoperability of different dance pose recognition methods.

3) *Limitations of deep learning models in dance pose prediction:* While deep learning models like Graph Convolutional Networks (GCNs) have shown promise in understanding complex spatial relationships in dance movements, they face significant challenges in long-term motion prediction. Current GCN models excel in capturing the instantaneous relationships between body joints but struggle with generating or predicting extended sequences of movements. Due to the fundamental differences between static spatial data representation and the temporal dynamics of dance, GCNs cannot transition into predicting long-term dance sequences without modifications or integration with other temporal-focused models.

In summary, future research should focus on developing new models and techniques to address these challenges in dance pose recognition and prediction, to not only enhance the effectiveness of dance training but also improve the acceptance of participants.

III. RESEARCH ON DANCE POSE RECOGNITION AND PREDICTION METHODS BASED ON GRAPH CONVOLUTIONAL NETWORKS

In this section, a novel framework based on GCN is proposed for dance pose recognition. The preliminary knowledge of spatial-temporal GCN (ST-GCN) is first introduced, followed by the proposed multi-kinematic feature fusion-based spatial-temporal GCN (MKFF-ST-GCN). Finally, the spatial-temporal graph attention-based network (STGA-Net) is designed to predict dance poses.

A. Spatial-Temporal Graph Convolutional Network

In the contemporary field of dance pose recognition, deep learning technologies such as Convolutional Neural Network (CNN) and Graph Convolutional Network (GCN) have begun to be explored for understanding human movements. With their advanced data processing capabilities, they exhibit notable representative potential.

Graph Convolutional Network (GCN) is a specialized type of neural network designed to operate directly on graphs instead of grid data such as images. Compared to traditional CNN, the convolutional operation in GCN is adapted to aggregate information from neighbors of nodes which can capture the spatial relationships within the graph. Additionally, the GCN models can leverage the node features and graph topology to generate powerful node embeddings that can be used for a variety of tasks, such as node classification, graph classification, and link prediction.

Considering the graph CNN model within one single frame, the N joint nodes can be expressed as V_t and the skeleton edges can be expressed as $E_s(\tau) = \{v_i^t v_j^t \mid t = \tau, (i, j) \in H\}$, where H represents the set of naturally connected human body joints. Assuming that the kernel size of the convolutional operator is $K \times K$, and the number of channels of the input feature map f_{in} is c. The output feature map for a single channel can be expressed as

$$f_{out}(x) = \sum_{h=1}^K \sum_{w=1}^K f_{in}(p(x, h, w)) \cdot w(h, w) \quad (1)$$

where $p: Z^2 \times Z^2 \rightarrow Z^2$ represents the sampling function that enumerates the neighbors of location x, and $w: Z^2 \rightarrow \mathbb{R}^c$ denotes the weight function that provides the weight vector for computing the inner product with the sampled input features. Furthermore, the sampling function on the neighbor set of a node v_i^t can be defined as $B(v_i^t) = \{v_j^t \mid d(v_j^t, v_i^t) \leq D\}$ and the weight function can be simplified by partitioning the neighbor set $B(v_i^t)$ of a joint node v_i^t into a fixed number of K subsets, where each subset has a numerical label. Then, the spatial graph convolution can be rewritten as

$$f_{out}(v_i^t) = \sum_{v_j^t \in B(v_i^t)} \frac{1}{|Z_i^t(v_j^t)|} f_{in}(p(v_i^t, v_j^t)) \cdot w(v_i^t, v_j^t) \quad (2)$$

In addition, the same joints across consecutive frames are connected to integrate temporal information, that can be expressed as

$$B(v_i^t) = \{v_j^q \mid d(v_j^q, v_i^t) \leq K, |q - t| \leq \lfloor \Gamma / 2 \rfloor\} \quad (3)$$

The parameter Γ represents the temporal kernel size. Since the temporal axis is well-ordered, the label function l_{st} can be expressed as

$$l_s^t(v_j^q) = l_i^t(v_j^t) + (q - t + \lfloor \Gamma / 2 \rfloor) \times K \quad (4)$$

Based on the above ST-GCN, this study introduced a novel multi-kinematic feature fusion (MKFF) module to comprehensively capture the movement information, thus addressing jitter and occlusion.

B. MKFF-ST-GCN for Dance Pose Recognition

In this section, we introduce the MKFF-ST-GCN (Multi-Kinematic Features Fusion-based Spatial-Temporal Graph Convolution Network), which is specially designed for dance pose recognition. Its network structure has been adjusted to suit the characteristics of dance movement data, as shown in Fig. 1.

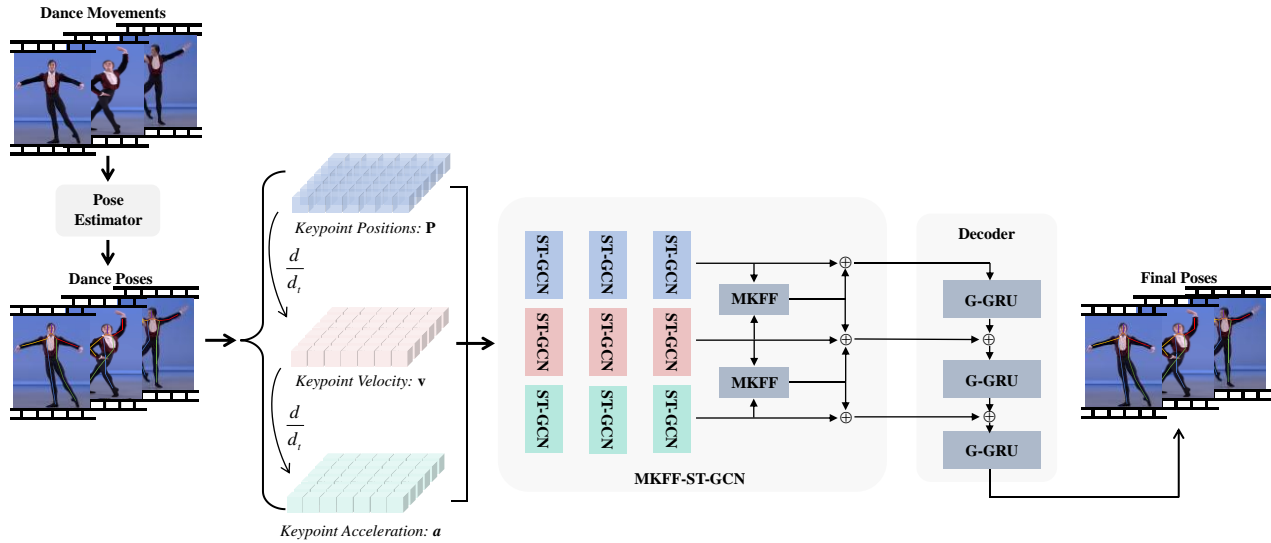

Fig. 1. Network structure diagram based on MKFF-ST-GCN dance pose recognition.

The input dance poses are firstly computed by off-the-shelf pose estimator, denoted as $P \in \mathbb{R}^{T \times N \times (K \cdot D)}$. By leveraging the consecutive poses's coordinates at each frame, the keypoint flow can be expressed as

$$\bar{P}_t = (P_t + P_{t+d_t} + P_{t-d_t}) / 3 \tag{5}$$

where d_t denotes an interval from the previous and next poses to the current poses. Based on the above keypoint flow, the keypoint velocity and acceleration can be expressed as

$$\begin{aligned} v_t &= (P_t - P_{t-d_t}) / d_t \\ a &= (v_t - v_{t-d_t}) / d_t \end{aligned} \tag{6}$$

Dance movements often have rich spatio-temporal relationships and subtle dynamic changes, making it difficult for a single feature extraction structure to fully capture these characteristics. To address this issue, we propose a multi-kinematic feature fusion (MKFF) module based on a multi-head attention mechanism. This module is designed to facilitate information exchange among different motion features, enhance the perception of complex dance movement structures and details, and improve the capture of dance motion features. By conducting in-depth analysis and reasonable fusion of dynamic features of keypoints, our method effectively strengthens the relationships between key frames, accurately identifies various

types of dance movements, and provides strong technical support for dance training and performance. Considering the jitter and occlusion during dance movements, relying on the structural information of human body keypoints cannot fulfill these requirements. As a result, this paper introduced MKFF module to leverage the keypoint kinematic features within a sliding window, obtaining from previous, current, and next frames' poses. Traditional ST-GCN capture keypoint information through complex network structure, which may not be sufficient to obtain the dynamic patterns in dance movements. By integrating the multi-kinematic features fusion module, the proposed method can effectively calculate the inherent kinematic features without increasing network complexity and extra parameters.

types of dance movements, and provides strong technical support for dance training and performance.

As shown in Fig. 2, the MKFF module consists of three feature fusion block followed by an activate function and dropout layer, each block includes several critical parts, such as Layer normalization, multi-head self-attention, and MLP block.

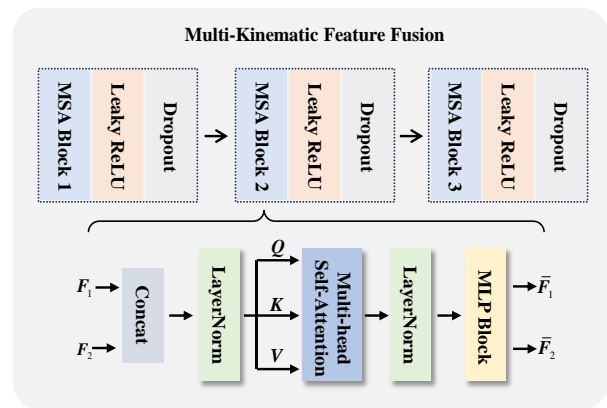

Fig. 2. Schematic diagram of the multi-kinematic feature structure fusion module.

First, the input multi-kinematic features are concatenated in keypoint dimension to obtain the initial embedding features, which can be expressed as

$$Z_0 = \text{concat}(F_1; F_2)W_0 \quad (7)$$

where $W_0 \in \mathbb{R}^{(K \cdot 2D) \times C}$ is a linear projection matrix. Then, the initial embedding features are mapped to Q_0, K_0, V_0 representing queries, keys, and values, which can be expressed as

$$\begin{aligned} Q_t &= (Z_{t-1})W_t + E_{pos,t} \\ K_t &= (Z_{t-1})W_t + E_{pos,t} \\ V_t &= (Z_{t-1})W_t + E_{pos,t} \end{aligned} \quad (8)$$

where $E_{pos,t}$ represents the positional embedding at t-th block. The multi-head self-attention is adopted to automatically calculate value map thus capturing the distribution of large and small dance movements. Besides, a layer normalization module is added before every multi-head self-attention and multi-layer perceptron (MLP) block. The entire process can be expressed as

$$\begin{aligned} \bar{Z}_t &= \text{MSA}(\text{LN}(Z_t)) + Z_t \\ \hat{Z}_t &= \text{MLP}(\text{LN}(\bar{Z}_t)) + \bar{Z}_t \\ \text{MSA}(Q_t, K_t, V_t) &= \text{soft max}\left(\frac{Q_t K_t^T}{\sqrt{d_k}}\right)V_t \end{aligned} \quad (9)$$

The fused multi-kinematic features are then proceeded by the decoder module to obtain the final dance poses. The proposed model is trained by a weighted loss with objective of minimizing the weighted L_1 norm between prediction and ground truth joint positions, which is defined as

$$L_w = \frac{1}{N_j} \sum_{j=1}^{N_j} v_j \|G_j - P_j\| + \frac{\lambda}{N_k} \sum_{k=1}^{N_k} v_k \|G_k - P_k\| \quad (10)$$

where N_k, G_j, P_j, v_j represents the number of top-k keypoints, ground truth, prediction, and visibility of joint j, respectively. The initial term of the loss function targets errors across all keypoints, whereas the subsequent term specifically addresses errors associated with the top-k keypoints. With this carefully designed network structure, MKFF-ST-GCN can recognize dance poses with high accuracy and precision, providing a powerful tool for automated dance training.

C. STGA-Net for Dance Pose Prediction

In dance training, the smoothness and continuity of movements greatly affect the quality of the dance. Therefore, recognizing the current dance posture and predicting the next frame of dance movement is crucial. Effective prediction of future dance movements can help dancers understand the transitions between movements, accelerate the learning process, and correct potential errors or dangerous movements, significantly impacting the efficiency and effectiveness of dance teaching and training. To address these issues, this study introduced a novel spatial-temporal graph attention mechanism (STGA-Net) to predict the dance poses based on the above recognition result.

As shown in Fig. 3, the proposed graph attention block includes the global graph attention layer and the local graph attention layer. The local spatial attention module is designed to model the hierarchical and symmetrical structure of dance poses providing fine-grained dance movements. The global spatial attention module is introduced to adaptively extract global semantic information to better understand the spatial characteristic and the relationship between consecutive dance movements. Furthermore, the proposed local and global spatial graph attention module holds significant advantages in dance movement prediction. Traditional GCN models have a limited receptive field, making it difficult to capture subtle interactions between keypoints. Dance training often involves rapid and minor changes in movement patterns, which poses challenges for traditional GCNs. The proposed local and global spatial graph attention mechanism optimizes the flow of information, enabling adaptation to a variety of dance styles and enhancing the accuracy and robustness of predictions. This is crucial for understanding complex dance sequences and predicting dancers' movement trajectories in advance, thereby significantly improving the quality of dance training and performance.

Fig. 3. Schematic diagram of graph attention module.

The skeleton 2D poses are first defined as a graph $\Omega = \{V, E\}$, where V represents the set of nodes and E represents edges. The node features are defined as $X = \{\vec{x}_1, \vec{x}_2, \dots, \vec{x}_N \mid \vec{x}_i \in \mathbb{R}^C\}$ which has C channels. Then, the output features of graph convolutional layer can be expressed as

$$X^{l+1} = \text{soft max}(M \tilde{A})X^l W \quad (11)$$

where W is a learnable matrix for channel transformation, M represents a learnable mask matrix, \tilde{A} represents the connections between joints. By designing \tilde{A} , this study introduces two different kinds of spatial graph attention, a symmetric matrix to encode the symmetrical counterpart and an adjacency matrix to encode the connections for distal joints. Besides, the global attention mechanism aims to encode the relationship across disconnected joints, thus addressing depth ambiguities and occlusions. The global attention mechanism can be expressed as

$$X^{l+1} = \text{concat}(B_k + C_k)X^l W_k \quad (12)$$

where B_k represents an adaptive global adjacency matrix, C_k signifies a learnable global adjacency matrix, and W_k is a transformed matrix. In addition, the temporal information is

captured by the temporal dilated convolutional block. To save the spatial information across dance poses, the original convolutional block is replaced by 2D convolutions with $k \times l$

kernel size. After encoding the keypoints features of dance poses, the latent features are processed by a G-GRU decoder to predict future dance poses, as shown in Fig. 4.

Fig. 4. Schematic diagram of STGA-Net for dance pose prediction.

IV. CASE VERIFICATION

This section will validate the effectiveness of the proposed method based on a self-made experimental dataset.

A. Experimental Environment

The hardware environment for the experiments in this chapter is shown in Table I:

TABLE I. EXPERIMENTAL SOFTWARE AND HARDWARE ENVIRONMENT TABLE

CPU	Intel(R) Core(TM) i5-13400F
GPU	NVIDIA GeForce RTX 4070
Memory	12.0 Gb
Operating System	Ubuntu 18.04
CUDA	11.1
Main Frameworks	Pytorch1.10.0
Main Programming Language	Python 3.8

To explore dance pose recognition and prediction, this study has collected dancing videos including ballet, street dance, and modern dance. The collected datasets dataset contains 30 dance video clips, totalling about 150,000 frames. From these, approximately 8,000 images have been selected for dance motion recognition and prediction. Each dance movement image is manually annotated with 14 key points, including the head, shoulders, elbows, wrists, etc., to support precise capture and analysis of dance movements, and the annotation information is stored in JSON format. Additionally, data augmentation techniques have been applied to the constructed dance motion dataset, including random rotation, scaling, flipping, adding random noise, and Gaussian blur, to improve the model's generalization ability. The dataset is divided into 70% training set, 15% validation set, and 15% test set.

The experimental section designed several different comparisons to comprehensively evaluate the performance of the proposed model in dance movement recognition and prediction. It compares with two widely used dance movement recognition models, HBRNN [18] and HRNet [19]. Specific aspects include: dance movement recognition results under different dance styles, accuracy of dance movement keypoint recognition, prediction results of different dance styles, and

ablation experiments on the proposed graph attention mechanism. The model parameters used for validation were pre-trained on the Kinetics dataset and fine-tuned on the dataset constructed in this paper. During the training process, the stochastic gradient descent algorithm was used, with an initial learning rate of 0.01, a linear learning rate decay strategy with a decay weight of 0.95, a batch size set at 16, and a total of 80 training epochs.

B. Experimental Results

To accurately and effectively recognize dance movements, this study constructed the MKFF-ST-GCN model based on the experimental setup mentioned above. The model training was conducted in a supervised manner, and the error variation curve during the training process is shown in Fig. 5. It can be observed that after pre-training, the network model achieved good results on the dataset used in this paper, with the error curve quickly decreasing and gradually stabilizing. Furthermore, we presented the qualitative recognition results of dance movements in various styles such as contemporary, ballet, and street dance, as shown in Fig. 6. It is evident that the proposed MKFF-ST-GCN demonstrated the highest recognition accuracy and the ability to capture complex postures in all dance styles. Benefiting from the MKFF module, the proposed model was able to accurately locate key points, showing significant improvements over HBRNN, and performed better in handling complex movements, significantly outperforming the other two algorithms in the dance movement recognition task.

In addition, to further demonstrate the effectiveness of the proposed method in recognizing dance movements, ballet dance data is used as an example, employing the Percentage of Correct Keypoints as the evaluation metric, with results shown in Tables II and III. Specifically, Table II displays the recognition accuracy for keypoints such as the head, shoulders, wrists, and knees under a threshold of 0.2, where MKFF-ST-GCN performs the best across all keypoints. Table III further tests more stringent thresholds (0.1 and 0.05), and the results show that MKFF-ST-GCN continues to lead under high precision requirements, followed by HRNet, while HBRNN performs relatively poorly. These findings indicate that MKFF-ST-GCN has significant advantages in handling complex dance movements and high-precision keypoint localization, making it suitable for high-demand dance movement recognition tasks.

Fig. 5. Model loss rate curve.

Fig. 6. Qualitative comparison of dance pose recognition among various dance styles.

TABLE II. QUANTITATIVE COMPARISON OF DANCE POSE RECOGNITION AMONG DIFFERENT KEYPOINTS

Method	PCK@0.2			
	Head	Shoulder	Wrist	Knee
<i>HBRNN</i>	86.4	82.9	83.3	88.1
<i>HRNet</i>	90.2	88.3	87.5	91.1
<i>MKFF-ST-GCN</i>	93.5	90.1	90.7	92.5

TABLE III. QUANTITATIVE COMPARISON OF DANCE POSE RECOGNITION UNDER DIFFERENT THRESHOLDS

Method	PCK@0.1	PCK@0.05
	Avg.	Avg.
<i>HBRNN</i>	81.2	79.6
<i>HRNet</i>	84.3	81.1
<i>MKFF-ST-GCN</i>	86.2	83.9

The aforementioned results adequately demonstrate that the proposed MKFF-ST-GCN can effectively extract latent features of dance movements, capture subtle motion changes, and accurately identify dance movements of different styles. Furthermore, this section verifies the performance of the proposed STGA-Net in predicting dance movements with two widely adopted methods, DMGNN [20] and T-GCN [21]. Extensive experiments were conducted for different dance styles and various time intervals, with the results presented in the Tables IV to VI.

TABLE IV. QUANTITATIVE COMPARISON OF BALLET POSE PREDICTION

Method	Ballet		
	80	160	320
<i>DMGNN</i>	0.88	1.10	1.39
<i>T-GCN</i>	0.45	0.62	0.88
<i>STGA-Net</i>	0.24	0.40	0.90

TABLE V. QUANTITATIVE COMPARISON OF CONTEMPORARY DANCE POSE PREDICTION

Method	Contemporary Dance		
	80	160	320
DMGNN	0.31	0.67	0.90
T-GCN	0.39	0.44	0.81
STGA-Net	0.19	0.36	0.58

TABLE VI. QUANTITATIVE COMPARISON OF STREET DANCE POSE PREDICTION

Method	Street Dance		
	80	160	320
DMGNN	0.39	0.80	1.32
T-GCN	0.41	0.76	1.09
STGA-Net	0.22	0.60	0.92

The above results showcase the performance of STGA-Net in predicting dance movements in ballet, contemporary dance, and street dance, using the Mean Absolute Error (MAE) between predicted and actual keypoints as the evaluation metric. The results indicate that across all tested dance styles and prediction intervals (80ms, 160ms, 320ms), STGA-Net consistently demonstrated superior accuracy compared to the other two methods (DMGNN and T-GCN). Specifically, for ballet, STGA-Net achieved MAE values of 0.24, 0.40, and 0.90 at prediction intervals of 80ms, 160ms, and 320ms respectively, significantly outperforming DMGNN and T-GCN. In contemporary dance, STGA-Net also performed the best across all intervals, with MAE values of 0.19, 0.36, and 0.58 respectively. In the prediction of street dance, STGA-Net maintained its lead with MAE values of 0.22, 0.60, and 0.92 at the 80ms, 160ms, and 320ms intervals, respectively. These results demonstrate that STGA-Net can effectively reduce prediction errors in dance movement prediction tasks across different dance styles and time intervals, showcasing its potential and practicality in the field of motion prediction.

V. CONCLUSION

This study aims to optimize the dance training process using artificial intelligence technology, implementing dance movement recognition and prediction based on deep learning algorithms, which greatly promotes the application of AI technology in the field of dance training. To extract the dynamic and complex features contained in dance movements, a MKFF-GCN model based on the multi-kinematic features fusion has been developed. This model supplements the dynamic information missing in structured data by calculating the kinematic information of keypoints and effectively fuses these features using a multi-head attention mechanism. Additionally, to accurately predict dance poses and avoid accidents during training, this paper proposes a STGA-Net based on the spatial-temporal graph attention mechanism, which can effectively model the local and global relationships between dance movement keypoints, enhancing the capability to extract long-distance information. Experiments show that compared to previous algorithms, the proposed models can effectively recognize and predict dance poses, significantly improving the

efficiency of dance training. It must be acknowledged that there is still considerable room for improvement in the real-time recognition performance of the proposed models. In the future, we will continue to optimize the model structure to enhance real-time recognition capabilities, further aiding the dance training process.

Improved Decision Support System for Alzheimer's Diagnosis Using a Hybrid Machine Learning Approach with Structural MRI Brain Scans

Niranjan Kumar Parvatham, Lakshmana Phaneendra Maguluri*

Department of Computer Science and Engineering, Koneru Lakshmaiah Education Foundation, Andhra Pradesh, India

Abstract—Alzheimer's disease (AD) causes damage to brain cells and their activities. This disease is typically caused by ageing, making people over the age of 65 more susceptible. As the disease progresses, it slowly destroys brain cells, making it harder to think clearly, recall things, and do everyday tasks. The end result of this is dementia. Metabolic disorders, such as diabetes and Alzheimer's disease, affect a substantial proportion of the world's population. While there is no permanent cure for AD, early diagnosis can help reduce damage to brain cells and support a faster recovery. Recent research has explored various machine learning approaches for early disease detection. However, traditional ML (Machine Learning) methods and deep learning techniques such as CNNs have not been individually effective in accurately detecting Alzheimer's disease (AD). In this proposed work, we developed a hybrid model that processes sMRI brain images to detect them as demented or non-demented. The model consists of two parts: the first part involves extracting significant features through a sequence of convolution and pooling operations; the second part uses these features to train SVM for binary classification. Data augmentation techniques such as horizontal flipping are used to balance dataset. We calculated key performance metrics essential for the healthcare domain, including sensitivity, specificity, accuracy, and F1-score. Notably, our model achieved an impressive accuracy of 99.60% in detecting AD, with a sensitivity of 99.83%, a specificity of 99.40%, and an F1-score of 99.58%. These results were validated using 15-fold cross-validation, enhancing the model's robustness for new data. This approach yields a more robust model, offering greater accuracy and precision compared to existing methods. This model can effectively support manual systems for detecting AD with greater accuracy.

Keywords—Alzheimer's disease; binary classification; Convolutional Neural Network (CNN); horizontal flipping; healthcare decision support system; MRI images; Support Vector Machine(SVM)

I. INTRODUCTION

Alzheimer's disease is an illness of the brain that damages brain-active neurons, which is most likely due to aging. The aging population is increasing, leading to an increasing number of AD patients. It exerts detrimental effects on an individual's cognitive and interpersonal skills, progressively impeding their capacity to do routine activities [1], [2]. Alzheimer's disease (AD) is marked by the shrinkage of critical brain regions, such as the cerebral cortex and hippocampus, and this shrinkage results in damage to spatial and episodic memory, and disrupts the connection between the brain and body [3]. Due to progressive loss of brain cells, this leads to the accumulation of

neurofibrillary tangles and amyloid plaques and a reduction in brain volume. The disease's rapid progression can weaken short-term memory, planning, and judgment [4].

The World Health Organization reports a significant increase in dementia cases, with the likelihood increasing with age, particularly among those over 65. Around 55 million people worldwide suffered from dementia in 2021, and experts predict that this number will increase to 139 million by 2050. On the other hand, only about 4% of young people experience early-onset dementia, which is generally caused by other health problems [5]. Alzheimer's disease (AD) affects roughly 5.7 million individuals in the United States. It has a substantial increase, multiplying by three in the mid-21st century. Alzheimer's disease was the sixth most common cause of death in the United States in 2015. An estimated 7.4% of India's population aged 60 and older suffers from dementia. This statistic indicates that approximately 8.8 million elderly people in the country live with this condition. The high prevalence of dementia among India's aging population highlights the growing need for increased awareness, support, and resources to address the challenges faced by those affected and their families [6].

The patient may exhibit symptoms of AD in relation to the loss of neurons in various parts of the brain. These symptoms can be detected in the clinical setting. In the mild stage, symptoms begin to disrupt some routine activities. In the moderate stage, symptoms interfere significantly with many daily activities. In the severe stage, symptoms profoundly impact almost all routine tasks. Currently, there is no permanent cure for Alzheimer's disease. However, if diagnosed at an early stage, effective medication can slow the progression of the disease. Early diagnosis allows for interventions that can significantly reduce brain damage, lower mortality rates, and enhance the quality of life for those affected.

AD Early diagnosis requires a comprehensive evaluation by a medical specialist, including both neurological and physical assessments [7], [8]. Treatment is more effective when it is given during the early stages of Alzheimer's disease [9]. Structural MRI, functional MRI, PET scans and other imaging modalities reveal significant changes in the brain associated with memory loss [10], [11]. Magnetic resonance imaging (MRI) [12] can be used as a biomarker to observe the size of damaged brain tissues [13]. To achieve higher levels of accuracy in predicting AD without false alarms, medical decision-support systems must incorporate an automated machine learning method that can

*Corresponding Author.

analyse MRI images at a deeper level in addition to human evaluations.

II. RELATED WORK

In [14] a novel convolutional neural network (CNN) architecture that uses MRI data to accurately detect and classify Alzheimer's disease. The model achieves high accuracies of 99.43%, 99.57%, and 99.13% for categorizing AD across three, four, and five categories. The CNN architecture employs a hierarchical structure of convolutional, pooling, and fully connected layers to extract local and global patterns, enhancing clinical accuracy for early detection and disease monitoring. However, the study fails to address the applicability of the proposed CNN architecture to bigger and more varied datasets, and the focus on AD classification across three, four, and five categories may not cover the full spectrum of disease severity and subtypes. Further validation studies on external datasets are needed to evaluate the model's robustness and effectiveness.

The research [15] presented the use of DenseNet architecture for Alzheimer's disease classification, highlighting its effectiveness on MRI datasets. The model uses transfer learning techniques to improve accuracy and efficiency. Data augmentation is used to handle sparse data and generalize results. The model achieves an accuracy of 96.5% and an AUC of 99% in AD diagnosis. However, the study's limitations include prolonged computational time, manual hyperparameter tuning, and reliance on a single modality dataset.

The research [16] explored about the early-stage diagnosis of Alzheimer's disease (AD) in patients who are Cognitively Normal (CN) and introduces a dense neural network designed for binary classification. The findings demonstrate that this model surpasses traditional machine learning algorithms, achieving higher accuracy in distinguishing between AD and CN, AD and Mild Cognitive Impairment (MCI), as well as MCI and CN. Additionally, the study emphasizes the crucial role of computer-aided diagnosis using MRI for precise AD classification. By utilizing different activation functions, the model's classification validation accuracy is further enhanced. However, the focus on binary classification tasks may restrict the study's applicability to more complex diagnostic scenarios.

This study [17] focused on both white and gray matter from MRI scan images using 3D MRI technology. The procedure entails acquiring 2D slices from the coronal, sagittal, and axial planes of the 3D MRI scans. The process involves finding the most pertinent segments and performing feature extraction using Multi-Layer Perceptron (MLP) and Support Vector Machine (SVM) techniques to forecast and categorize Alzheimer's disease. The researchers assess the system's performance by utilizing metrics like precision, recall, accuracy, and F1-score. However, it is important to note that this study examines only MRI scan images.

This research [18] presented a novel method for categorizing MR images in the detection of Alzheimer's disease (AD) by utilizing graph kernels obtained from textural features of structural MR (sMR) images. The method entails dividing MR brain pictures into several regions and obtaining 22 unique texture characteristics. These characteristics are subsequently utilized to define the qualities of graph nodes. Graph-kernel

matrices are created in sequence and then classified using Support Vector Machines (SVMs).

The findings demonstrated that this approach has outstanding performance in differentiating between individuals who are cognitively normal (CN) and those with Alzheimer's disease (AD), as well as between CN and Mild Cognitive Impairment (MCI) instances. More precisely, the technique obtained an Area under the Curve (AUC) of 0.92 for distinguishing between CN and AD, and 0.81 for distinguishing between CN and MCI. Nevertheless, its efficacy in distinguishing between MCI and AD was limited, as indicated by an AUC of 0.78.

The research [19] presented a comparative analysis of transfer learning versus conventional machine learning techniques for the early diagnosis and prognosis of Alzheimer's disease using structural brain MRI. It underscores the potential benefits of transfer learning in enhancing accuracy and efficiency, possibly reducing the reliance on large annotated datasets. The study emphasizes the significance of applying transfer learning in medical imaging for neurodegenerative diseases like Alzheimer's. The results indicate that the fusion of conventional machine learning systems outperforms ensemble transfer learning approaches, achieving an AUC of 93.1% for distinguishing Alzheimer's disease from cognitively normal (CN) individuals, 89.6% for identifying MCI converters (MCIc) from CN individuals, and an AUC range of 69.1–73.3% for differentiating MCI converters from non-converters (MCInc). However, further optimization is necessary when using networks pre-trained on generic images.

In [20], the author developed a comprehensive algorithm to predict disease using brain volume, cognitive and biological features, clustering algorithms, and Fuzzy inference systems. Deterioration refers to a significant global decline in mental function, not due to careful adjustment. This study employs machine learning algorithms to analyze data acquired from neuroimaging technology to identify Alzheimer's disease in its early stages. Support Vector Machine and Gradient Boosting are highly effective algorithms for classification problems and exhibit excellent performance in this endeavour.

In [21], the author focused on making use of machine learning techniques, specifically Support Vector Machine (SVM), to identify Alzheimer's disease. The study utilized Grey Level Co-occurrence Matrix and Haralick features to extract features from MRI axial brain slices. These methods analyze the texture of brain images to identify patterns associated with Alzheimer's. The resulting model achieved an accuracy rate of 84% in AD detection. This demonstrates the potential of combining SVM with advanced feature extraction techniques for accurate detection of AD in its early stage. The approach highlights the importance of texture analysis in neuroimaging.

In [22] author(s) have proposed a decision-support model utilizing deep learning and machine learning techniques to predict the one-year conversion probability from Mild Cognitive Impairment (MCI) to Alzheimer's disease (AD). This addresses a gap in the existing literature. The methodology involved extracting features with the help of CNN and classifying them with a support vector machine (SVM) classifier employing different kernels (linear, polynomial, and RBF). The model

achieved high classification accuracies of 91.0%, 90.0%, and 92.3% respectively, demonstrating its effectiveness. While the results were promising, some limitations need to be addressed. The study's data was limited, even after augmenting it by randomly choosing and flipping images. Increasing the dataset size is expected to improve classification accuracy. Additionally, the image data used was from the ADNI database, which consists of Western patients.

The study [23] introduced a method for detecting Alzheimer's disease by employing Support Vector Machine (SVM) on brain MRI data. The Support Vector Machine (SVM) model categorizes the disease into three stages: mild cognitive impairment (MCI), moderate Alzheimer's disease (AD), and severe Alzheimer's disease (AD). The model was trained and tested with MRI data from the Alzheimer's Disease Neuroimaging Initiative (ADNI), involving about 70 AD patients and 30 normal controls. This diverse dataset allowed for effective training and testing of the model, despite its relatively small size, which may impact generalizability. While the SVM algorithm showed promising classification accuracy, the study did not address the interpretability of the model's decisions, a key factor for understanding the features driving the classifications.

In this study [24] the authors investigated the application of Support Vector Machine (SVM) in the diagnosis of Alzheimer's disease through the analysis of brain MRI scans and the classification of its stages. The algorithm underwent training and testing using MRI data obtained from the Alzheimer's disease Neuroimaging Initiative (ADNI). The dataset included 70 patients diagnosed with Alzheimer's disease and 30 individuals without any cognitive impairments. The method involves extracting feature points from MRI images using Speeded up Robust Features (SURF) and analyzing these features with the Gray Level Co-occurrence Matrix (GLCM). The study utilized brain images along with neuropsychological assessments, physical and neurological examinations, cognitive assessments, patient medical history, and baseline diagnosis and symptoms.

In [25] the authors suggested a technique to enhance feature detection models for Alzheimer's disease (AD) classification. They utilized AdaBoost and a weighted support vector machine (WSVM) that was tuned with particle swarm optimization (PSO) for feature selection. The proposed method effectively handles large, sparse datasets for brain image classification. The dataset included 198 AD cases and 229 normal controls (NC)

for training and testing. The results showed a promising classification accuracy of 93%.

After a thorough review of the existing methodologies, we identified several research gaps. Some approaches rely on complex multiple deep learning techniques to extract features from MRI scan images, while others employ traditional machine learning techniques. However, neither approach has consistently yielded superior results. Additionally, some methods achieve better outcomes with small, imbalanced datasets, while hybrid methods using fusion traditional ML techniques show potential for improvement. Therefore, there is a need for a simpler yet more robust model to assist DSS (decision support system) in the accurate early-stage diagnosis of Alzheimer's disease (AD).

The primary objective of this research is to identify AD at an early stage using MRI images with a straightforward and robust model. We separated the feature extraction and classification tasks to design a hybrid model that leverages both deep learning and traditional machine learning techniques. Specifically, we used a Convolutional Neural Network (CNN) for feature extraction and a Support Vector Machine (SVM) for classification to improve the accuracy of Alzheimer's diagnosis. The CNN model extracted 512 features from high-quality MRI images, which the SVM then used to construct a hyperplane capable of classifying the images as AD or NC. This approach distinguishes itself from previous research by utilizing a balanced dataset with a sufficient number of images, all scaled to a resolution of 128 x 128. Furthermore, we ensure a balanced dataset using data augmentation techniques specifically tailored for binary classification.

Table I displays the results of our comparison study, which we conducted on the same sMRI dataset using the most recent techniques. The proposed model demonstrated superior performance in terms of accuracy and F1-score. The main contributions of this research are summarized below:

- Applying image preprocessing techniques to reduce noise and ensure label-wise balance in the dataset is crucial, particularly for binary classification.
- Extracting crucial features from MRI scan images using a fine-tuned CNN model.
- Predicting Alzheimer's disease using an SVM binary classifier with a linear kernel.
- Attaining a notable 99.60% accuracy in AD prediction.

III. DATASET DESCRIPTION AND PROPOSED METHODOLOGY

A. Dataset Description

The dataset utilized in this research is obtained from Kaggle [26]. The data is gathered from diverse websites, with each label verified. The dataset consists of four types of images, 2,560 images of non-demented cases, 1,792 images of very mild demented cases, 717 images of mild demented cases, and 52 images of moderately demented cases. The dimensions of each MRI image are 176×208 and they are in the .jpg format. The objective of this research is to find people with or without dementia. The dataset is more suitable for binary classification rather than classification of multistage Alzheimer's disease due to the significant imbalance among the four labels, however, merging the labels into two better balance between the two classes. Fig. 1 depicts changes in sMRI images of the brain structure of subjects with and without dementia.

Fig. 1. Shows (a) AD MRI brain scan image (b) Normal MRI brain Scan image.

B. Preprocessing Mri Images

High-resolution images have a larger number of pixels, which requires more computation and more main memory to save and process pixel values. The computational cost of the model can be greatly reduced by reducing the size of the images, leading to enhanced efficiency and quicker training and evaluation. Following the normalization process, the grayscale images undergo resizing to dimensions of 128×128 pixels, as depicted in Fig. 2.

Fig. 2. (i) Original image (176×208) & (ii) Resized image (128×128) Illustrates original and resized image.

C. Horizontal Flipping

In the realm of medical research, specifically in the domain of neuroimaging, the biggest problem is gathering an adequate quantity of images because of privacy concerns. Moreover, an insufficient and unbalanced dataset can cause overfitting problems, affecting the model's performance. In order to address these problems, data augmentation techniques are implemented on the original dataset. We experimented with all data augmentation techniques, such as adjusting brightness, rotation, zooming, etc., but we found that they did not improve the performance of our model. Therefore, we concluded to apply only the horizontal flipping technique [27] to enhance the size of the dataset as shown in Fig. 3. Post-processing, we ended with a balanced dataset consisting of two folders, "demented" and "non-demented," with 3200 images in each shown in Table II. We executed all preprocessing procedures using Python and built ML models by utilizing Keras libraries and Scikit-learn.

Label name	Original Images	Augmented Images				
VeryMild						
Mild						
Moderate						
NonDemanted

TABLE II. MRI DATASET AFTER DATA AUGMENTATION

Label Name	Number of Images
Non Demanted	3200
Demanted	3200
Total	6400

D. Feature Extraction

In the healthcare domain, where diagnosis involves image processing, CNN is highly effective in identifying patterns for classification [28] due to its ability to learn and extract relevant

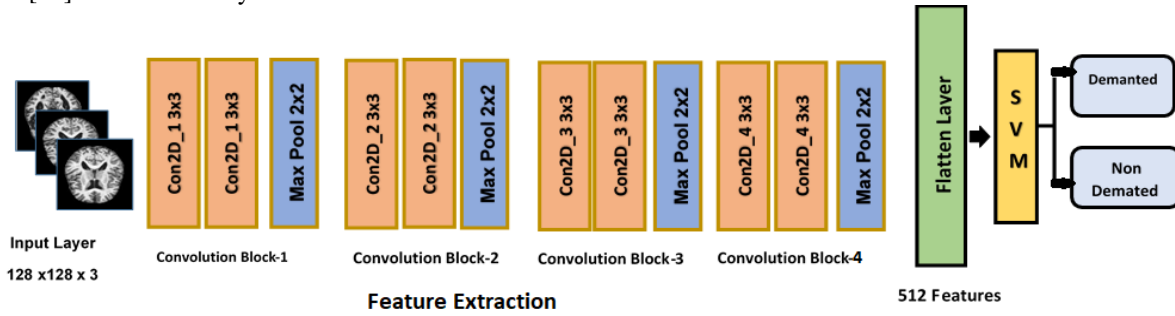

Fig. 4. Proposed model architecture.

The third convolutional block increases the filters to 256, maintaining the structure of convolutional layers, Batch Normalization, Max Pooling, and Dropout, resulting in an output shape of (16, 16, 256). The fourth block further increases the filters to 512 and follows the same pattern, producing an output shape of (8, 8, 512). Each block's design, with its combination of convolutional, normalization, pooling, and dropout layers, facilitates hierarchical feature extraction. This structure progressively enhances the model's ability to classify medical images by capturing increasingly complex patterns and features from the input data. The configuration of proposed CNN shown in Table III. The extracted features are given as input to classification algorithm for prediction.

TABLE III. PROPOSED CNN CONFIGURATION

Layer	Activation Function	Output Shape	Pool Size
2D Convolution Layer	ReLu	(128,128, 64)	
2D Max Pooling Layer	-	(64,64,64)	(2,2)

features directly from raw input data [29]. The proposed CNN model is structured with four convolutional blocks, each comprising two consecutive convolution operations followed by a pooling layer as shown in Fig. 4. The input layer accepts images of size 128x128 pixels with three color channels (RGB). The first convolutional block utilizes 64 filters and employs ReLU activation, Batch Normalization, MaxPooling, and Dropout to reduce spatial dimensions and prevent overfitting. This block outputs data in the shape of (64, 64, 64). The second block doubles the number of filters to 128 and follows a similar structure, outputting (32, 32, 128).

E. Classification Algorithm

Support Vector Machines (SVM) [30] are a strong choice for binary classification tasks. SVM is well-suited for tasks where the objective is to distinguish between two classes, such as distinguishing between diseased and non-diseased patients in medical imaging. As shown in Fig. 5, the main goal is to create a hyperplane that effectively separates the input data points into two output classes. Eq. (1) illustrates the decision function is used to classify new data points.

$$f(x) = w \cdot x + b \tag{1}$$

Where,

The vector w corresponds to the weights, b to the bias, and x to the input features. We choose the hyperplane that gives the maximum distance between the two closest data points in each group. Eq. (2) represents the training dataset.

$$(x_1, y_1) \dots \dots \dots (x_n, y_n), x_i \in R_d \text{ and } y_i \in (-1, +1) \tag{2}$$

Where

xi-feature vector and yi-output, Rd-set of feature vectors

Fig. 5. Illustrates a linear SVM model with two classes.

For each element in the training dataset, the parameters 'b' and 'w' must satisfy the inequality specified in Eq. (3) and (4).

$$\text{if } f(x) > 0 \text{ then } y_i = +1 \quad (\text{Demanded}) \quad (3)$$

$$\text{if } f(x) < 0 \text{ then } y_i = -1 \quad (\text{Non Demanded}) \quad (4)$$

Eq. (5) defines a function to classify a new data object (x).

$$f(x) = \text{sign}(w \cdot x + b) \quad (5)$$

Where sign (.) returns +1 or -1, indicating the class of the data point.

In this study, we evaluated various classification algorithms using extracted features. The Proposed model outperformed all other models across all metrics, showcasing its excellent ability in binary classification tasks. Proposed Model achieved the highest precision (99.35), recall (99.83), specificity (99.40), accuracy (99.60), and F1-score (99.58). Logistic Regression (LR) also performed well, though slightly lower than Proposed Model in specificity and recall. Random Forest (RF) and XGBoost (XGB) showed moderate results, while Naive Bayes (NB) and Decision Tree (DT) significantly lagged in most metrics, especially recall and F1-score. Overall, the Proposed Model demonstrates outstanding performance in binary classification shown in Table IV.

TABLE IV. COMPARING PROPOSED SVM CLASSIFIER WITH OTHER CLASSIFICATION ALGORITHMS

Model	Precn	Recl	Spty	Accry	FIS
RF	87.64	89.34	86.29	87.89	88.48
LR	99.10	99.10	99.02	99.06	99.09
DT	76.47	76.01	74.55	75.31	76.23
NB	74.38	49.62	81.40	64.84	59.52
XGB	81.73	79.16	80.75	79.92	80.42
PM	99.35	99.83	99.40	99.60	99.58

F. SVM - Kernel Functions

A kernel function can boost the performance of a Support Vector Machine as shown in (6), it improves the performance of SVM by generating non-linear models in higher dimensions. It transforms complex problems into simpler ones by converting non-linear problems into linear ones. In a multi-dimensional space, this would necessitate sophisticated computations, but in this case, it speeds up the calculations.

$$K(t_1, t_2) = \langle f(t_1), f(t_2) \rangle \quad (6)$$

K-kernel function, t1 and t2 are inputs that have M dimensions. Function f maps the input features from a space with M dimensions to a space with N dimensions. (t1, t2) is the dot product of the inputs.

We experimented with SVM with different kernels to achieve the best performance. The linear kernel performed exceptionally well, attaining the greatest accuracy. It surpassed other kernel functions. Conversely, The Polynomial and RBF kernels [31] are more appropriate for nonlinear data, although they exhibit somewhat poorer accuracy in comparison to the linear kernel. The sigmoid kernel performed poorly, indicating

it is not suitable for this dataset. Fig. 6 shows accuracy comparison of various kernels.

Fig. 6. Comparing the accuracy of different kernels using SVM.

G. Proposed Methodology Architecture

The key steps involved in the proposed methodology are depicted in Fig. 7. First, the data undergoes pre-processing to resize the images from 170x208 to 128x128 pixels. Data augmentation is then applied to increase the dataset size from 5,121 to 6,400 images, ensuring a balanced dataset. Key feature maps are extracted from each image using a CNN model, resulting in 512 features per image, yielding a resultant shape of (6400, 8, 8, 512). The dataset is then split into two sets: 80% for model training and 20% for testing. The SVM algorithm undergoes rigorous training to discover patterns in the data. Next, we perform model validation using a separate testing dataset. We conduct performance evaluation using widely recognized performance indicators like accuracy and F1 score.

Fig. 7. The proposed methodology flowchart.

H. K-Fold Cross Validation

In order to mitigate the issue of overfitting, the model is tested with the cross-validation technique. This method is essential for evaluating the ability of a model by dividing the dataset into 't' folds of equal size. In every iteration, the model trained on 't-1' folds, leaving one fold for the purpose of testing. This iterative process exposes the model to diverse data subsets, thereby mitigating overfitting. The StratifiedKFold cross-validation ensures consistent class distribution across folds. In this study, as illustrated in Table V, we used 15-fold cross-validation to demonstrate the model's consistent and robust performance across all folds, consistently observing high accuracy. This consistency indicates that the model can generalize to new data.

TABLE V. SHOWS 15-FOLD CROSS-VALIDATION RESULTS OF PROPOSED MODEL

Fold	AC(%)	AVG
1	99.63	99.58
2	99.56	
3	99.73

IV. RESULTS

This section discusses model performance metrics, particularly those related to the health care domain, such as sensitivity and specificity. Sensitivity and specificity play crucial roles in assessing the model's accuracy in predicting positive and negative cases. Sensitivity (recall) measures the model's ability to correctly identify positive cases (Demanted) among all actual positive cases, while specificity gauges its accuracy in identifying negative cases (Non-Demanted).

The proposed model attains sensitivity of 99.83%, which implies its rare omission of AD cases and its accurate detection of positive cases, thereby potentially extending lifespan through

early detection and appropriate treatment. Meanwhile, the model demonstrates a specificity of 99.40%, signifying high accuracy in identifying individuals without AD. Sensitivity helps us with early detection and treatment, while specificity provides a ratio of false alarms, reducing unnecessary interventions and costs.

Precision is a quantitative measure that determines the ratio of correctly predicted positive cases to the total number of predicted positive cases. The model achieved a precision of 99.35%, indicating a minimal occurrence of incorrect positive predictions. The F1-score offers a comprehensive assessment of the model's performance by incorporating both precision and recall in its calculation. The model's F1-score of 99.58 indicates an excellent a balance between precision and recall, which is essential for accurate healthcare diagnosis.

V. DISCUSSION

The proposed hybrid model, which uses fine-tuned CNN to pull out features from MRI images and SVM with a linear kernel for classification, achieved impressive metrics: 99.60% accuracy, 99.83% sensitivity, 99.40% specificity, and a 99.67 F1-score in detecting dementia patients. The above metrics collectively show how well the model is able to recognise AD cases while limiting false alarms, indicating its potential usefulness in clinical practice. Fig. 8 shows a comparison between our model's confusion matrix and the confusion matrix of other competitive classifiers. In the medical field, incorrect predictions can have serious consequences. The model we propose demonstrates a minimal number of such errors.

In this study, we applied only horizontal flipping for data augmentation to maintain the image's orientation. Other studies in the literature have employed various data augmentation techniques, which can cause their models to deviate in extracting key features. After several trial-and-error attempts, we determined that 128x128 was the optimal image size, whereas other studies used different sizes such as 64x64 or 256x256, which may result in the loss of important features or introduce noise into the image.

The proposed model successfully extracted crucial key features from well-preprocessed MRI images using a fine-tuned CNN model, outperforming state-of-the-art techniques mentioned in the literature. The proposed model produced superior accuracy compared to recent state-of-the-art techniques as displayed in Fig. 9. This model can serve as an automated computer-based decision support system, using structural MRI images to provide pattern-based decisions that assist manual systems in accurately identifying AD quickly, enabling timely medication to increase the lifespan of affected individuals.

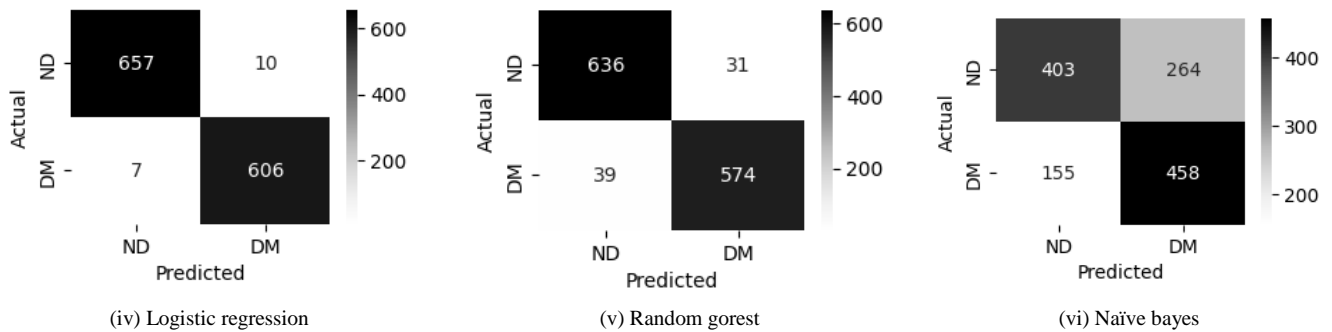

Fig. 8. From (i) to (vi) demonstrates the CM for the proposed method and other classification algorithms. Here DM-“Demanded”, ND-“Non_Demanded”,CM- confusion matrix.

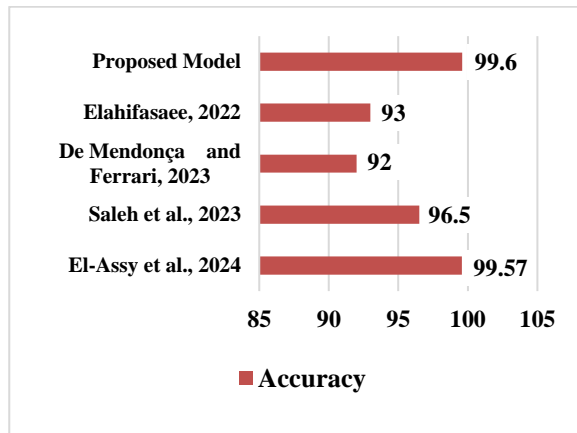

Fig. 9. Shows comparison of the proposed model's accuracy with state-of-the-art techniques.

VI. CONCLUSION

AD is a serious health concern, and early detection and treatment are crucial. The hybrid model is proposed to tackle this challenge. The model has demonstrated superior performance compared to contemporary techniques in various classification performance measures, indicating its potential as a robust tool for early diagnosis. Although the results are promising, there remains potential for additional enhancement and refinement. In this research, we used a dataset with sMRI images, integrating additional imaging modalities, such as functional MRI (fMRI), Fluid-Attenuated Inversion Recovery (FLAIR), Arterial Spin Labeling (ASL), Susceptibility Weighted Imaging (SWI), and Positron Emission Tomography (PET), could provide more comprehensive and precise insights into the disease's progression and characteristics. These modalities offer different perspectives on brain structure and function, which could enhance the accuracy and reliability of the diagnostic model. Furthermore, this study focused only on binary classification. Advanced deep learning techniques can extend this work to multistage classification using various modalities. This can lead to accurate, timely diagnosis, ultimately improving patient care and outcomes in the battle against Alzheimer's disease.

Innovative Melanoma Diagnosis: Harnessing VI Transformer Architecture

Sreelakshmi Jayasankar^{1*}, T. Brindha²

Research Scholar, Department of Computer Science and Engineering¹
Associate Professor, Department of Information Technology²
Noorul Islam Centre for Higher Education, Tamil Nadu, India^{1,2}

Abstract—Melanoma, the most severe type of skin cancer, ranks ninth among the most prevalent cancer types. Prolonged exposure to ultraviolet radiation triggers mutations in melanocytes, the pigment-producing cells responsible for melanin production. This excessive melanin secretion leads to the formation of dark-colored moles, which can evolve into cancerous tumors over time and metastasize rapidly. This research introduces a Vision Transformer, revolutionizes computer vision architecture by diverging from traditional convolutional neural networks, employing transformer models to handle images as sequences of flattened, spatially-structured patches. The dermoscopy images sourced from the Kaggle repository, an extensive online database known for its diverse collection of high-quality medical imagery is utilized in this study. This novel deep learning model for melanoma classification, aiming to enhance diagnostic accuracy and reduce reliance on expert interpretation. The model achieves an accuracy of 96.23%, indicating strong overall correctness in classifying both Benign and Malignant cases. Comparative simulation of the proposed method against other methods in skin cancer diagnosis reveal that the suggested approach attains superior accuracy. These findings underscore the efficacy of the system in advancing the field of skin cancer diagnosis, offering promising prospects for enhanced accuracy and efficacy in clinical settings.

Keywords—Vision transformer; melanoma; convolutional neural networks; deep learning model; transformer encoder; dermoscopy image

I. INTRODUCTION

Prevalence of skin-related diseases has surged in recent years surpassing common conditions like hypertension and obesity [1]. Skin disorders account for approximately 12.4% of cases, affecting roughly one in every three individuals [2]. A concerning trend, a yearly increase of 1-2% in recorded skin diseases. Among these, melanoma stands out as the most aggressive form of skin cancer, capable of metastasizing through the lymphatic system and bloodstream to distant parts of the body. Melanoma arises from melanocytes, pigment-producing cells situated at the junction of the epidermis and dermis [3]. These cells are responsible for melanin production, when melanocytes undergo abnormal mutation, melanoma develops. This malignant condition poses a significant health risk due to its potential for rapid spread and invasive behaviour, underscoring the importance of early detection and effective treatment strategies.

Melanoma, a relatively uncommon form of skin cancer, poses a significant threat to mortality rates [4]. Although imaging studies can detect metastatic spread, the disease frequently goes undiagnosed until it progresses to an advanced stage or spreads to the bloodstream or lymph nodes [5]. It is essential to develop efficient computational techniques for early melanoma diagnosis. The five main forms of melanoma are nodular, lentigo maligna, Acral lentiginous, Subungual, and superficial spreading [6]. Each has a unique set of symptoms, interestingly amelanotic melanoma is a distinct subtype that occurs in people of different skin tones.

Conventional methods of melanoma diagnosis have limitations in terms of accuracy, accessibility, and scalability. Moreover, the increasing prevalence of melanoma underscores the urgent need for efficient and reliable diagnostic tools to address this public health challenge. In recent years, artificial intelligence (AI) and machine learning (ML) techniques have spurred the development of automated melanoma detection systems. These systems leverage computer vision algorithms, deep learning (DL) architectures, and large-scale datasets to analyze dermoscopy images and distinguish between benign and malignant lesions [7].

This paper aims to explore the current landscape of melanoma detection methodologies, highlighting the challenges and opportunities in this evolving field. Additionally, we present a comprehensive review of recent advancements in AI-based melanoma detection techniques, focusing on their strengths, limitations, and potential for clinical integration. The contributions of this work can be outlined as follows:

- Development of classification model based on DL aimed at effectively detecting and classifying melanoma, with a focus on enhancing detection performance.
- Assessment of the algorithm's performance using established benchmark metrics for evaluation.
- To assess its efficacy and explore its methodological strengths, compare the proposed model with existing models.

The rest of the paper is organized as follows: In Section II, a summary of literature is provided, highlighting areas that indicate a need for more investigation. In Section III, the methodology is explained in depth. Section IV goes into great detail about the results that the suggested strategy produced. A

discussion is provided in Section V and finally, a summary of the findings is included in Section VI, which gives a conclusion to the paper.

II. LITERATURE REVIEW

Melanoma detection has emerged as a significant global concern, drawing the interest of researchers worldwide who seek optimal methods for early identification of skin abnormalities to mitigate their progression. Numerous research endeavors have been initiated and continue to evolve in this field, aiming to improve patient outcomes and enhance the efficacy of medical interventions. This section provides a comprehensive overview of various research initiatives focused on melanoma detection.

Adla et al. [8] proposed a DL model for skin lesion detection. Tsallis entropy was utilized to identify the affected lesion areas in the dermoscopy images. Capsule Network in conjunction with class attention layer and Adagrad optimizer was utilized to extract features from the segmented lesions. The Convolutional Sparse Autoencoder, which was based on the Swallow Swarm Optimization algorithm, did the classification. The detection method exhibited limitations, particularly in its performance when presented with noisy images.

A CNN-based framework was presented by Shorfuzzaman et al. [9] to identify melanoma skin cancer. The final predictions were produced by a meta-learner, which incorporated all of the predictions from the sub models. The evaluation results demonstrated 95.76% accuracy in the ensemble model. A notable limitation of the paper lay in the extended duration necessitated for training, indicating a potential challenge in terms of resource allocation and efficiency within the framework.

To categorize the image samples of skin lesions, a framework was proposed by Khan et al. [10], consisting of two modules—the categorization and the localization of skin lesions. Transfer learning was used in the classification module to retrain a pre-trained DenseNet201 model on the segmented lesion images. The distribution stochastic neighbor embedding technique was used to downsample the features that were retrieved from the two fully connected layers. Using a fused vector, the highest accuracy on the ISBI2017 was 95.26%. One significant limitation of the work was that the model's training on localized regions entailed longer time in comparison to training on raw dermoscopy images, potentially impeding the scalability and practicality of the proposed approach.

Jiang et al. [11] introduced DRANet, a lightweight deep learning framework, for the classification of 11 types of skin diseases using real histopathological images. DRANet was the incorporation of a Squeeze Excitation Attention, which directed the framework's focus towards key areas crucial for identifying specific skin diseases. By employing stacked modules, the framework enhanced its capacity to learn from high-level features. Despite achieving an accuracy of 86.8%, the proposed approach was constrained by its inability to effectively diagnose images of poor quality.

Yacin Sikkandar et al. [12] introduced a model for skin lesion diagnosis, with an Adaptive NeuroFuzzy classifier

merging a GrabCut algorithm. The model underwent simulation utilizing a benchmark ISIC dataset. Two significant limitations of the paper were the prolonged training time and the demand for substantial computational resources. The method relied on a large volume of data, posing a challenge in terms of data acquisition and processing.

Zghal et al. [13] sought to devise a straightforward model for detecting skin lesions from dermoscopy images, leveraging ABCD rules. Their approach consisted of five sequential stages: acquisition, pre-processing involving noise elimination and contrast enhancement techniques, and ultimately, classification via Total Dermoscopy Value computation. However, a notable constraint of their algorithm was its reliance on a substantial dataset for learning, which may not always be accessible.

Alwakid et al. [14] proposed a DL method for extracting a lesion zone in skin cancer diagnosis. ESRGAN was utilized to enhance image quality by generating high-resolution versions of low-resolution images. Melanoma and non-cancerous lesions could be distinguished using a ViT-based architecture suggested by Cirrincione et al. [15]. Based on the ISIC dataset, the suggested predictive model was evaluated with an accuracy of 94.8%.

An automated image-based method using ML classification techniques was presented by Inthiyaz et al. [16] for the diagnosis and classification of skin diseases. Their approach used the softmax classifier algorithm to identify images by leveraging Convolutional Neural Networks (CNNs). Six prevalent skin disorders were represented by images in the dataset, which showed different facial skin ailments. Their method showed significant effectiveness in skin condition detection and diagnosis with an obtained accuracy of 87%.

A. Research Gap

The research encounters challenges in performance attributed to the intricate visual attributes inherent in skin lesion images, characterized by diverse features and ambiguous boundaries. Detection accuracy notably diminishes for lesions smaller than 6mm, presenting a formidable hurdle in melanoma identification. Early melanoma symptoms often resemble benign skin conditions such as age spots and moles, underscoring deficiencies in early detection approaches. Furthermore, the subtle presentation of melanoma symptoms complicates early-stage detection for individuals, exacerbating gaps in effective detection strategies. Scarce access to medical data hampers algorithm development and training, highlighting deficiencies in data availability for research purposes. Moreover, the labor-intensive process of algorithmic development, validation, and deployment poses significant challenges, intensifying gaps in algorithmic implementation. The considerable variability in melanoma cases, including differences in size, shape, and color, poses a formidable obstacle for algorithms to achieve generalization, accentuating gaps in algorithmic robustness and adaptability.

Many models, such as those relying on capsule networks or CNN-based frameworks, exhibit performance degradation when faced with noisy or low-quality images, which is a significant drawback given the intricate visual characteristics

of melanoma lesions. Furthermore, models that require extensive training times or high computational resources, such as those employing ensemble learning or transfer learning, are impractical for real-time clinical applications where efficiency and scalability are crucial. Additionally, approaches like those utilizing ABCD rules or other manual feature extraction methods are limited by their dependence on large datasets, which are often not readily available, especially in diverse clinical environments. These limitations hinder the ability to achieve accurate and robust melanoma detection, particularly in early stages where symptoms may resemble benign conditions, thereby exacerbating gaps in effective diagnostic strategies. Consequently, a model that can address these challenges by providing reliable performance across varied image qualities, minimizing training time, and reducing dependence on extensive datasets is essential for improving melanoma detection and diagnosis. These limitations highlight the need for a more robust, adaptable, and efficient model capable of overcoming these challenges to provide accurate and timely melanoma detection.

III. MATERIALS AND METHODS

The proposed methodology leverages the Vision Transformer (ViT) architecture as shown in Fig. 1, a cutting-edge approach in computer vision [17]. The Vision Transformer model was chosen for this research due to its innovative approach to image processing, which marks a significant departure from conventional convolutional neural networks (CNNs). ViT processes images by segmenting them into sequences of spatially-structured patches, which undergo linear embedding and positional encoding to preserve spatial information. This ability to handle complex, high-dimensional data makes ViT particularly well-suited for dermoscopy images, where subtle variations in color, texture, and structure are critical for accurate melanoma classification. These patches are then fed into a stack of transformer encoder blocks, allowing the model to capture global contextual dependencies

and hierarchical features. Following this, the output undergoes global pooling to reduce spatial dimensions before being passed through a classification head comprising fully connected layers.

The classification phase translates spatial information into class predictions using softmax activation. Key components of the ViT architecture include patch extraction, patch embedding, and transformer encoder blocks. The self-attention mechanism within transformer encoder blocks allows the model to focus on relevant features while suppressing irrelevant ones. Residual connections and layer normalization facilitate gradient flow and stabilize input to subsequent layers. The Multi-Layer Perceptron (MLP head), the final component of the model, transforms aggregated representations from transformer encoder blocks into class predictions through fully connected layers and activation functions. Regularization techniques such as dropout layers employed to prevent over fitting. Ultimately, the methodology aims to learn representations for diverse visual patterns, fostering scalability and interpretability in image classification tasks.

A. Dataset

The data is collected from the Kaggle repository [18]. The dataset comprises a balanced collection of images representing two distinct categories: benign skin moles and malignant skin moles. Each category is represented by a folder containing 1800 images, with each image standardized to a size of 224x224 pixels. The standardized image size simplifies pre-processing tasks and ensures uniformity across the dataset, enabling straightforward integration into various ML pipelines. The balanced nature of the dataset ensures an equal representation of both benign and malignant cases, facilitating unbiased model training and evaluation. The inclusion of sample images, as depicted in the Fig. 2, provides a visual representation of the dataset contents, offering insight into the appearance and characteristics of both benign and malignant skin moles.

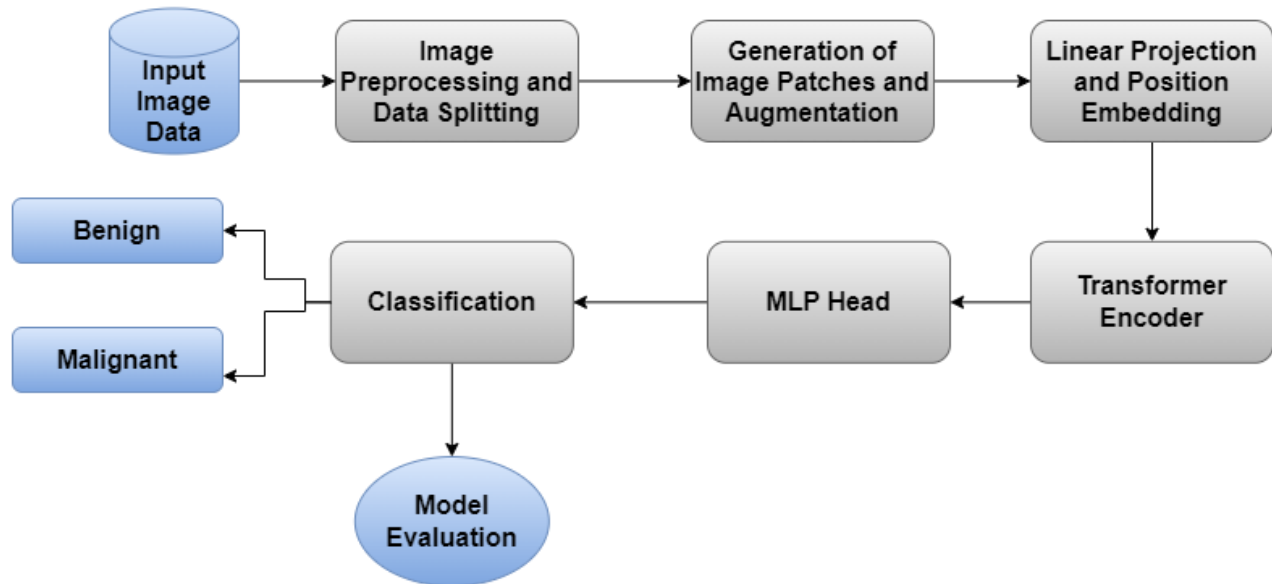

Fig. 1. Block diagram of the proposed system.

Fig. 2. Sample images from the dataset.

B. Pre-processing and Augmentation

Pre-processing involves preparing the input images for the model by standardizing various aspects to ensure consistency. One of the first steps in pre-processing is normalization, which calculates the mean and variance of the pixel values in the training images. By scaling the pixel values to a standard range, normalization minimizes the impact of intensity variations between different images. This is particularly important in medical imaging, where lighting conditions and image acquisition settings can vary significantly. Ensuring a uniform pixel intensity range helps the model focus on the relevant features of the melanoma lesions rather than being influenced by extraneous variations. Another key pre-processing step is resizing, where images are adjusted to a consistent size. This standardization ensures that all input images fit the model architecture requirements, making it easier for the model to process and analyze the images efficiently. Consistency in image dimensions also simplifies subsequent processing steps and improves the model's ability to learn from the data.

Data augmentation complements pre-processing by artificially expanding the dataset and introducing controlled variations to enhance model generalization. For melanoma detection, this often includes techniques such as horizontal flipping, rotation, and zooming. Horizontal flipping creates mirrored versions of the original images, introducing variability in image orientation. This technique helps the model learn to recognize melanoma lesions from different angles, enhancing its ability to generalize to real-world scenarios where lesions might not always be perfectly oriented. Random rotations further enrich the dataset by changing the angle at which the images are presented, making the model more adept at identifying melanoma regardless of its orientation in the image. Random zooming, on the other hand, introduces variations in the scale of the images. By simulating different distances from the lesion, zooming helps the model become proficient in detecting melanoma at various sizes and levels of detail.

C. Patch Generation

Patch generation phase extract patches from input images, a crucial process for uncovering localized features vital for a

spectrum of computer vision tasks, including image segmentation, object detection, and image classification. Patch parameterization offers adaptability to various task requirements, allowing for tailored patch extraction, dictating the dimensions of the patches to be extracted. Leveraging the information including batch size, height, width, and channels alongside the specified `patch_size`, computes the number of patches extractable in both height and width dimensions, ensuring exhaustive coverage of the image data. This meticulous extraction process ensures uniform and controlled patch extraction across diverse datasets.

The extracted patches undergo reshaping process, transforming them into a 3D tensor format optimized for subsequent processing and analysis within the DL model. This transformation ensures seamless integration of patches into the larger computational framework, facilitating efficient feature extraction and model training. This serialization of patches is carried out to ensure consistency in patch generation across different model instances, facilitating seamless integration and reproducibility. Fig. 3 provides a visual comparison between a sample image and the corresponding image patches generated from it.

Fig. 3. Sample image and generated image patches.

D. Linear Projection and Positional Embedding

Patch encoding phase encode patches extracted from input images, a critical process that enriches the representation of localized features. Since transformers operate on fixed-size sequences and lack inherent understanding of spatial relationships, positional encoding is performed. During the initialization step, two important parameters are determined: the number of patches retrieved from the input images and the dimensionality of the projected feature space to which the patches are mapped. The initialization phase establishes the foundation for effective feature extraction and spatial representation within the encoded patches. Within the initialization, two sub layers are instantiated to facilitate the encoding process. It plays a role in protecting the input patches into a higher-dimensional feature space, enabling robust feature extraction.

The primary function of this layer is to provide position embeddings for every patch, thereby capturing essential spatial information within the encoded representation. By creating position indices for the patches, this technique makes sure that every patch is associated with a unique position. The input patches are then projected into the feature space that has more dimensions. The position embeddings generated are then added to the projected patches, effectively incorporating spatial

information into the encoded representation. The resulting encoded patches, enriched with both feature and positional information. The transformer processes these embeddings through multiple layers of attention mechanisms and feed forward networks.

The transformer encoder is a crucial component of the ViT architecture, responsible for processing and extracting features from input patches. It consists of several layers, each containing a set of modules such as Multi-Head Self-Attention Mechanism, Residual Connections and Layer Normalization, Feed forward Neural Network (MLP). The Fig. 4 illustrates the architectural framework of the ViT.

The mechanism of Self-attention enables the model to assign varying weights to different input patch embeddings, prioritizing relevant information while disregarding irrelevant parts. The mechanism of self-attention in the model enables differential weighting of input patch embeddings, prioritizing relevant information while downplaying irrelevant aspects. Each patch embedding undergoes linear transformation into key, query, and value vectors, which are then utilized to compute attention score. These scores are derived from the product of query and key vector, and processed with softmax function to yield attention weights. These weights are subsequently applied to the values to generate the attention output. To aid in gradient flow during training, residual connections are introduced, merging the attention output with the input and subjecting it to layer normalization. This normalization process stabilizes the output of each attention block, maintaining a consistent input range for subsequent layers. Following the attention mechanism, the output traverses through MLP consisting of two fully connected layers.

The MLP head within a ViT serves as the final stage of the model, responsible for converting the aggregated

representations obtained from the transformer encoder blocks into class predictions. Typically, the MLP head comprises one or more fully connected layers, followed by an activation function. The input to this MLP head is the output derived from the last transformer encoder block, embodying the combined information extracted from the input image patches. Before being fed into the MLP head, these representations undergo flattening or global averaging. The resulting flattened or pooled representation is then passed through one or more dense layer, constituting the core of the MLP head. These layers enable the model to discern intricate non-linear relationships within the data. An activation function is applied after each fully connected layer to introduce non-linearity into the network.

E. Hardware and Software Setup

The research employed a computational setup that utilized a machine with powerful characteristics, including an Intel Core i7 processor. A powerful combination of 32GB RAM and the impressive NVIDIA GeForce GTX 1080Ti GPU. The model was implemented smoothly using the Keras library, which served as a prototype based on the Tensorflow architecture and executed using the flexible Python language. Keras, renowned for its intuitive interface and robust capabilities, played a crucial role in designing complex Neural Network structures. This framework guarantees optimal utilization of computational resources, effortlessly adapting to CPU, GPU, and TPU contexts. In order to take use of the powerful computational powers and optimise the process of training the model, the deployment was coordinated on Google Colab. Model training is made easier with this cloud-based Python notebook environment, which offers free access to powerful computing resources and supports interaction in development.

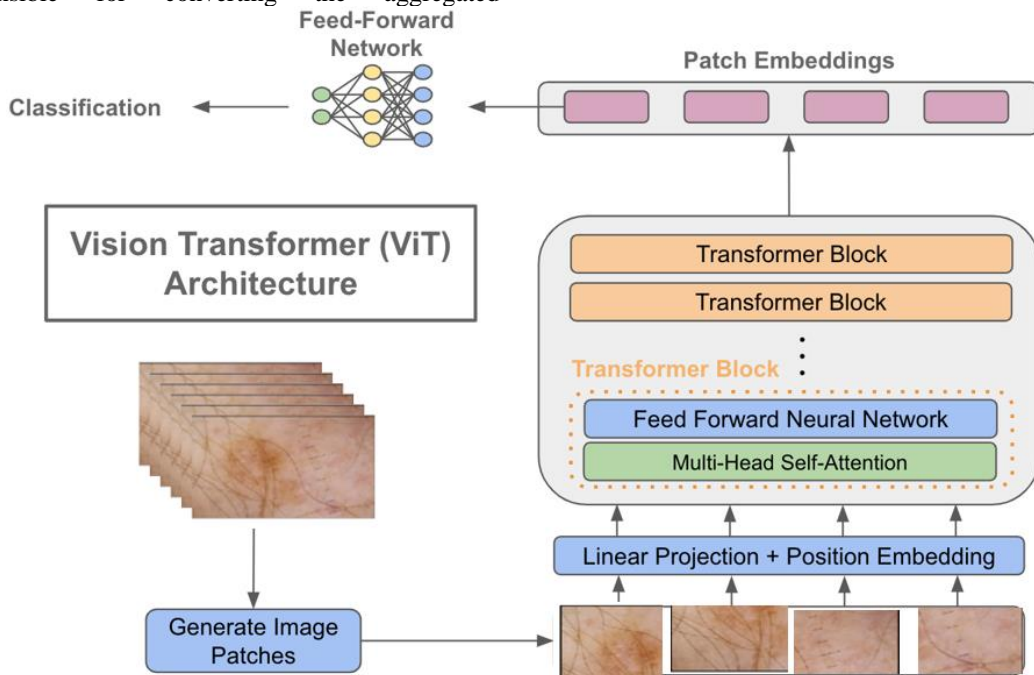

Fig. 4. Architecture of the VI transformer.

Hyper parameters are crucial configuration parameters that determine the behavior and attributes of a machine learning framework during the training phase. In contrast to the model's parameters, which are determined by the data itself, the user sets the hyper parameters prior to training. The neural network model utilizes the Adam optimizer. The training process is directed by the binary cross-entropy loss function. During the training process, the model handles input data in batches consisting of 32 samples per iteration. The training is conducted for 25 epochs, which represents the number of times the model processes the complete training dataset. The hyper parameter selections, including the optimizer, loss function, batch size, and number of epochs, determine the setup for training the neural network model. The goal is to optimise its performance in detecting melanoma. The proposed method's model configuration is presented in Table I.

TABLE I. MODEL CONFIGURATIONS

Parameters	Value
Learning rate	0.0001
Weight decay	0.00001
Image size	224
Patch size	6
Projection dimension	64
num_heads	6
transformer layers	6
mlp_head_units	[1024, 512]
Batch Size	32
Epochs	25

IV. EXPERIMENTAL RESULTS

The accuracy and loss plots are crucial for comprehending the performance and learning patterns of the proposed model. The accuracy plot visually depicts the model's ability to reliably predict data labels during training iterations on both the training and validation datasets. The alignment between the model's predictions and the actual labels is monitored to assess the model's performance throughout training.

The accuracy plot demonstrates the model's efficacy in differentiating between images containing signs of melanoma and those without, throughout the training process. Ideally, throughout the early stages, both the training and validation accuracies ought to increase simultaneously, demonstrating the model's ability to apply its knowledge beyond the training data. The trend illustrated in Fig. 5 indicates that the model is acquiring knowledge of fundamental patterns rather than only memorizing the instances presented in the training dataset.

The accuracy steadily increases from an initial value of approximately 0.8788 in the first epoch to around 0.9306 in the final epoch. This upward trajectory indicates that the model's performance improves over successive epochs as it learns from the training data. Notably, there are fluctuations in accuracy values throughout the training process, reflecting the dynamic nature of the optimization process and the model's adaptation to different patterns in the data.

A loss plot illustrates the trend of the model's loss function over different iterations or epochs during training. Fig. 6 illustrates the loss plot of the proposed model. The loss steadily decreases from an initial value of approximately 0.3062 in the first epoch to around 0.1707 in the final epoch. This downward trend signifies that the model's ability to minimize prediction errors improves over time. Lower loss values indicate better alignment between the model's predictions and the actual labels in the training data. Similar to accuracy, fluctuations in loss values are observed across epochs, reflecting the model's response to variations in the training data and optimization process.

An excellent way to assess the accuracy of the suggested model in detecting melanoma is by employing a confusion matrix. Fig. 7 presents the confusion matrix generated by the proposed model. The matrix offers a systematic summary of the model's performance by contrasting its predictions with the real labels across several classes. Essentially, it arranges the results in a tabular structure, with the rows representing the actual labels and the columns representing the predicted labels. Every individual cell in the matrix represents the number of occurrences where the model's predictions match or differ from the actual labels.

Fig. 5. Accuracy plot.

Fig. 6. Loss plot.

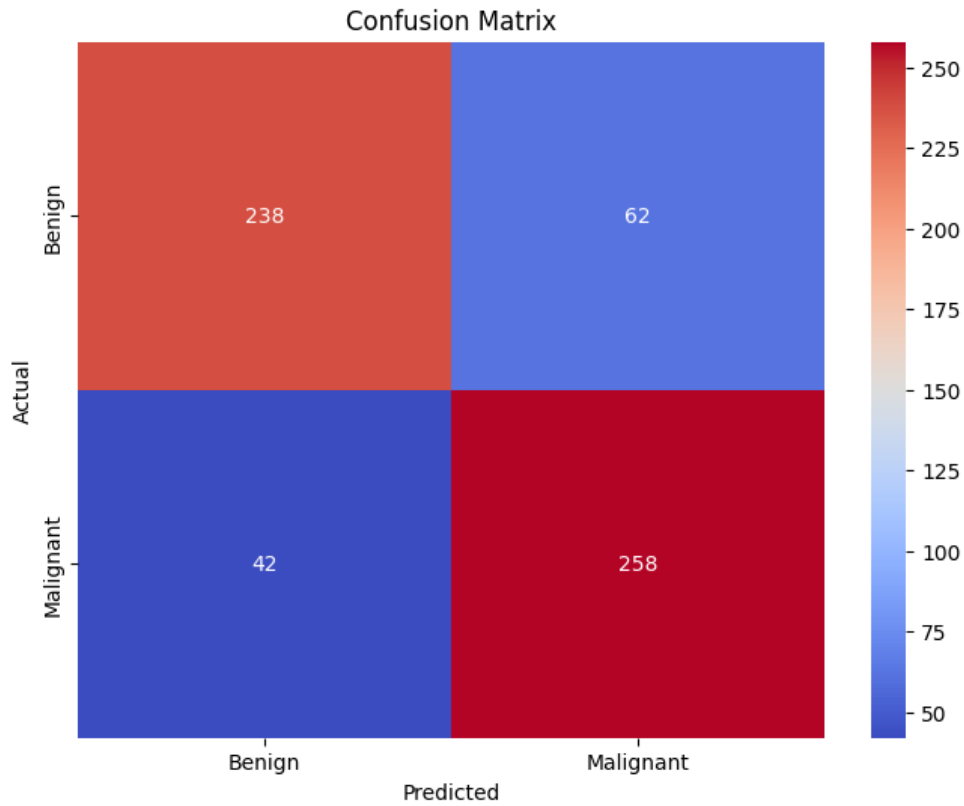

Fig. 7. Confusion matrix.

The confusion matrix is partitioned into four quadrants, where the items on the diagonal represent correct predictions and the elements off the diagonal represent cases of misclassification. This visual depiction allows for a comprehensive evaluation of the proposed model's efficacy in accurately detecting melanoma individuals. It reveals that the model accurately identifies 238 benign images as benign, but misclassifies 62 benign images as malignant. Similarly, it correctly identifies 258 malignant images as malignant, but erroneously classifies 42 malignant images as benign.

Performance metrics derived from the confusion matrix offer a thorough evaluation of the proposed model's efficacy in detecting melanoma. In order to thoroughly evaluate the efficacy and operational efficiency of the proposed model, the F1-score, accuracy, precision, and recall are the four primary metrics utilized. These measures, which are based on the concepts of False Positive (FP), False Negative (FN), True Negative (TN), and True Positive (TP), are essential for assessing the model's performance. These performance parameters have mathematical formulations that are shown in Eq. (1), (2), (3), and (4).

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \quad (1)$$

$$Precision = \frac{TP}{TP+FP} \quad (2)$$

$$Recall = \frac{TP}{TP+FN} \quad (3)$$

$$F1 - score = 2 \times \frac{precision \times Recall}{Precision + Recall} \quad (4)$$

The obtained performance metrics, as shown in Fig. 8, highlight the exceptional efficacy of the developed model. An accuracy of 96.23% indicates that the model correctly identifies melanoma cases and non-melanoma instances with a high degree of reliability. The precision of 96.63% demonstrates the model's capability to accurately predict true positive cases of melanoma, minimizing the rate of false positives. The recall, or sensitivity, at 96.98% reflects the model's effectiveness in detecting almost all actual melanoma cases, ensuring a low rate of false negatives. The F1-Score, a harmonic mean of precision and recall, is 96.80%, underscoring the model's balanced performance in terms of both identifying true cases and excluding false alarms. These metrics collectively suggest that the model is robust and highly accurate, making it a reliable tool for the detection and classification of melanoma in clinical settings.

Fig. 9 shows the Classification Output of the proposed system.

Fig. 9. Classification output of the system.

V. DISCUSSION

The proposed Vision Transformer (ViT)-based deep learning model marks a significant advancement in the field of skin cancer diagnosis, particularly in melanoma detection. By leveraging the innovative architecture of the Vision Transformer, which processes images as sequences of spatially-structured patches rather than relying solely on convolutional layers, the model exhibits superior accuracy and robustness. As demonstrated in the Table II and Fig. 10, the ViT-based model achieves an accuracy of 96.23%, notably surpassing the performance of other state-of-the-art methodologies. Jiang et al.'s DRANet achieves an accuracy of

86.8%, while Shorfuzzaman et al.'s CNN-based stacked ensemble framework achieves a higher accuracy of 95.76%. Khan et al. employ DenseNet201 with transfer learning, achieving an accuracy of 95.26%. Inthiyaz et al.'s CNN method achieves an accuracy of 87%. This substantial improvement underscores the potential of the ViT-based model to enhance diagnostic accuracy, which is crucial for early detection and treatment of melanoma, ultimately contributing to better clinical outcomes.

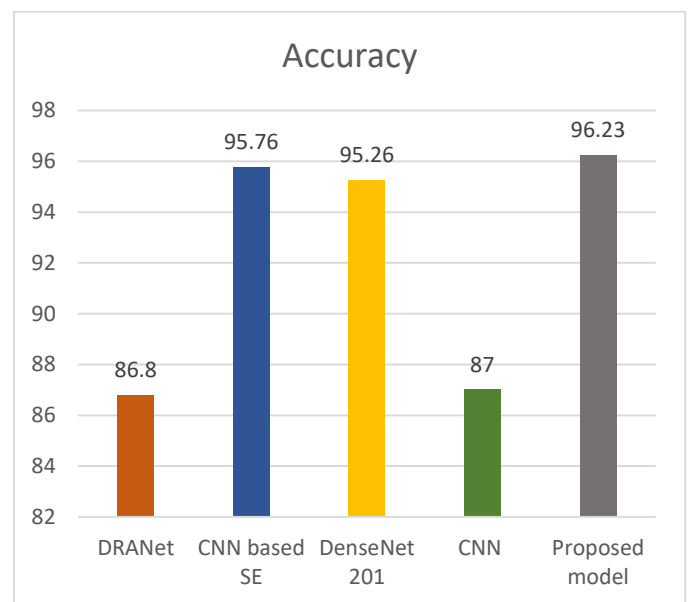

Fig. 10. Performance comparison.

The higher accuracy achieved by the ViT-based model is particularly noteworthy when considering the challenges associated with melanoma detection, including the complex and varied visual characteristics of skin lesions and the need for accurate differentiation between malignant and benign conditions. The model's ability to effectively handle these challenges, as evidenced by its outperformance of existing methods, highlights its robustness and adaptability. This advancement not only provides a powerful tool for clinicians but also addresses some of the key limitations of previous approaches, such as the extended training times, resource-intensive computations, and reduced efficacy in noisy or poor-quality images. The ViT-based model's success in overcoming these challenges and delivering high accuracy in skin cancer diagnosis positions it as a promising candidate for integration into clinical practice, where it could significantly improve the speed and accuracy of melanoma detection, ultimately saving lives through earlier and more precise intervention.

TABLE II. COMPARISON WITH EXISTING SYSTEM

Author	Methodology	Accuracy
Jiang et al	DRANet	86.8%
Shorfuzzaman et al	CNN based stacked ensemble framework	95.76%
Khan et al	DenseNet201 with transfer learning	95.26%
Inthiyaz et al	CNN	87%
Proposed model	Vi transformer based deep learning	96.23%

VI. CONCLUSION

Melanoma, a form of skin cancer originating in melanocytes, presents a significant global health concern due to its aggressive nature and potential for metastasis. With its incidence steadily rising worldwide, melanoma detection and classification have become pivotal areas of research in the medical field. Early diagnosis plays a crucial role in improving patient outcomes, as timely intervention can significantly enhance treatment efficacy and prognosis. This research endeavours to develop a model capable of effectively detecting and classifying melanoma using publicly available datasets, with a focus on performance enhancement. The proposed approach introduces a Vision Transformer-based melanoma classification model adept at distinguishing between Benign and Malignant cases. With an accuracy of 96.23%, the model demonstrates a strong overall correctness in classification. These findings underscore the efficacy and potential of the proposed method in advancing the field of skin cancer diagnosis, offering promising prospects for enhanced accuracy and efficacy in clinical settings. These outcomes emphasize the effectiveness of the method in advancing skin cancer diagnosis, indicating promising prospects for heightened accuracy and efficacy in practical clinical settings. However, several avenues for future work could further advance the field. Future research could focus on expanding the dataset to include a more diverse range of skin types, lesion characteristics, and image quality conditions to improve the model's generalizability and robustness. Additionally, integrating the Vision Transformer with other advanced techniques, such as multi-modal data

fusion or ensemble approaches, might enhance its performance further.

Enhancing Safety for High Ceiling Emergency Light Monitoring

G. X. Jun¹, M. Batumalay², C. Batumalai³, Prabadevi B⁴

Faculty of Data Science and Information Technology, INTI International University, Malaysia, Nilai, Malaysia^{1,2,3}
School of computer Science Engineering and Information Systems, Vellore Institute of Technology, Vellore, Tamil Nadu, India⁴

Abstract—The performance of information technology has gradually improved and advanced during this period for safety management. Nonetheless, there is no disputing that during power outages, emergency lights continue to be crucial to people's safety and comfort. Regrettably, businesses don't give emergency lighting in buildings enough thought. The primary causes of the problem are expensive spending and long-term management for high ceiling safety. Additionally, one aspect that must be considered and ensured is the safety of maintenance personnel when the light is installed in high-rise locations. Thus, by creating wireless global control and monitoring via Android mobile phones, our effort intends to increase the availability and reliability of the emergency light. The suggested light monitoring system collects information from Internet of Things devices and transmits it to users' mobile phones over the Internet. Moreover, the risk of employees keeping the emergency light will be significantly reduced because it is monitored via the Internet on mobile devices. Additionally, by using the information the sensor inside the emergency light collects, it is possible to estimate its current condition, including its battery life. This repair will also improve everyone's safety within the building by increasing the emergency light's dependability with good process innovation.

Keywords—Safety management; Internet of Things; high ceiling safety; high building safety; safety; process innovation

I. INTRODUCTION

Buildings with several levels have been constructed more quickly and easily because of advances in current technology in the construction industry, which also included utilizing the power of materials and other clever technologies. Emergency lights are necessary to handle power outages in these facilities. The Department of Economic and Social Affairs' Goal 17 (2022) requires the installation of emergency lighting during building projects when a power outage could negatively affect the surrounding environment or even endanger human life. However, organizations may find it challenging to keep a sizable number of emergency lights maintained due to considerations including time consumption and safety. Furthermore, there is no denying that Internet of Things (IoT) technology has become indispensable in the current trend due to its automation and low participation control. Companies can get around these challenges by integrating Internet of Things technologies into emergency lighting systems. With Internet of Things capabilities, emergency lights may be remotely monitored and controlled, reducing the need for manual maintenance and ensuring quick problem-solving. Moreover, businesses can optimize power usage, save costs, and manage energy more effectively thanks to the automated features of IoT technology [1].

Building construction on a huge scale has become commonplace in the modern era, which is notable for its technological and economic advancements. However, it is imperative that emergency lights be installed in these structures because they are essential for surviving power outages. To prevent catastrophic catastrophes, emergency lighting must be provided in public or commercial buildings per government rules, with the preservation of human life and the environment receiving top priority [2, 3]. When there is a decrease in light or an emergency brought on by a power outage, emergency lighting turns on. Its primary job is to create enough light automatically so that everyone within the building can leave safely. Due to varying safety rules in different buildings and areas, there are numerous types of emergency lights available on the market. Dominik Pfaff has proposed four different types of emergency lights [2]. They are emergency escape lighting, which is designed to prevent dangerous accidents during emergencies; standby lighting, which continuously supports normal activities in specific locations and buildings; high-risk task area lighting, which is essential to the escape lighting system and provides enough illumination for people to reach specific areas; and escape route lighting, which guarantees clear visibility of evacuation routes.

It is obvious that emergency lights are necessary to guarantee people's safety in unexpected situations. Nonetheless, managing the availability and dependability of these lights is a big problem for businesses. The lack of practical means to ensure the continuous operation and reliability of emergency lights is one of the major problems [3]. Moreover, the financial aspect is a significant challenge since companies are often reluctant to bear the associated costs, such as wages, software development, and maintenance fees. Especially on construction sites where there are a lot of emergency lights, workers face several challenges throughout the maintenance process. Handling this big array is going to take a lot of work. The placement of emergency lights in elevated areas significantly increases the risk of injury or even death to a maintenance worker while they are performing their task. The last problem is that relying just on visual observation to assess emergency lights' functioning by personnel jeopardizes the accuracy of the test results and could lead to incorrect evaluations of the lights' operational state. Emergency lights play an important role in protecting and ensuring human safety during emergency events. However, companies often neglect the management of reliability and availability of emergency lights due to various challenges. Firstly, there is a lack of efficient ways to maintain the performance and reliability of emergency lights. Moreover, cost spending is also a factor that companies are unwilling to face, including employee fees,

software development, and maintenance fees. In addition, there are various challenges that employees face during maintenance of emergency lights. For example, due to the large number of emergency lights on the construction site, it requires a lot of time to manage the lights. Some emergency lights are installed at higher locations, which may cause injury or even loss of life for maintainers if they fall while maintaining the emergency lights. Lastly, the accuracy of examination results is low because employees can only tell if the emergency lights are working by observation.

Consider a scenario where a maintainer is inspecting emergency lights that are located at a height to provide another example that will help clarify this idea. Because of how challenging it is to reach these areas; maintenance personnel may need to employ ladders or other risky climbing equipment. Such actions constantly increase the risk of injury to maintenance personnel. Should the ladder be unstable, or the process not be carried out correctly, maintenance personnel could fall from a height and suffer severe injuries or even lose their lives. Working at these high altitudes therefore necessitates extra safety procedures as well as personnel training to minimize potential hazards. In addition to highlighting the urgent need to address these problems, this example illustrates the dangers that maintainers may face during inspections. For companies that value the safety of their maintenance staff, it is imperative to establish strict protocols and norms for operating at elevated heights. protecting the emergency lighting. Routine maintenance and inspections should be performed to ensure the stability and dependability of ladders and other machinery. Companies can lower the risk of accidents and protect the health of their maintenance workers by implementing these safety precautions. Furthermore, ladders and other equipment need to have routine maintenance and inspections performed to guarantee their stability and dependability. Organizations can mitigate the likelihood of accidents and safeguard the welfare of their maintenance staff by implementing these preventive measures.

The IoT technology is a network of physical things that have related to sophisticated software and high-tech sensors to facilitate data interchange with other devices and computers over the internet [2]. IoT devices link to a cloud, like Google Firebase or an IoT gateway, to exchange the gathered data for local data analysis. The Internet of Things (IoT) system, which includes low-power sensor technology, cloud computing platforms, and sophisticated connectivity, can benefit from the integration of artificial intelligence and machine learning to improve the data collection process. As a concrete illustration of an IoT system, modern applications include supply chains, robotics, smartwatches, and health monitoring devices [1].

Several businesses could be revolutionized by IoT technology. IoT devices, for instance, may monitor machinery in real-time in the manufacturing industry, identifying any problems before they arise and enabling preventative maintenance. This can boost output and drastically cut down on downtime. IoT devices in the healthcare industry are able to monitor patient vitals and notify medical personnel in the event of an emergency. The Internet of Things (IoT), a revolutionary concept that connects diverse products and systems through the internet, has evolved with the rapid growth of technology. This

network's interconnection makes data sharing and communication easy, which has several advantages for a range of sectors. IoT technology has the power to completely change the way we live and work, from increasing productivity and efficiency to boosting safety and convenience. The capacity of IoT technology to facilitate predictive maintenance is one of its main benefits. IoT sensors, for instance, can be mounted on machines in the manufacturing sector to track performance and identify possible problems before they cause a breakdown [4]. Real-time data on variables like temperature, vibration, and power usage may be gathered by these sensors, and artificial intelligence algorithms can be used to assess the results. This minimizes downtime and increases overall equipment effectiveness by enabling maintenance professionals to proactively arrange repairs or replacements. IoT technology may also notify technicians about certain maintenance requirements, guaranteeing that the appropriate resources are available when needed [5]. IoT technology also has the potential to gather and evaluate data in order to spot patterns and trends, which helps maintenance specialists maximize maintenance plans and raise equipment dependability. An illustration of an IoT system can be found in Fig. 1.

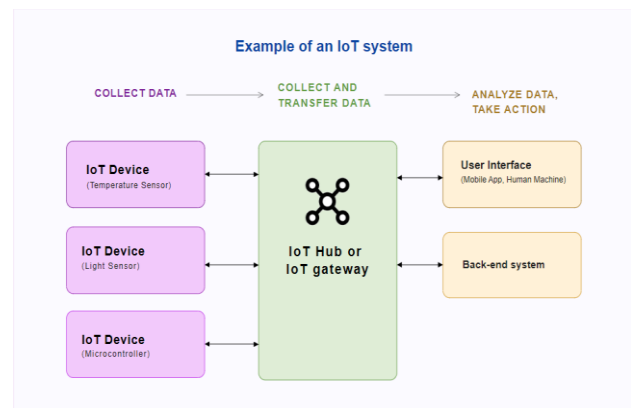

Fig. 1. Example of an IoT system.

The extensive attraction of IoT can be attributed to its pivotal role in intelligent management, which leverages automation to reduce human involvement and preserve time. This trend is further supported by the advantages it provides. Firstly, IoT increases productivity through task automation and simple connections between devices, systems, and processes. This reduces the requirement for manual intervention while optimising the utilisation of resources. Second, intelligent connectivity between IoT devices leads to enhanced decision-making capabilities and optimised operations. Real-time data monitoring and analysis enables people and businesses to respond swiftly to changing circumstances. Finally, IoT contributes to better resource management by enabling efficient asset monitoring and utilisation, which lowers costs and increases production. When everything is considered, the Internet of Things is not simply a fad but rather a revolutionary force that is facilitating state-of-the-art research and creating intelligent, effective, and adaptive products that satisfy the constantly shifting needs of our globalised society.

Large-scale construction projects are becoming more prevalent in the rapidly evolving 21st-century environment,

which is characterized by economic growth and technological advancements. Installing emergency lighting is also necessary in these kinds of locations to ensure residents' safety during power outages. Moreover, given the critical role emergency lights play in averting serious repercussions for human life and the environment, it is important to resolve maintenance-related concerns surrounding them (Goal 17 | Department of Economic and Social Affairs, 2022). Firstly, the proposed system addresses these problems head-on by providing a unique solution: a smartphone app designed to monitor emergency light conditions without forcing users to approach close. This promises to address concerns related to safety and enhance the efficiency of maintenance protocols.

The core of this innovative system is the Internet of Things (IoT) technology, which generates critical data through sensors [6]. Long-distance monitoring and control are also made possible by the data that is safely kept on the Firebase server and sent. Furthermore, because of its low cost and the availability of open-source tools and software, Arduino is selected as the Internet of Things device for data collection. This solution guarantees affordability and provides a wealth of resources through open-source, comprehensive software development modules.

The proposed approach extends its UI to an Android app, going beyond only integrating hardware. Users of this app can also easily regulate operations and monitor the status of emergency lights. While speed of performance is not the primary factor, the Android operating system was specifically selected for the application, emphasizing its ability to display data in real-time [6]. Because it makes use of Google's Firebase cloud server and online storage platform, which are both efficient and readily available, the system is also the best choice. The platform's easy setup and installation processes, in addition to its free plan for students and learners, contribute even more to the overall effectiveness of the recommended system. In essence, this innovative strategy uses contemporary technology to support accessible, safe, and effective building management while concurrently solving issues with emergency light maintenance. To improve routine check efficiency and human safety, this project aims to develop a system that integrates Internet of Things (IoT) sensors with a smartphone application to remotely monitor emergency light status.

II. METHODOLOGY

The waterfall model is one of the straightforward techniques in the Software Development Life Cycle (SDLC), an organised methodology used to produce high-quality products. The requirement analysis, design, development, testing, deployment, and maintenance phases are the six stages that this paradigm usually entails. But just the first four stages of the project—analysis, design, development, and testing—have been completed thus far. The waterfall model is a step-by-step process where the output from one phase becomes the input for the subsequent phase. It's important to remember that a variety of factors, including stakeholder preferences and project complexity, influence the decision between the waterfall model and alternative techniques. Phase 1, data collection, which included requirements analysis and design; Phase 2, system development, which covered the development activities; and

Phase 3, testing, which concentrated on the testing phase, comprised the three phases of the research approach. This methodology follows a step-by-step process, with each phase building on the output of the one before it. It is similar to the waterfall approach as mentioned by another team [7].

A. Phase 1: Data Collection

Initially, in-depth perspectives and opinions on the idea from Malaysian citizens were obtained through interviews, a qualitative data gathering technique. To ascertain whether the public appendices and papers in the report were acceptable to them, three individuals were interviewed. The purpose of this interview was to ascertain the significance of emergency lighting and the suggested system, as well as to assess people's comprehension of them. In addition, it aids in determining the qualities that people find appealing. Furthermore, the interviews also helped in identifying any potential concerns or issues that may arise with the proposed emergency lighting system. This feedback will be crucial in refining and improving the system before implementation. Overall, the interviews provided valuable insights that will inform the development and implementation of the emergency lighting system. By addressing any concerns raised and incorporating desirable features, the final product will be better tailored to meet the needs and expectations of the user.

Knowledge of the suggested high-ceiling emergency light monitoring system was obtained from talks with professionals in the field. An expert emergency light vendor stressed the significance of emergency lights in guaranteeing security during blackouts. The expert also voiced excitement about the potential advantages of an IoT system, emphasizing how it might improve system reliability by lowering the need for physical involvement during maintenance, thereby increasing safety. Furthermore, it highlighted how crucial practical aspects like battery life monitoring and long-distance control are in huge facilities. First, in a similar vein, an emergency mechanical engineer emphasized the need for emergency lighting for safe building evacuation in times of crisis. The engineer also said that the system would be more reliable and that inspectors would not have to be there in person as much. He suggested features like automated testing that could generate reports and long-range control by supporting the use of an IoT monitoring system. Finally, the suggestions made by industry professionals will have a significant impact on the design and development of the High Ceiling Emergency Light Monitoring System.

The use case diagram in Fig. 2, which is a representation of the functionality and extent of the system using the Unified Modelling Language (UML) language, then illustrates the interaction between the actors and various use cases [8]. The use case diagram provided below illustrates how actors and use cases relate to one another in the proposed system. The functioning of the high-ceiling emergency light monitoring system is also depicted in the diagram. It describes how communication between the three primary components—Firebase, IoT devices, and the Android app—works. The diagram emphasizes the seamless flow of commands and data between different components, highlighting their interconnectedness. It explains the intricate communication routes and shows how Firebase serves as a central hub for data storage and retrieval, enabling real-time control and monitoring.

As the system's senses, the Internet of Things devices communicate back and forth with Firebase and the Android app to maintain a continuous flow of critical data. [9]. Furthermore, the Android app acts as the user interface, facilitating a variety of operations for consumers. By illustrating the transparent communication channels and the relationship between user actions and system reactions, the graphic highlights the system's efficiency and eventually enhances the monitoring and control of emergency lights in situations with high ceilings.

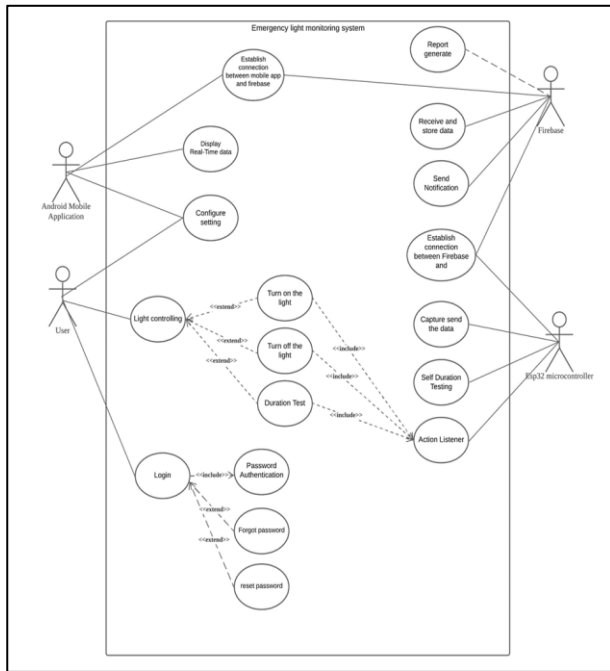

Fig. 2. Use case diagram for solid waste classification system.

B. Phase 2: System Development

Fig. 3 depicts the block diagram of the prototype system, which utilizes the ESP32 module as the core controlling and monitoring component. The system is composed of three distinct sections: the controlling board (navy blue), the controlling medium (green), and the original target device (orange).

Fig. 3. Block diagram of prototype system.

As illustrated by Fig. 4, the suggested emergency light monitoring system is organized around three main elements: data display via Android mobile phones, data storage in Firebase, and data sensing through IoT devices [10]. Furthermore, the system uses the Arduino ESP32 module as its microprocessor, which makes data management and wireless

network connections like Wi-Fi and Bluetooth possible. Furthermore, in order to improve its functionality, the ESP32 module supports a wide range of sensors, including voltage, light, and temperature. First off, the ESP32 may be connected to the internet and Firebase server networks thanks to Arduino's open-source software development tools, which include Wi-Fi, Bluetooth, and Firebase modules. Additionally, users can permanently store configuration data, such as the positions of emergency lights and Wi-Fi connections, using the ESP32's ROM storage. The ESP32's LED lights make effective performance testing possible [10]. After sensor data is gathered, it is sent over the internet to the Firebase server platform for real-time monitoring and archiving. In addition, the Firebase server has cloud messaging and cloud function messaging features that allow users to communicate with one another directly from the server [10]. The system's third component is an Android mobile application that lets users keep an eye on emergency light data. Additionally, the application gives users control over the emergency light switching during system inspections by displaying all collected data parameters saved in Firebase. The application also highlights the emergency light's condition with colour changes. Last but not least, since Google developed Android, connecting the Android application to Firebase is a simple process, ensuring seamless integration and user-friendly access to real-time emergency light monitoring [10, 11]. This comprehensive system design not only leverages IoT technology for efficient data sensing but also employs Firebase and Android integration to provide a user-friendly and effective emergency light monitoring solution [12].

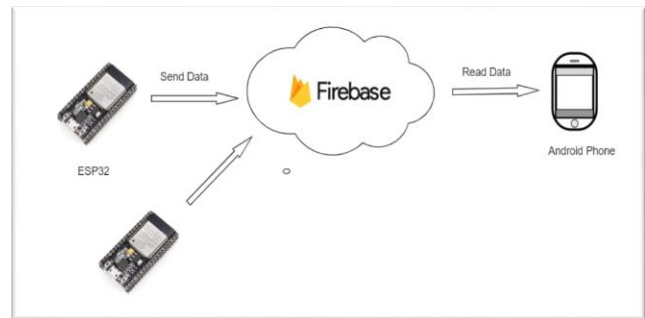

Fig. 4. Structure of proposed system development .

C. Phase 3: Testing

The High Ceiling Emergency Light Monitoring System went through a thorough testing process, including unit, integration, and acceptance testing to check its usability, reliability, and performance. In the unit testing phase, specific criteria for each component, from the ESP32 microcontroller [13] to various sensors and user interface activities, were carefully examined. Additionally, the successful completion of tasks, such as connecting to the internet, capturing sensor data accurately, and performing user actions, demonstrated the individual components' functionality. Moreover, integration testing further strengthened the system's robustness, ensuring smooth communication between modules. The system demonstrated cohesive behaviour and met the predetermined pass criteria, regardless of whether it was internet connectivity, real-time database interactions, or user interface functionalities. Furthermore, acceptance testing provided a complete

evaluation, confirming that the system effectively met user requirements and expectations [14, 15]. Documented procedures and results from each testing phase attest to the system's overall success, confirming its high performance, reliability, and user satisfaction and highlighting its readiness for deployment in monitoring emergency lights in high-ceiling environments. The system's ability to meet the pass criteria in various areas demonstrates its robustness and adaptability. Additionally, the positive feedback received from users during acceptance testing further validates its effectiveness and usability in real-world scenarios.

III. RESULTS AND DISCUSSION

The High Ceiling Emergency Lighting Monitoring System's useful features and characteristics make it a valuable tool for emergency lighting system maintenance is captured in Fig. 5.

Fig. 5. High ceiling emergency light monitoring system prototype.

One notable feature that guarantees emergency light dependability during power outages is the automatic testing feature. This feature allows for regular assessments of emergency lights without requiring operator intervention. Additionally, maintenance staff can effectively operate emergency lights from a distance thanks to the system's support for remote control. Additionally, a reliable testing function tracks battery life in compliance with safety standards. As a result, real-time monitoring features give precise information about the state of the system and enable prompt problem identification. The report-generating capability also gathers diagnostic data to facilitate prompt remediation and ongoing enhancement. All these carefully thought-out features together increase the system's ability to dependably sustain emergency lighting systems in rooms with high ceilings. Furthermore, the sophisticated technology of the system guarantees effective coordination in emergency scenarios by enabling a smooth interface with other building management systems. Furthermore, the interface is easy to use, making it simpler to adjust settings to suit individual requirements and tastes. IoT based monitoring supports easily scalable and can handle expanding or complex systems without significant additional infrastructure. It also help to reduces maintenance efforts with automated alerts, predictive analytics, and remote management capabilities. Finally, IoT also adapts easily to changes in system requirements or facility needs with minimal adjustments.

Still, there are a few things that could be done better with the High Ceiling Emergency Light Monitoring System. The first requirement for the system's correct operation is a reliable internet connection. The Internet of Things devices accountable for gathering data, storing it in Firebase, and receiving commands require a dependable and continuous internet connection. Furthermore, because the system only supports Android devices at this time, users of other mobile operating systems may find their accessibility limited [13]. Because of this, the overall efficacy and viability of putting the High Ceiling Emergency Light Monitoring System into place should be carefully considered while weighing these limitations.

IV. CONCLUSION AND FUTURE ENHANCEMENT

As the High Ceiling Emergency Light Monitoring System is developed further, a few possible enhancements become apparent. Initially and foremost, it is necessary to tackle the significant issue of enhancing the status reporting procedure. The current system can identify defective circuits, for example, but it may be enhanced by providing more precise information, even though it already provides a rudimentary diagnosis report. In addition, this comprehensive information would enable maintainers to carry out repairs with greater accuracy and efficiency. In addition, it would be very important to have an urgent notification system. Ignoring the lack of a notification system for users in the event of an emergency, like a fire tragedy or ongoing issues, would be one method to ensure prompt remediation and enhance overall safety. This means that looking into more advanced IoT device connectivity perhaps through a mesh network like Bluetooth mesh for the ESP32 which might end up being a game-changer. In the end, this would increase system responsiveness by enhancing group control, saving energy, and reducing network traffic. The installation process also needs to be optimized for the user's convenience. Adding features like auto-configuration and self-diagnosis could improve the installation process' efficiency and usability in the future. Keeping the system at the forefront of emergency light monitoring technology is the goal of all these significant enhancements. All things considered, the suggested improvements present a system that could significantly improve emergency light performance and reliability, setting a higher standard for general human safety.

Data-Driven Approaches to Energy Utilization Efficiency Enhancement in Intelligent Logistics

Xuan Long

School of International Trade Hainan College of Economics and Business, Hai'kou 571127, Haikou, China

Abstract—With the rapid development of intelligent logistics, new challenges and opportunities are presented for energy utilization efficiency improvement. This study explores the feasibility and effectiveness of using data-driven methods to improve energy utilization efficiency in an intelligent logistics environment and provides theoretical support and practical guidance for achieving the sustainable development of optimized logistics management procedures. First, a dataset was established by collecting relevant data in the optimized logistics management procedure, including transportation information and energy consumption data. Then, data analysis and mining techniques are used to conduct an in-depth dataset analysis to reveal the influencing factors of energy utilization efficiency and potential optimization directions. Then, strategies and methods for energy utilization efficiency improvement are designed by combining intelligent optimization algorithms. Finally, simulation experiments and case studies are utilized to verify the effectiveness and feasibility of the proposed methods. The results show that using data-driven methods can significantly improve the energy utilization efficiency of optimized logistics management procedures, reduce logistics costs, and enhance the sustainability and competitiveness of the system. Through in-depth analysis and empirical research, a series of actionable optimization strategies are proposed, providing new ideas and methods for optimizing energy and logistics management procedures. These results significantly promote the sustainable development of optimized logistics management procedures and enhance competitiveness.

Keywords—Intelligent logistics; energy; utilization efficiency; data-driven

I. INTRODUCTION

As of 2021, China's digital economy is expected to reach \$45.5 billion, according to a report by China's Ministry of Industry and Information Technology. With China's economy expected to grow by 4.5% in 2024, the digital economy is already playing an integral role in production and life [1]. Since the new Crown Pneumonia epidemic in 2019, the digital economy has contributed significantly to China's economic recovery and pushed various industries toward digital transformation. China's economy is developing coordinated and systematically, with the digital economy playing an increasingly prominent role in this process. China is in a critical period of industrial reform, and the digital economy will play a vital role in this process, driving the development of new industries and upgrading and transforming traditional ones. However, China faces many challenges to its long-term economic development, including colossal energy consumption and environmental concerns [2]. The international energy situation has recently been unstable, and China's dependence on imported resources is under pressure. It has therefore become particularly urgent to

ensure national energy security, avoid new energy bottlenecks, utilize digital technologies to improve energy efficiency, develop new clean energy technologies, improve the environment, and promote the development of a sustainable green society [3]. China needs to deepen the reform of its energy system, strengthen the clean and efficient use of coal, and accelerate the design and construction of new energy systems while promoting the two main objectives of coal. The Global Digital Energy Conference, Carbon Summit, and Carbon Neutral Forum 2022 emphasized accelerating the convergence of digital energy and innovative energy technologies [4]. The Chinese government has emphasized promoting the development of digital transformation in the green energy industry, accelerating the development of the clean energy industry, and building a safe and efficient electrical system. Applying the digital economy in the energy sector is critical to China's digitalization and achieving its "dual-carbon" goals, improving new clean energy technologies and enhancing green energy efficiency [5]. These initiatives are crucial to promoting green transformation and realizing high-quality economic development in China. Therefore, studying the factors affecting green energy efficiency in the digital economy is essential. In-depth research in this area can help address China's challenges in sustainable development and green transformation while providing essential references and guidance for future policymaking.

The rapid rise of the digital economy has attracted widespread attention globally, as it changes production methods and daily life and profoundly impacts overall energy utilization. With the widespread use of digital technologies, concerns about energy efficiency are increasing [6]. Improving energy utilization efficiency is urgently needed to ensure high-quality economic development and a sustainable social environment. Research on the impact of the digital economy on green energy efficiency is of dual significance, not only to deepen theoretical understanding but also to provide valuable insights for practice [7]. Although research on the impact of the Internet or ICT on global energy efficiency has been relatively adequate, research on the specific impact of the digital economy on urban energy efficiency still needs to be developed. Therefore, it is necessary to combine theoretical and empirical analyses to explore specific ways to improve the energy efficiency of various elements of the digital economy [8]. This research results will not only enrich the theoretical foundation of the digital economy field in terms of improving the eco-efficiency of various energy elements but also provide essential references for the formulation of specific policy recommendations in various regions.

II. BACKGROUND

In recent years, China has made some progress in restructuring its energy supply side. It has optimized its energy mix by strengthening its green policy and financial system [9]. Despite the gradual replacement of some of the use of coal by cleaner energy sources, total carbon emissions have continued to rise, resulting in China still needing to reach peak carbon emissions. This suggests that improving the efficiency of energy use remains an integral part of China's energy strategy. China faces an unbalanced energy mix, with shortages of traditional energy sources such as coal, oil, and natural gas, and coal dominates the energy consumption mix. Although China's energy mix has improved from 2011 to 2021, with coal's share of the energy mix decreasing, it has remained the dominant carbon in the overall energy mix [10]. With the restructuring of energy policies, CO₂ emissions are expected to increase further by 2030, posing challenges for China's environment and sustainable development. China's energy infrastructure is unlikely to be effectively upgraded in the short term, resulting in lower than global average energy utilization efficiency. This situation may not only hinder business development but also exacerbate environmental concerns. While most modern countries globally rely on clean and renewable energy sources, China's energy mix relies heavily on traditional carbon-intensive sources [11]. This means China still has a long way to go in its energy transition. Therefore, China needs to intensify its efforts further to improve energy utilization efficiency and actively promote energy structure transformation to achieve sustainable economic development and environmental improvement. Through innovative science and technology, policy support, and international cooperation, China can achieve a more significant transformation of its energy mix and contribute to the goal of carbon neutrality.

Improving energy efficiency involves reducing carbon dioxide emissions and addressing environmental and climate challenges. As China has gradually become one of the world's major CO₂ emitters, the international community's attention to reducing emissions has increased. In some developed countries, such as the EU member states, initiatives such as promoting CO₂ tariff programs and establishing green barriers have become essential strategies to combat climate change. These measures are expected to be further strengthened, and China, one of the world's largest greenhouse gas emitters, will be under even greater international pressure [12]. In addition, national economic issues are increasingly taking on an international dimension, such as trade wars and technological embargoes, and economic development is no longer confined to the domestic arena but is closely linked to the global economic landscape. Therefore, adapting to China's new economic development standards and realizing sustainable development has become a top priority [13]. Improving energy utilization efficiency reduces carbon emissions, solves the problems of unbalanced energy consumption and insufficient energy reserves in China, and promotes economic restructuring and upgrading. By adopting clean and efficient energy technologies, such as renewable and energy storage technologies, energy utilization can be maximized while reducing reliance on traditional fossil energy sources, providing solid support for China's sustainable economic development.

China's solemn commitment to achieving the "double coal" goal reflects its active role in global environmental governance and demonstrates its determination to build an ecological civilization. Achieving the "dual coal" goal is necessary for China's sustainable development and an essential contribution to the global ecological environment and climate stability [14]. The Chinese government has put forward a series of plans, including promoting the establishment of a zero-carbon energy sector, which will promote the optimization and transformation of the energy structure by encouraging enterprises to adopt advanced technologies, shift to cleaner energy sources, and significantly increase the use of renewable and cleaner energy sources [15]. However, despite a series of measures already taken, it will take time to realize the shift in energy consumption patterns, and there are several challenges to achieving the "double coal" goal. The Chinese government has implemented environmental protection documents on the agenda, but there still needs to be a gap in addressing the problem [16]. The inconsistent pace of market reforms is also a challenge, so the Chinese government is gradually exploring market-based environmental regulatory tools, including the introduction of a carbon planning system, an energy exchange system, and a carbon swap system, in order to adapt to market trends and facilitate the development and improvement of the carbon market. Despite the many challenges, improving energy efficiency remains one of the keys to realizing China's development goals in the new era. This will address China's energy consumption imbalance and reserve shortage, effectively respond to environmental and climate threats, and enhance the country's coping capacity [17]. Therefore, the Chinese government will continue to promote energy efficiency, realize the "double coal" goal, make more remarkable contributions to global sustainable development, and demonstrate the responsibility and commitment of a great country (Table I).

TABLE I. FACTORS AFFECTING ENERGY EFFICIENCY

Variant	Brochure	Average value	S.D	Minimum value	Maximum values
T	251	3.62	0	0.25	60.36
SO ₂	251	555.36	0	43.21	68423
CO ₂	251	0.516	0	0.0021	0.654
economic structure	251	47.62	0.36	12.36	651.52
GPD	251	983.36	0.54	44.636	66517
GNP	251	44.63	77.88	11.25	11158.32

Ensuring the proper functioning of the carbon dioxide trading system requires establishing a fair carbon dioxide allocation mechanism and effective carbon market regulation to ensure that enterprises comply with the relevant regulations. The fairness of such a mechanism directly affects the stability and sustainable development of the carbon trading market. In carbon markets set up abroad, the impact of the CO₂ quota method on company emissions and CO₂ intensity could be more precise, so further research and practice are needed to determine the most effective allocation method [18]. In addition, paying for CO₂ does not automatically change the transfer of costs to the energy sector, so regulatory mechanisms are needed to ensure that these costs are used correctly to promote the development and use of

clean energy. Different carbon allocation methods impact innovation, operational viability, and product prices. For example, historical intensity increases carbon prices, while reference rules incentivize firms to promote innovation. Therefore, the most suitable carbon allocation method needs to be selected by considering the actual situation of enterprises and the development trend of the market. Recently, China's carbon allocation mechanism has been widely discussed. Some scholars have developed carbon trading decision-making models and studied the impact of different carbon allocation methods on the economic efficiency of the carbon market. These studies provide essential references for constructing China's carbon market and help promote the regular operation and development of the carbon trading system.

III. METHODOLOGY

A. Study Design

The main reasons for choosing data from 2011 to 2019 to assess the digital economy and environmental efficiency can be summarized in two ways. First, 2011 marked the launch of China's 12th Five-Year Plan, which promulgated energy-saving and emission-reduction policies and new environmental and energy requirements. Implementing these policies had a profound impact on the economic structure, industrial layout, and energy consumption patterns of cities, so the data from this period can more accurately reflect the effects of these policies.

Second, 2019, as the last year of data collection, helps to avoid the interference of epidemics in the data and ensure the accuracy and comparability of the results.

The level of the digital economy is an essential criterion for assessing the degree of digitization of a city or region. It plays a crucial role in evaluating the degree of economic development of a city. China's digital economy development over the past timeframe has shown an average annual growth rate of 0.122. Although the overall level of development in the digital economy is relatively low, its potential is still enormous. Specifically, from 2011 to 2019, China's digital economy index grew from 0.07 to 0.162, indicating that the level of the digital economy has shown a steady improvement and that relevant policies have achieved significant results. Among the top 20 cities in Guangdong Province, six possess rich political, workforce, and resource advantages and excel in the digital economy. This phenomenon reflects the differences in the level of digital economy among cities and suggests the importance of factors such as politics, workforce, and resources in urban development. In order to promote sustainable economic development, innovative cooperation with high-level cities should be strengthened to enhance the digitalization level of cities, targeting low-level cities.

Intelligent logistics transportation process, as shown in Fig. 1.

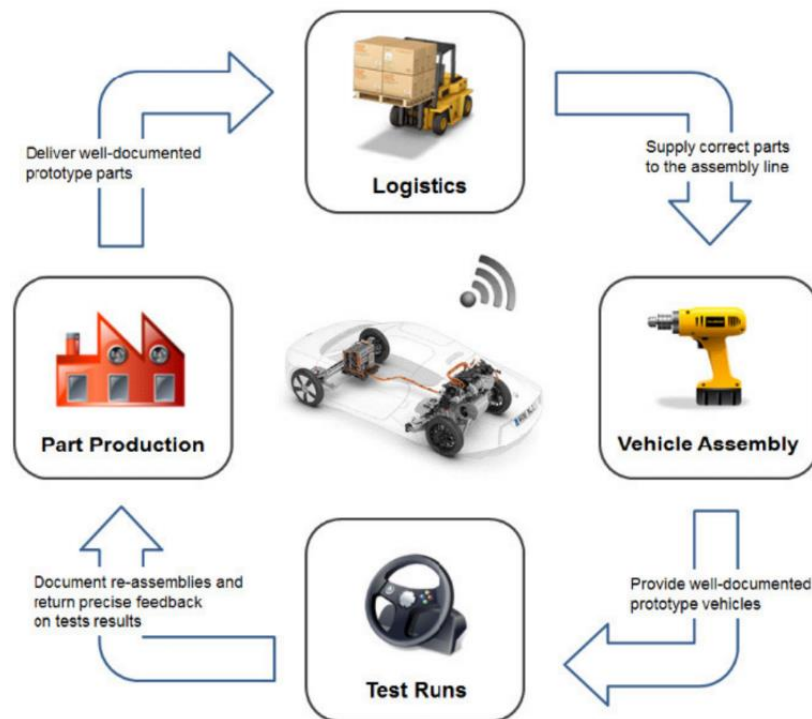

Fig. 1. Intelligent logistics transportation.

B. Indicators and Input-Output Ratios

In conducting the energy use efficiency assessment, the results of previous research were taken into account, and a system of assessment indicators was developed to analyze energy use in Chinese cities. These assessment indicators cover three main input variables: labor, capital, and energy. When

selecting the type of energy, the current energy structure of the cities was fully considered, with particular attention paid to the total amount of natural gas, gas, and liquefied natural gas (LNG) delivered, as well as the electricity consumption of the whole society. In order to accurately estimate the total energy consumption, the standard carbon dioxide conversion rates of various energy sources were used as reference standards. In

order to eliminate the influence of price distortions on the results, the real GDP of each city was adjusted to match its expected economic output, thus ensuring a more objective and accurate assessment.

Industrial waste and greenhouse gas emissions have also been introduced as indicators of adverse impacts to enhance the reliability and accuracy of the assessment results. These indicators include industrial waste emissions such as sulfur dioxide, water, and soot and greenhouse gas emissions such as carbon dioxide. These data were mainly obtained from the Annual Statistical Reports of Chinese Cities, and the vacuum

coefficients were estimated using linear interpolation. In calculating carbon dioxide emissions, reference was made to the calculation methods of other countries, specifically, the carbon dioxide emission coefficients published by the Natural Gas Commission in 2006 and the emission coefficients of the power grids of six regions in China, which were used. These comprehensive data and methods enable a more comprehensive assessment of the energy utilization efficiency of Chinese cities and provide valuable references for policymaking and urban development. The flow of the open and closed logistics system is shown in Fig. 2.

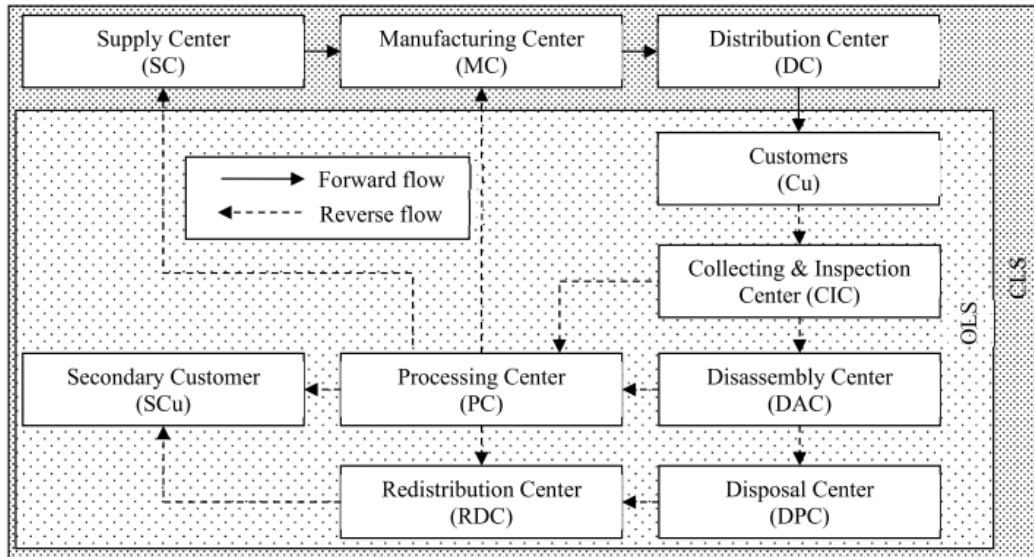

Fig. 2. Flow of open and closed logistics system.

A data-driven methodology model for energy use efficiency:

$$\pi = p(q_0 + \eta_1 e_1 + \eta_2 e_2) - \alpha e_1^2 - \frac{\beta}{e_1} e_2^2 \quad (1)$$

π in Eq. (1) is the unknown variable for efficiency improvement;

$$e_1^* = \frac{1}{2\alpha} p\eta_1 + K(1-D) \quad (2)$$

(1-D) in Eq. (2) is to get the actual distance of TOPSIS.

$$e_2^* = e_1^* \frac{p\eta_2 + KD + \theta(1+g)}{2\beta} \quad (3)$$

(1+g) Eq. (3) is the coefficient of θ .

Analyzing the diversity of urban agglomerations is critical to understanding urban energy use. In this study, we consider different city sizes and delve into the impact of the digital economy on green energy utilization. The results show that the level of digital economy in medium and large cities contributes significantly to green energy utilization, being able to increase green energy utilization by 1%. However, differences in energy efficiency between different groups of cities were also identified. This triggered a further examination of energy

efficiency between groups to assess its impact on environmental performance more fully. Although the model's p-value of 0.0681 fails at all levels of statistical significance, it passes the 10% group rate test, suggesting some unevenness in the impact of direct investment on environmental protection across different city sizes. We conducted a heterogeneity test to compare the regressors and obtained a high clustering value (0.594). This indicates significant differences between city groups, especially regarding battery eco-efficiency. Small city clusters have a higher impact on battery eco-efficiency in large cities (0.274), while small and medium-sized cities have a lower impact. This phenomenon can be explained by the fact that large cities have more developmental advantages, including geographic location, transportation infrastructure, technological innovation, and human resources, and are therefore more likely to achieve high efficiency in energy use.

Multiple dimensions characterize the indirect impact of the digital economy on urban green energy efficiency. First, the dynamic development of the digital economy promotes the rapid advancement and broad application of technological innovation, improving the efficiency of green energy utilization. Second, the rise of the digital economy has changed the industrial structure, promoted the rise and development of green industries, and indirectly improved the green energy efficiency of cities. The theoretical analysis identifies technological innovation, industrial structure, and rational industrial structure as the primary mechanisms by which the digital economy affects urban

green energy efficiency. Recent studies have shown that technological innovation is critical in improving energy efficiency and creating more favorable conditions for the innovation and application of low-carbon energy technologies. Therefore, the impact of the digital economy on urban green energy efficiency involves technological innovation, adjustment and optimization of industrial structure, and inherent economic mechanisms. Empirical evidence of energy utilization efficiency improvement in intelligent logistics is shown in Table II.

IV. RESULTS AND DISCUSSION

A. Discussion of Empirical Results on Green Total Factor Energy Efficiency (GTFE)

China faces energy and environmental challenges, including lower energy efficiency and environmental quality. In the context of green development, accelerating the development of the digital economy is critical to China's modernization and improvement of green energy efficiency. The rise of the digital economy provides new opportunities and impetus for China to realize its green transformation. On the energy front, China is developing traditional green energy production technologies, such as solar and wind power, and promoting low-carbon oil extraction technologies to reduce emissions from traditional energy use. The development of intelligent transportation is also vital, with digital technologies enabling the intelligent management and optimization of transportation systems, reducing traffic congestion and pollution, and improving the efficiency of urban energy use [19].

Regarding the environment, China uses digital technology to build a digital environmental management platform to monitor environmental conditions in real-time and provide accurate early warning and rapid response to environmental problems, thereby controlling the behavior of high-energy-consuming and high-emission enterprises and promoting sustainable environmental development. Digital means can realize comprehensive monitoring and analysis of environmental data, providing a scientific basis and technical support for environmental governance. China also needs to actively promote the development of the digital economy, accelerate the integration of digital technology with traditional industries, and especially promote the digital transformation of traditional industries. This process requires focusing on developing advanced industries, such as the modern service industry, and accelerating the intelligent development of traditional industries. Integrating digital technologies with traditional industries can help promote

the digital transformation of industrial structures, improve the green energy efficiency of cities, realize the green and low-carbon transformation of cities, and inject new vitality into China's sustainable development.

Cities rich in natural resources, although endowed with abundant natural resources, have a relatively low level of economic development, a unique industrial structure, and a high degree of dependence on natural resources. Over-exploitation of resources may not only lead to resource depletion but also cause damage to the environment, thus affecting the sustainable development of society. Therefore, there is an urgent need to promote the digital transformation of these resource-based cities into resource-saving cities and actively explore helpful regional resources. These resource-centric cities are improving resource efficiency and driving the digital revolution. In general, the industrial structure of resource-intensive cities is dominated by resource-saving industries. However, these resource-centric cities should seize the significant opportunity to develop a digital economy and promote the upgrading and transformation of traditional industries into new digital industries to unleash the potential of the digital economy while reducing energy consumption. Realizing the digital transformation of cities requires an overall improvement in green energy efficiency. Some cities have steel as their primary industry, while others have wood as their primary industry. These resources could be used to establish innovative partnerships with other cities, which would not only help to promote economic development but also change the integrated industrial structure and facilitate the digital transformation of resource-efficient cities. Strengthening collaboration with resource-efficient cities to support their digital transformation is crucial. Resourceful cities often depend solely on natural resources and need more geographic and economic advantages, leading to a widespread brain drain. Technical cooperation is critical. Cities without natural resources are rich in technical resources and can provide technical support and guidance to accelerate the digital transformation of resource-saving cities. At the same time, resource-saving cities can also learn from the experience of non-resource-saving cities to find the most suitable path of digital transformation. The second is talent cooperation. Resource-poor cities have sufficient human resources to support the recruitment and training of resource-saving cities. At the same time, resource-saving cities can attract and train high-quality digital change experts to improve the efficiency and quality of digital change. Energy use efficiency data map.

Modernizing the energy mix and strengthening technological innovation are critical. Although China currently relies on traditional energy sources, such as coal, its reserves must be increased to meet demand. At the same time, more oil and natural gas inventories are required to meet market demand, and it relies heavily on imports, leading to an imbalance between supply and demand. The use of traditional energy sources generates large amounts of harmful gases, causing severe damage to the environment. Under the guidance of the green development concept, strengthening technological innovation and promoting energy conversion and modernization are vital ways to achieve the goals of dual-carbon and high-quality economic development. To this end, it is necessary to strengthen energy technology innovation, optimize energy structure, reduce

traditional energy consumption, and improve energy efficiency. In particular, it should focus on developing traditional innovative energy exploration technologies, new energy technologies, clean energy technologies, and digital energy system technologies, as well as the construction of digital energy systems to gradually promote energy structure transformation. In addition to technological innovation, policy support and financial investment are equally crucial. The government should increase investment in R&D in the energy sector and provide sufficient funds for technicians to enhance the vigor of technological innovation in enterprises and promote the transition to clean and low-carbon energy, as shown in Fig. 3.

Fig. 3. Energy use efficiency data.

On the other hand, the government should pay attention to regions with high carbon consumption and provide appropriate policy incentives to promote the promotion and application of clean energy and new energy technologies to promote the green energy transition. Accelerating the modernization of the industrial structure and optimizing energy consumption is also crucial. Currently, the secondary industry occupies a larger share of China's economy, and its energy consumption per unit of GDP is much higher than that of the service sector, which means that industrial energy consumption is relatively high. However, the industry is the foundation of the real economy and the cornerstone of modernization, and reducing the proportion of the industry is not realistic. Improving industrial infrastructure and optimizing industrial energy use is the only way to improve environmental energy efficiency and promote sustainable urban development. In addition, according to relevant national laws and regulations, it is necessary to eliminate high-energy-consuming and high-polluting projects, eliminate excess capacity, rationally allocate social resources, and promote the green transformation of steel and other industries. Promoting the modernization of the energy structure reduces dependence on traditional energy sources, reduces environmental pollution, improves energy use efficiency, and lays a solid foundation for the sustainable development of China's economy and the realization of the dual-carbon goal [20].

B. Time-Space Evolution of Energy Use Efficiency

Based on the SBM super-efficiency model and MaxDE7 super software, the green energy efficiency of cities was calculated from 2011 to 2019. The study aims to explore the regional differences in the overall eco-energy efficiency of cities by analyzing them from a temporal and spatial perspective. During the study period, China's average energy efficiency was 0.508, indicating that China still has the potential to improve energy efficiency. Much work remains to be done to realize the goal of "dual-carbon" and sustainable green development of society. The temporal characteristics of the development of the national green energy efficiency coefficient show an increasing volatility trend. 2011-2016 is considered a period of energy efficiency improvement, 2016-2017 a period of energy efficiency decline, and 2016-2019 a period of energy efficiency improvement. 2016 marks the beginning of the 13th Five-Year Plan, which aims to reduce individual energy consumption and manage overall energy consumption. Although there is a time lag between policy liberalization and implementation, it will take time for regional industrial reforms and modernization to become established, which will reduce overall environmental impacts in the short term. As policies are implemented and local development adapts, the Green TFE will gradually improve its energy efficiency after 2017. To further improve China's energy efficiency, attention needs to be paid to the research, development, and application of green energy technologies, increasing the utilization rate of renewable energy and reducing dependence on traditional energy sources; optimizing the energy structure, encouraging clean energy to replace traditional energy sources, and improving the efficiency of energy use; and strengthening energy management, setting up a comprehensive energy monitoring and evaluation system, promoting changes in energy consumption patterns, and promoting green and low-carbon development. The government should introduce more robust policy measures to guide and support enterprises and residents in saving energy and reducing emissions and jointly promote improving China's energy efficiency level. Energy improvement efficiency data map, as shown in Fig. 4.

Fig. 4. Energy improvement efficiency data.

Analyzed from the perspective of control variables, the level of economic growth has a significant positive impact on all aspects of environmental effects at a significance level of 1%. Further, economic growth also attracts more investment, which

increases enterprises' production capacity and competitiveness and promotes technological innovation and the application of environmental management technologies. The capital mobilization of enterprises can be used not only to promote technological innovation but also to improve the production process and enhance resource utilization efficiency. On the other hand, population density (POP) significantly negatively impacted the overall ecological efficiency (significance level of 1%), indicating that high population density may lead to higher energy consumption and more severe pollution problems, thus hindering the improvement of ecological efficiency. Therefore, densely populated areas must adopt more effective environmental management and resource utilization measures to reduce environmental pressure and improve ecological performance. This finding underscores the positive impact of economic growth on environmental and energy efficiency, as economic progress helps to provide more resources for technological upgrading and industrial modernization, which in turn leads to the adoption of cleaner sources of energy, reduced use of traditional energy sources and pollution, and effective improvement of infrastructure. This further highlights the positive correlation between economic development and environmental protection and the mutually reinforcing relationship between economic prosperity and environmental sustainability. Infrastructure quality has a significant positive impact on the overall energy efficiency of green energy, with better quality infrastructure reducing transportation costs, improving energy use efficiency, and promoting technological advances that increase energy efficiency. Therefore, building high-quality infrastructure is one of the most important ways to improve environmental energy efficiency, which is of positive significance for promoting economic growth, improving the quality of life, and environmental protection.

Intelligent logistics construction principles and processes:

$$\pi_m = p_1(q_0 + \eta_1 e_1 + \eta_2 e_2) + K - \alpha e_1^2 \quad (4)$$

Thein Eq. (4) is a free variable introduced to guarantee the error value.

$$\pi_m^{2*} = p_2 q_0 + \frac{(p_2 \eta_2 + \theta(1 + g))^2}{4\beta} e_1^{2*} \quad (5)$$

The $p_2 q_0$ in Eq. (5) is the residual term of the least squares method.

Excellent infrastructure plays a significant role in reducing the transport coefficient, which helps optimize resource allocation and improve overall productivity and environmental sustainability. The entropy method was used to explain the potential regressors of economic levels, enabling the most influential variables to be extracted from many economic indicators, thus validating the stability of the model. The results show that PCADI significantly impacts green energy efficiency, with 0.00335 units per increase, which is significant for low-level regression, indicating the model's reliability. In addition, the study introduced foreign direct investment (FDI) as a new control variable to avoid the possible impact of omitted variables on the empirical results. The analysis results show that the level of the digital economy significantly negatively impacts overall

eco-efficiency, implying that technological development is only sometimes beneficial to eco-efficiency.

Meanwhile, FDI negatively impacts overall energy efficiency, especially when developed countries transfer highly polluting and energy-intensive industries to developing countries. To validate these findings, static panel data were used to test the regression model's robustness and investigate possible endogeneity issues. Local government policies and interventions significantly impact environmental energy efficiency in a given developing urban setting, suggesting that small changes in government policies may significantly impact overall energy efficiency. The p-value of 0.0092 for the two direct investments suggests that they may significantly impact energy efficiency. The analysis of the differences between the different factors shows that direct investment's impact on the urban environment varies between developed and developing countries.

Regarding recovery factors, developed cities have a significant positive impact on energy efficiency because they have advantageous resources such as high levels of digitalization, economic development, and technological innovation. Therefore, implementing environmental management strategies and the increased use of clean energy will help improve these cities' energy efficiency and promote their sustainable development. The weight of each type of energy is shown in Fig. 5.

Fig. 5. Share of various energy sources.

In this study, 272 heterogeneous samples were grouped. Although the effect of the inhaler on the energy efficiency of the green factor was insignificant, there was a significant difference between the two groups. In order to ensure the reliability of the results of the different studies, the researchers delved into the factors that differed between the two groups. This showed that the model had passed the 5% group gap test, again validating the inconsistency of the impact of non-resource direct investment on green energy efficiency. The diversity recession factor reveals that direct investment significantly impacts the overall environmental energy efficiency of cities that do not consume large amounts of resources. This is because resource-efficient

cities, despite having significant resources, are mainly made up of less developed cities with less digitization—global energy consumption shares, as shown in Fig. 6.

Fig. 6. Global energy consumption shares.

Over time, the industry has become the engine of economic development in resource-intensive cities; in the process of industrialization, although their economies are booming, these cities consume large amounts of national resources and bear environmental costs that do not contribute to sustainable development and more efficient use of society's resources. Resource-efficient cities are inherently less affluent than non-resource-efficient cities that rely on energy supplies or imports for economic development and daily life. However, in resource-scarce cities, industries change relatively quickly. While other cities rely on primary and secondary industries to drive GDP growth, some, such as Beijing, Shanghai, and Shenzhen, have shifted from primary and secondary industries to more environmentally friendly ones. These high-industry-consuming cities consume less energy, produce less waste and CO2 emissions, and have reduced energy waste and emissions in their cities. At the same time, the high degree of digitization, digitalization, and rapid digitization of natural resource-based cities has improved the eco-energy efficiency of various factors.

A comparison of domestic energy efficiency is shown in Fig. 7.

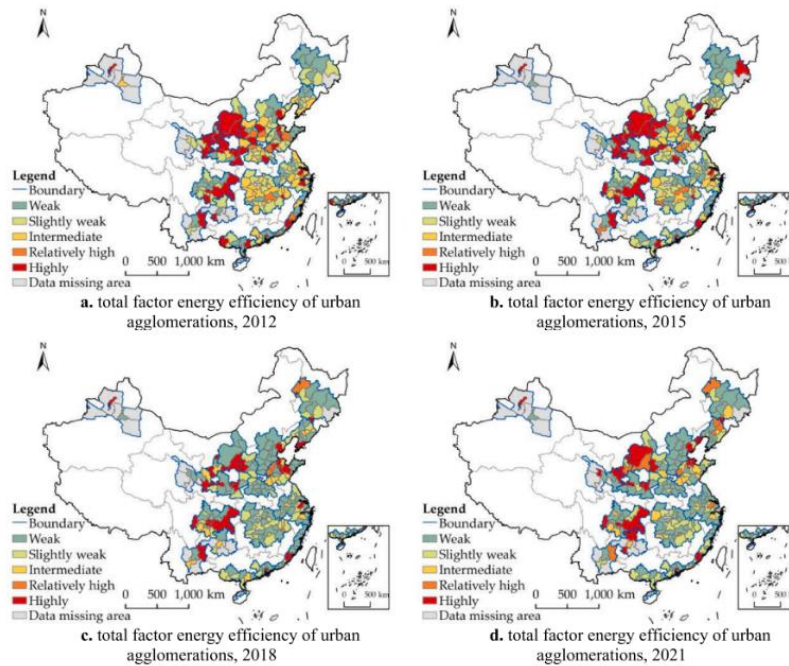

Fig. 7. Comparison of domestic energy efficiency.

V. CONCLUSION

Intelligent logistics is a current trend in the logistics industry, and one of its core objectives is to enhance energy utilization efficiency to reduce costs, minimize resource consumption, and improve the environment. This study systematically explores the feasibility and effectiveness of improving energy utilization efficiency through a data-driven approach in the context of global intelligence in various industries. The following conclusions are drawn from the introduction, purpose, methodology, and results: First, the large amount of accumulated data in the intelligent logistics environment becomes a valuable resource for improving energy utilization

efficiency. Through the collection and analysis of logistics transportation information, energy consumption data, and other data, the operational status and energy utilization of the optimized logistics management procedures are deeply understood, providing a solid foundation for subsequent optimization. Secondly, key factors affecting energy utilization efficiency and potential optimization directions are revealed through data analysis and mining techniques. For example, optimizing transportation routes and improving vehicle load factors are essential in improving energy utilization efficiency. These findings provide theoretical guidance for the development of targeted optimization strategies. A series of data-driven

optimization strategies and methods were designed at the methodological level by incorporating intelligent optimization algorithms. These methods not only consider the actual situation of optimizing logistics management procedures but also make full use of the advantages of big data and artificial intelligence technology to improve the precision and operability of the optimization effect. The effectiveness and feasibility of the proposed methods are verified through simulation experiments and case studies. The experimental results show that adopting the data-driven approach can significantly improve the energy utilization efficiency of the optimized logistics management procedure, reduce logistics costs, and improve the sustainability and competitiveness of the system.

In summary, through in-depth analysis and empirical research, this study demonstrates the feasibility and effectiveness of using data-driven methods to improve energy utilization efficiency in the context of global intelligence in various industries. The proposed series of optimization strategies provides new ideas and methods for energy management and optimization of optimized logistics management processes. These results significantly promote the sustainable development of optimized logistics management procedures and enhance overall competitiveness. In future research, optimizing other aspects of optimized logistics management procedures, such as environmental impact assessment and supply chain visualization, can be further explored to achieve the overall optimization and sustainable development of optimized logistics management procedures.

Design and Application of the DPC-K-Means Clustering Algorithm for Evaluation of English Teaching Proficiency

Mei Niu

Basic Courses Department, Jiyuan Vocational and Technical College, Jiyuan 459000, Henan, China

Abstract—Effective and precise methodologies for evaluating the proficiency in English language instruction are instrumental in enhancing educators' competencies and the effectiveness of educational administrative processes. The objective of this paper is to refine the neutrality and precision of such assessments by introducing a novel approach that leverages an advanced K-means algorithm in conjunction with convolutional neural networks (CNNs). Initially, a thorough examination of the issue at hand leads to the formulation of an assessment framework that integrates both a clustering algorithm and a CNN, with a comprehensive elucidation of the pivotal technical aspects. Subsequently, the paper introduces a data clustering and categorization technique grounded in the DPC-K-means methodology, specifically tailored for indices that measure English teaching proficiency, and employs CNNs to devise a model for evaluating these competencies. The integration of these two components—data clustering and the assessment model—gives rise to an innovative technique. Ultimately, the proposed method is implemented and its practicality is substantiated through an analysis of empirical data from educators' teaching proficiency indices. A comparative analysis with existing algorithms reveals that the proposed method achieves superior clustering performance and the lowest margin of error in predictive assessments.

Keywords—K-Means; density-peak clustering algorithm; ELT competency assessment; convolutional neural network

I. INTRODUCTION

As educational reforms progress and evolve, the caliber of education has emerged as a pivotal topic of societal interest [1]. Proficiency in teaching represents a critical facet of educational quality, reflecting not just the professional acumen of educators but also the trajectory of educational management's advancement [2]. English, being the lingua franca of the modern world, occupies a significant place among the mandatory courses within the academic curricula of higher education institutions [3]. The evaluation of English teaching capabilities is a crucial component in the pedagogical framework of universities and colleges, serving as a vital mechanism for educators to gather feedback, refine their instructional strategies, and uphold educational standards, as well as for students to refine their study approaches, enhance learning techniques, and boost academic performance [4]. In recent years, research into the assessment of English language teaching proficiency has predominantly focused on two key areas: the development of assessment indices and the formulation of algorithms for evaluating teaching proficiency [5]. Existing systems for evaluating English teaching skills are often examined from dual viewpoints—that of the educator and the student—yet they often

fall short in terms of being comprehensive, standardized, and providing timely feedback [6]. Current research into algorithms for assessing English teaching skills typically employs the assessment index system as input and the level of proficiency as output, with common methodologies including fuzzy logic [7], hierarchical analysis [8], clustering algorithms [9], and neural networks [10]. However, methods relying on fuzzy logic and hierarchical analysis are limited in their capacity to address intricate and varied mapping relationships and are generally straightforward to compute and implement [11]. On the other hand, clustering-based algorithms for assessing English teaching skills offer a temporal perspective on the assessment challenge, addressing the dynamic nature of teaching data and establishing a big data model for English teaching proficiency through quantitative recursive analysis [12]. Neural network-driven algorithms, meanwhile, are adept at managing the intricate and shifting relationships between the assessment indices and the proficiency levels, offering a degree of generalization [13]. With the advancement of intelligent algorithms, the integration of clustering methodologies with neural networks to cluster and train the indices of English teaching proficiency has become a burgeoning research avenue, aimed at achieving a quantifiable measure of teaching skills [14]. Despite these developments, there remain issues within the algorithms for assessing English teaching skills, including the need for improved generalization and the absence of well-defined quantitative criteria [14].

This paper addresses the aforementioned challenges in the construction of an English teaching proficiency assessment system and the design of its algorithms by integrating a clustering algorithm with a convolutional neural network. It proposes a method for developing an English teaching proficiency system grounded in an enhanced clustering approach and an assessment algorithm based on CNNs. Concentrating on the evaluation of English teaching skills, the paper delves into the conceptualization and resolution of the issue at hand, scrutinizing the critical technical aspects. It utilizes an improved clustering algorithm for the aggregation and synthesis of English teaching proficiency indices and employs a CNN to assimilate and refine the clustered data, ultimately verifying and analyzing the proposed methodology using a test dataset.

II. PROGRAMME RESEARCH DESIGN

A. Line of Research

To address the problem of assessing English teaching ability, this paper follows the basic research idea of "identifying

problems - analysing problems - proposing solutions - verifying solutions" [15] to study the English teaching ability index system (see Fig. 1). The paper follows the basic research idea of "finding the problem - analysing the problem - proposing the solution - verifying the solution" [15] to study the indicator system of English teaching competence, and at the same time, it adopts the data learning model to construct and analyse the model for assessing English teaching competence.

By integrating a clustering methodology with the advanced computational framework of convolutional neural networks (CNNs), a comprehensive scheme for the evaluation of teaching capabilities has been meticulously crafted, as delineated in Fig. 1. As depicted in Fig. 1, this scheme for assessing English teaching proficiency, grounded in both clustering techniques and CNNs, adheres to the foundational principles of assessment system development. It initiates with a thorough examination of the challenges inherent in evaluating English teaching skills, followed by the establishment of pertinent assessment criteria. The data undergoes a rigorous pre-processing phase that includes the mitigation of outliers, the imputation of missing values, normalization to ensure consistency, and a thorough analysis of inter-variable correlations and the reduction of data dimensionality to enhance computational efficiency. Subsequently, the refined indices are aggregated and scrutinized through the application of a clustering algorithm, which facilitates the identification of distinct levels of teaching proficiency. The subsequent phase involves the utilization of a CNN to train a labeled dataset, thereby fostering the development of a robust model capable of accurately assessing English teaching competencies.

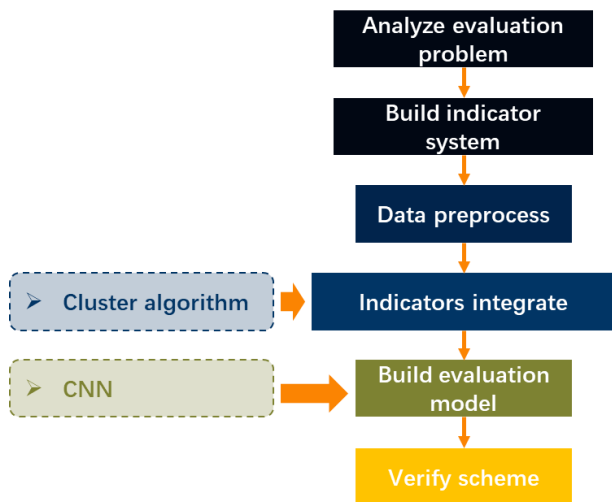

Fig. 1. ELT competency assessment research programme.

B. Analysis of Key Technologies

The system for evaluating English teaching ability, which integrates a clustering algorithm with a convolutional neural network, encompasses several pivotal technological components. These include the development of an assessment framework for English teaching proficiency, the initial handling of gathered data, the organization of data indices through clustering, the assembly of a model for gauging teaching capabilities, and the verification of the system's design, as illustrated in Fig. 2.

Fig. 2. Key technologies of the EFL assessment system.

1) *Establishment of an assessment indicator system:* According to the principles of objectivity, orientation, wholeness, operability and English characteristics [16] of the construction of assessment indicators (as shown in Fig. 3), through consultation, investigation and modification, we construct an assessment indicator system of English teaching competence that contains 20 indicators in five aspects, such as the purpose of teaching, the content of teaching, the language of teaching, the method of teaching, and the effect of teaching, as shown in Fig. 4.

Fig. 3. Principles for selecting assessment indicators.

Fig. 4. System of assessment indicators.

2) *Data pre-processing:* The precision and reliability of the English Language Teaching (ELT) competency evaluation model are often compromised by the absence of comprehensive raw data, the presence of anomalies, discrepancies in scaling, and significant data redundancy, which result in the model's performance falling short of the expected benchmark [17]. To address these issues and enhance the fidelity and exactitude of the assessment model, it is imperative to implement data preprocessing techniques on the collected data. In dealing with anomalies, the paper employs the 3σ rule [18], which designates any data point that lies beyond the mean by more than three standard deviations as an outlier, subsequently eliminating such points. For addressing missing data, the paper utilizes a proximity filling technique [19], which estimates the missing entries based on adjacent data points. To standardize the quantitative index values, the Z-score normalization method [20] is applied. Furthermore, to refine the accuracy of the assessment algorithm and mitigate computational overhead, the paper utilizes Pearson's correlation coefficient to assess the interdependencies among the assessment indicators, subsequently employing principal component analysis [21] to streamline the dimensions of the indicators and distill the core variables that capture the most variance in the data.

Fig. 5. Flow of data pre-processing technology.

3) *Indicator clustering integration*: In order to carefully classify the assessment values and grades of English teaching ability, this paper adopts the unsupervised learning method based on clustering algorithm to cluster and analyse the indicator data of English teaching ability assessment. Indicator data clustering integration mainly includes two steps, i.e., indicator data clustering and assessment score labelling division, as demonstrated in Fig. 5.

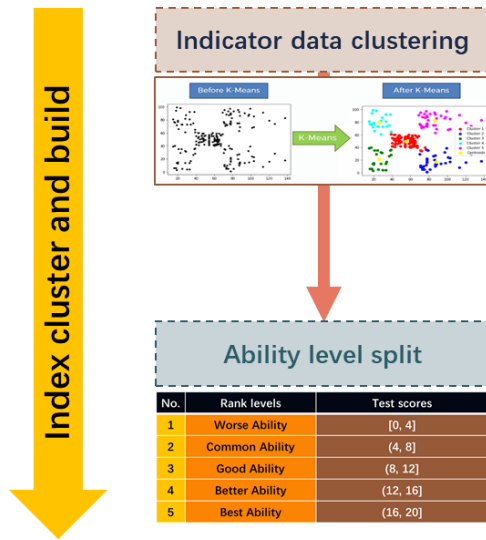

Fig. 6. Flow of indicator clustering integration technique.

For the indicator data clustering problem, this paper adopts the improved K-means clustering algorithm based on the assessment of English teaching ability indicator data clustering analysis, through the input of assessment indicator data, to represent the minimum relative distance between the sample point and the data sample point as the optimization goal, after many iterations of search, the output of clustering centre and the assessment of the indicator data division, the specific principle is displayed in Fig. 6 and Fig. 7. The data clustering model is calculated as follows:

$$X_{all-cluster} = f_{DPC-K-means}(X) \quad (1)$$

where, $X_{all-cluster}$ denotes the data segmentation results, $f_{DPC-K-means}$ denotes the improved K-means clustering algorithm, and X denotes the input indicator data.

Fig. 7. Data clustering model for assessment indicators.

To address the issues of assessment score labelling and grade division, according to the clustering results, this paper divides the assessment value of English teaching ability into five grades, and the corresponding scores are shown in Table I.

TABLE I. CORRESPONDENCE BETWEEN ENGLISH PROFICIENCY ASSESSMENT SCORES AND CLASSIFICATION LEVELS

No.	Rank Levels	Test Scores
1	Worse	[0,4]
2	Common	(4,8]
3	Good	(8,12]
4	Better	(12,16]
5	Best	(16,20]

$$Y_{rank} = \begin{cases} 5 & Y_{score} \geq 16 \\ 4 & 12 < Y_{score} \leq 16 \\ 3 & 8 < Y_{score} \leq 12 \\ 2 & 4 < Y_{score} \leq 8 \\ 1 & Y_{score} \leq 4 \end{cases} \quad (2)$$

where, Y_{score} denotes the ELT assessment score and Y_{rank} denotes the ELT level.

4) *Evaluation model construction*: In order to construct the mapping relationship between the index value of English teaching ability and the assessment score, this paper adopts the convolutional neural network to construct the English teaching ability assessment model, as shown in Fig. 8.

Fig. 8. Schematic diagram of the construction of the EFL assessment model.

$$Y_{score} = f_{CNN}(X) \quad (3)$$

where, Y_{score} denotes the ELA score, f_{CNN} denotes the convolutional neural network, and X denotes the input indicator data.

5) *Programme validation techniques*: In order to fairly analyse the performance of each capability assessment model, this paper analyses and compares the clustering delineation capability and assessment prediction capability, and the specific technical ideas are shown in Fig. 9. The clustering delineation ability uses the evaluation indexes such as contour coefficient SI, variance ratio criterion CHI, and Davis-Boulding index DBI to analyse the results [22]. The assessment and prediction ability is used to analyse and compare the results using evaluation indexes such as mean absolute error MAE, root mean square error RMSE, mean absolute percentage error MAPE [23].

Fig. 9. Programme validation technology roadmap.

III. DATA CLUSTERING AND COMPETENCY ASSESSMENT ALGORITHMS

A. Clustering of English Teaching Competence Division

The clustering algorithm's function is pivotal in categorizing the vast and intricate dataset of English Language Teaching (ELT) proficiency indicators into coherent groups based on their inherent characteristics [23]. This process is fundamental to establishing the groundwork for the subsequent development of the ELT proficiency assessment model. The efficacy of the clustering process is paramount, as the accurate segregation of data is directly proportional to the quality of the sample set formation. Consequently, identifying a clustering algorithm with superior performance is of utmost importance to ensure the robustness of the model.

Fig. 10. Principle of K-means clustering algorithm.

1) *K-means clustering algorithm*: The K-means methodology stands as a prevalent technique for partitioning datasets into distinct clusters, particularly adept at classifying extensive volumes of data [24]. This algorithm operates by identifying the optimal positions for cluster centroids and assigning data points to the nearest of these, thereby minimizing an objective function that is predicated on the sum of squared differences. The objective is to maximize the distance between centroids while ensuring that each data point is linked to the closest centroid. Within the K-means framework, the Euclidean distance serves as the standard metric for gauging the similarity between data points, where a shorter distance signifies a higher degree of resemblance and a longer one suggests dissimilarity, as depicted in Fig. 10.

The objective function of the K-means algorithm is defined as follows:

$$J = \sum_{i=1}^K \left(\sum_k \|x_k - c_i\|^2 \right) \quad (4)$$

where, K is the number of clusters, c_i is the centre of the cluster, and x_k is the k th data point in the i th cluster.

The algorithm proceeds as follows (see Fig. 11):

- Step 1: Determine the total number of categories K and randomly select K cluster category centres $C = (c_1, c_1, \dots, c_K)$.
- Step 2: Compute the partition matrix. A data point belongs to the cluster whose centre is closest to that data point. Therefore, the clusters are represented by the binary division matrix U . The elements in it are determined as follows:

$$u_{ij} = \begin{cases} 1 & \text{if } \|x_j - c_i\|^2 \leq \|x_j - c_t\|^2, \forall t \neq i \\ 0 & \text{otherwise} \end{cases} \quad (5)$$

where u_{ij} indicates whether the j th data point belongs to the i th cluster class.

- Step 3: Update the cluster centres. Define each cluster class centre c_i that minimizes the objective function as follows:

$$c_i = \frac{\sum_{j=1}^N u_{ij} x_j}{\sum_{j=1}^N u_{ij}} \quad (6)$$

where, N denotes the number of samples.

- Step 4: Compute the objective function using equation (4). Verify that the function converges or the difference between two neighbouring values of the objective function is less than a given threshold and stop; otherwise repeat step 2.

2) *DPC-K-means clustering algorithm*: Given that the initial selection of cluster centroids in the K-means algorithm is arbitrary, there is a propensity for the algorithm to converge on a local rather than global optimum, potentially resulting in erroneous classification outcomes [25]. To counteract this, the present study introduces an enhanced version of the K-means algorithm, aimed at elevating the precision of the clustering results. This enhancement is achieved by integrating the Density Peaks Clustering (DPC) approach [26], which facilitates the identification of more accurate initial centroids for the K-means clustering process.

a) *Peak density clustering algorithm*: The Density Peak Clustering (DPC) algorithm is based on two assumptions: 1) The local density of the cluster centre is higher than that of its neighbourhood samples. 2) The cluster centre is farther away from other high local density samples. According to the above assumptions, given a dataset $X = [x_1, x_2, \dots, x_N]$ with a

sample size of N , the attribute (dimension) of each sample x_i is D , the DPC process is shown in Fig. 12. The clustering process of the standard DPC algorithm is divided into three main steps:

Fig. 11. K-means clustering algorithm.

Fig. 12. DPC flowchart.

- Step 1: Calculate the local density of the sample point. For the sample point x_i , the local density ρ_i is described as follows:

$$\rho_i = \sum_j \chi(d_{ij} - d_c) \quad (7)$$

where, $\chi(x) = \begin{cases} 1, & x < 0 \\ 0, & x \geq 0 \end{cases}$. d_{ij} denotes the Euclidean

distance between x_i and x_j . d_c denotes the stage distance, the exact value of which needs to be set manually.

- Step 2: Calculate the minimum relative distance. The minimum relative distance between the sample point x_i and any other sample point δ_i that has a higher local density than it is calculated as follows:

$$\delta_i = \begin{cases} \min(d_{ij}), & \rho_j > \rho_i \\ \max(d_{ij}), & \rho_j < \rho_i \end{cases} \quad (8)$$

where, if x_i is a sample point with a local or global maximum in the density, its relative distance δ_i is much larger than the relative distance of the neighbouring sample points.

- Step 3: Generate decision diagram. Select the sample points where local density ρ_i is large while the minimum distance δ_i is large as the cluster centre and generate a decision diagram with ρ_i as the x coordinates and δ_i as the y coordinates. After selecting the cluster centres in the decision diagram, the remaining sample points are assigned to different cluster classes based on the minimum distance.

b) Improvement strategies: To address the issue of clustering inaccuracies in the K-means algorithm that arise from the suboptimal identification of cluster centroids, the paper presents a novel adaptation of the K-means algorithm, underpinned by the Density Peaks Clustering (DPC) strategy, termed DPC-K-means. This refined algorithm is structured into two distinct phases: initially, the DPC algorithm is deployed to pinpoint the precise locations of cluster centroids within the raw dataset; subsequently, these centroids are integrated into the K-means algorithm, which then proceeds through iterative refinements to achieve a more nuanced clustering resolution.

Stage 1 is the prerequisite basis for ensuring the clustering accuracy. In order to confirm the initial clustering centre more accurately, the DPC algorithm is improved in this paper. The standard DPC algorithm is very subjective about the selection of d_c . And different d_c often leads to a large variability in the final results of clustering. Since the standard deviation can reflect the degree of dispersion of the data set, d_c is redefined as:

$$d_c = \omega \frac{\sqrt{\sum_{j=1}^m (\sigma_j / \mu_j) \sum_{j=1}^m \mu_j (m-1)}}{2m^2} \quad (9)$$

where, σ_j and μ_j are the standard deviation and mean of attribute j , respectively. $\omega \in (0, 1]$ is the weight parameter that controls the size of the cutoff distance. d_c Approaching the 2-parameter of the standard deviation vector, which represents the standard deviation of all attributes, the cut-off distance is computed under the same mean criterion.

Facing multi-dimensional data, the metric error of standard Euclidean distance is large. Aiming at this problem, this paper designs a dynamic weight to correct the Euclidean distance in order to improve the final clustering accuracy. The basic design idea is: according to the magnitude of the difference between the corresponding attributes between two different data, matching different size weights. When the values of two attributes are more similar, the greater the proportion of in the overall similarity measure should be, and the greater the weights of should be assigned accordingly. The more distant the values of the two attributes are, the less weight should be assigned to the overall similarity measure, and therefore the less weight should be assigned accordingly. Dynamic Weight Correction Euclidean The exact form of the distance is as follows:

$$d_{ij} = \sqrt{\sum_{m=0}^D \frac{w_m}{W} (x_{im} - x_{jm})^2} \quad (10)$$

where, $W = \sum_m w_m$ is the normalisation factor. w_m is the dynamic weights and its expression is

$$w_j = e^{-\left(\frac{R_m - R_{MIN}}{R_{MAX} - R_{MIN}}\right)} \quad (11)$$

In the Eq. (11), $R_m = |x_{im} - x_{jm}|$, $R_{MAX} = \max \sum_{m=0}^D (x_{im} - x_{jm})$, $R_{MIN} = \min \sum_{m=0}^D (x_{im} - x_{jm})$.

c) *Algorithm flow:* In summary, the flowchart of the DPC-K-means algorithm is shown in Fig. 13 and the overall process is:

- Step 1: Calculate the dynamic weight-corrected Euclidean distance d_{ij} ;
- Step 2: Calculate the stage distance d_c ;
- Step 3: Calculate the local density ρ_i and the relative minimum distance δ_i ;
- Step 4: Generate a decision diagram to identify the clustering centres K ;
- Step 5: Calculate the division matrix U ;
- Step 6: Update the clustering centre C_i ;
- Step 7: Compute the objective function. Verify that the function converges and no longer changes, then stop; otherwise repeat step 2.

3) *Algorithmic applications:* To enhance the precision of the model assessing English teaching capabilities, this study employs a clustering approach that segments the indicators of English teaching proficiency using the DPC-K-means

methodology. The algorithm processes the input values representing the indicators of English teaching ability and yields both the categorized indicator data and the determined centroids of the clusters.

Fig. 13. Application of DPC-K-means clustering algorithm.

B. Algorithm for Assessing Competence in Teaching English

The assessment of English teaching ability is inherently a factual representation of the intrinsic laws governing teaching proficiency. To achieve autonomous capability evaluation, this study integrates convolutional neural networks to formulate a model for assessing English teaching ability.

1) *Convolutional neural network:* A CNN is an artificial neural network (structure as in Fig. 14) that consists of one or more convolution layers (convolution layer) [27], including two most important operations: convolution and pooling. The convolution layer uses the convolution operation instead of the matrix multiplication operation, which serves to detect the local connectivity of the features in the previous layer; the pooling layer serves to merge similar features [27]. The features of a CNN include 1) sparse connectivity, 2) weight sharing, and 3) pooling. The convolution operation of the convolution layer is defined as follows:

$$z_j^{(l)} = \sum_{i=1}^l w_i^{(l)} a_{i+j-1}^{(l-1)} + b^{(l)} \quad (12)$$

In this context, i signifies the identifier for the convolutional kernel, while l serves as a marker for the active convolutional layer, with $l-1$ representing its preceding layer. The dimension of the convolutional kernel is denoted by I . Post-convolution operations, the resultant feature map is referred to as $z_j^{(l)}$, which is derived from the shared weights $w_i^{(l)}$, the activation outputs of the preceding layer $a_{i+j-1}^{(l-1)}$, and adjusted by the bias term $b^{(l)}$ associated with the convolutional layer

2) *Algorithm application:* In order to portray the mapping relationship between the constructed ELT competence assessment indicators and the assessment scores, this paper adopts CNN to construct the ELT competence assessment model, as shown in Fig. 18. The algorithm applies the input as the value of English teaching ability index and the output as the assessment score and ability level.

Fig. 14. CNN network application.

IV. ALGORITHMIC APPLICATION PROCESS METHODOLOGY

This manuscript introduces an innovative approach to evaluating the proficiency in English language instruction by fusing the DPC-K-means clustering technique with convolutional neural networks (CNNs), as depicted in Fig. 15. The methodology for appraising English teaching skills is delineated through the following sequential stages:

- Step 1: A thorough analysis of the English teaching proficiency assessment is conducted, identifying key features across five dimensions—objectives, content, language, methodology, and outcomes—to forge a comprehensive indicator system for evaluation purposes;
- Step 2: Data pertaining to English Language Teaching competencies are sourced through expert deliberation, literature synthesis, and surveys, followed by a meticulous preprocessing regimen involving the 3σ criterion, imputation of missing data via proximity methods, standardization through Z-score normalization, and dimensionality reduction via principal component analysis;
- Step 3: The DPC-K-means algorithm is harnessed to perform clustering on the meticulously preprocessed indicator data, thereby categorizing the data into distinct groups;
- Step 4: The CNN framework is then engaged to cultivate the correlation between the quantified indicators of

English teaching proficiency and their corresponding assessment scores, effectively mapping the data to defined scoring echelons;

- Step 5: Validation analysis of the proposed ELT competency assessment method using the test set.

Fig. 15. Flowchart of algorithm application.

V. EXPERIMENTAL ANALYSIS

A. Experimental Environment Design

To substantiate the practicality of the English teaching ability assessment method that integrates DPC-K-means and CNN algorithms, this study scrutinizes the data collected from English teaching index measurements. In this evaluation, a quintet of algorithms has been selected for comparative analysis. Table II enumerates the configuration parameters for these comparative algorithms, with the DPC-K-means-CNN being the algorithm posited by this paper, alongside others for comparative purposes.

TABLE II. PARAMETER SETTINGS OF CLUSTERING ALGORITHM

Name	Composition method	Parameterisation
DPC-K-means-SVR	DPC-K-means SVR	SVR regularisation factor 1, kernel function is radial basis kernel function The number of K-means clusters is 5
DPC-K-means-RBM	DPC-K-means RBM	RBM with a learning rate of $10e^{-3}$ K-means clusters set to 5
DPC-K-means-ELM	DPC-K-means ELM	ELM featuring 50 nodes in the hidden layer K-means clusters set to 5
DPC-K-means-BP	DPC-K-means BP	Backpropagation (BP) training with 60 hidden layer nodes K-means clusters set to 5
K-means-CNN	K-means CNN	CNN with 100 nodes in the hidden layer network is 100, utilizing Adam's optimization K-means clusters set to 5

The experimental simulation environment uses Matlab programming language and the system is Win10.

B. Parametric Analysis

The determination of clustering precision is significantly influenced by the selection of the number of cluster centers. With the aim of enhancing the accuracy of the model and accelerating the efficiency of the assessment process, this study

delves into the impact of varying the number of clusters from two to ten on the model's accuracy, with the outcomes graphically represented in Fig. 16. A visual analysis of the figure reveals that at the threshold of five clusters, the DPC-K-means-CNN algorithm achieves the optimal precision in evaluating the capabilities of English language instruction Fig. 17 gives the results of the principal component analysis of the indicators of English proficiency assessment based on PCA technique. From

Fig. 17, when the indicator reaches 15, the cumulative contribution reaches 90 per cent.

C. Contribution of Indicators

An evaluation was conducted on the models DPC-K-means-SVR, DPC-K-means-RBM, DPC-K-means-ELM, DPC-K-means-BP, K-means-CNN, and DPC-K-means-CNN using a dataset comprising the profiles of 30 educators. The findings are detailed in Fig. 18 (a)-(f) and Tables III and IV. A review of Fig. 18 indicates that the method underpinned by the DPC-K-means-CNN algorithm outperforms others in terms of precision, with its assessment of English teaching proficiency closely mirroring the actual levels of competence.

Fig. 16. Accuracy with different number of clustering centres.

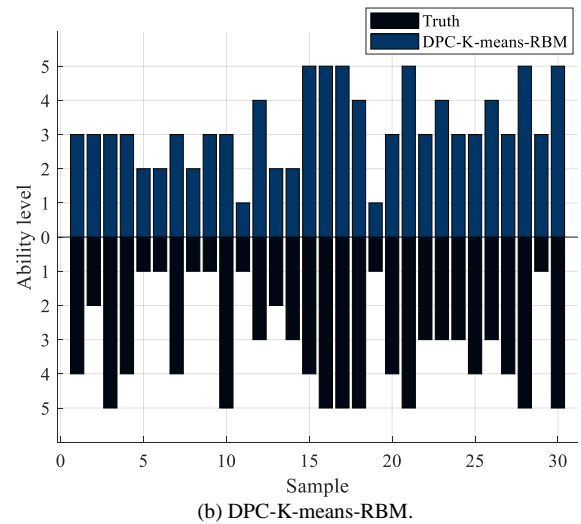

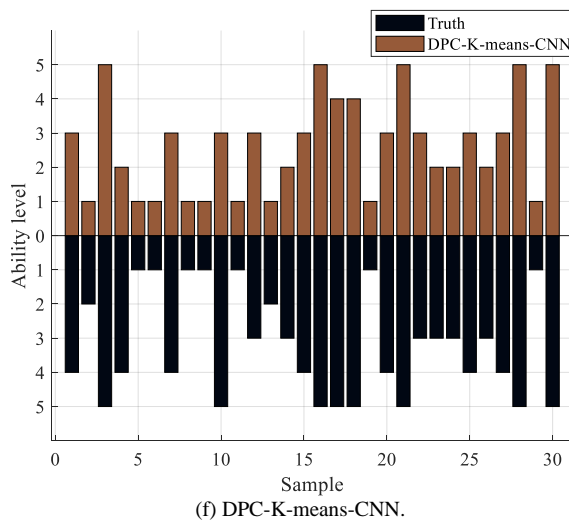

Fig. 17. Contribution of indicators.

(e) K-means-CNN.

(f) DPC-K-means-CNN.

Fig. 18. Comparison of assessment level results for different fusion assessment algorithms.

Upon examination of Table III, it is evident that the clustering of teaching ability data utilizing the DPC-K-means-CNN model yields the highest Silhouette Index (SI) value, with K-means-CNN, DPC-K-means-BP, DPC-K-means-RBM, DPC-K-means-ELM, and DPC-K-means-SVR trailing in sequence; concerning the CHI value, the DPC-K-means-CNN model demonstrates the most substantial ratio of inter-cluster to intra-cluster distance, peaking at 81.4, ahead of the DPC-K-means-BP, K-means-CNN, DPC-K-means-RBM, DPC-K-means-ELM, and DPC-K-means-SVR algorithms; regarding the Davies-Bouldin Index (DBI), the DPC-K-means-CNN algorithm exhibits the lowest average similarity score of 0.79 when comparing each cluster to its nearest cluster, outperforming alternative methodologies. A holistic assessment confirms that the DPC-K-means-CNN algorithm achieves superior clustering performance.

From Table IV, it can be seen that the DPC-K-means-CNN evaluates the best score prediction performance when analysed in terms of MAE, MAPE, and RMSE, with values of 0.0108, $2.7053e^{-04}$, and 0.0122, respectively.

TABLE III. DATA CLUSTERING RESULTS

Arithmetic	SI	CHI	DBI
DPC-K-means-SVR	0.12	34.2	1.18
DPC-K-means-RBM	0.29	56.1	1.41
DPC-K-means-ELM	0.28	37.3	1.23
DPC-K-means-BP	0.31	78.3	1.21
K-means-CNN	0.37	76.1	0.83
DPC-K-means-CNN	0.40	81.4	0.79

TABLE IV. RESULTS OF THE CAPACITY ASSESSMENT

Arithmetic	MAE	MAPE	RMSE
DPC-K-means-SVR	0.0506	1.2650e-03	0.0589
DPC-K-means-RBM	0.0323	8.0814e-04	0.0388
DPC-K-means-ELM	0.0492	1.2300e-03	0.0590
DPC-K-means-BP	0.0390	9.7548e-04	0.0447
K-means-CNN	0.0248	6.2057e-04	0.0291
DPC-K-means-CNN	0.0108	2.7053e-04	0.0122

VI. CONCLUDING REMARKS

The pursuit of an intelligent and precise system for evaluating English teaching skills stands as a pivotal aspect of the reform in English education, with the dual benefit of elevating the instructional proficiency of teachers and solidifying the neutrality of the criteria used in educational administrative decisions. This paper advances an assessment methodology that integrates clustering algorithms with advanced recognition techniques, thereby enhancing both the precision and the objectivity of the evaluation process. By dissecting the complexities inherent in assessing English teaching capabilities, the paper formulates a strategy that leverages the strengths of data clustering and optimized training routines. It presents a scheme for evaluating English teaching ability that synergizes the DPC-K-means clustering approach with the analytical prowess of convolutional neural networks (CNNs), scrutinizing the critical technologies underpinning this method. The paper introduces a novel clustering and categorization technique grounded in the DPC-K-means algorithm, complemented by an assessment methodology that harnesses the predictive capabilities of CNNs for English teaching proficiency indicators. Utilizing a dataset comprising the teaching ability indicators of 30 educators, the paper validates the proposed method's feasibility and scrutinizes its performance through established clustering and predictive metrics. The analysis affirms the proposed method's preeminence in clustering efficacy, reflected in the superior values of SI, CHI, and DBI—0.40, 81.4, and 0.79 respectively. Furthermore, the method demonstrates the minutest error in predictive assessment, with MAE, MAPE, and RMSE values recorded at 0.0108, $2.7053e^{-04}$, and 0.0122 respectively.

Abstract—Maximum Marginal Relevance (MMR) Summarization of text is very important in grasping quickly long articles particularly for people who are very busy. In this paper, we use LDA to give topic queries for news articles, which then become inputs to the MMR method. According to this paper's summarization system, the ROUGE metric is employed to evaluate the summaries of news articles with 30 percent compression and 50 percent compression. Experimental findings show that the LDA-MMR combination outperforms MMR on its own in all our tests across all query lengths or number of sentences used and gives highest average ROUGE value of 0.570 for a 50% compression rate; 0.547 at 30%. This implies that our system efficiently produces meaningful summaries using content-based keywords rather than click bait titles, which should not lead to complaints about misleading advertisements. This summarizer can convey the main points of a piece of news coverage in a concise form, thus offering people useful new tools for quickly digesting information.

Keywords—Indonesian summarization; LDA; MMR; ROUGE evaluation

I. INTRODUCTION

Natural Language Processing (NLP) is a field that combines computer methods and cognitive, seeking to make computers understand, process, or produce human language. This field entails such tasks as sentence analysis, terminology analysis, and decision-making. The usefulness of NLP is many including machine translation for instant translation between languages, electronic mail spam recognition and rejection of unwanted messages, information mining to recover relevant information from large text repositories, and chatbots as a kind of automatic customer service. An important application of NLP is the generation of automatic text summaries to produce shorter, more understandable summaries of long texts, while retaining all their essential meaning. This is particularly important with the explosion of textual data on the Internet and in digital archives [1].

By exploring and applying different methods or algorithms, automatic text summary aims to produce shorter versions of texts. These methods can be divided according to the input type (single document and multiple documents) and output type (extractive or abstractive summaries) [2]. Extractive summarization means picking sentences, phrases or sections

out of the original text, while abstractive summarization involves constructing new sentences in one's own voice which interpret or compress the essence of the original text. Extractive methods are often preferred for their simplicity and lower computational requirements vs. the more sophisticated natural language understanding and generation capabilities that are needed in abstractive techniques.

An important technique in extractive summarization is called Maximum Marginal Relevance (MMR). MMR checks sentence for their relevance to a given query and removes redundancy in a dataset containing similar content [3] while it uses the cosine similarity matrix plus Vector Space Model (VSM) to assess sentence significance. It is well suited to making summaries from both single documents and multiple. However, text queries must be made by hand, taking up a lot of time. And given the arrival of large-scale editorial systems that are now reaching their limits on efficiency through human interaction alone, automated query generation methods will therefore be needed to raise productivity and meet higher quality levels. Latent Dirichlet Allocation (LDA), a popular topic modeling technique, can uncover topics from a text corpus without any human intervention. Efficiently raising queries, the second use for LDA is to find topics hidden in a data set and model them [4]. The utilization of LDA can facilitate the streamlining of manual query generation, thereby enhancing the efficacy of the summarization process. Empirical evidence has demonstrated that the integration of LDA with other summarization techniques can markedly enhance the quality of the resulting summaries. For instance, the conjunction of LDA with MMR has been observed to yield outcomes that are superior to those obtained by either method in isolation [5].

The method proposed in this study serves an inventive approach to use LDA in conjunction with MMR constructed along the lines of an algorithm for efficient summary-making Indonesian news articles. It begins by using LDA to reveal the most important themes present in each article and then builds queries for MMR onto these constituent word distributions This no-nonsense approach is designed to make the summaries both brief and germane to the essence of the articles themselves, so that even if they give little by way of clue,

* Corresponding author

within five minutes readers will already gain some understanding about what contents this news offers [6].

In summarizing Indonesian text, LDA and MMR approaches have never been comprehensively challenged. Although past studies have demonstrated that both methods are effective enough in themselves, the uniqueness of news topics and characteristics requires their combined use to completely handle [7]. Our aim is to bridge this gap, utilizing the strengths of both LDA and MMR with the same final goal of getting better quality and relevance on resulting summaries.

The present research aims at creating an automatic summarization system that employs LDA for topic modeling and then MMR for extractive summarization, to generate accurate summaries of Indonesian news articles. By offering concise language summaries focused on the topic, this method is intended to improve the efficiency of retrieving information and also promote a better reading experience for people who need it. The novelty and contribution of this paper lies in combining LDA and MMR. This is expected to push forward the development of text summarization models as an efficient approach for managing large amounts of data.

The remainder of this paper is organized as follows: Section II provides an in-depth literature review, analyzing various current methods and their limitations. In Section III, we describe the method we propose by combining Latent Dirichlet Allocation (LDA) with Maximum Marginality Relevant (MMR) for text summarization. Section IV outlines the experimental settings, while in Section V we report results along with a discussion of them. Comparison is given in Section VI. Finally, Section VII and VIII concludes the paper and points out future research directions.

II. LITERATURE REVIEW

Most of the contemporary means developed for automatic summarization are made to supply summaries at least on par with these extracted by people. Most of this research has focused on high-resource languages, although there are some studies for low-resource language such as Indonesian. This summarization has shown state of the art results in LDA, MMR: two example techniques that have successfully been applied to automatic text summarization across various languages.

Saikumar and Subathra (2020) introduced a set of summarization method using LDA, MMR and Text Rank (TR), proving that the generated summaries are much precise comparing to standalone use of MMR or TR techniques. Finally, the performance of this two-level document summarization (DS) method with LDA was compared to that based on MMR and TR [3]. TextRank and MMR were integrated to be used for summarization of Indonesian news articles by Gunawan, Harahap & Rahmat (2019) [8].

Tuhpatussania, Utami and Hartanto in 2022 [9]: In their work on summarization of online Indonesian news text they have compared the performance between LexRank dan MMR Algorithm: proof that mmmr is better than lexrank for precision, recall and f-measure. Musyaffanto, Herwanto and Riassetiawan (2019), on the other hand integrated MMR with

Nonnegative Matrix Factorization (NMF) to ensure precision of online news articles [10].

LDA has been applied to text analysis problems in other research areas as well. To summarize Malayalam news documents closer to what human makes, Kondath, Suseelan and Idicula (2022) used LDA [5]. Rahman et al. (2021) used LDA to create summaries from Malay news documents that showed how system-generated news can save readers' time [6].

The other one is hybrid models for text summarization. Hybrid Approach Gurusamy, Rengarajan and Srinivasan [7] proposed a hybrid approach to this problem that combines semantic LDA and sentence concept mapping with transformer models for generation of coherent text summaries. LISJANA et al. [11], 2020 Classifiers used: They have also applied LDA classifiers with Latent Semantic Indexing (LSI), Similarity-Based Histogram Clustering (SHC) for multi-document text summarization.

Studies for enhancing MMR have started gaining momentum as well. Zheng, Liu, and Qin proposed an improved MMR algorithm that uses Word2Vec, TextRank with semantic information to make text summarization more efficient. [12]. Ramezani et al. (2023) [13] compared LSA vs. MMR in summarizing Persian broadcast news transcriptions, demonstrating LSA's superiority in generic summarization [13].

The above studies point to several research gaps which this study intends to address. Several studies have shown that LDA or MMR, both individually and combined with the other methods, are effective at detecting significant information in a document, but there is no unified approach combining these two aspects: prior to this study not yet proposed any research for Indonesian text summarization task. Besides, current studies usually do not consider the practical difficulty to generate concise summaries over articles of different subjects. This research tries to solve this problem by creating a new summarization method that combines the use of LDA (TextSum) and MMR, for Indonesian article summary generation can be done better with more relevant topics.

III. PROPOSED METHODOLOGY

Fig. 1 shows our proposed hybrid approach using Latent Dirichlet Allocation (LDA) and Maximum Marginal Relevance (MMR) in an Indonesian article summarisation system. It starts with the pre-processing of text documents, which consists of performing all the important steps needed to clean the data and make it ready for analysis. First, the text is broken down into small units such as sentences or words. Next, lowercase (): applies case folding to normalise the text by converting all characters to lowercase. Cleanup: removes all characters irrelevant to the analysis, such as unimportant symbols, punctuation or special characters. This is followed by the removal of stop words, which are common words that do not add any useful information to the summarisation process. The last step in the pre-processing is the stemming, where words are reduced to their root forms, so that different variants of a word can be treated equally.

In this step, the processed text is analysed using a technique called Latent Dirichlet Allocation and then Maximum Marginal

Relevance. We start by using LDA to find the natural topics in the text, which gives us an experienced explorer's view of what kind of information we want. A generative probability model helps to identify the content of the document, and it uses only key topics or words used to describe a single topic from the rest that was scattered. On the other hand, Maximum Marginal Relevance will select the sentences that are most relevant to the given query, i.e. the summary will be both comprehensive and contextually satisfying for the user. The combination of LDA and MMR helps to summarise the given text by capturing what is important in the text data. This dual approach not only increases summarisation accuracy, but also ensures that the output is contextually relevant and insightful optimizing real-world performance.

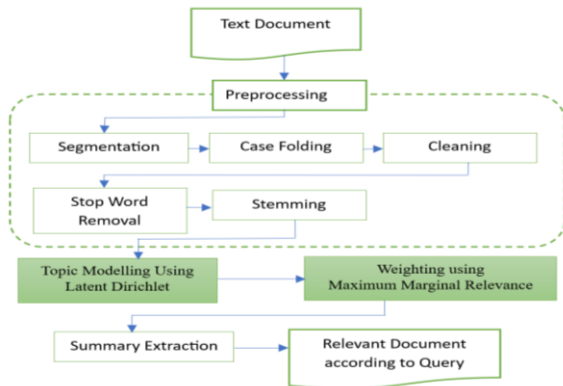

Fig. 1. Proposed system.

A. Dataset

Experimentally, we conducted the research on IndoSum dataset [14]. It was used in the current research. This corpus consists of around 14,290 news articles along with titles in which all are categorized into six classes (see Fig. 2) from ten different sources of the Indonesian press released to public [14]. The article URL and summary abstracts separately written by two native Indonesian speakers [14]. Rini Wijanti et al. used this dataset in their research [15]. Fig. 3 shows source of news.

The study carried out two testing experiments. This shown in experiment 2, reaching the best ROUGE measure by applying stemming without stopwords removal on test data.

B. Pre-processing

The preprocessing step is responsible for improving the structure of the input data. Preprocessing in NLP often involves tokenization. However, in this paper, we used data from the IndoSum dataset where tokenization has already been performed. Therefore, we can avoid repeating the process of tokenization in this study. Each paragraph consists of a list of clauses, with each clause containing a list of words (token). Segmentation, tokenization, case folding, stop word removal, stemming.

C. Segmentation

In the segmentation process, any paragraph separator is removed so that articles are divided directly on per sentence basis for further processing. During this stage, all paragraphs

within each article are combined and then divided into individual sentences by the segmentation process. As a result, each article has sentences, and in turn the sentence will contain words or Tokens.

D. Case Folding

Stage 2 - Case folding at this stage of the preprocessing, we have to convert all uppercase words to lowercase. This process will help to avoid any confusion in the meaning of a word based on whether it's capitalized or not. Step 6 - Lower case processing of the segmentation output (sentence list with tokenized sentence) at the end of this process, we have a list of lowercase words.

E. Cleaning

After tokenization, the third step is data cleaning: This is because only characters are needed for input, not punctuation or numerals, so characters other than letters are removed from the record. And then they have a data cleansing purpose to remove other academic input needed for the program by keeping only clean text as input.

F. Stop Removal

The fourth stage is the elimination of stop words, which is the identification and elimination of words that are common and occur frequently in the text, but often without providing important information. Removing stop words is primarily aimed at cleaning up text and improving text analysis/modelling quality. It is useful to remove keywords to focus the analysis on more relevant or significant words. An example of stopword is a conjunction. Each token is checked whether it is on the stopword list or not, if it is, the token is deleted and not included in the next process. If it is not on the stopword list, it is passed on to the next process.

Fig. 2. Category of news.

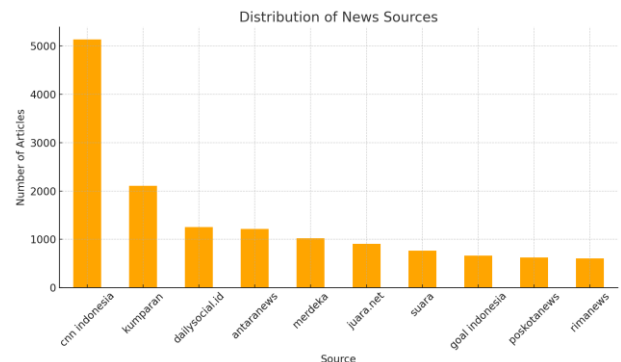

Fig. 3. Source of news.

G. Stemming

The next stage is stemming, which is a process in which words are transformed into their most basic forms. Removing inflections or affixes to ensure a consistent representation of words with a common root is the main goal of stemming. Each token is cross-referenced with the base word lexicon. If a token is missing, it is identified as an affixed word and stemming is initiated by deleting suffixes (-lah, -kah, -ku, -mu, -nya, -tah or -pun). Next, derivative affixes (-i, -kan, -an) are removed, followed by the removal of prefix affixes (be-, di-, ke-, me, pe-, se- and te-).

H. Final Preprocessing

The stemming process is carried out in the final preprocessing stage. The list of tokens will be transformed in this way. All empty strings and lists left over from the previous steps are removed in this final preprocessing step.

I. Latent Dirichlet Allocation

LDA is commonly used when the topics of the papers tend to cluster around a single focus. They are also used to produce topic model results in information technology papers, including domain-specific documents like research papers, news stories, and patents [16] [17] [18]. By using LDA on a set of documents, we can determine the distribution of hidden topics both across the set and within each individual paper. Each topic has its own probability distribution of words attached to it. It is a type of statistical modelling designed to represent the probability distribution of a set of data. This model is useful for generating new data [19], as it can generate data similar to the training data.

LDA models are shown in Fig. 4.

Fig. 4. Graphical representation of the smoothed LDA model [20].

The image shows the Latent Dirichlet Allocation (LDA) model, a generative statistical approach to uncover hidden thematic structure in text documents. The main elements of the model are α , θ , η , β_k , z and w . The hyperparameters α and η affect the distributions of topics and words respectively. θ denotes the topic proportions for a document derived from a Dirichlet distribution with parameter α . β_k represents the word distribution for a topic derived from a Dirichlet distribution with parameter η . The generative process involves selecting a topic z from θ and then a word w from β_k , thereby linking words to topics and topics to documents [21].

Recent advances in LDA have addressed several challenges and expanded its applications. The empirical prior LDA (epLDA) model, which uses latent semantic indexing to obtain

priors from the data, has shown notable improvements over the traditional LDA model [22].

The equation illustrates the joint probability distribution in Latent Dirichlet Allocation (LDA), a generative probabilistic approach to topic modelling. This model reveals thematic structures within a collection of documents by decomposing the joint probability into several elements: β_k (word distributions for each topic), θ_d (topic distributions for each document), Z_D (topic assignments for each word), and W_D (observed words). The hyperparameters α and η determine the Dirichlet priors for the topic and word distributions. This relationship is expressed in Eq. (1).

$$p(\beta_k, \theta_d, Z_D, W_D | \alpha, \eta) = \prod_{k=1}^K p(\beta_k | \eta) \prod_{d=1}^D p(\theta_d | \alpha) \prod_{d=1}^D p(Z_{d,n} | \theta_d) p(W_{d,n} | Z_{d,n}, \beta_{d,k}) \quad (1)$$

This product-based formula incorporates several essential elements: the distributions of words within topics (β_k), the distributions of topics within documents (θ_d), the topic assignments for each word in each document ($z_{d,n}$), and the observed words in the documents ($w_{d,n}$).

In this model, $\beta_{1:K}$ represent the topic-word distributions, which are influenced by the parameter η and which determine the likelihood of words given topics. The term $\theta_{1:D}$ denotes the document-topic distributions, which are influenced by the parameter α and which determine the likelihood of topics given documents. The term $p(\beta_{k,h})$ denotes the probability of the word distribution for topic k given the Dirichlet prior η , while $p(\theta_d/\alpha)$ is the probability of the topic distribution for document d given the Dirichlet prior α . The term $p(z_{d,n}/\theta_d)$ represents the probability of assigning the n -th word in document d to a topic, based on the topic distribution for that document.

Finally, $p(w_{d,n} / z_{d,n}, \beta_{d:k})$ represents the probability of the n -th word in document d being assigned to topic $Z_{d,n}$, given the aforementioned topic assignment and the word distribution for that topic, β_k . Recent advances in the latent Dirichlet allocation (LDA) approach have led to the introduction of enhanced models and methodologies, including the empirical prior latent Dirichlet allocation (epLDA) and StreamFed-LDA. The epLDA model improves the computation of topics by employing latent semantic indexing to derive priors from data, thereby enhancing prediction accuracy [22].

• Hyperparameter Selection and Impact

The selection of hyperparameters in Latent Dirichlet Allocation (LDA) has a significant impact on the quality of the results, particularly in terms of topic coherence and relevance. In this study, the value of α (the Dirichlet prior for the distribution of topics per document) was set to $1/K$, where K is the number of topics, and η (the Dirichlet prior for the distribution of words per topic) was set to $1/V$, where V is the vocabulary size. These values were selected to ensure a balanced distribution of topics across documents and words across topics. The parameter α regulates the diversity of topics within a document; higher values of α result in more uniform topic distributions, thereby enabling documents to encompass a broader range of topics. Conversely, the influence of the parameter η on the distribution of words within each topic is inverse. Lower values of η result in sparser distributions, which

in turn produce more focused and distinctive topics. The preliminary experiments demonstrated that varying α and η has a significant impact on the coherence of the topics and the relevance of the summaries produced. Further research could involve a more comprehensive investigation of these hyperparameters to enhance LDA performance in diverse contexts.

J. Maximum Marginal Relevance

The Maximum Marginal Relevance (MMR) algorithm is a well-established method in the field of information retrieval. The algorithm calculates a linear combination that includes both the relevance of the documents to the query and their similarity to previously chosen documents for summarization. This measure, known as 'edge correlation', is optimized during the retrieval and summarization processes to refine the final summary iteratively [23][24]. MMR summarizes text by evaluating the similarity between different parts of the text, showing efficiency in retrieving relevant information and uncluttering content. It identifies documents that match a specific query by combining two criteria: relevance and heterogeneity.

MMR summarizes text by evaluating the similarity between different parts of the text, thereby demonstrating efficiency in the retrieval of relevant information and the uncluttering of content. The method identifies documents that match a specific query by combining two criteria: relevance and heterogeneity.

In this framework, a linear combination is calculated in order to integrate a document's relevance to the query and its similarity to pre-selected documents for summarization. This metric, designated as 'edge correlation', is calibrated during the retrieval and summarization phases to incrementally refine the final summary. MMR employs a methodology whereby content is described by assessing the degree of similarity between text segments. This demonstrates the ability of the method to retrieve related data and avoid redundancy.

MMR employs a ranking system based on a combination of cosine similarity matrices in response to a given query. The calculation entails a comparison of the results pertaining to the relevance of the query with those concerning the similarity of sentences. A document is deemed to possess high marginal relevance if it exhibits a strong alignment with the document content and a high degree of similarity with the query. The MMR score can be calculated using the following Eq. (2) [25].

$$MMR = \operatorname{argmax} [\lambda * \operatorname{Sim}_1(S_i, Q) - (1 - \lambda) * \max \operatorname{Sim}_2(S_i, \text{Summ})] \quad (2)$$

In this context, S_i represents the candidate sentence, and Q is the query or main topic. The parameter λ (which ranges from 0 to 1) serves to regulate the equilibrium between relevance and diversity. The term $\operatorname{Sim}_1(S_i, Q)$ is employed to ascertain the degree of similarity between the candidate sentence S_i and the query Q , thereby ensuring that the selected sentences are highly relevant. The term $(1 - \lambda) \cdot \max \operatorname{Sim}_2(S_i, \text{Summ})$ is employed to ascertain the maximum similarity between the candidate sentence S_i and the sentences that have already been included in the summary. This serves to minimize redundancy.

In this context, the term " S_i " represents a sentence within the document, whereas "Summ" refers to the selected or extracted sentences. The relevance of a sentence is determined, and redundancy is minimized through the utilization of the coefficient λ .

The parameter λ is defined in the range of 0 to 1. When λ equals one, the MMR value is more pertinent to the original document. Conversely, when λ equals zero, the MMR value is more aligned with the previously extracted sentences. It is therefore recommended that λ be adjusted within this range to achieve optimal summarization. In the case of shorter texts, such as articles, the optimal value for λ is generally considered to be 0.7, which yields effective summary results [25].

IV. EXPERIMENTAL RESULTS

The experiment was conducted on the initial 50 article data entries within the train.03 JSON file, which forms part of the IndoSum dataset. The test scenario was conducted on articles 1 to 50 to ascertain the ROUGE-1 value for each system-generated summary. Prior to the generation of summaries, each article was subjected to topic modelling using the Latent Dirichlet Allocation (LDA) technique, which yielded one topic and ten keywords. In the LDA topic modelling process, the alpha value was set to $1/K$ and the eta value was set to $1/V$. The ten keywords were then employed as queries to generate summaries utilizing the Maximum Marginal Relevance (MMR) method. The MMR summarization process was conducted with three different lambda values, as follows: The values of 0.5, 0.7, and 0.9 were employed. The resulting summaries comprised either 50% or 30% of the total sentences in the original text.

A series of tests were conducted to compare the quality of human-generated summaries with those produced by the system. To obtain recall, precision, and F1-score values, this research employs the ROUGE-1 evaluation method. The greater the degree of alignment between the system summary and the human summary, the higher the recall value. Should the recall value attain its maximum value or a value of 1, it signifies that the entirety of the human summaries will be incorporated into the system summary. Conversely, if the precision value reaches the maximum value or 1, then the entire system summary will be included in the human summary. The combination of recall and precision, namely the F1-score, provides an overall picture of the system's ability to capture and present appropriate and relevant information in its summary.

The experiment was conducted using three values of λ : 0.5, 0.7, and 0.9. The results of Experiment 1 are presented in Table I.

TABLE I. ROUGE-1 EVALUATION RESULT EXPERIMENT 1ILDRMMR

λ	Compression rate		
	50%		
	Average Recall	Average Precision	Average F1-Score
$\lambda = 0.5$	0.863	0.402	0.534
$\lambda = 0.7$	0.865	0.404	0.536
$\lambda = 0.9$	0.864	0.402	0.535

Table I illustrates the Rouge-1 assessment outcomes for Experiment 1LDRMMR, which evaluates a document summarisation system at a 50% compression rate utilising diverse values of the smoothing parameter, lambda (λ). In this comparison, the following metrics are considered: recall average, precision average and F1 score average for λ values of 0.5, 0.7 and 0.9. As λ increases, there is a modest enhancement in recall average, from 0.863 to 0.865, before a slight decline to 0.864. The value of the Precision Average is observed to increase from 0.402 to 0.404 at $\lambda = 0.7$ and then to remain at this level of 0.402 when $\lambda = 0.9$. The F1-score average, which weighs precision and recall equally, demonstrates the most optimal performance at $\lambda=0.7$. It increases from 0.534 to 0.536 and then experiences a slight decrease to 0.535.

Fig. 5. Rouge-1 evaluation result experiment 1LDRMMR.

The graph in Fig. 5 demonstrates these trends, indicating that an increase in λ generally enhances the system's performance, with the optimal λ value being 0.7. At this value, the system attains the optimum balance between recall and precision, resulting in the highest F1 score. These findings suggest that while higher λ values produce marginal improvements in performance, the gains plateau beyond $\lambda=0.7$, indicating an optimal range for λ to optimise summarisation quality.

Additionally, in the second experiment, an evaluation was conducted with the results presented in Table II.

TABLE II. ROUGE-1 EVALUATION RESULT EXPERIMENT 2LDAMMR

λ	Compression rate		
	30%		
	Recall Average	Precision Average	Average F1-Score
$\lambda = 0.5$	0.778	0.485	0.580
$\lambda = 0.7$	0.775	0.484	0.578
$\lambda = 0.9$	0.781	0.486	0.581

The results of the Rouge-1 evaluation for the 2LDAMMR experiment, with a compression rate of 30%, are presented in Table II. The table presents a comparison of three distinct λ values: These values were 0.5, 0.7, and 0.9. For $\lambda = 0.5$, the recall average is 0.778, the precision average is 0.485, and the average F1-measure is 0.580. When $\lambda=0.7$, a slight decrease is observed in the Recall Average (to 0.775), while the Precision Average remains almost unchanged (at 0.484). The Average

F1-Measure also decreases, albeit to a lesser extent (to 0.578). At $\lambda=0.9$, the recall average increases to 0.781, the precision average rises slightly to 0.486, and the average F1-measure also increases slightly to 0.581.

It can be concluded from these results that the λ value influences the evaluation metrics. While the changes observed are minor, higher λ values tend to result in slight improvements in both the Recall Average and Precision Average. However, these changes are not significant and there is consistency in the Average F1-Measure, indicating that the model demonstrates stable performance across different λ values. For a more comprehensive visual representation, please see the graph below, which illustrates the comparison of the metrics for each λ value.

Here is the graph that illustrates the comparison of metrics for each λ value in greater detail, as shown in Fig. 6.

Fig. 6. Graph rouge-1 evaluation result experiment 2 LDAMMR.

Fig. 6 depicts the performance of Recall Average, Precision Average, and Average F1-Measure across λ values of 0.5, 0.7, and 0.9 for the 2LDAMMR experiment with a 30% compression rate. The Recall Average demonstrates a slight increase with elevated λ values, indicating enhanced recall capability, whereas the Precision Average remains stable, suggesting consistent precision. The Average F1-Measure, representing the harmonic mean of precision and recall, also shows minimal variation, indicating balanced performance. Overall, increasing λ results in minor improvements in recall and F1-Measure, demonstrating the model's robustness and consistent performance across the tested λ range.

Experiments were also conducted using MMR with title queries with the same dataset and λ value of 1, the results of which can be seen in Table III and Table IV.

TABLE III. ROUGE-1 EVALUATION RESULT EXPERIMENT 1MMR

Experiment 1MMR	Compression rate		
	50%		
	Average Recall	Average Precision	Average F1-score
1 ($\lambda = 0.5$)	0.843	0.407	0.536
2 ($\lambda = 0.7$)	0.843	0.407	0.536
3 ($\lambda = 0.9$)	0.843	0.407	0.536

Table III presents the findings of the evaluation conducted on the 1MMR experiment, utilizing a compression rate of 50%. Three distinct λ values (0.5, 0.7, and 0.9) were subjected to

evaluation. The results for Recall Average, Precision Average, and Average F1-Measure are consistent across all λ values. The Recall Average remains at 0.843, the Precision Average at 0.407, and the Average F1-Measure at 0.536 for each λ value. This consistency suggests that the λ parameter does not significantly affect the model's performance under these conditions.

TABLE IV. ROUGE-1 EVALUATION RESULT EXPERIMENT 2MMR

Experiment 2MMR	Compression rate		
	30%		
	Average Recall	Average Precision	Average F1-score
1 ($\lambda = 0.5$)	0.680	0.460	0.536
2 ($\lambda = 0.7$)	0.680	0.460	0.536
3 ($\lambda = 0.9$)	0.680	0.460	0.536

Table IV presents the results of the evaluation of the 2MMR experiment with a 30% compression rate. Once more, three distinct λ values (0.5, 0.7, and 0.9) are subjected to examination. As with the 1MMR experiment, the results for Recall Average, Precision Average, and Average F1-Measure are consistent across all λ values. The recall average is 0.680, the precision average is 0.460, and the average F1-measure is 0.536 for each λ value. The consistency across different λ values indicates that the λ parameter does not significantly impact the model's performance in the 2MMR experiment.

Fig. 7. Rouge-1 evaluation result experiment 1MMR.

Fig. 8. Rouge-1 evaluation result experiment 2MMR.

Fig. 7 and Fig. 8 present a graphical representation of the performance of Recall Average, Precision Average, and Average F1-score across λ values of 0.5, 0.7, and 0.9 for both the 1MMR experiment with a 50% compression rate and the

2MMR experiment with a 30% compression rate. In the case of the 1MMR experiment, all metrics remain constant regardless of λ . The values for these metrics are as follows: Recall Average at 0.843, Precision Average at 0.407, and Average F1-Measure at 0.536. Similarly, in the 2MMR experiment, the metrics demonstrate no variation with different λ values, maintaining a Recall Average of 0.680, a Precision Average of 0.460, and an Average F1-Measure of 0.536. This consistency across both experiments indicates that λ has a negligible impact on model performance in these scenarios. At a 50% compression rate, 1MMR achieves a higher recall than 2MMR at a 30% compression rate.

TABLE V. COMPARISON BETWEEN MMR AND LDAMMR

Methods	F1-score Average	
	Compression Rate 50%	Compression Rate 30%
MMR	0.536	0.536
LDA & MMR	0.536	0.581

Table V presents a comparison of the average F1-score between two methods. The study compares the effectiveness of two approaches to text compression: Maximal Marginal Relevance (MMR) and a combined approach of MMR and Latent Dirichlet Allocation (LDA), applied at two different compression rates, 50% and 30%.

The average F1-score for the MMR method remains constant at 0.536 for both compression rates of 50% and 30%. This consistency indicates that the performance of MMR alone is not affected by different levels of compression, suggesting that MMR is robust in maintaining its effectiveness regardless of the compression rate applied.

In contrast, the combination of MMR and LDA yielded a notable enhancement in the average F1-score at the 30% compression rate, which increased to 0.581. However, at the 50% compression rate, the combination yields the same average F1-score of 0.536 as MMR alone. This suggests that the incorporation of LDA with MMR improves performance, particularly at the lower compression rate of 30%. This implies that LDA provides supplementary contextual information, enhancing the model's efficacy when the data is more condensed.

The experiments conducted utilising MMR with LDA queries yielded superior ROUGE-1 evaluation scores in comparison to those employing MMR with title queries. However, both systems exhibit a commendable ROUGE-1 score. According to Deutsch, the discrepancy in ROUGE-1 scores below 0.5 between systems is less indicative of the human perception of the same two systems [26].

The results presented in Table V illustrates that while the MMR method demonstrates consistent performance across varying compression rates, the integration of MMR with LDA markedly enhances the Average F1-Score at the 30% compression rate. This suggests that LDA improves MMR's capacity to capture pertinent information in a more condensed dataset. The consistency of results at the 50% compression rate indicates that the advantages of LDA are more evident when dealing with higher levels of data compression.

Fig. 9 illustrates the comparison of the Average F1-Score for each method under both compression rates.

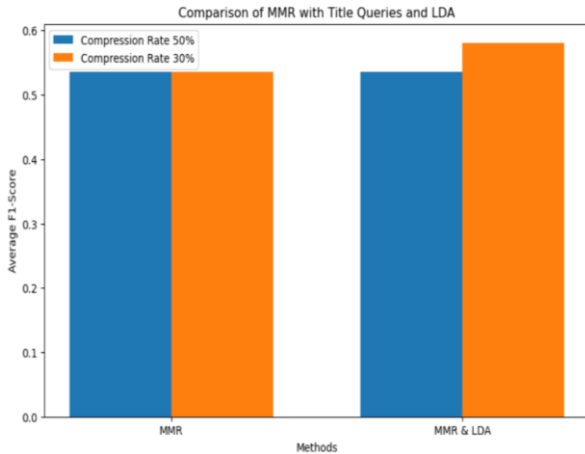

Fig. 9. Comparison of MMR with title query and LDA.

V. DISCUSSION

The combination of Latent Dirichlet Allocation (LDA) and Maximal Marginal Relevance (MMR) offers notable advantages that make it a more effective approach than traditional text summarisation techniques. Although MMR has been extensively employed for the selection of pertinent sentences based on title queries, its principal limitation resides in its reliance on manually crafted or title-based queries, which frequently impede the precision of the resulting summaries, particularly when the article title does not fully encapsulate the content.

The incorporation of LDA enables the generation of contextually rich topic queries, which results in summaries that more accurately represent the contents and themes of the articles. This is especially advantageous in cases where article titles may be deceptive or inadequate in representing the actual content, such as in the context of clickbait headlines.

The combination of LDA and MMR has been demonstrated to achieve a higher F1-score at a 30% compression rate, indicating an improvement in both the quality and relevance of the summaries. These findings indicate that the proposed method is not only effective for summarising Indonesian news articles but could also be adapted to other languages and document types, thereby enhancing its overall applicability and versatility.

This approach represents a significant step forward in the creation of more accurate and contextually relevant summaries, particularly in cases where traditional methods may be inadequate.

VI. COMPARISON

The objective of this research is to develop a document summarization system that can extract the essential information from documents. The study presents a distinctive profile when compared to the various methods and tests identified in other studies. Table VI provides a summary of these differences. In their study [3] employs the Two-Level LDA method with

customer opinion data on products and hotels, comparing LDA with MMR and TR. In contrast, our study employs the LDAMMR method and compares it solely with MMR. In contrast to the study [9] employs solely the MMR method, without comparison to other techniques. In contrast to the studies [6] does not undertake a comparative analysis; instead, it focuses on summarizing Malay language news articles using LDA. In their study [25] employed MMR and VSM to summarize students' final project abstracts. While existing research has demonstrated the effectiveness of LDA and MMR individually or in combination with other methods, there remains a lack of comprehensive approaches that specifically integrate LDA with MMR for summarizing Indonesian news articles. Additionally, existing studies often fail to thoroughly address the challenges of summarizing articles that cover a wide range of topics.

TABLE VI. TEXT SUMMARIZATION COMPARATIVE STUDY

References	Object	Methods	Comparison methods	ROUGE-1 Results (F1-Score)
[3]	Two categories: products, hotels	Two Level LDA	Compare with MMR and TR summarization techniques	Not provided
[9]	Indonesian News Article	MMR	Not compare	Not provided

Ours	Four Category Indonesian News Article	LDAMMR	Compare LDA vs LDAMMR	0.536 (50% compression) 0.581 (30% compression)

VII. CONCLUSION

The integration of Latent Dirichlet Allocation (LDA) with Maximum Marginal Relevance (MMR) has been demonstrated to enhance text summarization. This is achieved by generating more accurate and relevant queries, reducing redundancy, and providing a contextual understanding of the document's themes. This combination of techniques improves efficiency through the automatic generation of queries, while maintaining a balance between precision and recall. The results of the research demonstrate that while MMR exhibited a constant average F1-score of 0.536, the integration of LDA resulted in an increase to an average F1-score of 0.581 at a 30% compression rate. This illustrates that LDA augments MMR's capacity to capture pertinent information in a more efficacious manner, thereby rendering summaries more succinct and contextually pertinent, particularly in the case of diverse and evolving subject matter such as Indonesian news articles.

The potential for application in multiple languages is a further advantage of this approach.

This passage presents the findings of a study on the summarization of Indonesian news articles, employing a methodology that is not language specific. The key techniques employed, namely Latent Dirichlet Allocation (LDA) and Maximal Marginal Relevance (MMR), are language-agnostic, meaning that they can be applied to different languages with some adjustments. These modifications include the adaptation of preprocessing procedures, such as tokenization, stopword removal and stemming, to align with the linguistic characteristics of the target language. The study posits that this approach could prove beneficial for languages with limited resources, where sophisticated text summarization tools are not as readily accessible. Furthermore, it urges future research to apply this methodology to multilingual datasets, which could facilitate the advancement of more versatile and globally applicable summarization techniques.

VIII. FUTURE WORK

The encouraging outcomes of this study suggest several avenues for future research. One avenue for further research would be to explore alternative topic modelling techniques, such as non-negative matrix factorisation (NMF) or latent semantic analysis (LSA), to ascertain whether they can enhance the quality of summaries even further. Furthermore, applying this method to a broader range of document types, including legal texts, scientific articles, or social media content, could serve to test its versatility and robustness across different contexts. Another promising avenue for future research is the integration of this method with transformer-based models, such as BERT or GPT, to develop a hybrid approach that combines the strengths of both extractive and abstractive summarisation. This could result in the generation of more coherent and contextually rich summaries, thereby advancing the state of the art in automatic text summarisation. Furthermore, adapting this model for real-time or streaming data could make it a valuable tool for dynamic content summarisation, providing immediate insights in fast-paced environments such as newsrooms or social media monitoring.

Research on Traffic Flow Prediction Using the MSTA-GNet Model Based on the PeMS Dataset

Deng Cong

Sichuan Communications Vocational and Technical College, Chengdu Sichuan, 611130, China

Abstract—This study introduces the MSTA-GNet (Multi-Scale Spatiotemporal Attention Graph Network), a novel deep learning model which integrates spatiotemporal self-attention mechanisms to model heterogeneous dependencies in traffic networks. The primary objective of the study is to improve existing traffic flow prediction models to address the inadequacies of traditional models in complex big data environments. Key innovations of the MSTA-GNet model include positional encoding and global and local self-attention mechanisms to capture long-term and short-term dependencies. Using the PeMS (Performance Measurement System) dataset, the study conducted performance comparison experiments among various deep learning models, including LSTM (Long Short-Term Memory), GCN (Graph Convolutional Network), DCRNN (Diffusion Convolutional Recurrent Neural Network), STGCN (Spatiotemporal Graph Convolutional Network), STMetaNet (Spatiotemporal Meta Network), and MSTA-GNet. The results showed that MSTA-GNet significantly outperformed other models with improvements of 13.4%, 11.8%, and 9.7% in Mean Absolute Error (MAE), Root Mean Square Error (RMSE), and Mean Absolute Percentage Error (MAPE) metrics, respectively. Ablation studies further validated the significance of attention mechanisms, feature extraction, convolutional layers, and graph networks, confirming the effectiveness and practical application of MSTA-GNet in traffic flow prediction. This research provides important insights for AI-based congestion management, support for low-carbon traffic networks, and optimization of local traffic operations, demonstrating its significant practical value in intelligent transportation systems.

Keyword—MSTA-GNet; deep learning; PeMS dataset; traffic flow prediction

I. INTRODUCTION

Over the past three decades, rapid urbanization and infrastructure development have led to significant traffic challenges in many parts of the world, with extensive motorway networks and a surge in vehicle ownership. Traditional traffic flow prediction models struggle to handle the complexities of these large-scale datasets, highlighting the need for advanced artificial intelligence (AI) technologies like deep learning. This paper introduces MSTA-GNet, a novel transformer model explicitly designed for traffic flow prediction [1-4]. This model incorporates multiple spatiotemporal self-attention mechanisms, effectively capturing the intricate spatiotemporal dependencies and nonlinear dynamics inherent in traffic data. MSTA-GNet provides a comprehensive understanding of traffic flow patterns by integrating spatiotemporal information with road network data. The model has demonstrated exceptional performance on motorway networks within major

metropolitan areas [5-7]. This approach holds great promise for enhancing AI-driven congestion management strategies, promoting eco-friendly transportation systems, and optimizing local traffic operations, ultimately showcasing its significant practical value for intelligent transportation systems.

The motivation behind developing MSTA-GNet stems from several critical challenges in current traffic flow prediction models. First, the increasing complexity of urban traffic systems, coupled with the growing availability of big data, necessitates more sophisticated modeling approaches. Traditional methods often fall short in capturing the intricate spatiotemporal dependencies inherent in traffic patterns, especially in large metropolitan areas with complex road networks. Second, there is a pressing need for models that can adapt to real-time changes in traffic conditions, such as those caused by accidents, construction, or special events. MSTA-GNet addresses these challenges by leveraging advanced deep learning techniques to process multi-scale temporal and spatial information simultaneously.

The potential benefits of our proposed approach are manifold. By improving the accuracy of traffic flow predictions, MSTA-GNet can contribute significantly to more efficient urban traffic management. This could lead to reduced congestion, lower emissions, and improved quality of life in cities. Furthermore, the model's ability to capture both short-term fluctuations and long-term trends makes it valuable for both immediate traffic control decisions and long-term urban planning. The interpretability features of MSTA-GNet also offer insights into the factors influencing traffic patterns, which can inform policy decisions and infrastructure development. Ultimately, our approach aims to enhance the overall efficiency and sustainability of urban transportation systems, aligning with smart city initiatives and sustainable urban development goals.

Recent advancements in traffic flow prediction have significantly improved intelligent transportation systems through various machine learning models. Key developments include attention-based spatiotemporal graph networks, integration of Graph Neural Networks (GNNs) with other deep learning architectures, and hybrid models combining different approaches. Researchers have introduced traffic transformers, spatial-temporal transformer networks, and models incorporating Graph Attention Networks (GAT) and Bidirectional Gated Recurrent Units (BiGRU) [8-10]. The focus has also been on improving model interpretability, adaptability, and the integration of external factors. Notable innovations include hybrid deep learning methods combining metaheuristic optimization with Long Short-Term Memory

(LSTM) and approaches using Cellular Automata-based models with Convolutional Neural Network-Long Short-Term Memory (CNN-LSTM) architectures. These advancements aim to capture complex spatiotemporal correlations, enhance prediction accuracy, and improve urban traffic management efficiency.

Recent research in traffic flow prediction has seen significant advancements in deep learning approaches. Lu et al. [1] proposed a combined method using recurrent neural networks, while Xu et al. [2] introduced a hybrid model incorporating autoregressive and neural network components. Ma et al. [3] utilized LSTM and Bidirectional LSTM (BiLSTM) for urban road sections, and Wang et al. [4] developed a dynamic spatiotemporal framework. Graph-based models have gained prominence, with Zhou et al. [7] reviewing graph neural network approaches. Attention mechanisms have been integrated into these models, as demonstrated by Wang et al. [16] and Gao et al. [18]. Transformer-based models, such as those proposed by Cai et al. [25] and Xu et al. [26], have shown promise in capturing temporal dependencies. Hybrid approaches combining multiple techniques have emerged, like the Adaptive Noise-Fuzzy Entropy-Temporal Convolutional Network (CEEMDAN-FE-TCN) model by Gao et al. [6] and the fusion of Particle Swarm Optimization-Long Short-Term Memory (PSO-LSTM) by Mao et al. [30]. Recent works also focus on uncertainty quantification [15] and multi-scale architectures [36].

Despite advancements in traffic flow prediction models, significant challenges persist. Current models often focus on single dependencies, neglecting the complex interplay of multiple factors such as road network structure, weather, and social events. Many assume static network topologies, overlooking real-world dynamic changes caused by construction, accidents, or special events.

Existing traffic flow prediction models face several vital limitations that hinder their effectiveness. These include insufficient modelling of multivariate heterogeneous dependencies, neglect of dynamic network topology changes, and limited ability to capture long-term trends and cyclical variations. Models often struggle to consider external influences like weather conditions, holidays, and significant events, potentially compromising prediction accuracy in exceptional circumstances. Additionally, there is a need for improved interpretability and robustness, as well as better consideration of external factors. Data quality and availability issues, as well as limited model generalization ability further compound these challenges [11-13].

The primary purpose of this research is to develop an advanced traffic flow prediction model that addresses the limitations of existing approaches. This study aims to create a comprehensive model capable of capturing the complex interplay of multiple factors influencing traffic patterns,

including road network structure, weather conditions, and social events. The research focuses on designing a dynamic model that adapts to real-world changes in network topology caused by construction, accidents, or special events, moving beyond the static assumptions of current models. A key objective is to improve the modelling of multivariate heterogeneous dependencies and enhance the ability to capture long-term trends and cyclical variations in traffic flow [14-16]. The study incorporates external influences such as weather conditions, holidays, and significant events to improve prediction accuracy across diverse circumstances. Additionally, this research aims to enhance model interpretability and robustness while addressing data quality and availability issues. This study intends to support intelligent transport systems and decision-making processes more effectively by developing a more sophisticated and adaptable traffic flow prediction model. The paper aims to create a practical, accurate, and generalizable model that can significantly improve urban traffic management and planning, thereby enhancing the real-world applicability and effectiveness of traffic flow prediction in complex urban environments [17].

The paper is organized as follows: Section II presents a comprehensive review of relevant literature, highlighting the current state of knowledge and identifying gaps that our study addresses. Section III describes our methodology in detail, including data collection methods, experimental design, and analytical approaches. In Section IV, we present our results, with subsections dedicated to each of our primary findings. Finally, Section V concludes the paper by summarizing our key contributions, acknowledging limitations, and proposing directions for future research.

II. MULTI-SCALE SPATIOTEMPORAL ATTENTION GRAPH ATTENTION NETWORK

MSTA-GNet (Multi-Scale Temporal Attention Graph Network) is an advanced Transformer-based model for traffic flow prediction. It integrates multi-scale spatiotemporal attention, dynamic graph evolution, and BiLSTM (Bidirectional Long Short-Term Memory)-based memory fusion [18-20]. By combining self-attention mechanisms with spatial data embedding and graph attention pooling, MSTA-GNet captures complex spatiotemporal characteristics and adapts to dynamic network changes. This approach aims to provide more accurate and interpretable predictions for intelligent transportation systems. The MSTA-GNet structure is shown in Fig. 1.

A. Multi-Scale Spatiotemporal Attention Module

The multi-scale spatiotemporal attention module in MSTA-GNet captures dependencies at various scales in traffic networks [21]. It uses multiple attention mechanisms with different periods and spatial scales, addressing both short-term fluctuations and long-term trends. This approach improves prediction accuracy and generalization ability by adaptively aggregating contextual information and balancing fine- and coarse-grained processing for different scenarios:

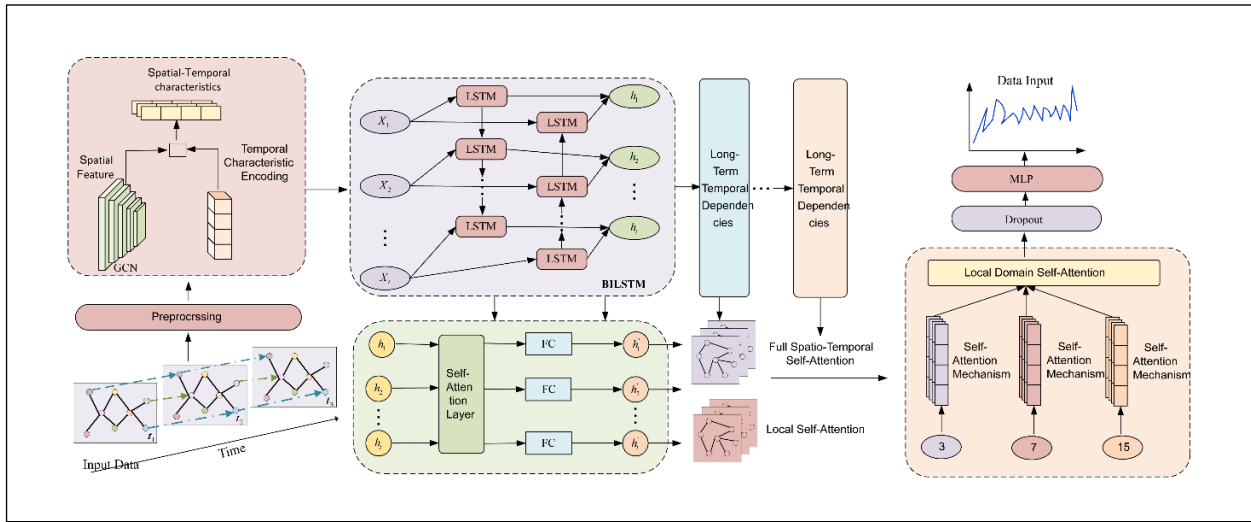

Fig. 1. The frame diagram of the MSTA-GNet model.

Given a time step t node v_i , the eigenvector of the node $x_i^{(t)} \in \mathbb{R}^d$, the module is computed as follows,

$$e_{ij}^{(t, k)} = \tanh(W_k \cdot [x_i^{(t)}, x_j^{(t-k)}] + b_k) \quad (1)$$

$$\alpha_{ij}^{(t, k)} = \frac{\exp(e_{ij}^{(t, k)})}{\sum_{j \in \mathcal{N}_i} \exp(e_{ij}^{(t, k)})} \quad (2)$$

$$x_i^{(t, k)} = \sum_{j \in \mathcal{N}_i} \alpha_{ij}^{(t, k)} \cdot x_j^{(t-k)} \quad (3)$$

$$X \in \mathbb{R}^{N \times T \times D} \quad (4)$$

where, the $k \in 1, 2, \dots, K$ denote different periods, the $W_k \in \mathbb{R}^{2d}$ and $b_k \in \mathbb{R}$ are learnable parameters. $\alpha_{ij}^{(t, k)}$ are the nodes v_i and v_j attention weights under periods k , and $x_i^{(t, k)}$ is the node v_i aggregation features under time span k .

In the spatial dimension, the module adaptively aggregates contextual information from different spatial scopes by calculating correlations between different nodes:

$$e_{ij}^{(t, r)} = \tanh(W_r \cdot [x_i^{(t)}, x_j^{(t)}] + b_r) \quad (5)$$

$$\alpha_{ij}^{(t, r)} = \frac{\exp(e_{ij}^{(t, r)})}{\sum_{j \in \mathcal{N}_i^{(r)}} \exp(e_{ij}^{(t, r)})} \quad (6)$$

$$x_i^{(t, r)} = \sum_{j \in \mathcal{N}_i^{(r)}} \alpha_{ij}^{(t, r)} \cdot x_j^{(t)} \quad (7)$$

where, $r \in 1, 2, \dots, R$ denote the different spatial extents, and $\mathcal{N}_i^{(r)}$ is the node v_i in the spatial range r the set of neighboring nodes within the spatial range, the $W_r \in \mathbb{R}^{2d}$ and $b_r \in \mathbb{R}$ are the learnable parameters. $\alpha_{ij}^{(t, r)}$ is the set of nodes v_i and v_j in the spatial range r under the attention weights, and $x_i^{(t, r)}$ is the node v_i in the spatial range r under the aggregation feature.

By fusing the multi-scale features in the temporal and spatial dimensions, the node is obtained v_i . The final feature representation of.

$$x_i^{(t)} = \text{Concat}(x_i^{(t, 1)}, \dots, x_i^{(t, K)}, x_i^{(t, 1)}, \dots, x_i^{(t, R)}) \quad (8)$$

$$x_i^{(t)} = \text{ReLU}(W_f \cdot x_i^{(t)} + b_f) \quad (9)$$

where, concat is the feature splicing operation, the $W_f \in \mathbb{R}^{(K+R)d \times d}$ and $b_f \in \mathbb{R}^d$ are the learnable parameters of the fusion layer. Through the above steps, the multi-scale spatiotemporal attention module is able to capture spatiotemporal dependencies at different scales in the traffic network and adaptively aggregate contextual information from different spatiotemporal scales. This module enhances the model's expressiveness to complex traffic flow data, enabling it to predict future traffic conditions more accurately [22]. Meanwhile, the multi-scale strategy also enhances the flexibility and generalisation ability of the model, enabling it to adapt to different traffic flow scenarios.

B. Dynamic Graph Evolution Module

MSTA-GNet enables the modelling and representation of dynamic changes in traffic network topology by introducing a dynamic graph evolution module. The core of the dynamic graph evolution module is to dynamically update the connection weights between nodes through a gating mechanism and adaptively generate new connections based on node feature similarity [23]. The principle of which is as follows:

The graph at each time step is encoded using a graph convolutional network (GCN) to obtain the node embedding matrix Z_t . Assuming time step t , there are N nodes and the feature vector of each node is $x_i^t \in \mathbb{R}^d$, where $i \in \{1, 2, \dots, N\}$, d is the feature dimension. The connection weight between node I and node j is a_{ij}^t .

1) *Dynamically update connection weights*: Firstly, the gating signal for updating the connection weights is generated through a gating mechanism g_{ij}^t :

$$g_{ij}^t = \sigma(W_g \cdot [x_i^t, x_j^t, a_{ij}^{t-1}] + b_g) \quad (10)$$

Of these, the W_g and b_g are the weight matrix and bias term of the gating mechanism, respectively, and σ is the sigmoid activation function, and $[\cdot, \cdot, \cdot]$ denotes the vector splicing operation. The connection weights are then updated using the gating signals:

$$a_{ij}^t = g_{ij}^t \odot a_{ij}^{t-1} + (1 - g_{ij}^t) \odot \tilde{a}_{ij}^t \quad (11)$$

where \odot denotes the element-by-element multiplication, and \tilde{a}_{ij}^t is the candidate connection weight, which can be generated by multilayer perceptron (MLP):

$$\tilde{a}_{ij}^t = \text{MLP}([x_i^t, x_j^t]) \quad (12)$$

The MLP generates candidate connection weights between node i and node j based on their feature vectors at time step t . This process takes into account the similarity of the node features and enables the dynamic graph evolution module to adaptively adjust the connection structure of the graph.

2) *Adaptive generation of new connections:* For node i and node j , calculate the similarity of their feature vectors s_{ij}^t :

$$s_{ij}^t = \text{sim}(x_i^t, x_j^t) \quad (13)$$

where, $\text{sim}(\cdot, \cdot)$ is the cosine similarity. Then, the probability of generating a new connection based on similarity p_{ij}^t :

$$p_{ij}^t = \sigma(W_p \cdot s_{ij}^t + b_p) \quad (14)$$

Of these, the W_p and b_p are the weights and bias terms for generating new connections. Finally, based on the probability p_{ij}^t decide whether to add a new connection between node i and node j or not:

$$\begin{cases} 1, & \text{if } p_{ij}^t > \text{threshold and } a_{ij}^{t-1} = 0 \\ a_{ij}^t, & \text{otherwise} \end{cases} \quad (15)$$

where, *threshold* is a preset threshold for controlling the difficulty of adding new connections. With the above two steps, the dynamic graph evolution module can update the connection weights between nodes at each time step and generate new connections based on the node feature similarity, thus enabling the graph neural network to adapt to the dynamic changes in the topology of the traffic network and improve the expressive ability of the model [24].

C. Long and Short-Term Memory Fusion Mechanisms

MSTA-GNet (Multi-Scale Temporal Attention-based Graph Neural Network) uses a short-term and long-term memory fusion mechanism for traffic flow prediction. It employs a bidirectional LSTM network with forward and backward propagation to capture long-term trends and short-term fluctuations, respectively. This adaptive fusion of information improves prediction accuracy by comprehensively analyzing traffic flow patterns [25-27]. Let the input sequence be $X = (x_1, x_2, \dots, x_T)$, the hidden state of forward LSTM is \vec{h}_t and the hidden state of the reverse LSTM is \overleftarrow{h}_t , then:

$$\vec{h}_t = \text{LSTM}(x_t, \vec{h}_{t-1}) \quad (16)$$

$$\overleftarrow{h}_t = \text{LSTM}(x_t, \overleftarrow{h}_{t+1}) \quad (17)$$

Finally, the hidden states of the forward and reverse LSTM are spliced to obtain the output of the bidirectional LSTM $h_t = [\vec{h}_t, \overleftarrow{h}_t]$. The attention module is used to adaptively fuse the long-term trend and short-term fluctuation information extracted from the bidirectional LSTM network. First, the attention weights are computed α_t , which indicates the degree of attention to the long and short-term information at moment t :

$$e_t = \tanh(W_e h_t + b_e) \quad (18)$$

$$\alpha_t = \text{softmax}(W_\alpha e_t + b_\alpha) \quad (19)$$

where, $W_e, b_e, W_\alpha, b_\alpha$ are the learnable parameters. Then, the output of the bidirectional LSTM is weighted and summed using the attention weights to obtain the fused feature representation c_t :

$$c_t = \alpha_t \odot h_t \quad (20)$$

where \odot denotes element-by-element multiplication.

Through the above steps, the long and short-term memory fusion mechanism of MSTa-GNet is able to adaptively fuse the long-term trend and short-term fluctuation information of traffic flow data to generate a comprehensive feature representation c_t . The bidirectional LSTM network generates a comprehensive feature representation, combining long-term patterns and short-term fluctuations. This improved representation, denoted as c_t , is then fed into a subsequent graph neural network, enhancing the model's overall predictive capability for traffic flow.

D. Graph Attention Pooling Layer

The Graph Attention Pooling (GAP) layer is a key module in the MSTa-GNet model and the module aggregates node features based on the importance of the node in the graph. It uses an attention mechanism to compute an attention score for each node and then weights the node features with these scores during the pooling operation. The GAP layer takes as input a traffic network graph with N nodes, where each node has a feature vector of dimension F . The GAP layer is a graph with N nodes. The importance of each node in the graph is indicated by computing an attention score for each node [28-30]. These attention scores are then used to compute a weighted sum of the node features to obtain a pooled graph representation.

Let $\mathbf{X} \in \mathbb{R}^{N \times F}$ be the input node feature matrix, where $\mathbf{x}_i \in \mathbb{R}^F$ is the feature vector of node i . $\mathbf{Z} = \mathbf{X}\mathbf{W}$, where $\mathbf{W} \in \mathbb{R}^{F \times 1}$ is the learnable weight matrix. Apply the *softmax* function to obtain the attention score:

$$\alpha_i = \frac{\exp(z_i)}{\sum_{j=1}^N \exp(z_j)} \quad (21)$$

Among others z_i is the i -th element of \mathbf{Z} the i th element of the graph. Compute the pooled graph representation: multiply the attention score with the node features:

$$\mathbf{X}_{\text{weighted}} = \mathbf{X} \odot \alpha \quad (22)$$

where, \odot denotes the element-by-element multiplication,

and $\alpha \in \mathbb{R}^N$ is the attention score vector. Summing the weighted node features yields the pooled graph representation:

$$\mathbf{h} = \sum_{i=1}^N \mathbf{x}_{weighted, i}$$

where, $\mathbf{h} \in \mathbb{R}^F$ is the graph representation after pooling.

Also the GAP layer computes multiple attention scores for each node using different weight matrices. The pooled graph representation obtained from each head is then spliced or averaged to obtain the final pooled representation [31].

The specific steps of the model are as follows:

Step 1: Preprocess traffic flow data: standardize, fill missing values.

Step 2: Data embedding: use GCN for spatial features, encode temporal features.

Step 3: BiLSTM layer: capture long-term temporal dependencies.

Step 4: Design global and local self-attention mechanisms.

Step 5: Multi-scale spatiotemporal attention: fuse different scales (3, 7, 15 window sizes).

Step 6: Process features through fully connected layer for prediction.

Step 7: Set training parameters: learning rate 0.001, batch size 32, epochs 100-300, RMSprop optimizer.

Step 8: Train the model using RMSprop optimizer. Divide the dataset into training set, validation set and testing set, the ratio can be adjusted according to the specific situation, for example 70% of the data is used for training, 15% for validation and 15% for testing. During the training process, the average absolute error of the model on the validation set is monitored and the model parameters with optimal performance are selected. Finally, the final performance of the model is evaluated on the test set.

Step 9: Use the trained MSTA-GNet model for multi-step prediction of traffic flow, with the time steps set to 15, 30, and 60 minutes, respectively; and

Step 10: Evaluate using MAE, MAPE, RMSE; visualize results.

III. MATERIALS AND METHODS

A. Materials

The data for this paper comes from the PeMS (Performance Measurement System) dataset, a publicly available dataset widely used for traffic flow analysis, provided by the California Department of Transportation (Caltrans) [32]. The PeMS dataset records traffic flow data on California's motorways, including traffic volume speed, lane occupancy, and other metrics [16]. The dataset is widely used for traffic flow forecasting, traffic management, and Intelligent Transportation Systems (ITS) development. The data is due on 15 September 2021, for a full day of traffic monitoring statistics, with data recorded every five minutes

for a total of 24 hours. The Information on Dataset is shown in Table I.

TABLE I. THE INFORMATION OF DATASET

Timestamp	Detector_ID	Flow	speed	Occupancy
2021-09-15 00:00:00	11375	10	65.5	0.12
2021-09-15 00:01:00	11375	12	63.0	0.15
2021-09-15 00:02:00	11375	15	60.5	0.18
...

B. Environmental

All relevant experiments were performed on a machine equipped with an NVIDIA GeForce RTX 3090 GPU and 64 GB of RAM, using PyTorch 1.13.1 and Python 3.9.16 experimental environments. Where time steps were set to 15, 30, and 60 minutes. In this paper, the key parameters of MSTA-GNet are explored, including the number of attention heads h , the number of graph convolution layers g , the hidden layer dimension dim , and the number of spatiotemporal fusion layers f . Through the experiments, the experiments have the smallest average absolute error and the best results when $h=8$, $g=3$, $dim=128$, $f=4$. The optimizer adopts the RMSprop optimizer with a learning rate of 0.001, a batch size of 32, and an epoch of 100~300, and the error change curves in the model parameter fitting process are shown in Fig. 6. Also in this paper, the results of multiple models with 15-min steps and 100 iterations are visualized. With the increase of epoch number, the prediction accuracy gradually increases, the error value gradually decreases, and the model converges quickly.

C. Selection of Evaluation Indicators

In this paper, Mean Absolute Error (MAE), Mean Absolute Percentage Error (MAPE) and Root Mean Square Error (RMSE) are used as the evaluation indexes for determining the prediction performance of the model. The specific formula of each evaluation index is as follows [33-35]:

where

$$MAE(y, \hat{y}) = \frac{1}{n} \sum_{i=0}^{n-1} |y_i - \hat{y}_i| \quad (23)$$

$$MAPE(y, \hat{y}) = \frac{1}{n} \sum_{i=0}^{n-1} \frac{|y_i - \hat{y}_i|}{y_i} \quad (24)$$

$$RMSE(y, \hat{y}) = \left[\frac{1}{n} \sum_{i=0}^{n-1} (y_i - \hat{y}_i)^2 \right]^{\frac{1}{2}} \quad (25)$$

where, n is the traffic flow observation period, y is the real value of the observed traffic flow, and \hat{y} indicates the predicted value of the traffic flow simulated by the model.

D. Baseline Modelling

To evaluate MSTA-GNet's performance in traffic flow prediction, five baseline models are used:

- 1) BiLSTM: temporal dependency modeling.
- 2) GCN: spatial dependency modeling.
- 3) DCRNN: combined temporal and spatial modeling.
- 4) STGCN: dynamic graph evolution and spatiotemporal dependency modeling.
- 5) ST-MetaNet: adaptation to dynamic traffic environments.

Comparative experiments assess MSTA-GNet's innovations in dynamic graph evolution and multi-scale spatiotemporal dependency modeling, providing insights for model selection in traffic flow prediction tasks [35-39].

IV. RESULTS AND ANALYSIS

A. Experimental Results

Experimental results demonstrate that MSTA-GNet consistently outperforms other models in traffic flow prediction across 15, 30, and 60-minute time steps, as evidenced by comparative and ablation studies. The results are presented in Tables II, III, and IV, respectively:

TABLE II. TRAFFIC FLOW PREDICTION ERRORS FOR DIFFERENT MODELS WITH 15-MINUTE TIME STEPS

Model	MAE	RMSE	MAPE (%)
LSTM	3.45	5.82	10.21
GCN	3.32	5.65	10.07
DCRNN	3.25	5.51	9.89
STGCN	3.18	5.39	9.92
STMetaNet	3.11	4.78	9.32
MSTA-GNet	3.04	4.75	9.21

Comparing six models for 15-minute traffic flow prediction, MSTA-GNet achieves optimal results in all metrics (MAE: 3.04, RMSE: 4.75, MAPE: 9.21%), outperforming the second-best STMetaNet by 2.25%, 0.63%, and 1.18% respectively. Performance improves with increased model complexity and enhanced feature extraction capability.

TABLE III. TRAFFIC FLOW PREDICTION ERRORS FOR DIFFERENT MODELS WITH 30-MINUTE TIME STEPS

Model	MAE	RMSE	MAPE (%)
LSTM	3.69	6.32	11.23
GCN	3.58	6.24	11.18
DCRNN	3.51	6.06	11.08
STGCN	3.42	5.93	9.84
STMetaNet	3.34	5.28	9.81
MSTA-GNet	3.27	5.26	9.75

Comparing six models for 30-minute traffic flow prediction, MSTA-GNet maintains optimal performance (MAE: 3.27, RMSE: 5.26, MAPE: 9.75%), outperforming STMetaNet by 2.10%, 0.38%, and 0.61% respectively. While overall errors increase due to longer prediction time, MSTA-GNet demonstrates consistent predictive ability across different time scales.

TABLE IV. TRAFFIC FLOW PREDICTION ERRORS FOR DIFFERENT MODELS WITH 60-MINUTE TIME STEPS

Model	MAE	RMSE	MAPE (%)
LSTM	3.87	6.67	11.71
GCN	3.66	6.53	11.47
DCRNN	3.60	6.39	11.09
STGCN	3.51	6.01	10.92
STMetaNet	3.41	5.78	10.54
MSTA-GNet	3.37	5.75	10.51

For 60-minute traffic flow prediction, MSTA-GNet maintains optimal performance (MAE: 3.37, RMSE: 5.75, MAPE: 10.51%), slightly outperforming STMetaNet. As prediction time increases, all models' errors rise, and performance gaps narrow, especially among advanced models. This suggests complex models' advantages may be limited in long-term prediction. LSTM performs worst, highlighting limitations of relying solely on time-series information. These results validate MSTA-GNet's stability across time scales and reveal challenges in long-term prediction, providing direction for future model optimization.

The predictions of each algorithm are visualized below:

1) *LSTM model for traffic flow simulation:* The comparison of traffic flow predictions by LSTM model is shown in Fig. 2.

2) *GCN model for traffic flow simulation:* The comparison of traffic flow predictions by GCN model is shown in Fig. 3.

3) *DCRNN model for traffic flow simulation:* The comparison of traffic flow predictions by DCRNN model is shown in Fig. 4.

4) *STGCN model for traffic flow simulation:* The comparison of traffic flow predictions by STGCN model in Fig. 5.

5) *STMeta-Net model traffic flow simulation:* The comparison of traffic flow predictions by STMeta-Net model in Fig. 6.

6) *MSTA-GNet model traffic flow simulation:* The comparison of traffic flow predictions by MSTA-GNet model in Fig. 7.

Fig. 2. The comparison of traffic flow predictions by LSTM.

Fig. 3. The comparison of traffic flow predictions by GCN model.

Fig. 4. The comparison of traffic flow predictions by DCRNN model.

Fig. 5. The comparison of traffic flow predictions by STGCN model.

Fig. 6. The comparison of traffic flow predictions by STMeta-Net model.

Fig. 7. The comparison of traffic flow predictions by MSTA-GNet model.

B. Comparative Analysis of Ablation Experiments

Ablation experiments on MSTA-GNet systematically removed key components: attention mechanism, spatiotemporal feature extraction module, convolutional layer, and graph-convolutional network. Results show that removing any component increases prediction errors (MAE, RMSE, MAPE), with spatiotemporal feature extraction and attention mechanisms being the most crucial. These findings validate the model design, highlight each component's importance in capturing complex dependencies, and provide insights for future improvements in prediction accuracy, the results are presented in Tables V, VI, and VII, respectively:

TABLE V. ABLATION STUDY RESULTS (15-MINUTE INTERVAL)

Model Variants	MAE	RMSE	MAPE (%)
Original Model	3.11	5.21	9.87
Without Attention	3.45	5.82	10.21
Without Spatio-Temporal Feature Extraction	3.32	5.65	11.07
Without Convolutional Layer	3.25	5.51	11.89
Without Graph Convolution Network	3.18	5.39	11.92

Ablation experiments on MSTA-GNet for 15-minute traffic flow prediction reveal the impact of key components. The full model performs best (MAE: 3.11, RMSE: 5.21, MAPE: 9.87%). Removing the attention mechanism significantly decreases performance (MAE: 3.45, RMSE: 5.82, MAPE: 10.21%). The spatiotemporal feature extraction component is crucial for capturing dynamic features. Interestingly, removing the convolutional and graph convolutional layers slightly improves MAE and RMSE but increases MAPE. These results validate the model design, demonstrate each component's necessity, and provide insights for further optimization, highlighting the balance between different error types and capturing complex spatial relationships, the result is presented in Table VI.

TABLE VI. ABLATION STUDY RESULTS (30-MINUTE INTERVAL)

Model Variants	MAE	RMSE	MAPE (%)
Original Model	3.27	5.54	9.71
Without Attention	3.57	5.93	10.01
Without Spatio-Temporal Feature Extraction	3.46	5.71	10.82
Without Convolutional Layer	3.87	6.32	10.13
Without Graph Convolution Network	3.92	6.11	10.25

Ablation experiments for MSTA-GNet at 30-minute prediction show:

- 1) Full model performs best (MAE: 3.27, RMSE: 5.54, MAPE: 9.71%).
- 2) Removing attention mechanism increases errors significantly.
- 3) Spatiotemporal feature extraction is crucial for long-term dependencies.
- 4) Convolutional layer and graph convolutional network

removal have the most impact, suggesting their critical role in longer-term predictions.

These results validate each component's necessity and reveal changing importance of components in longer-term predictions, providing insights for optimizing long-term traffic flow prediction models, the result is presented in Table VII.

TABLE VII. ABLATION STUDY RESULTS (60-MINUTE INTERVAL)

Model Variants	MAE	RMSE	MAPE (%)
Original Model	3.71	5.65	11.07
Without Attention	3.78	5.51	10.89
Without Spatio-Temporal Feature Extraction	3.81	5.39	9.92
Without Convolutional Layer	3.85	4.78	9.32
Without Graph Convolution Network	3.96	4.75	9.21

Ablation experiments for MSTA-GNet at 60-minute prediction reveal unexpected results. Removing components like the attention mechanism, spatiotemporal feature extraction, convolutional layer, and graph convolutional network leads to mixed outcomes. While MAE generally increases, RMSE and MAPE show a decreasing trend. Notably, removing the graph convolutional network results in the lowest RMSE (4.75) and MAPE (9.21%), despite increased MAE (3.96). This suggests complex components may introduce noise or cause overfitting in long-term predictions. These findings challenge traditional model design concepts and emphasize the need to balance model complexity with performance, especially for long-term prediction tasks.

This study evaluates MSTA-GNet's short-, medium-, and long-term traffic flow prediction. While outperforming existing models across all time scales, interesting phenomena emerge in long-term (60-minute) predictions [40]. Ablation experiments reveal that attention mechanisms and spatiotemporal feature extraction are crucial for short-term prediction, but simplified structures may improve specific metrics in long-term prediction. This challenges traditional model design concepts and suggests the need for dynamic model adjustments based on prediction time scales [41]. Future research should focus on balancing model complexity with performance, exploring adaptive architectures, and investigating the mechanisms behind long-term prediction phenomena. Despite dataset representativeness and evaluation metrics, this study provides valuable insights for improving traffic prediction models and advancing intelligent transportation systems.

V. CONCLUSION

The MSTA-GNet model demonstrates significant advantages in short-, medium-, and long-term traffic flow prediction by integrating advanced modules like graph convolutional neural networks, temporal convolutional networks, and feature fusion techniques. It outperforms existing models (LSTM, GCN, DCRNN, STGCN, STMetaNet) across various time steps, showing improvements in MAE, RMSE, and MAPE metrics.

Key strengths of MSTA-GNet include its novel integration

of multi-scale spatiotemporal attention mechanisms, which improve prediction accuracy across various time scales. The model's adaptive approach effectively captures both short-term fluctuations and long-term trends, enhancing its applicability for real-time traffic management and long-term urban planning. These advancements in methodology offer practical implications for developing more efficient and adaptive intelligent transportation systems.

Ablation experiments provide critical insights into the model's components, revealing their importance for different prediction horizons and challenging traditional model design assumptions. The spatiotemporal feature extraction and attention mechanisms prove crucial for short-term predictions, while the results for long-term predictions suggest the need for dynamic model adjustments based on prediction time scales.

However, limitations exist, such as not considering external factors (weather, holidays) and relying on traditional evaluation metrics. Future research should address these limitations, explore dynamic model adjustments for long-term predictions, develop new evaluation metrics, and investigate counterintuitive phenomena in long-term forecasting.

MSTA-GNet provides valuable insights for improving traffic prediction models and advancing intelligent transportation systems.

Laboratory Abnormal Behavior Recognition Method Based on Skeletal Features

Dawei Zhang*

School of Information Engineering, Liaodong University, Dandong, China

Abstract—The identification of abnormal laboratory behavior is of great significance for the safety monitoring and management of laboratories. Traditional identification methods usually rely on cameras and other equipment, which are costly and prone to privacy leakage. In the process of human body recognition, they are easily affected by various factors such as complex backgrounds, human clothing, and light intensity, resulting in low recognition rates and poor recognition results. This article investigates a laboratory abnormal behavior recognition method based on skeletal features. One is to use Kinect sensors instead of traditional image sensors to obtain characteristic skeletal data of the human body, reducing external limitations such as lighting and increasing effective data collection. Then, the collected data is smoothed, aligned, and image enhanced using moving average filtering, Discrete Fourier Transform, and contrast, effectively improving data quality and helping to better identify abnormal behavior. Finally, the OpenPose algorithm is used to construct a laboratory anomaly behavior recognition model. OpenPose can be used to connect the entire skeleton through the relationships between points during the process of extracting human skeletal points, and combined with multi-scale pyramid networks to improve the network structure, effectively improving the accuracy and recognition speed of laboratory abnormal behavior recognition. The experiment shows that the accuracy, precision, and recall of the behavior recognition model constructed by the algorithm are 95.33%, 96.68%, and 93.77%, respectively. Compared with traditional anomaly detection methods, it has higher accuracy and robustness, lower parameter count, and higher operational efficiency.

Keywords—Skeletal features; abnormal behavior recognition; OpenPose algorithm; Kinect sensor; Discrete Fourier Transform

I. INTRODUCTION

In recent years, the rapid development of computer vision and artificial intelligence technology has brought major changes to many industries. Among them, motion recognition technology, as a key branch, is gradually being integrated into all aspects of people's lives. In the scientific research laboratory environment, efficient and accurate identification of abnormal behaviors is essential to ensure the safety of personnel, the normal operation of equipment, and the reliability of experimental results. However, the traditional recognition method based on video surveillance has shortcomings in dealing with lighting changes, line of sight blocking and viewing angle restrictions, which affects the accuracy and stability of recognition. To meet these challenges, this study proposes a strategy for identifying abnormal behaviors based on human skeletal Features. By using the OpenPose algorithm and the Kinect depth sensor, it is possible to accurately capture

and extract the three-dimensional bone structure data of the experimenter. As the internal manifestation of human movement, bone characteristics can not only effectively reflect the relative position and trajectory of joints, but also have a higher tolerance and anti-interference ability to light, color changes and background complexity, and show excellent robustness in complex laboratory environments.

By constructing a laboratory abnormal behavior recognition model based on skeletal Features, it aims to break through the limitations of traditional video surveillance technology, realize in-depth analysis of the movements and attitudes of experimenters, and detect and warn of potential safety hazards or operational errors in a timely manner. This research is expected to significantly improve the level of safety management in the laboratory, and provide strong support for the optimization and efficiency improvement of the experimental process. Therefore, the introduction of skeletal features into the field of abnormal behavior recognition in laboratories is not only an inevitable trend of technological development, but also a practical need to ensure the smooth progress of scientific research activities and promote the sustainable prosperity of scientific undertakings.

II. RELATED WORK

Abnormal behavior recognition is the process by which a monitoring system compares and identifies behaviors or events that do not conform to known conventional behavior patterns [1-2]. This method can analyze the patterns existing in the data, identify some behaviors that do not conform to the norm, and timely discover and respond to potential problems or dangers. Li Lin developed an abnormal behavior recognition method based on the spatiotemporal background of learning behavior. The specific recognition method adopts a top-down strategy and evaluates the effectiveness of local behavior themes and abnormal behavior recognition using spatiotemporal context learning [3]. Guan Yepeng proposed an abnormal behavior recognition method based on three-dimensional convolutional neural network (CNN) and long short-term memory (LSTM), which replaces the three primary color images with a feature image composed of optical flow and motion history images as input [4]. Hao Yixue combined Graph Convolutional Network (GCN) and 3D Convolutional Neural Network to propose an end-to-end anomaly behavior detection framework from a new perspective. Specifically, a class of classifiers is trained to extract features and estimate anomaly scores to improve the performance of anomaly behavior detection [5]. Shi Xiaonan proposed an underground abnormal behavior recognition method based on optimized Alphapose-GCN. Firstly, he defogged and enhanced the image set captured in the

underground monitoring video. Secondly, he optimized AlphaPose object detection using the YOLOv3 model. Finally, he performed abnormal behavior recognition [6]. Bae Hyun-Jae proposed a method to identify abnormal behavior using only joint keypoints and joint motion information. He extracted joint keypoints of body parts through AlphaPose and sequentially inputted the extracted joint keypoints into the LSTM model for recognition [7]. Lee Jiyoo proposed an anomaly behavior detection model based on deep learning models, which reflects the accuracy of this research method for anomaly behavior detection by detecting violent and fainting behaviors in videos [8]. In summary, although the existing methods can cope with the challenges of lighting, occlusion, and viewing angle changes, the recognition accuracy rate may decrease in extremely complex scenes, and enhancing the robustness of the algorithm in complex environments is an urgent problem to be solved. At the same time, the definition of abnormal behavior in different scenes and contexts is different, and there are ambiguities and ambiguities. Building a common and highly explanatory abnormal behavior recognition framework to adapt to different application scenarios is another important issue. To this end, this article will use the bone feature research method to study it, hoping to improve the accuracy of recognition.

Behavior recognition based on bone features is a combination of machine vision and deep learning, which can analyze and recognize human motion and behavior [9-10]. This method monitors and analyzes human movement by detecting key parts in the human skeleton. TIAN Zhiqiang designed a temporal divergence model based on skeleton points to describe the motion state of skeleton points, amplifying the inter class differences in different human behaviors. At the same time, he also designed an attention mechanism with temporal divergence features to highlight key skeleton points, and this algorithm has a relatively high accuracy in authoritative human behavior datasets [11]. Liu Yuchao extracted key points of the human 3D skeleton in time series using YOLOv4, and applied the Meanshift object tracking algorithm to convert the key points into spatial tricolors. He put it into a multi-layer convolutional neural network for recognition, which can quickly identify various abnormal behaviors [12]. Li Maosen used two chart scales to clearly capture the relationship between body joints and body parts, and conducted experiments on skeleton-based motion recognition and prediction on four datasets, achieving good results [13]. Gao Guohong introduced an extraction technique that combines jawbone skeleton features, using skeleton heatmap descriptors and Kalman filtering algorithm to extract skeleton features of the upper and lower jaw bones. This method has better recognition accuracy than other models [14]. Shu Xiangbo proposed a new skeleton joint method to capture spatial consistency between joints and temporal evolution between skeletons. At the same time, he found through experiments on human motion prediction that the proposed method is superior to other methods on the feature maps that are of common concern to the skeleton joints [15]. Through the integration of machine vision and deep learning, the behavior recognition method based on bone characteristics has significantly improved the accuracy of human movement and behavior analysis. The current research mainly focuses on the

precise detection of key bone points and the establishment of motion state models. Technical methods such as time divergence model, attention mechanism, and tracking of key points of the three-dimensional skeleton are used to further highlight the differences between different behaviors, thereby improving the accuracy of recognition. These studies have not only enhanced bone feature recognition technology, but also provided solid support for practical application scenarios such as laboratory abnormal behavior monitoring.

Today, with the increasing awareness of laboratory safety, it is crucial to effectively detect and prevent abnormal laboratory behavior. Although traditional video monitoring technology can monitor the situation inside the laboratory in real time, it often requires manual monitoring and analysis, which is not only inefficient but also prone to missed detections. The abnormal behavior recognition method based on bone features automatically identifies abnormal behaviors by capturing and analyzing bone movements, to improve the efficiency of laboratory safety management. This project aims to identify abnormal behaviors in the laboratory based on bone characteristics.

III. BONE FEATURE EXTRACTION TECHNOLOGY

This article uses bone feature extraction technology to extract bone points from abnormal behaviors in the laboratory. Firstly, the video data in the laboratory is captured by a camera, and more features are extracted from human bones using Kinect depth sensors. By analyzing the collected bone structure data, important evidence can be provided for subsequent identification of abnormal behavior [16-17]. Skeleton points are a type of landmark data. The human skeleton is the internal framework of the human body, which generally includes two elements: joints and bones. Bones are the lines connecting points and edges, and joints and bone elements correspond exactly to edges and points in the shape [18]. Therefore, the skeleton structure is shown in Fig. 1.

Fig. 1. Skeleton diagram.

There are two main methods for obtaining human skeletal information: one is posture estimation [19], and the other is motion capture devices [20-21]. The human skeletal sequence is based on the two-dimensional or three-dimensional coordinates of human joints. On this basis, the coordinate vectors of each node can be correlated and an independent feature vector can be generated between each frame. This article utilizes Kinect depth sensors for bone feature extraction.

Kinect depth sensors first obtain a continuous stream of human body sequence data based on the actions of the experimenters. Through this stream of sequence data, corresponding depth images can be obtained. By preprocessing the obtained images, the coordinates of the actions in three-dimensional space and time series can be obtained. By collecting joint point data through Kinect, the first step is to segment the collected human body contours. During this process, Kinect filters and distinguishes each pixel point to find the pixel that is most likely to be the human body boundary. Then, edge detection algorithms are used to identify the contour area of the target. On this basis, the extracted human body contours were used to segment the torso and limbs of the human body.

When performing behavior recognition, only representative skeletal parts such as hands and feet are usually needed to make corresponding recognition and judgment of actions. These skeletal points all have one thing in common, which is that they are far from the center of gravity of the body, have a larger range of motion and higher flexibility. Compared to the more fragile skeletal parts of the human body, the wrist and ankle joints play a more important role in human behavior recognition. Taking the center of gravity of the human body as a reference, the line h connecting the center of gravity to other bone points represents the relative distance between each bone point and the center of gravity of the human body. Therefore, at adjacent moments $[t + \Delta t]$, the average distance H from bone point j_i to the center of gravity can be expressed as:

$$\bar{h}_i^t = (|h_i^t| + |h_i^{t+\Delta t}|)/2 \quad (1)$$

Among them, the $\bar{h} \in [0,1]$ and \bar{h} values are too small to serve as characterizations. Here, β is used to activate the function and normalize \bar{h} to a new interval $[x, y]$. The specific expression is as follows:

$$\beta(a) = \ln(a + q) + p \quad (2)$$

Let $a = H$ analyze the original interval $[0,1]$ and the generated inter new area $[x, y]$ to solve.

$$q = 1/(e^{y-x} - 1) \text{ and } p = y - \ln\left(\left(e^{y-x}/(e^{y-x} - 1)\right)\right).$$

Human abnormal behavior is very random and difficult to predict. It is impossible to describe the entire abnormal behavior of the human body well if only one feature is extracted. So, this article uses two skeletal features, namely the aspect ratio of the human body and the structural vector, to study, and the expression for the aspect ratio of the human body is as follows:

$$x = \frac{a}{b} \quad (3)$$

Among them, x represents the aspect ratio of the human body, a represents the width of the smallest outer rectangle, and b represents the height of the smallest outer rectangle.

IV. DATA COLLECTION AND PREPROCESSING

A. Data Collection

With the rapid development of the chemical industry, the number of chemical laboratories is gradually increasing, and their safety issues are also increasingly attracting social

attention. To ensure safety during the experiment, it is necessary to detect and identify potential abnormal behaviors of the experimental personnel. A unique chemical laboratory dataset was established by collecting and cleaning chemical experimental data from public datasets. To improve the efficiency and accuracy of data classification and labeling, YOLOv5 is introduced in the process of establishing the behavior model to complete relevant behavior classification and labeling, thereby enhancing the overall recognition performance of the model. The tag files used in this article are in the format of the dataset and are marked using current open and convenient tagging tools. In behavior recognition experiments based on human bones, the NTU RGB+D dataset has the largest number of samples so far, including multiple video sequences. This article collects a total of 60 different action categories. This dataset was collected by Kinect sensors and synchronously observed from multiple perspectives. The collected data is shown in Fig. 2.

Fig. 2. Partial dataset collection.

B. Data Preprocessing

1) *Data smoothing processing*: Due to the performance of Kinect sensors themselves, there may be some additional noise in the collected data. In addition, when experimental participants engage in behavioral movements, noise may also be present in the data due to factors such as body tremors. To eliminate noise in the data, it is necessary to perform smoothing processing, i.e. filtering, on the data. For this purpose, this article uses the moving average filtering method [22-23] to process the collected data. This method averages a fixed length signal to achieve the goal of eliminating noise. Take the data segment A_1, A_2, \dots, A_H with a fixed length of H , and the specific calculation formula is as follows:

$$\bar{A} = \frac{1}{H} \sum_{i=0}^H A_{H-1} \quad (4)$$

Among them, \bar{A} is the average value of H data points, which can be used to replace the current position of A_1 data points. Then, starting from A_2 , H data points are taken, and the average value is calculated to replace A_2 . After n iterations of the above process, n filtering smoothing results are obtained.

The data smoothing effect based on the moving average method is shown in Fig. 3. It can be found that using moving average to smooth the data has achieved very good results, and the data can retain more original features.

Fig. 3. Data smoothing effect based on moving average method.

2) *Data alignment processing*: The process of obtaining human bone data based on Kinect sensors is real-time, and different action intervals result in different lengths of each set of data even at the same sampling frequency [24-25]. In addition, the influence of factors such as the technical level and operating habits of the experimenters results in different completion times for the same action participants, leading to different data lengths. Therefore, it is necessary to align the collected bone data to achieve effective learning and prediction of human behavior. Discrete Fourier Transform is the process of converting n signals that were originally in the time domain to obtain an equal number of signals in the frequency domain [26-27]. Assuming that a non-periodic continuous time signal is denoted as $y(t)$, the Fourier transform expression for this signal is as follows:

$$Y(\beta) = \int_{-\infty}^{+\infty} y(t)e^{-j\beta t} dt \quad (5)$$

This article adopts the data alignment method of Fourier transform, and the specific effect diagram is shown in Fig. 4.

Fig. 4. Data alignment effect based on fourier transform.

As shown in Fig. 4, the length of the bone action data signal is 414, and the target length is 450. By interpolation, human behavior data of the same length can be obtained. Therefore, this also indicates that using Fourier transform can obtain human behavior feature data of the same length, achieving the purpose of data alignment.

3) *Contrast enhancement*: Image contrast refers to the difference in brightness of an image, while contrast enhancement refers to the difference in grayscale colors in an image, making the content of the image clearer [28-29]. The expression for contrast enhancement is as follows:

$$h|(a) = xg(a) + y \quad (6)$$

Among them, $g(a)$ represents the input data; $g(x)$ is the output data; x is the gain, which can set the contrast of the image; y is paranoia, which can set the brightness of the image.

If it is necessary to enhance the contrast of non-linear images, x and y methods are usually automatically selected. Assuming the height of the input matrix Q is H and the width is W , $Q(s, t)$ represents the grayscale value of the s row and t column. The minimum grayscale value in matrix Q is Q_{min} , and the maximum value is Q_{max} , which means the grayscale value of the matrix is $Q_{min} \leq Q(s, t) \leq Q_{max}$. The range of the output matrix R is $[R_{max}, R_{min}]$, and the expression is as follows:

$$R(s, t) = \frac{R_{max}-R_{min}}{Q_{max}-Q_{min}} (Q(s, t) - Q_{min}) + R_{min} \quad (7)$$

Among them, $0 \leq s \leq H$, $0 \leq t \leq W$, and $R(s, t)$ represent the grayscale values of the s row and t column. Generally, $R_{min} = 0$ and $R_{max} = 255$ are set.

The effect of using contrast enhancement to enhance the collected laboratory behavior images is shown in Fig. 5.

Fig. 5. Effect image based on contrast enhancement.

As shown in Fig. 5, 'a' is the original image, and 'b' is the image after contrast enhancement. The use of contrast enhancement methods can effectively enhance the clarity of images, making their brightness more pronounced and highlighting key information.

V. CONSTRUCTION OF A LABORATORY ABNORMAL BEHAVIOR RECOGNITION MODEL BASED ON OPENPOSE

Compared with 2D images, bone sequences can more accurately reflect the spatial distribution positions of various joints in the human body, but cannot effectively characterize the connection status between joints in the human body. To better express the semantics of complex interaction behaviors, this article can use graph data structures to characterize the connection states between joints, and based on this, study a behavior feature description method based on time-space graphs. On the one hand, spatial graph connections can be designed based on the characteristics of individual bones in the frame and the corresponding joint interactions between two individuals; On the other hand, connectivity methods for temporal graphs can be studied based on the mapping relationships between nodes in each frame. Through these operations, the connectivity status of each bone node in the spatial region can be achieved, achieving spatiotemporal description of interaction behavior. The OpenPose algorithm is a bottom-up approach for behavior recognition. This algorithm can recognize human body movements, facial expressions, etc., and has good noise resistance [30-31]. The backbone extraction network of OpenPose adopts a variant based on ResNet, mainly composed of deep residual neural networks. This network can accept input from images of any size and convert the input images into feature maps of the same size. In the transformed feature map, multi-layer convolution and pooling layers are used to extract features from the image. At the final layer of the network, the obtained feature map is transformed into a local thermal spectrum for extracting bones, thereby achieving localization of various parts of the human body. This method maps the temperature distribution of various parts of the human body to obtain the temperature distribution of each part of the human body, thereby completing the pose estimation of the human body.

When using preprocessed data with OpenPose to identify abnormal behavior, although the novelty of this method may be affected by the wide application of OpenPose, it does not prevent innovation in data processing and model construction. As a key link to ensure the performance of the model, data preprocessing explores a more efficient bone feature extraction technology for the data generated by OpenPose, and tries to incorporate novel features to enhance the expressive force of the data. The construction of recognition model is the core of this study. Based on the skeleton information extracted by OpenPose, a variety of machine learning and deep learning models are skillfully designed and trained to achieve a breakthrough in the field of abnormal behavior recognition. These measures not only highlight the innovation of research, but also are expected to significantly improve the accuracy of abnormal behavior identification.

OpenPose has excellent ability to identify and locate key points of human body, and can capture multiple key points of face, hands, feet and main parts of the body at the same time, with a total of 25 points. This comprehensive detection enables the algorithm to grasp the human posture more accurately, and then accurately judge the abnormal behavior in the laboratory. At the same time, the algorithm uses the human body component decoder to determine the relationship between key

points, which helps the algorithm to understand the human posture structure more deeply, thus improving the recognition accuracy. This design makes the algorithm perform better in dealing with complex human movements and posture changes, and effectively reduces misjudgment. In addition, OpenPose also uses multi-scale pyramid network to detect the human contour and key points, and then improves the positioning accuracy through gradual thinning. This structure is efficient and accurate. In practical application, lightweight OpenPose models can be selected to reduce the computational load and improve the recognition speed. These models significantly reduce the demand for computational resources while maintaining high accuracy. In addition, OpenPose also adopts efficient strategies such as parallel processing and cache optimization to further reduce the amount of computation and time consumption, and ensure that the algorithm can quickly process the input and output the recognition results.

In this article, human behavior and actions are recognized based on human bone data, mainly through the acquisition of human bone information through Kinect sensors. The obtained bone information is used as the three-dimensional coordinate values of various joint nodes in the human body. After completing a behavior, the experimental participants can obtain the corresponding bone data stream and save this bone data with a dimension of $48 * L$, where L refers to the length taken during the data alignment process. OpenPose can be used to connect the entire skeleton through the relationship between points during the extraction process of human skeletal points [32-33]. The coordinate vectors of S joint points can be used to express the initial input bone data within one frame. For any t -the frame, the initial input data can be represented as $A_t \in Q^{Z_0 * S}$, Z_0 represents the coordinate dimension of the input original bone data, and t represents the t -th frame bone data. To better capture the relationship between the corresponding joint connections and behavioral semantics between adjacent frames, a frame-to-frame time graph connection design is performed for each frame of joint data, combined with the joint data of the previous and subsequent frames. The expression is:

$$m_{a,b} = \begin{cases} \alpha & (a,b) \in \aleph_5 \\ \beta & (a,b) \in \aleph_6 \\ 0 & a = b \end{cases} \quad (8)$$

Among them, $m_{a,b}$ describes the different weights α and β given to the edge response calculation when the joint point a and the joint point b belong to different connection categories \aleph_5 and \aleph_6 in the connection diagram.

Therefore, the adjacency matrix of the inter-frame time graph can be expressed as:

$$W_{t,t+1} = \begin{bmatrix} E_1 & E_2 \\ Q_1 & Q_2 \end{bmatrix} \quad (9)$$

Among them, E_1 and E_2 describe the joint relationship between the interaction parties between frames and themselves, as well as the joint connection relationship between Q_1 and Q_2 interaction parties and the interaction object between frames, jointly constructing a time graph description of interaction behavior between frames.

When human behavior is different, there can be a certain angle relationship between limbs due to deformation, and the

angle information has good scale invariance. In addition, in laboratory settings, abnormal behavior exhibits strong mobility in many aspects compared to normal behaviors such as standing or standing on the left. Therefore, using joint angles as separate data to analyze abnormal behavior is very useful. The formula for calculating the joint angle is as follows:

$$\theta_{n,m} = \arccos \frac{\gamma \cdot \delta}{|\gamma| |\delta|}, |\gamma| \neq 0, |\delta| \neq 0 \quad (10)$$

Among them, $\theta_{n,m}$ represents the angle value of the n th joint in frame m , m is the inner product of the vector, $\|$ is the modulus of the vector, γ and δ represent the limb vectors corresponding to the joint angle, respectively.

The appearance characteristics of the human body reflect the proportion of the body shape during movement, which is a highly recognizable information. In laboratory settings, abnormal human behavior exhibits more significant movement characteristics than normal behavior, that is, during the movement process, abnormal behavior can undergo corresponding changes in its appearance due to the significant movement of limbs. The expression for calculating the proportion of human body shape is as follows:

$$ratio_i^k = \frac{\max(l_1^k, \dots, l_m^k) - \min(l_1^k, \dots, l_m^k)}{\max(d_1^k, \dots, d_m^k) - \min(d_1^k, \dots, d_m^k)} \quad (11)$$

Among them, i represents the current frame rate, k represents the k th person in the current frame, (d_1^k, \dots, d_m^k) and (l_1^k, \dots, l_m^k) represent the d and l coordinates of the k th human joint point, respectively.

This article can input preprocessed data into the OpenPose model. Firstly, the image features can be extracted through the backbone extraction network. Then, the key points in the image can be associated with each other to extract the confidence interval of the bone points. The optimal algorithm can be used to locate the key points, resulting in a bone structure map. The identification results of key areas for abnormal behavior (sleep) of experimental personnel are shown in Fig. 6.

Fig. 6. Comparison of abnormal behavior before and after processing.

As shown in Fig. 6, the OpenPose model can effectively identify abnormal behaviors of experimenters. When abnormal behaviors occur during sleep, the OpenPose model can quickly capture and process corresponding bone information. On this basis, the OpenPose model utilizes convolutional neural networks to extract bone features and inputs them into a recurrent neural network to model the sequence. Therefore, it

can effectively obtain time series information of human posture and improve the estimation accuracy of moving targets.

VI. EXPERIMENT OF LABORATORY ABNORMAL BEHAVIOR RECOGNITION MODEL BASED ON OPENPOSE ALGORITHM

A. Experimental Preparation

The specific environment configuration of the server is shown in Table I.

TABLE I. MODEL PARAMETER SETTINGS

Serial number	Experimental environment	Parameter
1	Central processing unit	Intel Xeon(R) E5-2620
2	Operating system	Ubuntu6.04 LTS
3	Deep learning framework	Pytorch 0.4.0
4	Programming language	Python 3.5
5	Initial learning rate	0.01
6	Weight attenuation coefficient	1×10^{-4}

Based on the characteristics and safety requirements of the laboratory itself, abnormal behavior can be classified according to specific regulations and laboratory safety needs. Meanwhile, corresponding discrimination criteria were established based on different types of abnormal behaviors. The specific abnormal targets that need to be detected for each type of experiment are shown in Table II.

TABLE II. REQUIREMENTS FOR DETECTING ABNORMAL TARGETS IN DIFFERENT EXPERIMENTS

Serial number	Abnormal behavior	Test set	Experiment set	Verification set	Total
1	Sleep	1040	130	130	1300
2	Long hair	640	80	80	800
3	Without gloves	720	90	90	900
4	Illegal disposal of waste	400	50	50	500
5	Eat	960	120	120	1200
6	Smoking	1120	140	140	1400
7	Play with mobile phone	1760	220	220	2200
8	Playing and running	2400	300	300	3000
Total		9040	1130	1130	11300

As shown in Table II, it can be observed that abnormal behavior is divided into eight categories, each of which is divided in a certain proportion into test set, experimental set, and validation set. Among them, the abnormal behavior of playing and running has the highest amount of data, while the abnormal behavior of illegal disposal of waste has the lowest amount of data.

B. Experimental Analysis

To achieve more accurate and scientific experimental results, multiple iterative experiments can be conducted. The 11,300 image data extracted in Table II are studied. In order to make the experimental results more accurate and scientific, multiple iterative experiments will be conducted, and the accuracy, accuracy, recall rate, and F1-Measure (F1 value) obtained from the laboratory abnormal behavior recognition model constructed based on the proposed method will be experimentally compared with the convolutional neural network (CNN) [4], Spatial-Temporal Context visual tracking (Spatio-Temporal Context, STC) [3], AlphaPose algorithm [6], Long Short-Term Memory network (Long Short-Term Memory, LSTM) [7], Graph Convolutional Network (GCN) [5] and Meanshift [12] abnormal behavior recognition model constructed by the algorithm is compared, and the specific model performance comparison results are shown in Table III.

TABLE III. PERFORMANCE COMPARISON OF DIFFERENT ABNORMAL BEHAVIOR RECOGNITION MODELS

Algorithm	Accuracy (%)	Precision (%)	Recall (%)	F1 value (%)
Proposed	95.33	96.68	93.77	94.38
CNN	87.41	88.12	84.14	85.31
STC	86.25	84.91	80.47	81.59
AlphaPose	80.94	81.48	77.75	75.09
LSTM	86.39	89.12	82.66	80.67
GCN	82.63	84.39	83.97	82.07
Meanshift	84.61	82.77	81.73	80.33

As shown in Table III, the performance of the laboratory abnormal behavior recognition model constructed by the proposed algorithm in this paper is better than that of other algorithms in all aspects, which shows that the method studied in this paper can better detect and identify abnormal behaviors that occur in the laboratory. Behavior. The accuracy rate of the behavior recognition model constructed based on the proposed method is 95.33%, which is higher than that of the abnormal behavior recognition model constructed based on CNN, STC, AlphaPose, LSTM, GCN, and Meanshift algorithms. 7.92%、9.08%、14.39%、8.94%、12.7% And 10.72%.The high accuracy rate of the proposed method not only reflects its

strong feature extraction and classification capabilities, but also its effectiveness in dealing with diverse abnormal behaviors in a laboratory environment. Compared with traditional visual methods such as CNN and STC, the proposed method can more accurately capture subtle changes in key points of human bones, so as to accurately distinguish between normal behavior and abnormal behavior. The accuracy rate of the method studied in this paper is 96.68%, which is 8% higher than the accuracy rate of the model constructed based on CNN, STC, AlphaPose, LSTM, GCN and Meanshift algorithms, respectively..56%、11.77%、15.2%、7.56%、12.29% and 13.91%, which means that the model has a lower false positive rate when identifying abnormal behavior, that is, it is less likely to misjudge normal behavior as abnormal.

At the same time, the recall rate of up to 93.77% ensures that the model can detect most real abnormal behaviors, significantly reducing the risk of missed inspections. This dual guarantee makes the proposed method of great practical value in laboratory safety control. The F1 value, as the reconciled average of the accuracy rate and recall rate, can more comprehensively show the overall performance of the model. The F1 value of the proposed method as high as 94.38% shows that it has done an excellent job in balancing accuracy and recall, once again confirming its superiority as a laboratory abnormal behavior recognition tool. The proposed algorithm can extract key point data of human bones from videos or images in real time and accurately, providing a valuable source of information for analyzing human posture and movement patterns. Although the comparison algorithms such as LSTM and GCN in Table III also incorporate time and graph structure information, the method relies on its unique attitude evaluation architecture to more naturally combine space-time background information, so as to more effectively capture the dynamic evolution of behavior evolution.

Research can be conducted on the extracted abnormal behavior data in Table II. Skeleton point extraction can be performed on the extracted abnormal behavior data images. The faster the extraction speed, the better for subsequent behavior recognition. This article can use the OpenPose algorithm to extract bone points from the collected images. The required extraction time can be compared with models constructed based on CNN, STC, AlphaPose, LSTM, GCN, and Meanshift algorithms. The specific comparison results are shown in Table IV.

TABLE IV. COMPARISON OF BONE POINT EXTRACTION SPEEDS AMONG DIFFERENT MODELS

Algorithm	1	2	3	4	5	6	7	8	Average value
Proposed	1.95	1.84	2.16	2.49	1.74	1.91	2.31	3.08	2.19
CNN	6.87	6.17	5.86	4.69	7.08	5.47	6.22	7.96	6.29
STC	3.34	2.96	2.88	4.02	4.81	4.39	5.93	5.22	4.19
AlphaPose	4.91	3.34	3.17	4.49	4.02	5.17	4.61	5.06	4.35
LSTM	5.64	4.06	5.49	6.07	4.86	6.02	4.77	5.83	5.34
GCN	5.13	4.46	4.97	6.39	4.08	3.84	5.06	6.28	5.03
Meanshift	3.58	3.27	4.51	3.28	5.18	4.63	5.88	6.31	4.58

As shown in Table IV, the comparative experimental results of different algorithms on the extraction speed of bone points are shown. First of all, the proposed method showed a significant speed advantage when extracting bone points of abnormal behavior images in Table II. The average extraction time is only 2.19 seconds, which is 4.1 seconds, 2 seconds, 2.16 seconds, 3.15 seconds, 2.84 seconds and 2.39 seconds lower than the time required for models built based on CNN, STC, AlphaPose, LSTM, GCN, and Meanshift algorithms, respectively. The time required for the model is 4.1 seconds, 2 seconds, 2.16 seconds, 3.15 seconds, 2.84 seconds, and 2.39 seconds. This advantage is not only reflected in the average time, but also in the stability and efficiency of the proposed method when dealing with various types of abnormal behaviors. Further analysis found that although the number of slapsticks running images numbered 8 is large, the proposed method can still complete bone point extraction within 3.08 seconds, compared to other algorithms such as CNN's 7.96 seconds, LSTM's 5.83 seconds, etc., its time advantage is particularly obvious. This proves the efficiency and robustness of the method in handling complex dynamic scenes. On the contrary, for the eating image numbered 5, although the number of images is large, the amplitude of its movement is relatively clear. The method can quickly capture these subtle changes and

complete the bone point extraction at an extremely fast speed of 1.74 seconds, which further verifies the advantages of the algorithm in accurately capturing the posture of the human body. In addition, the proposed method can maintain a relatively stable time consumption when extracting bone points of different abnormal behavior images, without significant fluctuations, which shows that the algorithm has good generalization ability and stability, which is conducive to dealing with diverse scenarios and needs in practical applications. In summary, the proposed method with its excellent extraction speed and stability, provides strong support for the rapid and accurate identification of bone points in abnormal behavior images, and lays a solid foundation for subsequent behavior recognition work.

Eight possible abnormal behaviors that may occur in the laboratory were selected in Table II, and the eight selected abnormal behaviors were numbered 1-8. A laboratory abnormal behavior recognition model based on OpenPose algorithm can be used to detect these eight abnormal behaviors, and the accuracy of detecting each abnormal behavior can be obtained. The detected experimental results can be compared with the accuracy of models constructed based on CNN, STC, AlphaPose, LSTM, GCN, and Meanshift algorithms. The specific comparison results are shown in Fig. 7.

Fig. 7. Comparison of accuracy of different abnormal behavior recognition models for abnormal behavior recognition.

In Fig. 7, the x-axis represents the abnormal behavior number, and the left and right y-axis represent the abnormal behavior recognition accuracy. Among them, the recognition accuracy of the proposed method, STC, LSTM, and Meanshift algorithms refers to the left y-axis, while the CNN, AlphaPose, and GCN algorithms refer to the right y-axis. As shown in Fig. 7, the method has excellent performance in identifying these abnormal behaviors, and its average recognition accuracy rate is as high as 96.81%. Compared with other algorithms, the accuracy rate of the method is 8% higher than that of CNN, STC, AlphaPose, LSTM, GCN, and Meanshift, respectively. 0.01%、12.1%、12.27%、8.44%、7.41% and

10.91%. Among them, the method's recognition rate exceeded 95.07% when dealing with all eight behaviors. Especially when it comes to identifying complex and subtle abnormal behaviors such as playing with mobile phones, its accuracy rate is as high as 98.27%, far surpassing other algorithms. Compared with other algorithms, the proposed method not only leads in the average accuracy rate, but also performs well in the recognition of each type of abnormal behavior. Compared with CNN and STC, the average accuracy rate of the method has improved significantly, showing high reliability and accuracy in dealing with diverse and complex abnormal behaviors in the laboratory. Compared with AlphaPose, which is also an attitude estimation

algorithm, the method has more obvious advantages in identifying subtle movements and behaviors in complex scenes. Although the recognition rate of GCN in some cases is close to that of the method, overall, the proposed method still has an advantage in recognition accuracy and stability. In summary, this study experimentally verifies the excellent performance of the abnormal behavior recognition model based on the method in the laboratory environment. The model is not only efficient in bone point extraction, but also has a significant breakthrough in recognition accuracy, which provides strong support for behavioral monitoring fields such as laboratory safety management.

When key points cannot be detected, in order to accurately identify character behavior, we need to combine other characteristics, not just rely on posture estimation results. However, the introduction of non-skeletal posture features may

have an impact on the real-time performance of behavior recognition algorithms. Through the observation of the NTU RGB+D data set, it is found that the camera is installed in a position with a large field of view and can avoid looking down or looking up from a large angle. This good camera position can effectively reduce occlusion, thereby capturing clearer images. Therefore, the requirements for the installation angle of the camera are put forward, which can not only meet the needs of real-time detection, but also improve the accuracy of multi-target behavior recognition to a certain extent. After obtaining the model-related data and the test data of the simple scene video, some materials in the laboratory environment were selected to test the algorithm. Using the laboratory abnormal behavior recognition model constructed by the method, the renderings of the abnormal behavior bone extraction of laboratory personnel are shown in Fig. 8.

Fig. 8. Recognition effect of the proposed laboratory abnormal behavior recognition model.

As shown in Fig. 8, normal is marked in Fig. 8(a), which indicates the normal laboratory behavior of the experimenter, while abnormal is marked next to Fig. 8(a), which represents the abnormal behavior of the experimenter. In this paper, the proposed method is used to effectively identify the abnormal behavior of laboratory personnel. In Fig. 8(b), the standing position of the experimenter in the laboratory is identified. The algorithm studied in this paper can be well identified for the laboratory behavior of more complex personnel. Normal is marked for normal experimental behavior, while abnormal experimental behavior is marked as abnormal. The proposed method has good motion and posture estimation capabilities, and can accurately detect and track human joints in real time. This allows the model to accurately identify the posture and movements of personnel in the laboratory. At the same time, this method can also achieve multi-person posture estimation, without knowing the specific location of the human body in advance, multiple human bodies can be positioned.

C. Discussion

The obtained results were discussed in the context of previous research findings and methods. Comparative analysis highlights that the proposed method has better performance advantages in detecting abnormal laboratory behavior compared to conventional detection methods. The proposed method focuses on the research of laboratory abnormal behavior detection methods for human skeletal features, which better reduces the interference of complex background environments and other factors in the behavior recognition process. The method uses Kinect sensors to obtain human skeletal feature information, which has a smaller data volume and higher security compared to conventional image data

acquisition. The use of moving average filtering, Discrete Fourier Transform, and contrast to preprocess data has improved data quality and recognition performance. Using OpenPose algorithm to achieve fast and stable extraction and classification of behavioral skeletal features. The laboratory abnormal behavior detection model based on skeletal features has higher accuracy and robustness, lower parameter count, and higher operational efficiency compared to traditional laboratory abnormal behavior detection methods.

VII. CONCLUSIONS

In recent years, with the continuous deepening of laboratory safety management, effective identification of abnormal behaviors during the experimental process has become one of the current research hotspots. This article takes human bones as the research object, analyzes the characteristics of human bones, and constructs a laboratory abnormal behavior recognition model based on bone features. The model mainly uses OpenPose algorithm and sensor devices to complete behavior recognition. Meanwhile, the model studied in this article mainly analyzes the changes in the spatial trajectory of human skeletal joints, which can effectively identify abnormal behavior in the laboratory. In this study, personnel behavior data was collected in the laboratory, and the YOLOv5 algorithm was used to extract bone features. Then, a laboratory abnormal behavior recognition model was established based on the OpenPose algorithm. The experimental results show that this method can effectively identify abnormal behavior in the laboratory, and performs excellently in accuracy and recall. The main research results obtained are as follows: 1) A model for identifying abnormal

behavior can be established, which has a very high accuracy in identifying abnormal behavior; 2) The recognition performance of the constructed model is superior to other models; 3) The recognition model based on OpenPose algorithm can extract human bone feature points more quickly. In summary, the method studied in this article not only has high recognition accuracy, but also has good real-time and stability, which can provide better assistance for laboratory safety management work.

When discussing the superiority and effectiveness of the laboratory abnormal behavior recognition model based on skeletal features studied in this article, it is also necessary to consider its limitations and future improvement directions. The following are several main limitations: Limitations of the dataset: The dataset used in the study may be limited to specific types of laboratory environments and behavioral patterns, thus the model's generalization ability may be limited. Algorithm complexity and computational resources: Although OpenPose algorithm performs well in bone feature extraction and behavior recognition, they have higher computational complexity, which in turn puts higher demands on the hardware resource conditions of the application environment. In the future, further research will be conducted to optimize model performance, enhance model adaptability, and expand the applicability of the model.

Twitter Truth: Advanced Multi-Model Embedding for Fake News Detection

Yasmine LAHLOU, Sanaa El FKIHI, Rdouan FAIZI

IRDA Group-ADMIR Laboratory-Rabat IT Center-ENSIAS, Mohammed V University in Rabat, Morocco

Abstract—The identification of fake news represents a substantial challenge within the context of the accelerated dissemination of digital information, most notably on social media and online platforms. This study introduces a novel approach, entitled "MT-FND: Multi-Model Embedding Approach to Fake News Detection," which is designed to enhance the detection of fake news. The methodology presented here integrates the strengths of multiple transformer-based models, namely BERT, ELECTRA, and XLNet, with the objective of encoding and extracting contextual information from news articles. In addition to transformer embeddings, a variety of other features are incorporated, including sentiment analysis, tweet length, word count, and graph-based features, to enrich the representation of textual content. The fusion of signals from diverse models and features provides a more comprehensive and nuanced comprehension of news articles, thereby improving the accuracy of discerning misinformation. To evaluate the efficacy of the approach, a benchmark dataset comprising both authentic and fabricated news articles was employed. The proposed framework was tested using three different machine-learning models: Random Forest (RF), Support Vector Machine (SVM), and XGBoost (XGB). The experimental results demonstrate the effectiveness of the multi-model embedding fusion approach in detecting fake news, with XGB achieving the highest performance with an accuracy of 87.28%, a precision of 85.56%, a recall of 89.53%, and an F1-score of 87.50%. These findings signify a notable improvement over traditional machine learning classifiers, underscoring the potential of this fusion approach in advancing methodologies for combating misinformation, promoting information integrity, and enhancing decision-making processes in digital media landscapes.

Keywords—*Fake news detection; transformer-based models; text classification; sentiment analysis*

I. INTRODUCTION

In recent years, the rapid spread of fake news on social media has emerged as a significant challenge to public opinion and even to democratic processes. The widespread dissemination of fake news can cause considerable societal damage, including political polarisation, the erosion of trust in legitimate sources of information and the manipulation of public behavior. In order to meet this challenge effectively, it is essential to implement robust and accurate systems capable of detecting fake news in real time, with the aim of preventing its spread and mitigating its effects.

The traditional methods for the detection of fake news, which often rely on manual verification and heuristic approaches, are no longer sufficient in the context of the current

volume and speed with which information is propagated on social media.

In contrast, advanced machine learning techniques offer a promising solution, automating the detection process and improving the accuracy of the results. These techniques facilitate the rapid analysis of large data sets, enabling the identification of patterns and anomalies that may indicate the presence of misinformation. As Lahlou et al. [1] have observed the deployment of machine learning and natural language processing techniques is vital for the identification and categorisation of fake news, given their capacity to handle extensive datasets and extract meaningful attributes. The objective of this study is to utilize advanced methods for optimizing the detection of fake news, particularly on Twitter. Similarly, Shu et al. [2] emphasize the potential of data mining and machine learning in combating the dissemination of fake news on social media platforms.

A number of studies demonstrate the effectiveness of NLP transformation models in identifying fake news, with promising results. In the field of natural language processing (NLP), BERT (Bidirectional Encoder Representations from Transformers) has emerged as a seminal model, distinguished by its capacity to discern intricate contextual nuances in textual data. Developed by Devlin and colleagues [3], BERT has achieved notable levels of accuracy in various Natural Language Processing (NLP) benchmarks through the utilisation of a bidirectional training process and a transformer architectural approach. The utilisation of BERT in the detection of fake news involves the analysis of textual content in an effort to identify any subtle linguistic cues that may indicate misinformation. Another advance in the field of transformer models is represented by the introduction of ELECTRA (Efficiently Learning an Encoder that Classifies Token Replacements Accurately), as proposed by Clark et al. [4]. In comparison to the conventional masked language modelling approach used by BERT, ELECTRA offers a more streamlined training mechanism. This methodology concentrates on the identification of substituted tokens within the textual data, thereby enhancing the model's capacity to discern intricate textual subtleties. In the domain of fake news detection, ELECTRA's discriminative training has demonstrated efficacy in discriminating between authentic and disingenuous content with enhanced precision.

The XLNet approach, as described by Yang et al. [5], integrates autoregressive and auto-encoding methodologies to capture bidirectional contextual dependencies, representing a significant advancement over previous models. By overcoming the limitations of traditional pre-training tasks, the XLNet model

achieves a superior performance in understanding complex linguistic structures and capturing subtle semantic relationships. In the domain of fake news detection, XLNet's capacity to model bidirectional dependencies allows it to identify intricate patterns of misinformation, enhancing the precision and dependability of detection. Recent research has further explored the integration of these transformation models into sophisticated frameworks for the detection of fake news. For instance, Liu et al. [6] illustrated the efficacy of integrating BERT and ELECTRA into a hybrid model. This model combines the respective strengths of both models, thereby achieving enhanced robustness in the detection of various types of fake news.

Despite the advances made to detect fake news, there are still some limitations to existing approaches. Many studies focus only on textual content, neglecting the rich contextual information available from user behavior and social context features as described by Lahlou et al. [7]. Furthermore, a single-model approach may not capture all language features needed for accurate detection [8] [9].

To address these limitations, we propose an advanced, representative approach to detecting fake news by harnessing the collective power of cutting-edge NLP transformative models and additional contextual features. These models, including BERT, ELECTRA, and XLNet, are at the forefront of natural language understanding, each offering unique capabilities to capture complex linguistic nuances [3] [4] [8]. BERT features context-sensitive language modelling using bidirectional transformers, while ELECTRA improves efficiency through a discriminative training approach. XLNet comprehensively captures bidirectional contextual dependencies by incorporating autoregressive and auto-encoding mechanisms.

The objective of this study is to integrate advanced transformer models derived from deep learning with traditional machine learning classifiers for classifying news articles into fake or real categories. A novel approach is introduced that harnesses the capabilities of BERT, ELECTRA, and XLNet transformers to extract contextual embeddings from tweets. These embeddings, in conjunction with sentiment analysis-derived features, serve as comprehensive input features for the classifiers.

The value of our work lies in its innovative approach to integrating state-of-the-art transformer models with traditional machine learning classifiers to tackle the ubiquitous problem of detecting fake news. The study exploits models such as BERT, ELECTRA and XLNet, which are capable of understanding and extracting complex contextual information from news headlines. This in-depth understanding of context is essential for accurately discerning the nuances between true and fake news, which often require a nuanced interpretation of language and sentiment. Furthermore, the incorporation of sentiment analysis-derived features enhances the model's capacity to discern subtle emotional nuances embedded in text, thereby providing a more comprehensive foundation for decision-making in classification tasks.

This study is structured as follows: Section II, titled "Related Works," provides an overview of existing AI techniques and methodologies employed to detect fake news on twitter. Section III delves into the problem formulation, detailing the

architectural design and the proposed approach. Section IV outlines the methodology used in this research, describing the experimental setup, data preprocessing techniques, sentiment analysis, and the feature extraction process. It also covers the evaluation metrics used. Section V presents the experimental results, including a detailed comparison of classifier performance on both fused and individual model embeddings, assessing the effectiveness of the fusion approach. Finally, Section VI concludes the research by summarizing key findings, discussing the limitations of the current approach, and proposing potential directions for future work.

II. RELATED WORKS

In the past ten years, there has been a great deal of scientific research conducted on the detection of fake news on social media platforms. This study will present an overview of the key scientific research models developed to detect fake news on Twitter. The aim is to provide a comprehensive summary of these models. A threefold classification of the models in question is proposed: traditional machine learning models, deep learning models and transformation models.

With regard to machine learning, varieties of techniques are available for the differentiation between true and fake news on Twitter. These techniques include, but are not limited to, logistic regression, long-term memory, K-mean, support vector machine (SVM), random forest (RF), and Naive Bayes (NB). These techniques employ data pre-processing, feature extraction and sentiment analysis in order to enhance the accuracy of classification models. The linear SVM classification algorithm, which employs TF-IDF feature extraction, demonstrated the highest accuracy of 99.36% [10] [11]. Similarly, Raja [12] achieved a high level of accuracy (93%) using TF-IDF and an SVM classifier. Srinivas [13] employed TF-IDF in conjunction with MNB, RF, SVC and LR classifiers, achieving an accuracy of 79.05%.

Recent advancements in automated fake news detection have increasingly emphasized the integration of contextual features, including temporal patterns, social context, and cross-platform data. The analysis of temporal patterns, particularly in terms of how information spreads over time, can provide invaluable insights into the veracity of the content in question. For example, the rate and timing of tweet propagation frequently display anomalous spikes when fake news is disseminated.

The incorporation of contextual data into the process of feature extraction represents a pivotal stage in aligning the core intent of tweets with their content. This approach facilitates the enhanced detection of misinformation propagation on Twitter [14]. Zhou and Zafarani [15] demonstrated that temporal dynamics, when analysed with machine learning models, enhance the detection of fake news by capturing the evolving nature of misinformation. Furthermore, the utilisation of social context is an efficacious methodology for the identification of misinformation. The analysis of social signals, including user interactions, follower networks and retweet patterns, can provide valuable additional information that can be used to distinguish between genuine and fabricated content. As demonstrated by Shu et al. [16], machine-learning models trained on social network data are capable of effectively assessing the credibility of users disseminating information,

which facilitates improved detection of fake news. The study demonstrated that incorporating social context into feature extraction enables models to not only detect fake news but also trace its propagation paths, thereby providing valuable insights into the dynamics of misinformation spread.

Shetty et al. [17] put a comprehensive framework that incorporates linguistic features, user engagement models, and network analysis, thereby demonstrating effective detection of fake news. Bhogi et al. [18], employed a range of machine learning (ML) techniques, including natural language processing (NLP), classification algorithms, and anomaly detection, achieving an accuracy of 93% with the passive-aggressive classifier.

Another promising approach to the automatic detection of fake news is cross-platform analysis. Misinformation frequently disseminates across a multitude of social media platforms; thus, cross-platform analysis can discern patterns that may evade detection on a single platform. In a related study, Nguyen et al. [19], developed a framework that integrates data from various social media platforms with the objective of detecting inconsistencies in the manner in which news is presented and shared. The results indicate that machine-learning models incorporating cross-platform data are more resilient and effective in identifying fake news, as they are capable of detecting anomalies characteristic of coordinated misinformation campaigns.

Collectively, these studies demonstrate the potential of ML in detecting fake news on social networks.

The transition from machine learning to more sophisticated models, including those based on deep learning, has been instrumental in advancing the field. This has been achieved through the exploitation of the abilities of convolutional neural networks (CNNs), recurrent neural networks (RNNs) and long-term memory networks (LSTMs). Such models can successfully identify and analyse complex patterns within tweet content, user behavior and propagation dynamics. For example, Manaskasemsak and Rungsawang [20] proposed a deep neural network model that leverages tweet content published time and social graph features for the detection of fake news sources on Twitter with high accuracy.

Furthermore, Alghamdi, Lin, and Luo explored the integration of users' posting behavior clues with deep learning techniques, namely Convolutional Neural Networks (CNNs) and Bidirectional Gated Recurrent Units (BiGRUs), for the improvement of fake news detection on social media platforms [21]. Naik and Kumar emphasised the effectiveness of Long Short-Term Memory (LSTM) models in the automatic detection of fake news. They demonstrated the ability of these models to address the challenges presented by the rapid dissemination of misinformation on social media platforms [22]. Additionally, Monti and Sahoo [23] [24] emphasize the significance of considering social network structure and user behavior, in addition to content-based analysis. Monti's model, based on geometric deep learning, achieved an accuracy of 92.7% in detecting fake news on Twitter. In a further development, Kaliyar proposed a deep convolutional neural network (FND Net), [25] that attained a remarkable 98.36% accuracy in detecting fake news. Sedik [26] subsequently improved upon

these results by proposing a deep learning-based system that combines concatenated and recurrent modalities, achieving an impressive 99.6% accuracy.

The recent advancements in deep learning have significantly enhanced the ability to detect fake news by integrating textual and contextual features. Mouratidis et al. [27] proposed a schema for textual inputs that are pairwise in nature, incorporating both the content of the news items in question and their context. The combination of content and context enables the model to more effectively capture the semantics and detect inconsistencies that are often indicative of fake news.

In a recent study, Bhatia et al. [28] introduced a deep neural network model that integrates multiple contextual features, including tweet content, publishing time, and social graph information. This multi-modal approach enables the model to consider a range of elements pertaining to the news, including the timing of publication and the social network of users sharing the content, in addition to the textual content itself. The combination of these diverse features enables the model to achieve an accuracy rate of 98.7% on the FakeNewsNet dataset. The incorporation of temporal and social graph features facilitates an enhanced comprehension of the broader context of news dissemination, thereby augmenting the model's capacity to identify fake news with greater reliability. This comprehensive approach underscores the significance of integrating diverse contextual data to enhance the efficacy of detection.

In the same context, Rajakumaran et al. [29] concentrated their attention on the possibility of early detection of fake news by examining propagation patterns and user interactions. The deep learning model employs contextual features, including user behavior and the propagation dynamics of news articles, to identify instances of fake news at the earliest possible stage of their dissemination. By monitoring early signals and interactions, their approach enables detection within hours of initial propagation, thereby providing a timely response to emerging misinformation. This capability is crucial for mitigating the impact of fake news and ensuring that accurate information prevails. The integration of contextual features related to propagation patterns enhances the model's sensitivity to early indicators of fake news, thereby demonstrating the importance of timely detection in combating misinformation.

In general, these deep learning techniques provide effective solutions for the automatic detection of fake news on Twitter, outperforming traditional classifiers and potentially complementing content-based approaches.

Transformer models, a subset of deep learning architectures, differ significantly from traditional deep learning models like Convolutional Neural Networks (CNNs) and Recurrent Neural Networks (RNNs). While CNNs excel at handling spatial data and capturing local dependencies, and RNNs are adept at processing sequential data by maintaining temporal dependencies, they both have limitations in capturing long-range dependencies efficiently [30]. Transformers, on the other hand, utilize a self-attention mechanism that allows them to consider the entire context of a sentence simultaneously, making them highly effective at capturing long-range dependencies and contextual relationships across a text c.

The combination of the self-attention mechanism with the parallel processing capabilities of transformers results in more efficient training and a greater suitability for large datasets than that observed with RNNs, which are sequential in nature [31].

Furthermore, transformers benefit greatly from transfer learning through pre-training on extensive corpora followed by fine-tuning on specific tasks, leading to significant performance improvements in natural language processing tasks [32] [33]. Notable examples of transformer models include BERT, GPT, and T5, which have set new benchmarks in the field by leveraging these advanced techniques [32] [34].

Varieties of approaches are currently under consideration, including the TSRI model, which combines the characteristics of the text, source, and user response in order to obtain accurate predictions [35].

Recent research has focused on transformer-based approaches for fake news detection, leveraging both news content and social contexts. These models aim to address challenges such as early detection and limited labeled data [36]. The proposed frameworks utilize transformer architectures to learn representations from news articles and social media data [37].

The utilisation of transformative models, such as RoBERTa, has demonstrated promising results in the detection of fake news across diverse datasets, with RoBERTa exhibiting superior performance in terms of accuracy and training time compared to other models [38]. Similarly, Mina Schütz and colleagues [39] investigated the potential of pre-trained transformer models for the detection of fake news, using the FakeNewsNet dataset. The methodology entailed the application of transformer-based models to the text of news articles and a combination of the text of news articles and their titles, with an accuracy rate of up to 85%. In their study, Divyam Mehta et al., [40] examine the

effectiveness of BERT. The authors fine-tune BERT on LIAR datasets and improve its performance by incorporating additional inputs such as human justification and metadata. Their methodology involves adapting BERT's deep contextual capabilities to classify news articles into both binary and six-label categories. The study shows that BERT significantly outperforms traditional models in binary classification, achieving 74% accuracy. While the improvement in the more complex six-label classification is modest, it remains important and highlights BERT's ability to capture and utilise nuanced textual and contextual information.

These advances underscore the significant potential of transformer-based models in enhancing the accuracy and efficiency of fake news detection on platforms like Twitter, pushing the boundaries of what is achievable in this critical area of research.

Table I provides a comprehensive overview of the different machine learning, deep learning and transformer models used for fake news detection.

This comprehensive analysis compares and contrasts traditional machine learning, deep learning, and transformer models to illustrate the advancements in the detection of fake news. The application of traditional machine learning techniques, including logistic regression, SVM and Naive Bayes, is contingent upon data pre-processing and feature extraction. However, these techniques often encounter difficulties in addressing complex relationships and handling large data sets. Deep learning models, such as convolutional neural networks (CNNs) and long short-term memory (LSTM) units have advanced the field by automatically extracting complex patterns and processing large amounts of data, achieving significant results in terms of accuracy and user behavior analysis.

III. PROPOSED MULTI-MODEL EMBEDDING APPROACH

Before presenting the approach and methodology of the proposed fusion framework, it is imperative to define the problem in order to establish the objective of the proposed model.

A. Problem Definition

In the context of the detection of fake news on Twitter, the problem is defined as a supervised learning task with the objective of determining whether a specific tweet is true or fake. The task is formulated as a binary classification problem with the objective of accurately classifying tweets based on both the textual content and supplementary features derived through the utilisation of multiple transformer models.

Given a collection of tweets $T = \{T_1, T_2, \dots, T_n\}$, each tweet T_i consists of textual data. The corresponding labels L indicate the authenticity of each tweet, where:

- 0 indicates that the tweet is real.
- 1 indicates that the tweet is fake.

The objective is to model a prediction function F that takes as input a comprehensive feature vector $\mathbf{X}(T)$ derived from a fusion of multiple transformer models (BERT, ELECTRA, and XLNet) and additional handcrafted features. The function F predicts the label of the tweet, i.e., $F(T) \rightarrow \{0,1\}$, where:

- $F(T)=0$ if the tweet T is predicted to be real.
- $F(T)=1$ if the tweet T is predicted to be fake.

In this fusion approach, the feature vector $\mathbf{X}(T)$ is composed of:

- Transformer-Based Embeddings:
 - CLS token embeddings from BERT and ELECTRA.
 - Mean-pooled embeddings from XLNet.
- Additional features:
 - Sentiment label and sentiment score.
 - Tweet length and word count.

The prediction function F is implemented as a machine learning classifier (e.g. Random Forest, XGBoost) that is trained on the fused feature vector $\mathbf{X}(T)$. The objective is to classify tweets as true or false using the diverse linguistic and contextual information provided by the fusion of multiple models and additional features.

The following section will provide a comprehensive explanation of the proposed approach.

B. Approach and Methodology

The objective of this article is to introduce the Multi-Model Embedding Approach to Fake News Detection (MT-FND), which represents a novel approach specifically designed for detecting fake news. It works by leveraging advanced natural language processing (NLP) techniques and integrating multiple transformer models—BERT, ELECTRA and XLNET.

The transformer models are selected for their robustness in NLP tasks, particularly in generating contextual embeddings that capture semantic nuances and contextual understanding, as demonstrated by prior research.

To operationalize the selected models within MT-FND, specific functions are employed for tokenizing text entries and extracting embeddings. For BERT and ELECTRA, embeddings are derived from the [CLS] token, while XLNet calculates embeddings by averaging all token embeddings. These embeddings serve as fundamental representations of the textual content. Additionally, technical features such as tweet length, word count, sentiment tags, and sentiment scores obtained through sentiment analysis are incorporated into the feature vector. Furthermore, MT-FND employs graph representation techniques using NetworkX in order to extend the scope of its analysis beyond that of textual embeddings. In this context, each tweet within the dataset is treated as a node within a graph, and is subsequently enriched with a number of attributes including labels, sentiment metrics, tweet length, word count, and sentiment scores. A placeholder function is employed to convert these attributes into preliminary embeddings, thereby establishing the foundation for representing articles within the graph structure.

This approach enables MT-FND to identify relationships between tweets, potentially revealing patterns that may not be discernible through text analysis alone.

The next step in the MT-FND approach involves using these enriched feature vectors to train two different classifiers: the Random Forest Classifier and the XGBoost Classifier.

The Random Forest Classifier is employed to utilise the combined embeddings derived from BERT, ELECTRA, and XLNet, in conjunction with supplementary features, to ascertain the veracity of a given tweet. This combination exploits the diverse strengths of each transformer model, thereby facilitating predictions that are more accurate. In contrast, the XGBoost Classifier is configured to assess the discrete embeddings from BERT and XLNet individually, thereby enabling it to capitalise on the distinctive capabilities of each model in formulating its predictions. The dual-classifier approach guarantees that MT-FND will benefit from both ensemble learning and the distinctive capabilities of each transformer model.

In summary, MT-FND improves the detection and classification of fake news by combining multiple transformer models (BERT, ELECTRA, and XLNet) with cutting-edge natural language processing techniques. It offers a comprehensive view of text content by fusing text elements with technical features like sentiment scores and tweet length. By utilizing Random Forest and XGBoost classifiers, MT-FND seeks to increase the precision of disinformation identification. Subsequent enhancements could involve utilizing NetworkX for graph representations, which could lead to better comprehension of relational data models via sophisticated graph neural network methods. This methodical approach uses complementary machine learning techniques and sophisticated transformers to tackle the challenges of detecting fake news. Fig. 1 provides an overview of the approach proposed and tested in this article.

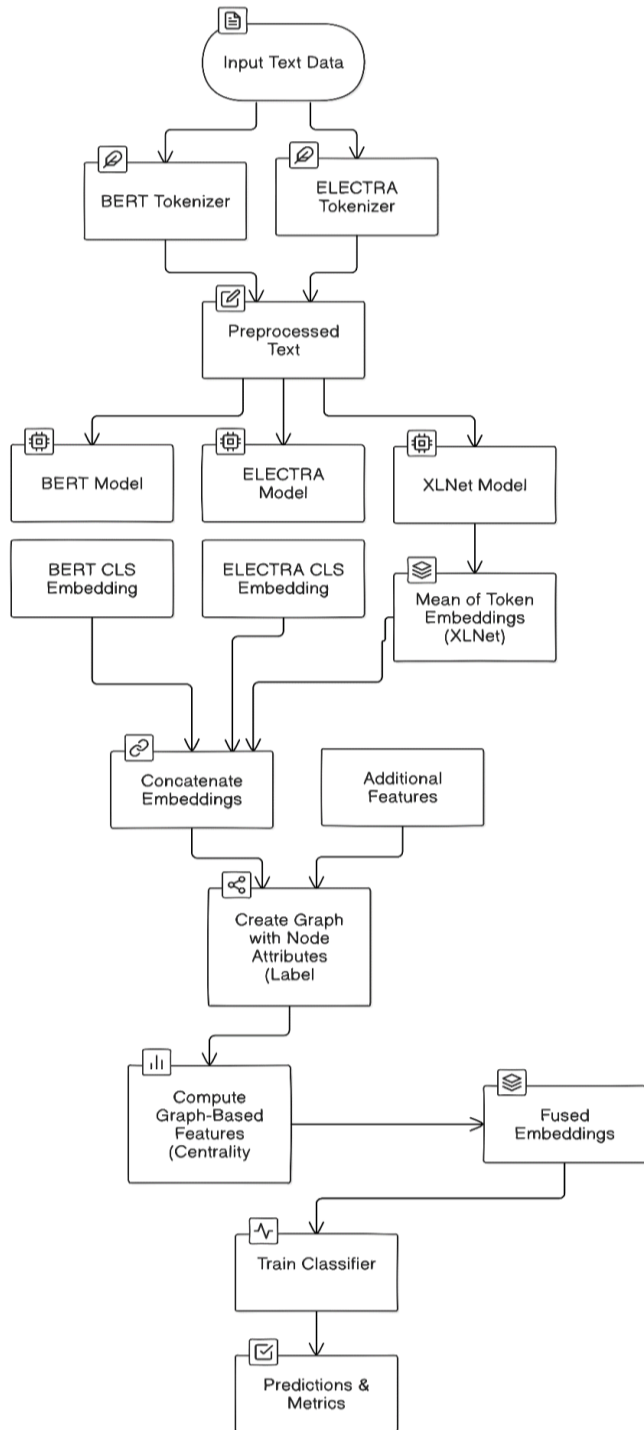

Fig. 1. Multi-model embedding approach to fake news detection (MT-FND).

IV. EXPERIMENTAL SET UP

In MT-FND approach, we opted for BERT, ELECTRA, and XLNet due to their established proficiency in natural language understanding tasks, each offering unique advantages such as contextual understanding, discriminative training efficiency, and bidirectional context capturing. By incorporating these diverse perspectives, we aimed to enhance the detection capabilities, effectively capturing the intricate nuances present

in news articles, particularly within the constrained context of Twitter.

A. Dataset Description

For the purposes of this study, we utilized the FakeNewsNet dataset. The dataset is a comprehensive collection that was designed to help researchers study fake news detection and analysis. Two primary sources of data are included: BuzzFeed and PolitiFact. The dataset contains various features such as news content, social context, and spatiotemporal information. In the dataset, there are 11,510 news articles, with a proportionally balanced number of real and fake articles, with 5,755 articles labeled as real (label 1) and 5,755 articles labeled as fake (label 0). The balanced distribution of this dataset makes it possible for models trained on it to learn how to distinguish between real and fake news, which provides strong evaluation metrics and makes detection algorithms more reliable in real-world situations.

Fig. 2 shows the balance distribution of the dataset:

Fig. 2. Distribution of the balanced dataset.

B. Feature Engineering and Sentiment Analysis

The initial phase of feature engineering comprises the tokenization and embedding of news articles' titles, which is conducted through the utilisation of three distinct pre-trained transformer models. The models used are BERT, ELECTRA, and XLNet. Each model processes the text differently, thereby capturing various nuances of language. For example, BERT focuses on contextual relationships between words by employing bidirectional attention, while XLNet emphasize sequence order by considering permutations of input tokens. The output from each model is a high-dimensional vector representing the semantic content of the article's title. These embeddings serve as the foundational features for the classification model. In addition to the text embeddings, a sentiment analysis pipeline is utilised for the evaluation of the titles in question. This phase of the process classifies each 'tweet' as either "positive" or "negative" and assigns a corresponding sentiment score.

In order to represent the relationships between the tweets in a graph, the proposed approach involves constructing a graph using the NetworkX library. In this graph, each node represents a tweet, and edges are created based on cosine similarity between the text embeddings. Should the similarity between two articles exceed a specified threshold, an edge is formed, with the strength of this connection quantified by the similarity score.

Subsequently, centrality measures (such as degree centrality) and clustering coefficients are calculated for each node, thereby providing insights into the article's importance and its tendency to cluster with similar articles. These graph-based features are of paramount importance for understanding the broader context in which an article exists.

In the final stage, the extracted features are integrated into a unified representation for each article. The embeddings from BERT, ELECTRA, and XLNet are concatenated with sentiment analysis features and graph-based features such as centrality and clustering coefficients. This fusion creates a comprehensive feature set that captures both the textual and relational properties of each article.

C. Evaluation Criteria

The evaluation criteria used in this study are:

- Accuracy: The purpose of the accuracy metric is to ascertain the proportion of correctly predicted labels out of the total number of predictions. It is a simple yet effective metric for assessing the overall performance of the MT-FND model.

Metric: the accuracy metric is calculated during the testing phase by comparing the predicted labels (test_predictions) with the true labels (test_labels). The accuracy is computed using the accuracy_score function from the sklearn.metrics library, which divides the number of correct predictions by the total number of predictions. This metric provides a clear indication of the model's effectiveness in distinguishing between real and fake news articles.

- Precision: The purpose of the precision metric is to measure the accuracy of the positive predictions made by the MT-FND model. Specifically, it assesses the proportion of true positive predictions out of all positive predictions made by the model.

Metric: precision is calculated during the testing phase by comparing the predicted labels (test_predictions) with the true labels (test_labels). The precision is computed using the precision_score function from the sklearn.metrics library, which divides the number of true positive predictions by the total number of positive predictions. This metric is particularly important in scenarios where the cost of false positives is high, as it reflects the model's ability to avoid incorrect positive classifications.

- Recall: The purpose of the recall metric is to measure the model's ability to correctly identify all actual positive instances. It calculates the proportion of true positive predictions out of all actual positive cases.

Metric: recall is calculated during the testing phase by comparing the predicted labels (test_predictions) with the true labels (test_labels). The recall is computed using the recall_score function from the sklearn.metrics library, which divides the number of true positive predictions by the total number of actual positive instances. This metric is crucial in scenarios where missing a positive instance (false negatives) is costly, as it reflects the model's effectiveness in capturing all relevant instances.

- F1 Score: The purpose of the F1 score is to provide a balance between precision and recall, offering a single metric that accounts for both false positives and false negatives.

Metric: the F1 score is calculated during the testing phase by comparing the predicted labels (test_predictions) with the true labels (test_labels). The F1 score is computed using the f1_score function from the sklearn.metrics library, which combines precision and recall into a single metric.

V. RESULTS AND DISCUSSIONS

A. Performance of MT-FND

In our evaluation of various classification models on a balanced dataset of real and false news articles, we introduced the Multi-Model Embedding Approach to Fake News Detection (MTFND), which integrates BERT, ELECTRA, and XLNet embeddings with graph features. This approach significantly enhances the accuracy and robustness of misinformation detection. The results clearly demonstrate the superiority of MTFND over models utilizing individual embeddings.

The performance of the proposed MTFND framework, which integrates fusion embeddings with graph features, demonstrates a strong enhancement in predictive capabilities across various classifiers. Among the models evaluated, the XGBoost classifier within the MTFND framework stands out, achieving an impressive accuracy of 87.28%. This model also shows a high precision of 85.56%, a recall of 89.53%, and an F1-score of 87.50%. These results highlight the ability of the MTFND framework to effectively capture and leverage complex features, providing a significant improvement over individual embedding approaches.

Table II presents a detailed comparison of model performance across various approaches, including the proposed MTFND framework and individual embeddings from BERT, XLNet, and ELECTRA.

TABLE II. FINDINGS OF THE EXPERIMENTS

Approach (Embedding type)	Model	Results by metrics type			
		Accuracy	Precision	Recall	F1-score
Proposed framework MTFND (Fusion embeddings + Graph Features)	RF	85.55	87.65	82.56	85.03
	SVM	84.97	84.09	86.05	85.06
	XGB	87.28	85.56	89.53	87.50
Individual BERT embeddings:	RF	84.97	84.09	85.06	84.97
	SVM	86.71	84.62	87.01	86.71
	XGB	84.97	84.09	85.06	84.97
Individual ELECTRA embeddings:	RF	79.19	82.89	73.26	77.78
	SVM	77.46	78.31	75.58	76.92
	XGB	81.50	83.75	77.91	80.72
Individual XLNET embeddings:	RF	78.03	79.27	75.58	77.38
	SVM	75.72	72.92	81.40	76.92
	XGB	78.61	77.53	80.23	78.86

When we evaluated models without the MTFND enhancements—relying solely on BERT embeddings or other contextual embeddings—the performance metrics were generally lower, highlighting the benefit of our approach.

For instance, the Random Forest classifier, when using only BERT embeddings without additional graph features, achieved an accuracy of 87.86%, a precision of 86.52%, and an F1 score of 88.00%. Although these figures are strong, they demonstrate that the inclusion of graph features in MTFND helps to provide a more nuanced understanding of the data, leading to predictions that are more accurate.

Similarly, the SVM classifier without the MTFND approach achieved an accuracy of 87.86%, a precision of 84.95%, and an F1 score of 88.27%. Again, while these results are respectable, they fall short of those achieved using the MTFND-enhanced models, particularly in terms of precision and F1 score, where the nuanced data representation provided by fusion embeddings and graph features shows its value.

The XGBoost classifier, even though robust, showed a noticeable drop in performance without the MTFND approach, recording an accuracy of 83.02%, a precision of 81.81%, and an F1 score of 79.27%. This further underscores the efficacy of the MTFND approach in enhancing the model's capability to detect and classify misinformation.

In conclusion, the MTFND approach significantly improves the performance of traditional machine learning models by enhancing their ability to analyze and interpret complex data patterns in news articles. The results clearly indicate that incorporating multimodal features, such as those in MTFND, is a powerful strategy for advancing the state of misinformation detection.

B. State-of-the-Art Comparison

Table III presents a comparative analysis of the proposed MTFND framework with several recent models from the literature. The MTFND framework achieved an accuracy of 87.28% using the XGB model, thereby demonstrating a significant improvement over the approaches described in study [39]. In particular, the BERT model proposed in study [39] achieved an accuracy of 85.0%. This comparison demonstrates that the MTFND framework, which integrates fusion embeddings (BERT, ELECTRA and XLNET) with graph features, exhibits superior performance in the detection of fake news in comparison to these transformer-based approaches. The XGB model within MTFND not only outperforms BERT and ALBERT in terms of accuracy but also demonstrates the efficacy of integrating diverse features and techniques. This suggests that the MTFND approach effectively harnesses both global text semantics and advanced features, resulting in a notable enhancement in performance. Further optimization and refinement of the MTFND framework may potentially yield even greater improvements.

TABLE III. COMPARATIVE MT-FND WITH OTHER WORKS

References	Comparative MT-FND with other works		
	Dataset	Technique	Accuracy
[39]	FakeNewsNet	BERT	85.0%
[40]	LIAR	BERT	74%
[13]	MNB, RF, SVC, LR	Twitter	79.05%.
Proposed framework MTFND	FakeNewsNet	Fusion embeddings (BERT,ELECTRA,XLNET)+ Graph Features with XGB classifier	87.28%

VI. CONCLUSION AND FUTURE WORK

This study presents a comprehensive approach to the detection of fake news, which integrates transformer-based embeddings with graph-based features. The integration of embeddings derived from BERT, ELECTRA, and XLNet with graph-based metrics has yielded a promising enhancement in performance, with notable improvements in accuracy, precision, recall, and F1-score values.

The fusion of transformer models' embeddings with additional features, such as sentiment scores, tweet length, and word count, provided a robust feature set that captures nuanced patterns in the data. By incorporating graph-based features like centrality and clustering coefficients, the model further enriched the representation of the data, enabling it to leverage the interrelationships between data points for improved classification. This hybrid approach outperforms traditional methods that rely solely on textual or structural features, underscoring the effectiveness of combining diverse sources of information.

By integrating the embeddings derived from three language models (BERT, ELECTRA, and XLNet) with graph-based features, the framework attains an exceptional accuracy of 87.28% on the FakeNewsNet dataset. This fusion approach exploits the distinctive capabilities of each model. The combination of BERT's contextual embeddings, ELECTRA's efficient training, and XLNet's permutation-based learning allows for the capture of a comprehensive representation of the text. Furthermore, the incorporation of graph features derived from cosine similarity and centrality measures enhances the feature set by capturing relational dynamics and structural patterns among articles.

This comprehensive approach not only enhances the model's capacity to discern subtle distinctions between authentic and fabricated news items but also improves its resilience and generalisability. The fusion of diverse embeddings with graph-based insights represents a significant advancement in the field of fake news detection, offering a more nuanced and effective solution.

Further research could be enhanced by the incorporation of additional graph-based metrics, such as those pertaining to community detection and influence propagation. These advanced graph features have the potential to capture more intricate relationships and patterns within the data, thereby enhancing the model's ability to understand and detect nuanced misinformation. Furthermore, the investigation of novel or domain-specific transformer models, such as GPT-3, may facilitate enhancements in feature extraction and classification accuracy. By leveraging the latest advancements in model architecture and integrating these with graph-based insights, future models could achieve enhanced performance in the detection of fake news.

Finally, the expansion of the dataset through augmentation and enrichment represents another promising avenue of enquiry. The incorporation of diverse sources and the generation of synthetic data could improve the model's generalisation and robustness, addressing class imbalances and simulating various news scenarios. Furthermore, the development of real-time detection capabilities and the integration of the system with social media platforms would facilitate the timely and effective detection of fake news.

Abstract—Small proteins encoded by small open reading frames (sORFs) exhibit significant biological activity in crucial biological processes such as embryonic development and metabolism. Accurately predicting whether sORFs encode small proteins is a key challenge in current research. To address this challenge, many methods have been proposed, however, existing methods rely solely on biological features as the sequence encoding scheme, which results in high feature extraction complexity and limited applicability across species. To tackle this issue, we proposed a deep learning architecture UAsORFs based on hybrid coding of sORFs sequences. In contrast to mainstream prediction methods, this framework processes sORF sequences using a mixed encoding approach, including both one-hot and gapped k-mer encodings, which effectively captures global and local sequence information. Additionally, it autonomously learns to extract features of sORFs and captures both long-range and short-range interactions between sequences through U-Net and coordinate attention mechanisms. Our research demonstrates significant progress in predicting encoded peptides from eukaryotic and prokaryotic sORFs, particularly in improving the cross-species predictive MCC index on the eukaryotic dataset.

Keywords—Small open reading frames; deep learning; hybrid coding; U-Net; coordinate attention

I. INTRODUCTION

With the rapid development of transcriptomic and proteomic technologies, researchers have come to better understand the potential coding regions of the genome [1]. Open reading frames (ORFs) are widely recognized as important sequence regions for protein coding [2], but short open reading frames (sORFs), as a group of ORFs up to 300 nucleotides in length, which were previously considered unlikely to code due to their short length [3, 4]. However, recent studies have shown that sORFs have a wide range of biological functions and can be directly transcribed and translated into biologically active small proteins [5-8]. These small proteins are involved in a variety of biological processes, including embryonic development [9], muscle function [5, 10-12], the regulation of cell growth and development [13-16], and the control of metabolic pathways [17]. Researchers have identified several sORFs with ribosomal activity by using versatile histological sequencing techniques, such as mass spectrometry and ribosome profiling [7, 18-20].

A prerequisite for the search for new protein-coding sORFs is their correct identification. Due to the short length, low expression levels, and lack of experimental validation for their functionality, sORFs have long been insufficiently annotated and studied. Investigating the coding potential of sORFs for small proteins is complex. Therefore, there is an urgent need for

accurate and rapid methods to predict the coding ability of sORFs.

One of the main problems in predicting the microproteins-coding sORFs is to design an effective biological sequences coding scheme. The coding features are also crucial for distinguishing between coding and non-coding sORFs. Biological sequence coding schemes can be mainly divided into two types: sequential models and discrete models. Sequential models assign numerical values to each nucleotide in the biological sequence while preserving the order of the bases [1]. A prominent example of this is one-hot encoding (also known as C4 coding) [21], where each of the four nucleotides is represented by a unique four-bit binary vector (A-[1,0,0,0], C-[0,1,0,0], etc.). Each nucleotide's binary number is orthogonal to each other and has the same Hamming distance. In contrast, discrete models aim to design a set of features based on knowledge from the biological sequence. Some commonly used biological features include the codons usage [22], codon prototype [23], hexamer usage [24] and Z curves [25].

The sequential and discrete encoding models each present distinct advantages and limitations. While the sequential model preserves the global sequences order information [26], but this approach cannot fully capture biological features. Neural networks are not easily able to learn higher-order correlations from very low-level input [27]. Additionally, one-hot coding is unable capture frequency domain features such as k-mer [28]. On the other hand, taking 3-mer as an example, it is a discrete model of biological sequences and has become one of the features used to distinguish small proteins from non-encoding ones. Although the 3-mer is effective, it can only incorporate the local sequences order information between neighboring nucleotides and cannot reflect the global sequences order information [26].

Therefore, we designed a coding-protein prediction tool, named UAsORFs, utilizing a hybrid encoding strategy. This tool incorporates U-Net and Coordinate Attention (CA) mechanisms within its deep learning framework. This method effectively utilizes global sequence information, non-overlapping gapped k-mers and deep learning to autonomously learn sORF sequence features. By employing hybrid encoding, the method effectively extracts global and local sequence information of sORFs. Additionally, neural networks are employed to automatically differentiate between encoding and non-encoding sORFs.

The main contributions of this article are summarized as follows:

- A hybrid coding scheme combining sequence model and discrete model is designed. Unlike previous prediction tools that only use discrete models to extract sequence features, UAsORFs introduces sequence coding, effectively capturing global sequence information with one-hot coding, thereby enriching the encoding scheme and expression level.
- By exclusively using gkm as the discrete biological feature, excessive manual feature extraction is reduced, and gkm features significantly improve predictive performance on prokaryotic datasets.
- U-Net is used for the first time in the prediction of coding-protein sORF, facilitating the extraction of multi-scale, long-range and short-range interaction features of sORF sequences. A combined model (UCA) of U-Net and CA is constructed, leading to improved cross-species prediction results.

II. RELATED WORK

In numerous biological prediction tasks, combining sequence information with biological features can lead to significant performance enhancements in specific applications. For instance, iTIS-PseTNC [26] introduced a sequence-based predictor for identifying translation initiation sites in human genes and claims that using k-mer representation in DNA sequences only reflects local sequence order information while losing global sequence order information. To overcome this limitation, the approach leveraged collaborative representations known as pseudo trinucleotide assemblies, integrating physicochemical properties into DNA sequences alongside k-mer features [26]. MHCDG [29] is a hybrid sequence-based deep learning model that integrates MeDIP-seq data with histone information to predict DNA methylation CpG status. By incorporating multiple biologically relevant features and sequence information, it outperformed other methods achieves more satisfactory promoter prediction performance. These works demonstrate the importance of hybrid coding.

In the prediction work of protein-coding sORFs, many prediction tools solely utilize various biological features for coding schemes. Among them, MiPepid [30] identified protein-coding sORFs using a logistic regression model and tetramer (4-mer) features from sequences. CPPred [31] is an SVM-base classifier that uses 38-dimensional biological features such as ORF coverage, Fickett score and CTD, etc., to predict the coding potential in both regular ORFs and sORFs. CPPred-sORF [32], based on CPPred coding, incorporates additional features such as GC count and mRNN-11 codons, and evaluates sORFs using non-AUG start codons. PsORFs [33] predict protein-coding sORFs in other species using 64 codon frequencies based on a random forest model trained on sORFs from prokaryotes. CodingCapacity [34] predicts the coding potential of sORFs using the Z-curve, codon frequencies, k-mer, and all features included in CPPred-sORF. DeepCPP [35] use a 589-dimensional feature set composed of nucleotide bias information and minimal distribution similarity. Notably, DeepCPP employs a convolutional neural network based on deep learning for prediction.

All the aforementioned work gives us a strong intuition that combining global sequence order information with biological features (such as gkm [36]) can enhance the prediction of protein-coding sORFs.

III. MATERIALS AND METHODS

The prediction problem of protein-coding sORFs aims to determine whether an sORF has the ability to be transcribed and translated into a small protein. Given an sORF sequence $S = s_1s_2\dots s_n$, the label of the sequence is $y = i, i \in \{1, 0\}$, i represents coding (1) or noncoding (0). Our goal is to convert the original sequences into a computer-recognizable format and predict it as either coding or noncoding sORFs using a deep learning framework.

A. Data Description

Our study aimed to establish a model for predicting the coding potential of sORFs in multiple species, covering both prokaryotes and eukaryotes. We utilized the standard dataset from PsORFs, which was generated based on a random order strategy. The same prokaryotic training dataset Pro-1282 and five test datasets (Hum-7111, Mou-7385, Ara-2125, Pro-6318 and Bac-150) from PsORFs were employed. Prokaryotic sORFs were selected from the Ref-Seq database [37]. Whereas human and mouse sORFs were downloaded from the sORFs.org database [38], while Arabidopsis thaliana sORFs were obtained from the TAIR database [39]. An experimental validation dataset (Bac-150) published by Hemm et al [40], included 150 positive sORFs and 53 negative sORFs detected from the E. coli genome. The detailed information of the datasets is presented in Table I, where coding sORFs refer to sequences capable of being translated into small proteins.

TABLE I. NUMBER OF DATASETS FOR EACH SPECIES

Dataset	Species	Number of coding sORFs	Number of non-coding sORFs	Number of sORFs
Hum-7111	Prokaryotic genomes	7111	7111	14222
Mou-7385	Mouse	7385	7385	14770
Ara-2125	Arabidopsis thalian	2125	2125	4150
Pro-6318	Prokaryotic genomes	6318	6318	12645
Pro-1228	Prokaryotic genomes	1228	1327	2556
Bac-150	E.coli genome	150	53	203

The length distributions of sORFs across six datasets are illustrated in Fig. 1. The length distributions of sORFs in the Hum-7111 and Mou-7385 dataset are very similar, predominantly concentrated within the range of 60 to 140 nucleotides. In contrast to mammals, Arabidopsis, which is also a eukaryotic organism, exhibits a different distribution, with sORF lengths mainly distributed between 200 and 300 nucleotides. The length distributions of sORFs in the prokaryotic datasets Pro-6318 and Pro-1282 was similar, primarily concentrated between 150 and 300 nucleotides. Thus, it is evident that there are significant differences in sORF lengths among different species.

Fig. 1. Distribution of sORFs length of six datasets.

The differences in sORFs lengths among different species may pose challenges in predicting protein-coding sORFs in multiple species. sORFs with short lengths may be overlooked or misinterpreted as noise in certain species, thereby increasing the difficulty of prediction. Additionally, significant differences may exist in the sequence characteristics and preferences of sORFs across different species, making it challenging to identify universal features and patterns for predicting protein-coding sORFs across species. To address these challenges, the consideration of deep learning models is warranted, as deep learning offers advantages such as automatic feature learning, strong generalization capabilities, and flexibility.

B. Overview of the Designed Framework

As illustrated in Fig. 2, the overall workflow of UAsORFs comprises three stages. Firstly, the sORF sequences in the fasta file are preprocessed and encoded into one-hot and gkm coding formats. Subsequently, the one-hot coding is fed into the neural network UCA, which is composed of a U-Net and CA that can learn the importance of each nucleotide in the sequence. The resulting one-hot coding processed by the UCA model is concatenated with gkm coding to form a hybrid encoding representation. Finally, the hybrid encoding undergoes processing through a Multilayer Perceptron (MLP) and SoftMax activation function to obtain the final prediction results.

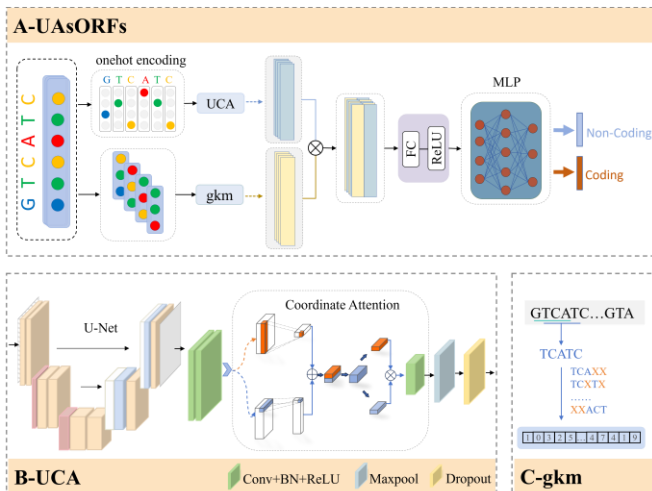

Fig. 2. The overall workflow of UAsORFs.

C. Hybrid Coding

To overcome the limitations of sequential models and discrete models, we propose a hybrid encoding scheme that combines global sequence models and biological features. The aim is to fully utilize the advantages of both, thereby enhancing the prediction of protein-coding sORFs. As illustrated in Fig. 3, For a given sequence s , the hybrid encoding scheme can be formulated as follows:

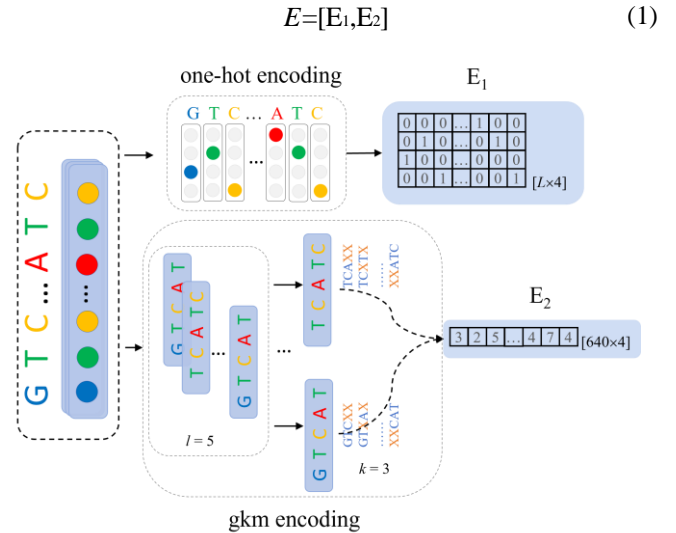

Fig. 3. Hybrid encoding scheme. E_1 is one-hot sequential model, E_2 is gkm discrete model.

Here, we utilize the one-hot sequential model [41] to capture the global sequence order information, Therefore, E_1 can be expressed as:

$$E_1 = [x_1, x_2, \dots, x_i] \quad (2)$$

$$x_i = \begin{cases} [1, 0, 0, 0], & \text{if } i = 'A', \\ [0, 1, 0, 0], & \text{if } i = 'T', \\ [0, 0, 1, 0], & \text{if } i = 'G', \\ [0, 0, 0, 1], & \text{if } i = 'C', \\ [0, 0, 0, 0], & \text{otherwise.} \end{cases} \quad (3)$$

During one-hot encoding, we employ binary vectors of length 4 to encode the four nucleotides in biological sequences. Specifically, the position corresponding to a base is represented as 1, while the other positions are represented as 0. Additionally, when dealing with shorter sequences, we use the encoding [0,0,0,0] for sequence padding to maintain consistency in sequence length. Once a small protein sequence N of length i is inputted, a feature vector matrix is obtained to be fed into the model for training.

For the discrete model, we employ non-overlapping gkm [36] to capture local sequences order information effectively. K-mer, as a classic and effective feature representation, have been widely used in the field of bioinformatics, notably in the prediction of protein coding regions [42-44], coding potentials [31, 45], and identification of regulatory elements [29, 41].

Nevertheless, traditional k-mer methodologies are constrained by a pivotal issue that the increase of k leads to a very long and sparse feature vector [36]. To overcome this issue, we introduce the concept of gaps, which allows for certain mismatch exist in the k-mer sequence [36]. Gkm not only effectively reduce the dimensionality and sparsity of the feature vector but also demonstrates outstanding predictive prowess over conventional k-mer approaches, as evidenced by multiple studies in the biological domain [36, 46].

The gkm [36] method has two parameters: the length of the whole word l and the number of informative positions k . Therefore, the gap count is $l - k$. Combining previous work [1] and the dimension range of one-hot feature vectors, which is [100, 1200], we set $l = 5$ and $k = 3$. This not only effectively reduces the feature vector's dimensionality from $451,024$ to $C_5^2 4^3 = 640$, which is close to the dimension of the one-hot feature vectors, but also allows using both together to enhance the ability to learn relevant patterns. This benefits the deep learning model by improving its expressive power and predictive accuracy. But also encompasses non-overlapping 3-mers information (e.g., AAAXX, ..., TTTXX). As shown in Fig. 3, when $l = 5$ the length of each sORF subsequence is 5. For $k = 3$, calculate the frequency of occurrence of each subsequence with three consecutive nucleotides. Thus, E_2 can be expressed as:

$$E_2 = [f(XXAAA), f(XAXAA), \dots, f(TTTXX)] \quad (4)$$

Where $f(XXAAA)$ calculates the frequency of non-overlapping gapped trinucleotides (XXAAA) occurring in biological sequences. By introducing two gaps XX, the two words *GTACA* and *CTACA* of length 5 have the same gapped trinucleotides *XTXCA*.

D. UCA Model

Considering the hybrid coding approach used for sORF sequences, effectively integrating global sequence order information and gkm through deep learning, and autonomously learn features of sORFs of different lengths in different species is a problem that needs to be addressed. To this end, as illustrated in Fig. 2, we propose a UAsORFs architecture aimed at addressing this issue. In the UAsORFs architecture, sORF sequences are first encoded into one-hot coding and gkm feature representations. These are then processed through the UCA module and concatenated with gkm encoding.

While the issue of hybrid encoding has been discussed in previous sections, the focus of this section is to provide a detailed explanation of the UCA network module. The UCA module mainly consists of two key components: the U-Net [47-49] and the CA [50] based on convolutional neural network (CNN).

We are the first apply U-Net to the prediction of protein-coding sORFs in order to extract multi-scale, long-range and short-range interaction features from input sequences. This design is intended to ensure that the network can capture sufficient contextual information for longer sequences and maintains effective representation capabilities for shorter sequences.

Fig. 4. U-Net model.

As shown in Fig. 4, the input of the U-Net network is denoted as E_1 after a convolution operation, while the output is represented as Y . The numbers at the top of the image represent the number of channels, while the lower-left corner shows dimensions as length \times width. The kernels for Double conv and Up conv are 3×3 , Conv uses a 1×1 kernel, and the max-pooling layer uses a 2×2 kernel. Through convolutional operations, $E_1 \in \{0,1\}^{304 \times 4}$ is transformed into $\in \{0,1\}^{16 \times 304 \times 4}$, where K can be regarded as an image that contains 16 color channels with a size of 304×4 . Each channel signifies one of 16 possible nucleotide combinations, enabling the model to explicitly consider long-range interactions among nucleotides. Following processing by the U-Net, the output feature layer Y , $Y \in R^{16 \times 304 \times 4}$ forms a matrix of size $16 \times 304 \times 4$. Compared with the original one-hot coding, feature map Y can capture more abundant sORF sequence feature information, extract local patterns, context relations and higher-level semantic information in the sequence after multi-layer convolution and pooling layer processing of U-Net. It can provide powerful support for the next prediction work.

Next, for CA-based CNN, in image processing, CNN plays a crucial role in image processing, enabling the learning and extraction of effective image features. In the feature extraction phase, we employ a series of layer structures including Convolutional Layer, Batch Normalization (BN), Revised Linear Unit Activation Function (ReLU), Coordinate Attention, Max-Pooling and Dropout operation. The collaboration between these layer structures helps to achieve effective feature extraction and characterization of the input data.

In the traditional convolutional pooling process, applying channel attention mechanisms like Squeeze-and-Excitation (SE) attention [51] can assess the importance of each channel to learn the weights of different channel features [50]. However, the SE attention only considers encoding inter-channel information but neglects the importance of positional information, especially in cases of global sequential encoding (such as one-hot coding). The CA mechanism considers both inter-channel relationships and positional information within the feature space. Such a mechanism effectively focuses on different spatial locations of the input feature maps, enhancing the model's perception of key features and aiding in the better learning of useful features by the network model.

The CA Block is divided into two processes: Coordinate Information Embedding and Coordinate Attention Generation, as illustrated in Fig. 5.

Fig. 5. Coordinate attention model.

$$y = \sigma(W_c \times f(W_g \times x)) \times x \quad (5)$$

Where x denotes the input feature map, W_c and W_g are the weight matrices of generation attention and channel attention, \times denotes element-by-element multiplication, σ denotes the sigmoid function, and f denotes the weight coefficients of channel attention. Through the generative attention mechanism, a weight coefficient is learned for each spatial location. This weight coefficient is multiplied element-by-element with the input feature map to obtain a weighted feature map. Then, a weight coefficient is learned for each channel through the channel attention mechanism.

This weight coefficient is multiplied element-by-element with the weighted feature map and is used to weight the different channels of the feature map. This allows the network to pay more attention to the important channel information and suppress the unimportant channels to extract more effective feature representations and get the final output feature map.

IV. TRAINING AND EVALUATION

A. Loss Function

To enhance the generalization ability and robustness against noise ability of the model, we use Label Smoothing (LS) loss as the loss function. The Label Smoothing loss function reduces the risk of overfitting and overconfidence by introducing a certain degree of smoothness. Its formula is as follows:

$$L = (1 - \varepsilon) \times CE(y, y') + \varepsilon \times CE(\mu, y') \quad (6)$$

$$CE(p, q) = - \sum (p_i \times \log(q_i)) \quad (7)$$

Where y is the true label, y' is the output label probability distribution of the model, μ is the smoothed label, ε is the smoothing factor, and CE is the cross-entropy loss function. In the loss function, we multiply the loss of the true labels by $(1 - \varepsilon)$, multiply the loss of the smoothed labels by ε , and then weight and sum the two portions to get the final loss value. $\varepsilon > 0$ the loss portion of the smoothed labels will play a certain role of regularization, which helps to reduce the risk of overfitting.

B. Evaluation Indicators

We adopted four evaluation metrics, including Sensitivity (SN), Specificity (SP), Accuracy (ACC), and Matthews Correlation Coefficient (MCC), to evaluate the robustness of the

model and its predictive performance for encoding sORFs. The formulas are as follows:

$$SN = \frac{TP}{TP + FP} \quad (8)$$

$$SP = \frac{FP}{TP + FP} \quad (9)$$

$$ACC = \frac{TP + TN}{TP + TN + FP + FN} \quad (10)$$

$$MCC = \frac{TP \times TN - FP \times FN}{\sqrt{(TP + FP)} \sqrt{(TP + FN)} \sqrt{(TN + FP)} \sqrt{(TN + FN)}} \quad (11)$$

Among them, TP and TN represent the number of correctly predicted coding and coding sORFs. FP and FN denote the number of incorrectly predicted coding and non-coding sORFs. SN and SP measure the model's ability to identify coding and non-coding sORFs. ACC reflects the proportion of correct predictions among all predictions. On the other hand, MCC comprehensively considers the relationships among TP, TN, FP, and FN, evaluating the correlation between predictions and annotations within the range of [-1, 1]. This metric system provides a comprehensive assessment of the model performance.

C. Training Parameter Settings

During training, we employed a learning rate decay strategy to prevent overfitting and accelerate the convergence of the learning algorithm. The initial learning rate was set to $4e-3$, step size = 10 and gamma = 0.7. The Adam optimizer was chosen for parameter adjustment and optimization. In addition, set the batch size to 256, the number of epochs to 20 and the random seed to 42. Table II provides the UCA network architecture and parameters, with the U-Net and CA network architectures illustrated in Fig.4 and Fig.5. Our experimental environment consists of a CPU: AMD Ryzen 7 5800H and a GPU: NVIDIA GeForce RTX 3060.

TABLE II. UCA NETWORK ARCHITECTURE AND PARAMETERISATION

Layer	Size

V. RESULTS

In this section, we conducted four experiments on six datasets. The first demonstrated the importance of hybrid coding. The second and third experiments compared our approach with current popular methods on multiple species datasets. The fourth experiment demonstrated the importance of each module of UAsORFs.

A. Significance of Hybrid Coding

To validate the effectiveness of hybrid coding, we conducted ablation experiments aimed at separating hybrid coding and observing the performance of single coding in sORFs prediction. Specifically, as shown in Table III and Fig. 6, the hybrid coding was divided into one-hot and gkm encoding, which were then fed into MLP and CNN models (e.g., one-hot + CNN and gkm + MLP). We used a training and evaluation strategy trained on the Pro-6318 dataset and tested on the Ara-2125 (Fig. 6A) and Pro-1228 (Fig. 6B) datasets to evaluate the performance of hybrid coding on both eukaryotic and prokaryotic datasets.

TABLE III. DESIGN AND RESULTS OF ABLATION EXPERIMENTS FOR HYBRID CODING

Dataset	Methods	SN	SP	ACC	MCC
Ara-2125	PsORFs	0.4706	0.8613	0.6974	0.443
	one-hot+CNN	0.4815	0.9562	0.7188	0.4973
	k-mer+MLP	0.6918	0.8216	0.7267	0.5078
	gkm+MLP	0.5153	0.9501	0.7327	0.5168
	one-hot+k-mer+CNN	0.5976	0.9082	0.7529	0.5322
	one-hot+gkm+CNN	0.5962	0.9205	0.7584	0.5462
	one-hot+gkm+UAsORFs	0.6316	0.9031	0.7682	0.5571
Pro-1228	PsORFs	0.8698	0.8997	0.8908	0.7814
	one-hot+CNN	0.6458	0.9525	0.8051	0.6333
	k-mer+MLP	0.798	0.8432	0.8215	0.6424
	gkm+MLP	0.8739	0.9546	0.9142	0.8311
	one-hot+k-mer+CNN	0.8278	0.8964	0.8705	0.7418
	one-hot+gkm+CNN	0.8772	0.9584	0.923	0.8482
	one-hot+gkm+UAsORFs	0.9137	0.9435	0.9292	0.8582

According to the data presented in Table III and Fig. 6D, one-hot+gkm+CNN and one-hot+k-mer+CNN outperform one-hot+CNN, gkm+MLP, and k-mer+MLP on both the prokaryotic and eukaryotic datasets, which indicates that the hybrid coding scheme has a better prediction than the single coding model. It is worth noting that gkm+MLP achieved better predictive performance than k-mer+MLP, especially on the prokaryotic dataset, where ACC and MCC are improved by 9.27% (0.9142-0.8215) and 18.87% (0.8311-0.6424), demonstrating the effectiveness of gkm (l=5, k=3) features in distinguishing coding and non-coding fields regions. Meanwhile, one-hot+CNN has outperformed PsORFs in Ara-2125, which proves the effectiveness of global order information.

In conclusion, our results suggest that there is a complementary relationship between one-hot coding and gkm

features, and their combination helps deep learning methods to capture coding features more comprehensively.

B. Multi Species Predictions Results

To evaluate the performance of the different models, we conducted two experiments: (a) Training on the prokaryotic dataset Pro-1282 and testing on the remaining five datasets (Hum-7111, Ara-2125, Mou-7385 and Pro-6318, Bac-150). (b) Training on the prokaryotic dataset Pro-6318 and testing on the remaining five datasets.

Since there is no overlap of sequences in the test and training datasets, the multi-species validation is considered as independent dataset testing. With these two multi-species experiments, we evaluate the generalization performance of the model in multi-species prediction. These experimental designs help to validate the model's ability to generalize across different biological species and provide an important reference for further model improvement.

In our study, we evaluated seven different computational algorithms, some of which have been tested in the original literature on sORF [33]. As shown in Table IV, tools such as codingCapacity, PsORFs, CPPred-sORF, and DeepCPP employ discrete encoding schemes based solely on biological features. In contrast, UAsORFs enhances this discrete encoding framework by incorporating one-hot encoding, thereby increasing the representational capacity of sORFs. Furthermore, U-Net can integrate one-hot encoded features with spatial features, improving the accuracy of identifying specific regions or categories within sORFs data and enhancing segmentation performance, thus capturing details that other tools might overlook. The CA mechanism can emphasize crucial channels within the one-hot encoded data, ensuring that key classification information is prioritized and enabling the capture of significant features that might be missed by other tools.

As can be seen in Fig. 7 and 8, UAsORFs showed improvements across various independent datasets, particularly in terms of ACC and MCC metrics. On eukaryotic datasets, UAsORF achieved the highest ACC and MCC, surpassing the best-performing tool codingCapacity. In the Mou-7385 dataset, our method exhibited increases in ACC and MCC by 2.38% (0.5935-0.5697) and 7.57% (0.2398-0.1641). Similar improvements were observed in the Hum-7111 and Ara-2125 datasets. In the Pro-6318 dataset, UAsORF outperformed PsORFs but slightly lagged behind codingCapacity. On the Bac-150 dataset, UAsORF saw improvements in ACC and MCC by 2.15% (0.79-0.7685) and 8.96% (0.4715-0.3819).

From Fig. 8, it is evident that experiment (b) achieved better predictive performance compared to the training evaluation strategy of experiment (a). On the Bac-150 dataset, compared to PsORFs, UAsORFs showed approximately 5.12% increase in ACC (0.8-0.7488) and approximately 27.09% increase in MCC (0.5764-0.3055). With an increase in the number of training samples, UAsORFs more effectively captured sORF sequence features, resulting in better predictive performance. This also underscores the importance of constructing high-quality training and evaluation data.

In summary, our study demonstrates that UAsORFs exhibit strong generalization capabilities, showcasing excellent cross-

species predictive ability, and demonstrating their capacity to distinguish coding sORFs from non-coding ones. Furthermore, by altering training and evaluation strategies, we further validate the outstanding performance of the UAsORFs model in cross-species prediction.

C. UAsORFs Ablation Experiments

To investigate the robustness and reliability of the UAsORFs model, we conducted a series of ablation experiments. As shown in Table V, we systematically remove various components from the UAsORFs model, including the U-Net, CA and other modules. We utilized the Pro-1228 dataset for training and compared their predictive performance on both the eukaryotic (Hum-7111) and the prokaryotic (Pro-6318) dataset.

Fig. 9A and Fig. 9B show a performance comparison of the ACC and MCC across three eukaryotic test datasets (Hum-7111, Ara-2125, and Mou-7385) and two prokaryotic test datasets (Pro-6318 and Bac-150) under different methods. Fig. 9C and

Fig. 9D show a performance comparison of ACC and MCC between Base, CA+LS and joining U-Net block on multi-species test datasets. Performance comparison of ACC index and MCC index on multi-species test dataset by adding CA(Fig. 9E), LS(Fig. 9F) block with Base et al.

From Table V and Fig. 9, it is evident that compared with the Base version, after adding U-Net, CA, and LS modules, the UAsORFs model improves the ACC(Fig. 9A) and MCC (Fig. 9B) to 62.39% and 29.59% on the eukaryotic dataset, and 91.7% and 83.67% on the prokaryotic dataset respectively. Specifically, in Fig. 9C and Fig. 9D, compared Base and CA+LS, the inclusion of the U-Net module in UAsORFs lead to significant improvements in ACC and MCC, increasing by 2.19% and 3.36% on the Hum-7111 test dataset. Fig. 9E and Fig. 9F demonstrate the enhancement in predictive performance after incorporating the CA and LS modules. The experimental results demonstrate the effectiveness of using U-Net, CA, and LS modules for extracting sORFs features.

D. Summarize

Through cross-species experiments and ablation studies on datasets from different species, we comprehensively evaluated the performance of the UAsORFs model, and verified the effectiveness of hybrid coding, U-Net, CA, and LS in the UAsORFs, which can effectively distinguish coding sORFs from non-coding ones. There are two main reasons for the outperformance of UAsORFs over the other methods. Firstly, the hybrid coding strategy can access and combine the global and local sequence information of sORFs to enhance the sORF representation. Secondly, deep learning effectively and autonomously learns to extract the features of sORFs, the feature fusion mechanism of up-sampling and intermediate variables in the U-Net module contribute to deep feature mining of sORFs. The CA attention mechanism is able to better capture the complex dependencies between nucleotides, thereby improving the understanding of interactions in sORF sequences. The channel attention mechanism can adaptively learn the importance of each channel, which enhances the model's representation of nucleotide pairing features.

VI. CONCLUSIONS

In this work, our study uses a hybrid encoding of one-hot and gkm coding, which retains both the global sequence order information and captures biological features. This approach fully utilizes the advantages of both methods, enhancing the encoding capability of the sequences and greatly avoiding the shortcomings such as insufficient sequence features and human intervention caused by a single encoding method. Additionally, we propose a deep learning architecture called UAsORFs, the deep learning framework distinguish between coding sORFs and non-coding sORFs through autonomous learning. The framework used in this study does not require extensive manual extraction of features, effectively learns essential sORFs features across multiple species and achieve remarkable predictive performance for multi-species sORFs. Additionally, the UAsORFs is a new, novel and efficient method for the prediction of protein-coding sORFs.

The study has several limitations. Firstly, the smaller sORFs dataset restricts the ability of the model to learn sORFs features. This is supported by the Multi-species predictions experiment (b), which demonstrates that increasing training samples allows UAsORFs to better capture sORFs sequence features, resulting in better predictive performance. Additionally, models trained on prokaryotic species exhibit suboptimal performance on eukaryotic protein-coding sORFs, suggesting that the current prokaryotic models may not capture certain features present in eukaryotic organisms. Future research should focus on expanding the sORF dataset and constructing a large-scale multi-species dataset to enhance capture features of eukaryotic sORFs and improve the applicability for sORF prediction. Furthermore, exploring species-specific characteristics and integrating other types of biological data (e.g., epigenetic marks, RNA-Seq data) could lead to the development of new biological sequence encoding schemes and further enhance prediction accuracy.

ACKNOWLEDGMENT

All the data mentioned in this article can be available at <http://guolab.whu.edu.cn/codingCapacity/download.html>.

We would like to thank the research team that provided the dataset.

An Improved YOLOv8 Method for Measuring the Body Size of Xinjiang Bactrian Camels

Yue Peng, Alifu Kurban, Mengmei Sang

Department School of Software, Xinjiang University, Urumqi, China

Abstract—Camel body size measurement has initially been applied in livestock production. However, current methods suffer from low measurement accuracy due to detection box localization loss and occlusions. This study proposes an effective algorithm, Camel-YOLOv8, specifically designed for detecting Xinjiang Bactrian camels and calculating their body sizes. By integrating the Selective Kernel Networks (SKAttention) mechanism and an enhanced Asymptotic Feature Pyramid Network structure (AFPNet), the algorithm successfully captures the body characteristics of Bactrian camels in natural environments and converts these into precise size data. We have developed a Xinjiang Bactrian camel body size measurement dataset and applied the enhanced YOLOv8 model for accurate classification and detection. By extracting key point pixel values and applying Zhang Zhengyou's calibration method, the coordinate system data is converted into accurate body size measurements. The Camel-YOLOv8 achieves a detection accuracy of 76.4% on the Xinjiang Bactrian camel dataset, marking a 3.7% improvement over the baseline model. In terms of body size calculation, the average relative errors for height and chest circumference are -3.39% and 4.1%, respectively, demonstrating high measurement precision. The algorithm not only maintains high detection accuracy but also achieves a reasonable balance between detection speed and efficiency, providing an effective solution for rapid acquisition of camel body size information.

Keywords—YOLOv8; Asymptotic Feature Pyramid Network; SKAttention; Bactrian camel body size measurement

I. INTRODUCTION

The scaling and precision enhancement in modern camel farming have led breeders to recognize the critical importance of selecting, cultivating, and fostering the healthy development of superior camel breeds. The physical development and size of camels are reflected through body measurement indicators, closely linked to the camels' adaptability to their environment, productivity, reproductive performance, and economic value [1]. Accurate determination of camel body size and morphological assessments are vital for monitoring camel growth, genetic selection within herds, improving reproductive capabilities, enhancing productivity, and standardizing rearing practices [2]. Traditional livestock measurement and condition assessment methods, which typically involve contact tools like tape measures, can induce stress in animals, impacting their growth and development. With the evolution of technologies such as image processing [3], pattern recognition [4], and artificial intelligence [5], machine learning [6] has increasingly been applied in China's livestock industry, yielding significant results. Leveraging machine vision for measuring camel body size and performing morphological evaluations facilitates a comprehensive analysis of camel development, quickly

assessing their growth conditions and preparing for potential health crises.

The application of computer vision [7] in livestock management is diverse and widespread, enhancing management efficiency, productivity, and animal welfare through advanced image analysis techniques. Computer vision systems can autonomously monitor animal activities, behavioral patterns, and body language, identifying behaviors such as eating, resting, and socializing. These insights are crucial for assessing animal health, welfare, and productive performance. By analyzing appearances and behaviors, computer vision technologies can aid in the early identification of disease signs or health issues, such as limping, weight changes, or decreased appetite, enabling timely intervention [8]. Computer vision can also measure animal body dimensions, such as length and height, to estimate weight and monitor growth, aiding in nutritional management and breeding program improvements. By integrating computer vision with automation technologies, feeding quantities and nutritional ratios can be automatically adjusted based on an animal's weight, health condition, and growth needs, supporting individual animal management, population structure analysis, and breeding and selection decisions [9].

The advancement and implementation of computer vision technology have significantly raised the productivity and management levels in the livestock industry, also providing strong support for enhancing animal welfare and ensuring food safety. Through target detection technologies, camel body size data can be calculated using detection boxes. However, ensuring the accuracy of these calculations is crucial, as the precise positioning of detection boxes is paramount. Detection box localization loss refers to inaccuracies in positioning detection boxes during the object detection process due to various factors, impacting the accuracy of body size calculations. Additionally, occlusion among camels, a common issue due to their large size and tendencies to move closely within groups, can cause some parts to be obscured by other camels or objects, affecting the accuracy of detection box positioning. This occlusion can lead to inaccuracies in the detection box area, thereby affecting the results of body size calculations. The primary contributions of this paper include:

- 1) Establishing a rich dataset containing images of camel postures in various environments, providing necessary data support for algorithm training and evaluation.
- 2) Current camel body size detection methods suffer from detection box localization loss; in YOLOv8 [10], the

SKAttention mechanism is added to reduce this loss, thereby minimizing errors in calculating camel body size.

3) Using the Asymptotic Feature Pyramid Network (AFPN-beta) structure effectively resolves issues of camel occlusion, ensuring that the body size information of obscured camels can be more accurately calculated.

4) Employing the camera calibration method from Zhang Zhengyou's calibration technique to obtain camera model parameters, such as internal, external, and distortion parameters. Based on the single-camera imaging principle and the transformation relationships between coordinate systems, a measurement model for the body size of Xinjiang Bactrian camels is established, facilitating the measurement of body size information for Bactrian camels.

In summary, Section II of this paper reviews the existing research in the field of camel body measurement and analyzes the current state of computer vision and object detection technologies in livestock management. Section III provides a detailed description of the improved YOLOv8 method proposed in this paper, including feature selection, integration of the SKAttention mechanism, application of the AFPN-beta structure, and the computation methods for camel body metrics. In Section IV, we present the experimental design, dataset preparation, training parameter settings, and evaluation metrics of the model, and provide an in-depth analysis of the experimental results. Section V summarizes the main research findings of this paper and discusses future research directions.

II. RELATED WORK

The use of computer technology for animal biometric measurement through image processing and feature extraction facilitates efficient and accurate measurements, widely applied in biological research and ethology. Federico Pallottino [11] and colleagues compared manual measurements with stereovision measurements, finding a high overall correlation and lower variability, with an average error below 3%. The variability in error magnitude depends on the specific traits, but Pallottino's study did not delve into the theoretical basis of the measurement algorithm. Additionally, the research focused mainly on correlation analysis without involving the design and optimization of specific algorithms, limiting its potential for technical deepening and application expansion. Qin [12] and others introduced deep learning, proposing a unique method for measuring livestock body dimensions using Mask R-CNN [13] to measure cattle and goats of various sizes against different backgrounds. This study initially utilized the idea of human joint location to accurately position livestock body feature points and perform precise measurements. However, due to the unique physiological structure of camels, especially the presence of humps, the use of deep learning models like Mask R-CNN and the search for measurement points can cause significant interference. This issue limits the suitability and accuracy of this technology in camel measurement. Mahdi Khojastehkey [14] and colleagues used SPSS software and Pearson correlation coefficients to select features more relevant to single-humped camel measurement, discovering the mathematical relationships between digital image-extracted features and camel body dimensions. This

finding provides an important theoretical basis for developing more accurate camel body dimension calculation models, further supporting the feasibility and effectiveness of using digital image technology for camel body measurement.

Computer vision, a critical component of the field of artificial intelligence, plays a vital role across various industries. With the development of machine learning, especially deep learning, the application of object detection [15], [16] has expanded beyond emerging industries. In traditional sectors, such as livestock, object detection algorithms are gradually showcasing their significant functions. AlNujaidi [17] and others researched a camel-vehicle collision mitigation system through computer vision. Although progress was made in camel detection, the study did not extend to specific calculations of camel body dimensions, limiting its completeness and practicality in biometric applications. Wang [18] and others proposed a portable and automated Xtion measurement system for assessing pig body sizes, which showed significant advantages in measuring pig body dimensions and confirmed the importance of these dimensions in predicting weight. However, this system needs more detailed measurement methods for body dimensions to ensure accuracy when adapting to the more complex morphology of camels. Finally, Li and Teng [19] studied deep learning-based body dimension measurement methods for goats and cattle against different backgrounds. While this method performs well in measuring cattle and goat body sizes, the complexity and specificity of camel body dimensions pose significant challenges for this technology in camel measurement. Wang Yusha [20] and others developed a computer vision-based device for measuring the body dimensions and body mass traits of large yellow croaker, performing well in measuring organisms with smooth body surfaces. However, the same measurement point positioning strategy may not be suitable for camels, which have more structurally complex body surfaces. Munir Ahmad et al. [21] developed a deep transfer learning-based animal face identification model, demonstrating the significant potential of deep learning in the field of biometric identification, particularly for recognizing complex body structures. However, the study primarily focuses on facial recognition and does not fully explore the application of this technology to the measurement of more complex body parts, such as the humps of camels. Additionally, the model's scalability to handle the complex morphological structures of different animal species still requires further validation. Dhivya Mohanavel and Muthu Ishwarya [22] developed a deep learning and computer vision-based animal detection warning system for agricultural environments, highlighting the growing importance of these technologies in agriculture. However, the limitation of this study lies in its primary focus on animal detection and warning functions, without addressing the collection and analysis of specific biometric data. While it provides valuable insights into the application of deep learning in animal management within agricultural settings, the potential for precise animal body measurement and biometric analysis has not been fully explored.

III. RESEARCH METHOD

The Camel-YOLOv8 model primarily consists of three components: the Backbone, the Neck, and the Head networks.

Initially, the input image is processed through multiple convolutional layers (Conv) for preliminary feature extraction. This is followed by several c2f modules that refine the features further. During this process, the SK Attention module enhances the attention mechanism in feature extraction, enabling the model to focus more on important feature regions. Subsequently, features undergo multiscale processing via the SPPF (Spatial Pyramid Pooling - Fast) module. The Neck network then integrates multiple layers of features using convolutional layers and the AFPN-beta (Asymptotic Feature Pyramid Network - beta) module, with further processing by c2f modules. In the Head network, a series of convolutional layers transform the feature map into the format required by the output layer, calculating both the Bounding Box Loss (BBox Loss) and the Classification Loss (Cls Loss). Ultimately, the model outputs the detection results in the image, including bounding boxes and class labels. Overall, the YOLOv8 model, through its multi-layer feature extraction and integration mechanisms, effectively enhances the accuracy and efficiency of object detection while maintaining computational efficiency. The proposed model structure is illustrated in Fig. 1.

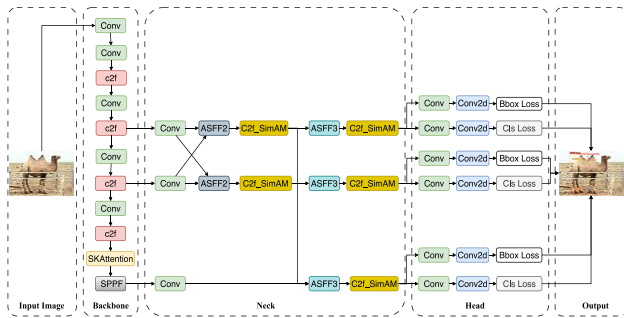

Fig. 1. Structure diagram of camel-YOLOv8 model.

A. Feature Selection

Many research findings indicate that chest girth, body length, pelvic width, and shoulder height are the most suitable and reliable parameters for estimating the live weight of animals. Fig. 2 shows diagram of camel body measurement points.

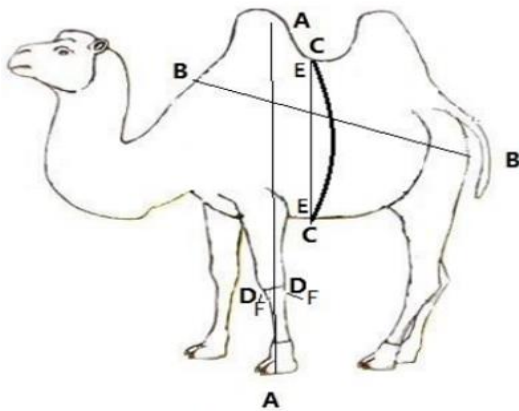

Fig. 2. Diagram of camel body measurement points.

In recent studies, in some cases, features from digital images have been used to estimate the body size of livestock

[23]. The camel body measurement points are shown in the diagram. For the Xinjiang Bactrian camel, the height (A) refers to the vertical distance from the base of the camel's front hump to the ground, the body length (B) refers to the distance from the shoulder end to the hip end, the chest girth (C) is the vertical circumference measured from the base of the front hump down through the center of the horny pad at the chest bottom around the body, the cannon circumference (D) refers to the horizontal circumference measured around the cannon at the upper third of the left forelimb, chest diameter (E), and cannon diameter (F).

Using SPSS software, this paper analyzes the correlation between camel weight and other body metrics from existing camel data in Fuyun Town, Fukang City, Xinjiang Uighur Autonomous Region. We have chosen to use the Pearson correlation coefficient [24] to measure the linear relationship between them. The Pearson correlation coefficient is a statistic used to measure the degree of linear correlation between two variables. It is employed to assess the linear relationship between two variables, with values ranging from -1 to +1. A correlation coefficient of 1 indicates a perfect positive correlation; a coefficient of -1 indicates a perfect negative correlation; and a coefficient of 0 indicates no linear correlation between the variables. The formula for calculating the Pearson correlation coefficient is as follows:

$$r = \frac{\text{cov}(X,Y)}{\sigma_X \sigma_Y} \tag{1}$$

Here, Cov represents covariance, and σ represents standard deviation. Specifically, the Pearson correlation coefficient is calculated as the covariance of the two variables divided by the product of their respective standard deviations. Below are the correlation coefficients between camel characteristic information and body weight in the camel data from Ziniquanzi Town, Fukang City, Xinjiang Uighur Autonomous Region:

From the Table I, it can be observed that there is a positive correlation between body weight and body measurement indicators, with the height, chest girth, and chest diameter all showing correlations above 0.5. This indicates that in this dataset, these features may have a strong linear relationship with body weight and can be used to predict it. Therefore, by improving the YOLOv8 algorithm for classifying the body parts of Xinjiang Bactrian camels, the indicators of body length and chest diameter are selected as the main subjects of study in this paper.

TABLE I. PEARSON CORRELATION COEFFICIENTS BETWEEN CAMEL BODY MEASUREMENT FEATURES AND BODY WEIGHT

Feature	Correlation Coefficient
Body Height	0.538
Body Length	0.138
Body Diagonal Length	0.252
Chest Girth	0.793
Chest Diameter	0.594
Teat Diameter	0.256
Teat Length	0.255

B. SKAttention

Different sizes of receptive fields have varying effects on targets of different scales. In the process of classifying different parts of a camel, such as the camel's hump, body, and foot, the appropriate receptive field varies due to the varying sizes of these parts. To address the issue of the camel's body being obscured, we propose the SKAttention mechanism [25], which allows the network to automatically utilize information captured by effective receptive fields for classification. The structure of the Selective Kernel Attention is shown in Fig. 3. And consists of three parts: Split, Fuse, and Select. We input a feature map with dimensions $C \times H \times W$, and in the Split part, the input image undergoes convolution operations with 3×3 and 5×5 kernels, resulting in two feature maps, U_1 and U_2 . Fuse involves calculating the weights of the two convolution kernels, summing the feature maps element-wise, and then averaging along the H and W dimensions to obtain a one-dimensional vector of size $C \times 1 \times 1$. This weight information represents the importance of each channel's information. The formula is as follows:

$$U = U_1 + U_2 \quad (2)$$

In this process, U is generated through global average pooling (AvgPool) to provide channel statistics. A linear transformation is then applied to map the original C-dimensional information to Z-dimensional information. Following this, two linear transformations are used to convert from Z dimensions back to the original C dimensions, thereby completing the extraction of channel dimensions. In the Select part, a softmax operation is performed on the channel dimension to merge the soft attention vectors of each branch, allowing for the selection of multiple branches with different kernel sizes. An SKNet composed of multiple SK units can capture objects of various scales through its neurons.

Fig. 3. Selective kernel attention structure diagram.

In the backbone part of YOLOv8, we set the input feature channel number (Channel parameter) to 512, the size list of convolution kernels (kernels parameter) to [1, 3, 5, 7], the dimension reduction ratio (reduction parameter) to 16, the number of convolution groups (group parameter) to 1, and the dimension (L parameter) to 32. Notably, in this process, adopting an adaptive receptive field size allows the model to better adapt to targets of varying scales, thereby enhancing accuracy and efficiency.

C. Asymptotic Feature Pyramid Network AFPN-beta Structure

Inspired by the Asymptotic Feature Pyramid Network (AFPN) [26], we propose a target detection method, AFPN-beta, for detecting various body parts of the Xinjiang Bactrian camel. This method helps to address the issues of target box

loss and occlusion among camels, thereby enhancing detection accuracy. The AFPN-beta mainly consists of two key components: the Feature Pyramid Network and the Adaptive Spatial Fusion operation.

The Feature Pyramid Network allows for direct interaction between different layers, preventing the loss of feature information. By extracting features at various scales and integrating them, the model can better capture target features across different scales and semantic levels. This direct interaction helps to improve detection accuracy, especially for targets with complex shapes and varying sizes. The Adaptive Spatial Fusion operation is another crucial component within AFPN-beta. It helps to resolve conflicts of information during the feature fusion process. By dynamically adjusting the fusion weights according to the spatial distribution of features at different layers, the Adaptive Spatial Fusion operation effectively merges features from different levels, reduces information conflicts, and enhances the accuracy of target detection. The specific structure of the AFPN-beta module is illustrated in Fig. 4 [24].

Fig. 4. AFPN-beta module structure diagram.

D. Camel Body Measurement Calculation Algorithm

During the data collection process for Xinjiang Bactrian camels, a set of calibration images using Zhang Zhengyou's calibration board [27] is essential. These images should include a calibration board whose corners have precisely known three-dimensional coordinates. Throughout this process, computer vision techniques such as Harris or Shi-Tomasi corner detection algorithms are utilized to accurately detect these corners on the calibration board. By aligning these detected corners with their established three-dimensional points and employing the camera's projection model, we can accurately estimate the camera's internal parameters—such as focal length and principal point—as well as external parameters, including rotation and translation vectors. Utilizing Zhang Zhengyou's calibration method ensures the precision of the measurement setup, which is crucial for accurate data collection. The calibration process and its results are depicted in Fig. 5, showing the setup used specifically in the data collection of Xinjiang Bactrian camels.

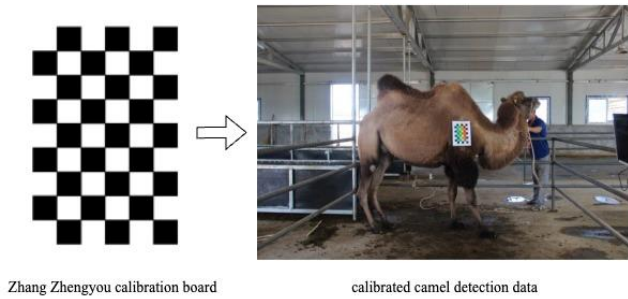

Fig. 5. Apply the Zhang Zhengyou calibration board on the left to the camel data collection on the right.

After the classification is complete, in order to facilitate the extension of the calculation method to three-dimensional space, the Minkowski distance is chosen to calculate the pixel information of various camel parts. The Minkowski distance [28] is a method for measuring the distance between two points in multidimensional space. It is a very common method for measuring the distance between numerical points, with the coordinates of points P and Q assumed to be as follows:

$$P = (x_1, x_2, \dots, x_n) \text{ and } Q = (y_1, y_2, \dots, y_n) \in R^n \quad (3)$$

Thus, the Minkowski distance is defined as:

$$\left(\sum_{i=1}^n |x_i - y_i|^p \right)^{\frac{1}{p}} \quad (4)$$

Once the pixel information is calculated, we can use the similar triangles formula to determine the distance to the object. This process typically requires camera calibration information, including focal length and pixel size parameters. This can be achieved through the internal and external parameters obtained from camera calibration. Below is a basic formula for this conversion:

$$D_{\text{real}} = \frac{P \times S}{f} \quad (5)$$

Where:

D_{real} is the actual distance.

f is the focal length of the camera, $P = \text{camera_matrix}[1, 1]$.

S is the actual distance between the object and the camera.

P is the width of the object in the image.

After completing the calculation of camel body measurements, the mean relative error (MRE) [29] is used to represent the degree of deviation of the measurement error relative to the actual measurement values. The calculation method is shown in the following formula.

$$\text{MRE} = \frac{\sum \frac{\text{Actual Value} - \text{Predicted Value}}{\text{Actual Value}}}{n} \quad (6)$$

where, n is the number of samples, Σ represents the sum over all samples, and $|x|$ denotes the absolute value of x .

IV. EXPERIMENT

A. Dataset Preparation

Images of Xinjiang Bactrian camels were taken in Ziniqanqi Town, Fukang City, Xinjiang Uygur Autonomous

Region, using a Canon 60D camera and an 18-135 lens. Images were collected in December 2020, March to April 2021, and July 2021, capturing 146 Bactrian camels under different lighting conditions, angles, distances, and various occlusions, resulting in 389 valid images. Due to the small dataset size, additional data was collected in September 2023 in Keping County, Aksu Prefecture, Xinjiang Uygur Autonomous Region, amounting to approximately 400 valid images.

A total of 789 images were used to create the dataset for calculating the body measurements of Xinjiang Bactrian camels. The dataset was annotated using the LabelImg software [30].

1) *Image selection*: Poor quality images were discarded. According to the requirements of the network model, images where key parts of the camel's body were obscured were excluded. Such images were discarded due to overlapping or large occlusions caused by the presence of too many camels in the same frame, which severely affected the training quality of the model. This resulted in 789 valid images.

2) *Image annotation*: The open-source software LabelImg was used for manual annotation of the targets. SPSS software analysis revealed that four indicators—body size, chest diameter, chest girth, and pipe diameter—are highly correlated with the weight of Bactrian camels. Therefore, the annotated categories include "Camel," "Hump," "Body," "Bottle," and "Foot." The annotations were saved in .txt files with the same names as the images.

3) *Data augmentation* [31]: The statistical distribution of the sample numbers in the training set showed an imbalance in the number of images of different Xinjiang Bactrian camels. To enhance the model's robustness and adapt to different weather conditions farmers might encounter during camel body detection, techniques such as weather changes, noise addition, and occlusion were randomly applied to the training set images for augmentation.

4) *Dataset formatting*: The dataset was randomly sampled from images collected at different times and divided into training, validation, and test sets. The training and validation sets together comprise 80% of the dataset, with a 9:1 ratio, while the test set comprises 20%. To verify the model's generalization performance, the collection times of the images in the test set were as different as possible from those in the training set.

B. Training Parameter Settings

The experiments were conducted using an NVIDIA GeForce RTX 3060 GPU, with the operating system being Ubuntu 16.04. The model was built using the Pytorch deep learning framework, with Python version 3.8 and CUDA version 10.2. The improved YOLOv8 model used input images of size 640×640, with an epoch set to 400 and a batch size of 32.

C. Model Evaluation Metrics

The performance of the model was evaluated using precision (P), recall (R), mean average precision (mAP), frame

per second (FPS), and memory usage. FPS measures the number of image frames detected per second.

D. Results and Analysis

1) *Analysis of body part classification results of xinjiang bactrian camels:* In the Xinjiang Bactrian camel dataset, the original training set contained 721 images. Through the application of image augmentation techniques such as weather effect simulation, color jittering, noise addition, and blurring, the training set was expanded to 2518 images for model training. The dataset also included a validation set of 629 images and a test set of 99 images. The model was trained over 400 epochs, and the results of camel body part recognition are shown in Table II.

TABLE II. RESULTS OF COMPARATIVE EXPERIMENTS ON CAMEL PART RECOGNITION

	Epoch	loss	P	R	mAP ₅₀	mAP ₅₀₋₉₅	FPS
YOLOv3-tiny	400	0.622	0.745	0.95	0.854	0.69	303.0
YOLOv5n	400	0.648	0.687	0.934	0.804	0.677	285.7
YOLOv5m	400	0.485	0.690	0.943	0.831	0.741	149.2
YOLOv5s	400	0.696	0.730	0.952	0.87	0.717	357.1
YOLOv6n	400	0.569	0.691	0.948	0.833	0.726	357.1
YOLOv6s	400	0.628	0.686	0.943	0.833	0.714	333.3
YOLOv8n	400	0.619	0.691	0.959	0.836	0.719	344.8
YOLOv8s	400	0.611	0.735	0.962	0.879	0.738	303.0
YOLOv10s	400	0.533	0.708	0.923	0.836	0.729	204.1
Camel-YOLOv8	400	0.588	0.745	0.964	0.888	0.764	303.0

From the table above, it is evident that the improved YOLOv8 model performs better in measuring the body dimensions of Xinjiang Bactrian camels compared to YOLOv3, YOLOv5, YOLOv6, YOLOv8, and YOLOv10. The improved YOLOv8 model achieves a precision rate of 74.5%, a recall rate of 96.4%, a mAP50 of 88.88%, a mAP50-90 of 76.4%, and an FPS of 303.03 frames per second. Although the FPS has decreased slightly and the model's memory usage has slightly increased compared to the original YOLOv8 model, other metrics have improved, with the mAP50-95 increasing by 3.7 percentage points. Compared to YOLOv3-tiny, YOLOv5n, YOLOv5s, YOLOv6n, YOLOv6s, YOLOv8n, and YOLOv8s models, the improved model shows an increase in detection accuracy, with the mAP50-95 improving by 7.4, 8.7, 4.7, 3.8, 5.0, 4.5 and 2.6 percentage points, respectively. Additionally, compared to the YOLOv5m and YOLOv10s models, although

the bounding box errors have significantly decreased, there has also been a substantial increase in FPS, resulting in a decrease in detection speed.

Therefore, this study successfully enhances the accuracy of body measurement for Xinjiang Bactrian camels while ensuring detection speed, validating the effectiveness of the proposed method. After training for 400 epochs, the training results of the Camel-YOLOv8 model are shown in Fig. 6.

Fig. 6. Training results of the camel-YOLO v8 model.

2) *Ablation study:* To evaluate the enhancement effects of the proposed improved modules, we designed four ablation experiments. These experiments include the standard YOLOv8 model, YOLOv8 with the SKAttention mechanism, YOLOv8 with the AFPN-beta structure, and a combination of these improvements. Each experimental setup was trained and tested on the same dataset, and consistent evaluation metrics were used to measure changes in model performance. The purpose of these ablation studies is to isolate and quantify the impact of each individual module on the overall performance of the YOLOv8 model. These experiments provide a comprehensive understanding of how each modification contributes to the model's efficacy. The experimental results are presented in Table III.

3) *Analysis of Bactrian camel body measurements:* The pixel length of the camel's body is determined from the detection bounding box results, and then the actual length of the camel's body is calculated using Formula (6). Partial results of the estimated camel body lengths are shown in Table IV.

Table V presents the error results of this experiment, evaluated using the mean relative error as the metric. The findings indicate that the proposed object detection model demonstrates a high level of accuracy in estimating the pixel-based body measurements of camels.

TABLE V. RESULTS OF ERRORS IN CAMEL BODY DIMENSION INFORMATION

	MRE
Camel Body Height	-3.39%
Camel Chest Diameter	4.1%

V. CONCLUSION AND FUTURE WORK

A. Conclusion

This research significantly enhances the model's ability to recognize the features of different parts of Bactrian camels, raising the precision, recall, and mean average precision to 74.5%, 96.4%, and 88.8%, respectively. These performance metrics surpass those of the existing YOLOv3, YOLOv5, YOLOv6, YOLOv10, and the original YOLOv8 models. Moreover, the improved model detects at a speed of 303.03 frames per second (fps), demonstrating good real-time performance, and occupies only 14.45MB of memory with fewer parameters, facilitating quick deployment and portability across various devices. Compared to the actual size dimensions of camels, the model's computational results are highly accurate, with an average relative error of -3.39% for height and 4.1% for girth.

In the current context of scaled and refined breeding environments, real-time detection, monitoring, and management of camel populations are becoming increasingly important [32]. Therefore, the outcomes of this study hold significant appeal for camel breeders. By utilizing this model, breeders can more rapidly and precisely assess the growth conditions of camels and calculate their body measurements and weight [33], which is crucial for optimizing selection, improving breeding strategies, and enhancing economic benefits. Additionally, the low error in calculating the body size of Xinjiang Bactrian camels can aid breeders in promptly identifying health issues [34], thereby enabling early intervention measures to reduce the impact of diseases and other health risks on camel breeding.

B. Future Work

Although this study has made significant progress in calculating the body dimensions of camels, there are still some limitations:

1) The model primarily focuses on algorithm optimization for Xinjiang Bactrian camels, and its applicability to other camel breeds or camels from different geographical areas requires further validation.

2) While some technical issues have been addressed through algorithm improvements, the results have not met expectations, particularly in handling occlusions and feature extraction. Therefore, future efforts could explore more effective improvement methods to further enhance the model's accuracy and reliability [35].

Looking ahead, applying this method to other fields will present certain technical challenges. For example, when applied to other animal species, the model may need significant adjustments to accommodate different body features and behavioral patterns. The universality of the model in detecting other livestock or animal body types still needs to be validated and optimized through more experiments. Future research directions include exploring more advanced attention mechanisms and feature fusion techniques to further improve the model's performance in various application scenarios [36][37]. These efforts will help enhance the model's practicality and provide more comprehensive and reliable technical support for intelligent breeding [38].

Towards Secure Internet of Things-Enabled Healthcare: Integrating Elliptic Curve Digital Signatures and Rivest Cipher Encryption

Longyang Du*, Tian Xie

School of Artificial Intelligence, Jiaozuo University, Jiaozuo 454000, Henan, China

Abstract—The expansion of Internet of Things (IoT) applications, such as wireless sensor networks, intelligent devices, Internet technologies, and machine-to-machine interaction, has changed current information technology in recent decades. The IoT enables the exchange of information and communication between items via an internal network. Nevertheless, the advancement of technology raises the urgent issue of ensuring data privacy and security, particularly in critical sectors like healthcare. This study aims to address the problem by developing a hybrid security scheme that combines the Secure Hash Algorithm (SHA-256), Rivest Cipher 4 (RC4), and Elliptic Curve Digital Signature Scheme (ECDSS) to ensure the confidentiality and integrity of medical data transmitted by IoT-enabled healthcare systems. This hybrid model employs the Elliptic Curve Digital Signature Scheme (ECDSS) to perform exclusive OR (XOR) operations inside the RC4 encryption algorithm. This enhances the RC4 encryption process by manipulating the encryption key. Moreover, SHA-256 is used to convert incoming data in order to guarantee data security. An empirical investigation validates the superiority of the suggested model. This framework attains a data transfer rate of 11.67 megabytes per millisecond, accompanied by an encryption duration of 846 milliseconds and a decryption duration of 627 milliseconds.

I. INTRODUCTION

A. Background

The conventional healthcare system faces challenges in meeting the demands of an extensive population due to its constraints in terms of cost and accessibility [1, 2]. The emerging concept of smart healthcare empowers individuals regarding their health conditions, enabling them to manage certain medical situations and enhance the quality of care [3]. This technology permits remote patient monitoring, reducing healthcare expenses and allowing medical practitioners to extend their services across geographical boundaries [4]. An operationally intelligent healthcare system corresponds with the development of innovative urban areas, offering inhabitants a better lifestyle [5]. The National Sanitation Foundation (NSF) examined how nanotechnology and Information and Communication Technology (ICT) could enhance human well-being. This convergence enables the interconnection of items via nanotechnology, embedded systems, sensors, and wireless networks, giving each Internet-connected object its own unique identity [6]. The Internet of Things (IoT) covers a broad

spectrum of technologies providing connectivity between different objects, and it has been successfully applied in several industries, particularly healthcare facilities [7]. IoT-enabled healthcare is a sophisticated process involving computer science, medical technology, medicine, microelectronics, and other related fields [8].

B. Challenges

According to current projections, the industrial IoT domain is anticipated to have a market worth \$110.6 billion by 2025 after a substantial growth trend in recent times [9]. Projections suggest that by 2030, the quantity of IoT objects and devices in operation will exceed 50 billion, forming an extensive interconnected system that encompasses smartphones and household appliances [10]. The widespread adoption of IoT, combined with the declining costs of electronic devices and networking, has significantly facilitated the proliferation of its use in the healthcare industry. The introduction of IoT in the healthcare field holds immense potential. The utilization of IoT for remote health monitoring is expected to have a substantial influence on both healthcare establishments and people's homes [11]. The technology offers considerable potential to augment healthcare quality and save costs by enabling early identification and avoidance of illnesses and other hazardous situations [12]. The potential uses of this technology include managing long-term medical conditions, providing elderly care, facilitating physical fitness endeavors, and several other domains. Using technology to enable remote patient monitoring can significantly decrease hospitalization expenses by communicating up-to-date health information to healthcare professionals and promptly identifying and managing health conditions [13].

The IoT combines health sensors, imaging, and diagnostic devices to provide healthcare services that improve efficiency and prolong patient lives. The IoT allows healthcare professionals to remotely manage equipment, effectively allocate resources, and support cost-efficient interaction through safe, real-time communication among medical facilities and patients [14]. This helps in minimizing equipment downtime and improving overall efficiency in healthcare operations. Moreover, healthcare networks enabled by the IoT are positioned to assist in timely identifying diseases, managing long-term medical conditions, handling medical crises, and providing healthcare services as needed, aided by database systems, entry points, and medical servers [15].

Recent advancements in machine learning, such as the multi-expert large language model architecture for Verilog code

generation, have shown promise in automating complex design tasks, potentially offering new avenues for secure and efficient hardware design in IoT applications [16]. The automatic synthesis of models from communication traces in System-on-Chip (SoC) designs has been shown to streamline the development of secure and efficient systems, which is critical for managing the complex data flows in IoT-enabled healthcare environments [17].

C. Problem Statement

Security is a significant concern in large-scale network configurations, particularly in healthcare IoT deployments that handle sensitive patient information. The wireless nature of most devices and their communications in IoT-enabled healthcare systems raises considerable privacy and security concerns [18, 19]. For example, under a Medical Sensor Network (MSN), an IP-enabled sensor might send health information to distant healthcare services. Nevertheless, patient privacy becomes a significant concern when medical data is transmitted through potentially untrustworthy network infrastructures, such as the Internet [20]. Therefore, it is imperative to guarantee the confidentiality and security of health information in healthcare IoT applications. Ensuring the identity verification and permission granting of distant healthcare facilities or caregivers and safeguarding data during its transmission are crucial requirements in healthcare IoT to avoid unauthorized access to confidential medical information or intentional disruption of particular operations. Given individuals' ongoing engagement with these applications, ensuring secure and reliable data communication across healthcare sensors, patients, caregivers, and actuators is vital. Concerns about misuse or privacy issues might deter people from embracing IoT-based healthcare applications.

D. Contribution

This paper introduces a hybrid model that combines the Secure Hash Algorithm (SHA-256), Rivest Cipher 4 (RC4), and Elliptic Curve Digital Signature Scheme (ECDSS) to enhance the security of patient data collected through IoT and various health devices. SHA-256+RC4+ECDSS employs RC4 encryption using ECDSS and introduces shift-right operation to improve the Pseudo-Random Number Generation Mechanism (PRGM) stage. Through the use of shift-right, the key is modified, and subsequently, the plaintext is encrypted. ECDSS encrypts the resulting ciphertext, which is further processed by SHA-256. This combination of algorithms prevents third-party access to data and ensures complete privacy assurance. The following questions guide the study:

- How can a hybrid security framework improve the confidentiality and integrity of data in IoT-enabled healthcare systems?
- What are the computational trade-offs involved in integrating SHA-256, RC4, and ECDSS in a single security framework?
- How does the proposed framework perform in comparison to existing security solutions?

The paper is formatted in the following fashion. Section II comprehensively analyzes previous research on the same topic.

Section III outlines the suggested approach. Section IV presents a comprehensive overview of the simulation parameters and presents the findings. Section V discusses the obtained results in detail. Finally, Section VI concludes and discusses potential future enhancements for this research.

II. RELATED WORK

Research efforts in recent years have shown significant progress in securing IoT-enabled healthcare systems. Security, privacy, and efficient data management have been addressed in numerous studies. Table I compares the methodologies, key contributions, and performance metrics of several research studies on data encryption, attack detection, blockchain integration, energy efficiency, anomaly identification, and medical image security.

Al Shahrani, et al. [21] proposed an efficient hashing technique that utilizes digital certificates to boost safety measures. At first, medical data is collected and filtered through normalization before being saved on the IoT device. In this process, digital certificates play a role in authentication. Their approach, known as the Discrete Decision Tree Hashing Algorithm (DDTHA), incorporates the Ant Colony Optimization (ACO) algorithm to hash the unsigned certificates. Encryption is carried out using the Blowfish algorithm, resulting in signed digital certificates for authentication. The proposed method underwent analysis and comparative evaluation against existing approaches, demonstrating superior performance for crucial factors such as energy consumption, avalanche effect, execution time, decryption time, and encryption time compared to other existing methods.

Aruna Santhi and Vijaya Saradhi [22] proposed a method to identify attacks on healthcare IoT devices by using an improved deep learning framework to support the Bring Your Own Device (BYOD) concept. Their approach involves modeling a simulated hospital environment where numerous IoT devices and medical equipment communicate. The datasets on malware assessment in medical IoT devices are collected from every node and treated as features. The processing of these characteristics is carried out using a Deep Belief Network (DBN), which is a constituent of the deep learning algorithm. To optimize the DBN's performance, they fine-tune the number of hidden neurons by leveraging a hybrid meta-heuristic algorithm, a combination of the Spider Monkey Optimization (SMO) and Grasshopper Optimization Algorithm (GOA), called Local Leader Phase-based GOA (LLP-GOA). The DBN trains the nodes by constructing an extensive data store, including attack specifics, allowing precise detection throughout testing. The analysis shows that the suggested LLP-GOA-based DBN model achieved a higher accuracy of 0.25% compared to Particle Swarm Optimization (PSO)-DBN, 0.15% compared to Grey Wolf Algorithm (GWO)-DBN, 0.26% compared to SMO-DBN, and 0.43% compared to GOA-DBN. In addition, the LLP-GOA-DBN model demonstrated a 13% improvement in accuracy compared to the Support Vector Machine (SVM), a 5.4% improvement over the K-Nearest Neighbor (KNN), an 8.7% improvement over the Neural Network (NN), and a 3.5% improvement over a regular DBN.

Improved security, reduced storage load, and improved transaction processing for E-healthcare compared to centralized systems.
[24]	Utilizing permissioned blockchain, MEC, and DRL-enabled IoT for secure and energy-efficient healthcare services.	Integration of permissioned blockchain and MEC to enhance security and energy efficiency. The application of DRL is to optimize system security and energy consumption.	Balanced security and energy efficiency to combat COVID-19-related challenges.
[25]	Introduction of PRISM, an edge-centric system for intelligent healthcare tools assessment using IoT trials.	A systematic approach for IoT-based trials in domestic healthcare settings. Achieved high precision in anomaly identification.	High precision in models trained on individual patients, decline in accuracy observed on diverse patients.
[26]	Exploration of medical image security within IoT-based healthcare systems using cryptography-based networks.	Use of ResNet-50 architecture for encryption and decryption of medical images. Implementing reconstructive network for decryption and Return on Investment (ROI) framework.	Strong security outcomes in medical image encryption/decryption and potential for precise therapy assessments.

Khan, et al. [23] have proposed a comprehensive strategy to address security concerns in exchanging patients' records across centralized server-based systems. Their solutions address node connectivity rates, parallel data-sharing failures, and delivery complications. The strategy comprises three main components. Initially, it presents a new and reliable framework for ensuring the security of electronic healthcare data by utilizing blockchain-distributed ledger architecture. Furthermore, it improves how medical Wireless Sensor Networks (WSNs) operate by implementing a distributed tiered structure, improving network capacity, and promoting confidence in the blockchain-enabled Peer-to-Peer (P2P) environment. Also, it utilizes the NuCypher threshold re-encryption process to encrypt data, guaranteeing the security of shared resources stored in blocks inside an immutable blockchain. The system utilizes chain codes to automate the processes of verification, logging, distribution of index information, and transaction traceability to prevent illegal actions in the e-healthcare distributed application. In addition, it implements tailored, efficient blockchain systems that utilize both multi-proof-of-work (PoW) and multi-proof-of-stake (PoS) mechanisms, together with digital signatures. These enhancements optimize resource usage, minimize storage requirements, and streamline the transaction process specifically for e-healthcare.

Liu and Li [24] proposed a novel system that combines a permissioned blockchain with Deep Reinforcement Learning (DRL)-enabled IoT to address privacy and power constraints. The proposed mechanism aims to provide healthcare services in real time, ensuring security and energy efficiency. Its primary focus is on assisting in the management of the COVID-19 pandemic. To deal with issues regarding security, a technique based on permissioned blockchain has been developed to guarantee the system's security. The strategy incorporates mobile edge computing (MEC) to disperse computing tasks to

address energy restrictions. This helps decrease the proposed H-IoT system's computational load and energy consumption. Additionally, the system employs energy harvesting techniques to enhance performance. Moreover, using a DRL technique simultaneously improves the system's energy efficiency and security aspects. The simulation findings demonstrate that the suggested method successfully achieves a harmonious equilibrium between security and energy efficiency, providing a solid and effective response to the issues brought about by the COVID-19 pandemic.

Hadjixenophontos, et al. [25] introduced PRISM, an edge-centric system designed to assess innovative healthcare tools within domestic settings. They established a systematic approach rooted in automated IoT trials. Leveraging an extensive real-world dataset from in-home patient surveillance across 44 residences of People Living with Dementia (PLWD) spanning a two-year duration. Findings revealed anomaly identification with precision reaching 99%, alongside an average training duration as brief as 0.88 seconds. Despite the high precision observed in models trained on the same individual, a decline in accuracy occurred when assessed on diverse patients.

In healthcare, preserving the confidentiality, integrity, and availability of medical images is critical for precise diagnoses, treatment planning, and patient well-being. Consequently, Nadhan and Jacob [26] explored medical image security within IoT-based healthcare systems. Their study focused on using cryptography-based networks to encrypt and decrypt medical images, especially in secure image transmission through deep learning. The critical network was built upon the ResNet-50 architecture to establish the correlation between various image representations, enabling the incorporation of these intricate elements into the learning model for fine-tuning the encryption technique in specific domains. A reconstructive network was

then used in the decryption process to convert the encrypted image to its original "plaintext" form. Upon revealing the concealed components, an accessible Return on Investment (ROI) framework was established, streamlining data mining by accessing information directly from the user's local environment. The proposed system presented highly reliable imaging tools for assessing therapy outcomes. The utilization of two distinct publicly available datasets facilitated the accomplishment of their research objectives. The robust empirical setup and security analysis outcomes strongly suggest that the proposed approach can offer unparalleled security and yield powerful outcomes in medical image encryption and decryption.

Researchers have focused on efficient hashing techniques and digital certificates but may overlook the importance of integrating multiple cryptographic methods to enhance both security and efficiency. The work of Aruna Santhi and Vijaya Saradhi on attack detection using deep learning frameworks is innovative but does not specifically address encryption and integrity of medical data transmission. In the same way, Khan et al.'s blockchain-based approach enhances security in centralized systems but may introduce complexities in terms of data management and computational overhead. A hybrid security framework combining RC4, ECDSS, and SHA-256 is proposed in our research to address these gaps, providing a balanced solution to the challenges of encryption, authentication, and data transmission in IoT-enabled healthcare systems.

III. PROPOSED APPROACH

Securing the privacy and integrity of healthcare data transmission via networks is an ongoing and dynamic problem in IoT technologies. Conventional approaches to network access control are often ineffective and susceptible to unauthorized access or replication. Novel techniques like encryption algorithms have been developed to provide a highly efficient data invisibility framework. However, encryption algorithms encounter difficulties as a result of the strong relationship between the original message and the encrypted message, which facilitates the extraction of encryption keys and the retrieval of the original message by attackers. This study addresses these concerns, proposing a hybrid algorithm called RC4+ECDSS+SHA-256 to enhance the privacy and security of incoming data originating from healthcare and IoT equipment.

The RC4 technique has two primary stages: the Key Scheduling Process (KSP) and PRGM. The KSP populates the S-Box, a 256-byte table, by distributing the elements based on a key. The PRGM then generates a pseudo-random key, which is then used for XOR encryption to form the ciphertext. For more extensive plaintext data, the encryption time may be longer. Moreover, the ECDSS produces a cryptographic key for the RC4 method. ECDSS relies on the Discrete Logarithmic Problem (DLP) and operates within a group of cycles known as EC(Fp), which has a designated generator (G) and a co-factor (h) of 1. ECDSS utilizes key sets comprising a public key (PuK) and a private key (PrK). The SHA-256 is employed to guarantee data integrity. SHA-256 is a cryptographic hash algorithm used to validate data integrity. The suggested hybrid technique enhances privacy and security for medical data exchanged over

IoT networks by integrating the RC4, ECDSS, and SHA-256 algorithms.

In the proposed technique, the efficiency and security of the system are improved by leveraging ECDSS for faster key generation during the PRGM process in RC4. KSP in RC4 modifies the key, which can be 40 to 256 bits depending on specific requirements. The suggested approach enhances security resilience versus various threats and improves storage effectiveness by incorporating modifications of ECDSS into RC4. The XOR operation encrypts the plaintext by combining it with the pseudo-random bits generated via the PRGM procedure. This process occurs after the critical encryption is performed by ECDSS and the permutation operation is performed in the KSP section.

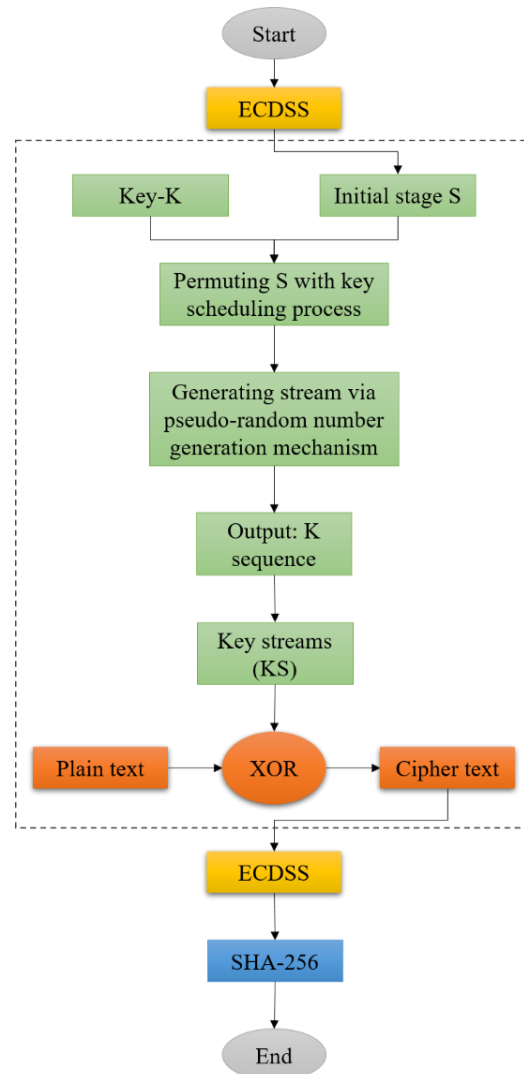

Fig. 1. The workflow of SHA-256+RC4+ECDSS.

To further increase security, a shift-right function is employed to choose a value prior to executing the XOR function. The plaintext is encrypted using the RC4 technique, and the entire process is further encrypted using the ECDSS certification. In addition, to ensure data integrity, the SHA-256 algorithm is used to encrypt the ECDSS signature. This ensures

that only authenticated users with access rights can access the ciphertext. Fig. 1 illustrates the process of the proposed SHA-256+RC4+ECDSS architecture. It provides a comprehensive overview of the various steps of the encryption process, including key generation, encryption with RC4, and data integrity verification with SHA-256. Overall, this hybrid approach combines the strengths of ECDSS, RC4, and SHA-256 to ensure security, efficiency, and data integrity in transmission and improve medical data via IoT networks.

The encryption process involves the following steps. Firstly, an elliptic curve (EC) is selected, and a generator (G) is chosen from its cyclic group. Next, the public-private key pair (PuK, PrK) is generated using ECDSS. This is achieved by randomly selecting a private key (PrK) within a specific range and computing the corresponding public key (PuK = PrK * G). The public key is then used as input for the KSP within the RC4 algorithm, modifying the S array (the key schedule) and determining its final state. The modified S array is employed in the PRGM to generate a pseudo-random key for encryption. Shift-right operations are performed on the PuK vector values to create a new key. The plaintext is encrypted using XOR encryption with the generated pseudo-random key. Additionally, a signature is generated for the Encrypted Plaintext (EP) using ECDSS with the private key and other parameters. The signature is then hashed using the SHA-256 algorithm. The encrypted message and the signature are the final output of the encryption process.

On the other hand, the decryption process involves the following steps. Given the encrypted message (EM) or ciphertext, the message is decrypted using the SHA-256 decryption process. The signature is verified to determine its acceptance or rejection. Signature verification involves the computation of various values using the ECDSS parameters and the received signature. The R.y value is calculated using the square root method. To verify the signature, the computation of $RwPrK + uPuK * EM (FPrK)$ is performed. The signature is accepted if $x(R)$ is congruent to $k \pmod{n}$, where $x(R)$ represents the x-coordinate of R. Finally, the ciphertext is decrypted using the RC4 algorithm, and the resulting plaintext is the output of the decryption process.

Algorithm 1 outlines the pseudocode of the proposed technique, which incorporates the use of ECDSS, RC4, and SHA-256 algorithms in the workflow. In this situation, users transmit medical data from Internet of Things (IoT) devices to cloud storage. At this point, the initial task is to create the procedure for each workflow utilizing the SHA-256, ECDSS, and RC4 algorithms. ECDSS is a public key cryptography algorithm used for generating digital signatures, ensuring the authenticity and integrity of the data. RC4 is a widely used stream cipher algorithm for encryption and decryption, providing confidentiality to the transmitted data. SHA-256 is a cryptographic hash function that generates a unique hash value to ensure data integrity and detect modifications. Subsequently, the S array is altered for the data arriving utilizing the ECDSA public key. This phase guarantees that the received data is thoroughly validated and certified securely. Ultimately, users execute the encryption and decryption processes according to the instructions outlined in Algorithm 1. This allows for the

secure transmission and retrieval of medical data, ensuring confidentiality and privacy.

Algorithm 1. Pseudocode of the proposed method

Input: Elliptic Curve Parameters (EC)

Output: Key Pairs (Public Key PuK, Private Key PrK)

Encryption process:

Iterate over each EC(Fp) to choose a point G from order n.
Generate the Elliptic Curve over Fp (GEEC(Fp)).
Select a random integer PrK within the range $2 < PrK < n-2$.
Compute PuK = PrK * G.
Apply PuK as input for the KSA function.
Generate the state S = KSA(PuK, S).
Define the key length for S, modify the S array using PuK, and execute the PRGA function for S.
Assign S as PuK, shift-right the PuK vector values, and create a new key based on shift-right operations.
Encrypt the plaintext using the XOR operation, defining the encrypted plaintext as EP, private key PrK, and ECD parameters.
Choose a random integer r within the range $2 < r < n-2$.
Calculate R = rG.
Determine $k = x(R) \pmod{n}$.
Compute $S = r^{-1} * (h(M) + dk) \pmod{n}$.
Hash(S) using SHA-256.
Generate the Encrypted Message EM.

Decryption Process: Input the Encrypted Message EM or Cipher Text.

Decrypt the message using SHA-256-decryption.
Accept or reject the signature.
Compute $v = S^{-1} \pmod{n}$ for verification.
Compute $w = h(M) * v \pmod{n}$.
Calculate $u = k * v \pmod{n}$.
Calculate R.y value.
Retrieve point R by k value using the square root method.
Calculate $R = wPrK + uPuKeEM(FPrK)$.
Accept the signature If $x(R) = k \pmod{n}$.
Decrypt the cipher text using RC4.

Output: Plaintext

The input submitted for encryption is converted into an array using ECDSS, which is altered using the public key of the ECDSS encryption scheme. To illustrate, the original key "abcd" is converted into array K by the ECDSS process. The strings are then converted into bytes. Encryption and decryption are done using the RC4 algorithm based on the byte arrays. For example, array A is obtained as [97, 98, 99, 100] from abcd, and the encrypted RC4 key is generated using ECDSS, resulting in array K as [65, 121, 53, 47, 104, 87, 86].

The proposed model aims to improve data security for healthcare infrastructure and applications. In these systems, diverse health information is collected from IoT devices, archived in the cloud, and transmitted to medical facilities, healthcare institutions, and private doctors for assessment. However, the focus is on unauthorized access by third parties, which poses a significant risk to the confidentiality of the data. In the suggested algorithm, the collected IoT data is encoded and decoded by a combined approach of RC4+ECDSS+SHA-256. This ensures that only trusted parties, such as doctors, health centers, and research centers, can access the data, lowering the risk of unauthorized access.

In this proposed hybrid algorithm, RC4, ECDSS, and SHA-256 are individually complex cryptographic components, and their sequential application determines the algorithm's computational complexity. As a stream encryption algorithm, RC4 has a time complexity of $O(n)$, where n is the length of the input data. However, KSP and PRGM in RC4 incur some overhead due to their iterative nature. For key generation and signature generation, the ECDSS, which uses elliptic curve cryptography, requires $O(\log(n))$ and $O(n)$, respectively. SHA-256 is a cryptographic hash function that operates with a fixed complexity of $O(n)$. These algorithms, particularly the repetition of key generation and transformation steps, result in a complexity of $O(n)$ for encryption and decryption, but with additional overhead from elliptic curve operations and hash computation, making the hybrid approach computationally intensive but robust against various security threats at the same time.

IV. SIMULATION RESULTS

We evaluated the presented security framework using various performance metrics, including throughput, decryption time, and encryption time. A summary of the components and parameters considered in the system is outlined in Table II. The CPU is an Intel i5 processor running at 3.2 GHz, while the operating system is Windows 10. The system boasts 4 GB of RAM and operates on a 32-bit architecture. The simulation leverages Python with the Cryptography class for its configuration. Moreover, various cryptographic models and their respective specifications, including key size, block size, and other specific parameters like S-box size for RC4, are outlined in Table II, providing a comprehensive overview of the system used for the study.

A ratio of original data size to encryption time determines encryption throughput. An increase in encryption throughput indicates higher algorithm efficiency. As shown in Table III, we adopted a file size of 10 MB for the test, which resulted in a throughput time of 11.67 ms. Eq. (1) calculates encryption throughput. The analysis of encryption throughput compared to other techniques is shown in Fig. 2.

$$E_t(KB/ms) = \frac{\Sigma \text{input file}}{\Sigma \text{encryption time}} \quad (1)$$

Likewise, the decryption throughput is calculated by dividing the input file size by the decryption time. For a file size of 10 MB, the analysis resulted in a decryption throughput of 12.79 ms, as shown in Table IV. The calculation of the decryption throughput follows Eq. (2). Fig. 3 illustrates the analysis of the decryption throughput.

$$D_t(KB/ms) = \frac{\Sigma \text{input file}}{\Sigma \text{decryption time}} \quad (2)$$

TABLE II. SIMULATION PARAMETERS

Cryptographic model	Block size (bits)	Key size (bits)
RC2	128	128
AES	128	256
RC4	S-box (256 bytes)	256
ECDSS	128	256
3DES	64	256

Fig. 2. Encryption throughput comparison.

TABLE III. ENCRYPTION THROUGHPUT ANALYSIS

Size of the original file (MB)	Average duration taken for encryption throughput			
	SHA-256+AES+RC4	SHA-256+3DES+ECC	SHA-256+RC2+ECC	SHA-256+RC4+ ECDSS
1	7.48	7.11	8.16	10.83
2	7.55	7.16	8.63	11.14
3	7.69	7.21	8.97	11.03
4	7.44	7.26	9.37	11.12
5	7.75	7.35	9.73	11.79
6	7.48	7.16	9.32	11.33
7	7.65	7.13	9.74	11.17
8	7.74	7.29	9.89	11.28
9	7.64	7.08	10.02	11.21
10	7.71	7.13	10.41	11.67
Average time	7.613	7.188	9.424	11.257
Total time	83.743	79.068	103.664	123.827

Fig. 3. Decryption throughput comparison.

Table V compares the proposed hybrid algorithm with other algorithms regarding the encryption time. All files with the suggested algorithm were encrypted in 331.5 ms on average, indicating a faster encryption process. Fig. 4 provides a visualization of the encryption time analysis. Furthermore, In Table VI, the developed method and alternatives are compared in terms of decryption times. Our method has a shorter decryption time of 312.1 ms than any other method. Fig. 5 provides a graphical representation of the decryption time analysis and illustrates the performance of the proposed and existing methods.

The results show that the proposed hybrid security framework has superior performance in terms of encryption and decryption efficiency. The observed encryption throughput of 11.67 KB/ms and decryption throughput of 12.79 KB/ms with a file size of 10 MB indicates a highly efficient process that outperforms many existing methods. The average encryption time of 331.5 ms and the decryption time of 312.1 ms further underline the effectiveness of the model, as these times are significantly lower than those of other algorithms. These metrics justify the conclusion that the proposed framework increases both security and efficiency, making it suitable for real-time applications in IoT-enabled healthcare systems. The

reduced processing times mean the framework can process large volumes of sensitive data quickly, ensuring robust security without compromising performance, which is critical in healthcare environments where timely data processing is essential.

V. DISCUSSION

The proposed hybrid security framework combining RC4, ECDSS, and SHA-256 has demonstrated significant improvements in healthcare systems' efficiency and security. The encryption and decryption throughput results show that the framework can process large amounts of data quickly, which is critical in real-time healthcare environments where timely access to patient data can be life-saving. Integrating ECDSS with RC4 not only increases key management efficiency but also strengthens encryption against common cryptographic attacks. Using SHA-256 ensures data integrity and provides an additional layer of security that is essential to maintaining patient confidentiality and complying with healthcare regulatory standards.

Furthermore, the empirical analysis confirms that the proposed framework outperforms existing security models in terms of encryption and decryption times, indicating its suitability for resource-constrained IoT devices commonly

used in healthcare. This performance improvement is critical for practical use as it minimizes computational overhead while maximizing security. The hybrid approach also addresses the identified gaps in previous research by providing a more comprehensive solution that integrates multiple cryptographic techniques, providing robust protection against unauthorized access and ensuring the integrity and confidentiality of medical data during transmission. This makes the proposed framework a viable option for improving the security of IoT-enabled healthcare systems in an increasingly connected and vulnerable digital landscape.

VI. CONCLUSION

This study addresses the critical challenge of data privacy and security in IoT-based healthcare systems by proposing a hybrid security framework. The framework combined ECDSS, RC4, and SHA-256 to preserve the integrity and confidentiality of data sent. The experimental analysis demonstrated the superiority of the proposed model, particularly when encrypting

data of 10 MB. The framework achieved a high throughput of 11.67 MB per millisecond, with an encryption time of 846 milliseconds and a decryption time of 627 milliseconds. These results highlighted the efficiency and effectiveness of the proposed hybrid security framework. Compared to existing techniques such as SHA-256+3DES+ECC, SHA-256+AES+RC4, and SHA-256+ RC2+ECC, the proposed model outperformed for encryption time, decryption time, and overall security. It provided a robust solution for protecting sensitive healthcare data transmitted through IoT devices.

Further investigation in healthcare IoT security could concentrate on using advanced cryptographic techniques, such as homomorphic encryption and quantum-resistant algorithms, to enhance data protection. Exploring decentralized identity management and blockchain applications has the potential to improve identity verification in healthcare systems. In addition, creating machine learning models to identify anomalies in healthcare data collected by IoT devices could facilitate proactive security measures. Furthermore, the combination of edge computing with federated learning has the potential to resolve privacy issues by locally processing confidential data. These instructions guarantee the enhancement of the durability of healthcare IoT systems against advancing cyber dangers while promoting innovation in patient data confidentiality and protection.

Abstract—This study explores the implementation of a Dose Archiving and Communication System (DACS) in Moroccan healthcare, highlighting the importance of X-ray dose management in modern radiology. It emphasizes patient safety and the ALARA principle to minimize radiation exposure while maintaining diagnostic accuracy. The research discusses advancements in imaging technologies, such as dose-reduction algorithms and real-time monitoring systems. A survey of 1000 healthcare professionals reveals significant challenges in X-ray dose management, including poor dose tracking, regulatory non-compliance, and inadequate radiation protection training. Noteworthy findings reveal that 10% of patients received doses exceeding 5 Gray, underscoring the exigency for robust dose management systems. The article delineates a strategic implementation approach for DACS in Moroccan hospitals, comprising meticulous needs assessment, infrastructure fortification, and stakeholder engagement. By harnessing cloud-based storage, blockchain technology, and industry-standard encryption protocols, the envisioned DACS endeavors to furnish a secure, scalable, and efficient framework for radiation dose management. This holistic approach, underpinned by empirical statistics regarding training in radiation protection, network infrastructure, and DACS implementation strategies, aims to elevate patient outcomes and ensure stringent regulatory compliance.

Keywords—DACS; Real-time monitoring; radiation protection; radiology practice; healthcare professionals; x-ray doses; regulatory compliance; patient safety; Moroccan healthcare

I. INTRODUCTION

X-ray dose management represents a fundamental aspect of contemporary radiology practice, emphasizing the ethical imperative to prioritize patient safety while harnessing the diagnostic potential of X-ray imaging. By fostering a culture of radiation stewardship and embracing evidence-based strategies, healthcare institutions can uphold the principles of ALARA (As Low As Reasonably Achievable) and deliver high-quality care that maximizes clinical efficacy while minimizing radiation-related risks [1].

In the realm of modern medical imaging, X-ray technology stands as a cornerstone for diagnostic and therapeutic purposes, facilitating crucial insights into the human body's intricate structures. However, alongside its undeniable benefits, the utilization of X-ray radiation carries inherent risks, particularly concerning cumulative radiation exposure and its potential adverse effects on patients and healthcare professionals alike.

Effective X-ray dose management encompasses various dimensions, including dose monitoring, optimization of imaging protocols, equipment calibration, personnel training, and patient education. Through meticulous monitoring and analysis of radiation doses delivered during diagnostic and interventional procedures, healthcare providers can gain valuable insights into radiation utilization patterns, identify potential areas for improvement, and tailor interventions to mitigate unnecessary exposure.

Within this framework, Garba et al. [2] conducted research focusing on the development of a manual radiation dose management system to monitor and track radiation doses and scan parameters for brain CT scans. The system monitored CTDI vol and DLP, using notification values to identify procedures requiring optimization. Data analysis was conducted to compare with national and international diagnostic reference levels (DRLs) to ensure compliance and enhance patient safety. Heron et al. [3] examined the impact of X-ray-based medical imaging on staff safety and explored how new technologies affect medical staff's exposure to X-rays. They highlighted the crucial importance of using protective measures and ongoing training. Polizzi-et al. [4] carried out a study to standardize X-ray cabinet irradiator dose, geometry, and calibration reporting, focusing on a dual X-ray source cabinet irradiator (CIXD, Xstrahl Limited, UK). They assessed dose distribution under various experimental conditions using methods such as half-value layer (HVL) measurement, profile measurements, and output calibration with an ion chamber, alongside two weeks of constancy measurements. Film measurements evaluated percent depth dose and homogeneity. The X-ray tubes showed an output of 1.27 Gy/min with an HVL of 1.7 mm Cu. Simultaneous operation of the tubes reduced the heel effect observed in individual tubes. Despite a 15% dose inhomogeneity within the tray area, film measurements indicated only minor nonuniformities. Additionally, Silva et al. [5] undertook a study to investigate and evaluate the radiation doses received by professionals during chest CT scans and to assess the effectiveness of personal protective equipment (PPE). Computational scenarios were simulated using pediatric (1 and 10 years old) and adult virtual anthropomorphic phantoms to represent patients and professionals. The MCNP 6.2 Monte Carlo code was employed to determine conversion coefficients for equivalent (CC[HT]) and effective (CC[E]) doses. Another noteworthy contribution to radiation protection research was offered by Kawauchi et al. [6]. Their study

emphasized the importance of protecting lenses during cerebral angiography examinations to ensure patient lens safety. To assess lens doses, they employed both a phantom and a real-time dosimeter. Additionally, they computed an artifact index for evaluating image quality through pixel and noise analysis.

Healthcare professionals and patients face increased health risks from radiation overdoses due to inadequate use of protective measures and passive dosimeters during imaging exams. Developing effective X-ray dose management systems is essential to mitigate these risks by ensuring rigorous dose monitoring and adherence to safety protocols. In this context, Choi et al. [7] conducted a study focusing on implementing a Dose Archiving and Communication System (DACS) in a large healthcare system to manage radiation doses. Liu et al. [8] provide a comprehensive review of DACS in radiation oncology, focusing on its capabilities, challenges, and future prospects. Furthermore, Faggioni et al. [9] describe the implementation and evaluation of a DACS tailored for pediatric cardiac catheterization procedures. The study evaluates how DACS improves radiation dose monitoring and management in pediatric settings. Rehani et al. [10] explore the comprehensive landscape of radiation dose management systems, including DACS, discussing challenges in monitoring doses across various medical imaging modalities. Wang et al. [11] examine the advancements in DACS technology and its role in enhancing radiation dose management in clinical settings. Moreover, Martin et al. [12] explore how the implementation of DACS affects clinical workflow and patient care outcomes, highlighting both benefits and challenges.

We have designed an innovative Dose Archiving and Communication System (DACS) that offers several significant advantages. This system operates independently and adapts seamlessly to any IT infrastructure installed in the relevant departments. Unlike other solutions, our DACS is engineered to meet the constraints of network infrastructure and limited access, providing exceptional flexibility and compatibility. It can be used with both new equipment technologies and older technologies, making it a durable and adaptable solution. Furthermore, our system allows for real-time dose monitoring, with alerts and notifications to ensure optimal management of prescribed examination protocols for patients and the doses absorbed by healthcare personnel during their daily tasks. This level of control and responsiveness helps improve the safety and efficiency of radiological practices.

This paper is organized into seven sections. The first section is Introduction. Section II describes the general context. Section III explores the study's foundational aspects and methodology. Section IV is devoted to elucidating the dose system management. Following that, Section V sheds light on the results and fosters discussions. Then, Section VI concentrates on outlining an approach for implementing dose archiving and communication systems in healthcare institutions. Finally, Section VII presents the conclusion.

II. GENERAL CONTEXT

X-ray dose management emerges as a pivotal discipline within radiology and healthcare at large, aiming to optimize the utilization of X-ray imaging while minimizing radiation exposure risks. By implementing comprehensive strategies,

protocols, and technologies, X-ray dose management endeavors to strike a delicate balance between acquiring diagnostically valuable images and safeguarding patient safety. Moreover, advancements in imaging technology, such as dose-reduction algorithms, dose-tracking software, and real-time dose monitoring systems, offer invaluable tools for enhancing X-ray dose management practices. These innovations empower healthcare professionals to optimize imaging parameters, adjust radiation doses based on patient characteristics and clinical indications, and ensure that diagnostic goals are achieved with the lowest feasible radiation exposure.

In the domain of X-ray exposure, a nuanced understanding of various dose metrics is indispensable for assessing radiation risks and ensuring patient safety. These metrics provide crucial insights into the amount of radiation absorbed by individuals during imaging procedures. Among the key types of X-ray doses, the Entrance Skin Dose (ESD) stands out as it quantifies the radiation absorbed by the skin at the point of entry of the X-ray beam, serving as a critical indicator of potential skin effects. Additionally, Organ Dose evaluation allows for a targeted assessment of radiation absorbed by specific organs or tissues, recognizing their differing sensitivities and facilitating a more accurate estimation of associated health risks. The Effective Dose (ED) metric goes further by synthesizing the varying sensitivities of different tissues and organs, offering a comprehensive assessment of the overall risk posed by a particular radiation exposure, measured in Sieverts (Sv). Dose Area Product (DAP) is instrumental in quantifying the total radiation delivered to a specific area during an X-ray procedure, factoring in both radiation intensity and exposed area. Peak Skin Dose (PSD) is particularly pertinent in interventional radiology procedures, identifying the maximum skin dose reached during a specific imaging intervention. Cumulative Dose accounts for the total radiation accumulated over time from multiple X-ray exposures, particularly crucial for individuals undergoing frequent medical imaging. Finally, Effective Dose Equivalent (EDE) provides a refined measure of radiation risk by considering the biological harm associated with different types of ionizing radiation, thereby guiding radiation protection strategies. For medical professionals, radiologists, and radiation safety experts, a comprehensive grasp of these dose metrics is essential in ensuring that X-ray procedures are conducted with utmost precision and minimal risk to patients, while still yielding valuable diagnostic insights [13-15].

The legal framework governing nuclear and radiological safety, security, and ionizing radiation control in Morocco is outlined in references [16-19]. These documents articulate three fundamental principles of radiation protection: justification, optimization, and limitation. Justification dictates that no activity involving exposure to ionizing radiation should occur unless it produces a positive economic, social, or other benefit that outweighs potential health risks. Optimization requires minimizing individuals' exposure to ionizing radiation to the fullest extent possible, taking into account economic and social considerations. Limitation mandates that cumulative doses from all activities must not exceed the dose limits specified by regulations.

To complement these regulatory efforts, several agencies have been established to serve specific purposes such as dosimetry monitoring, calibration, and metrology of ionizing radiation devices, as well as control and expertise in radiation protection, quality assurance in medical imaging, radiological environmental monitoring, and radiation protection training. These agencies include "The National Center for Radiation Protection of the Ministry of Public Health," "The National Commission for Radiation Protection," "The National Commission for Nuclear Safety," "The Department of Nuclear Energy of the Ministry of Energy and Mines," and "The National Center for Energy of Nuclear Sciences and Techniques" [16-19].

The integration of dosimetry control and monitoring is an increasingly prevalent trend within Moroccan healthcare establishments, influenced by various challenges: technological (quality, safety, and innovation), regulatory, and economic considerations. This research is crafted for the benefit of all practitioners involved in ionizing radiation. The primary objectives of this study revolve around the adoption of best practices in radiation protection. Additionally, it aims to promote the utilization of both individual and collective protective measures. Lastly, the research emphasizes the significance of monitoring the dosimetry of each individual to ensure personal protection and minimize absorbed radiation doses.

III. STUDY BACKGROUND AND METHODOLOGY

While technology continues to evolve and regulatory standards change, the field of X-ray dose management remains a major challenge for the Moroccan authorities, particularly in terms of the doses absorbed by healthcare professionals.

To understand users' needs in X-ray dose management, a survey was conducted among 1000 healthcare professionals. The results revealed that the main challenges encountered included: X-ray dose tracking, regulatory and normative compliance and lack of adequate training, underscoring the importance of an integrated dose management system to address users' diverse needs and enhance patient and worker safety.

The significance of network infrastructure in the context of radiology departments is paramount for enhancing radiation protection and dose management. A robust network infrastructure plays a crucial role in facilitating the integration of advanced technologies and tools that contribute to the overall safety and efficiency of x-rays practices [20-22]. Several key points highlighting the importance of network infrastructure in this regard:

1) *Data management and storage:* Network infrastructure enables seamless data management and storage of radiological images and patient information. This centralized approach allows for efficient access, retrieval, and secure archival of critical data, supporting comprehensive dose monitoring and analysis.

2) *Integration of imaging systems:* A well-developed network allows for the integration of various imaging systems and devices within the radiology department. This integration

enhances the coordination and interoperability of equipment, ensuring a streamlined approach to dose control and radiation protection protocols.

3) *Real-time monitoring and analysis:* Network connectivity facilitates real-time monitoring of imaging procedures and radiation dose levels. With instant access to this information, healthcare professionals can make informed decisions promptly, adjusting protocols as needed to optimize radiation exposure for patients and staff.

4) *Telemedicine and remote consultations:* Network infrastructure supports telemedicine initiatives and remote consultations, enabling radiologists to collaborate and share expertise regardless of physical location. This capability contributes to more extensive knowledge exchange, fostering best practices in radiation protection.

5) *Implementation of dose tracking systems:* Dose tracking systems, crucial for monitoring and managing radiation exposure, rely on a robust network infrastructure. The connectivity provided by the network allows for the seamless collection, analysis, and reporting of dose data, aiding in the implementation of dose optimization strategies.

6) *Security and compliance:* A secure network infrastructure is essential to protect sensitive patient data and ensure compliance with regulatory standards. Compliance with security protocols is integral to maintaining the integrity of radiation protection measures and preventing unauthorized access to patient information.

7) *Education and training programs:* Network connectivity supports online education and training programs for healthcare professionals involved in radiology. This allows for continuous learning, ensuring that the staff stays updated on the latest advancements in radiation protection practices.

Dose Archiving and Communication System (DACS) aims to enhance dose monitoring and management practices in medical imaging by providing comprehensive solutions for capturing, storing, and analyzing dose data. Through advanced tracking and reporting functionalities, DACS facilitates the optimization of radiation dose levels, ensuring patient safety, regulatory compliance, and the quality of diagnostic imaging procedures. By centralizing dose data and promoting data-driven decision-making, DACS empowers healthcare providers to improve patient care and enhance operational efficiency in medical imaging facilities.

In the context of analyzing the needs for managing and analyzing X-ray doses, understanding users (Biomedical, Radiology, Oncology and Surgery staff) specific requirements and the current challenges faced by professionals in this field is paramount. Our system is a comprehensive solution designed to manage and monitor radiation doses administered to patients during radiological procedures. Upon launching the system, users are greeted with a secure authentication screen, ensuring that only authorized personnel can access sensitive patient and dose information. Once logged in, users are directed to the main dashboard, which serves as the central hub of the system. The interface is intuitively organized into several key sections, providing seamless navigation and functionality.

The settings section allows administrators to configure system parameters, user roles, and access permissions, ensuring that the system operates according to institutional protocols and user needs. The statistics display provides real-time analytics and visualizations of dose data, including charts and graphs that illustrate trends, compliance with safety standards, and individual patient dose histories. This feature empowers healthcare professionals to make informed decisions and optimize patient safety. Additionally, the dashboard includes a comprehensive dose archive section, where detailed records of all administered doses are stored and easily retrievable. The interface also supports advanced search capabilities, enabling users to quickly locate specific patient records or procedure details. Overall, the system interface is designed to be user friendly, efficient, and secure, facilitating x-ray dose management and communication within radiology departments.

Our solution is designed with four primary objectives (Fig. 1) to ensure optimal radiation dose management and patient safety. First, the collect objective focuses on the systematic collection and secure storage of dosimetric data. This involves gathering detailed records of all administered doses, ensuring that data integrity and confidentiality are maintained. Second, the monitor objective enables continuous, real-time tracking of patient radiation doses. This feature provides healthcare professionals with immediate feedback on radiation exposure levels, allowing for timely adjustments and interventions. Third, the evaluate objective involves comprehensive statistical analysis of dosimetric information. By utilizing advanced analytics tools, the system can identify trends, generate reports, and support evidence-based decision-making to improve radiation safety protocols. Finally, the optimize objective aims at the assessment and enhancement of radiation dose safety and efficacy. This includes evaluating current practices, implementing optimization strategies, and ensuring compliance with regulatory standards to minimize patient exposure while maintaining diagnostic image quality. Together, these objectives create a robust framework for x-ray dose management in radiological practices.

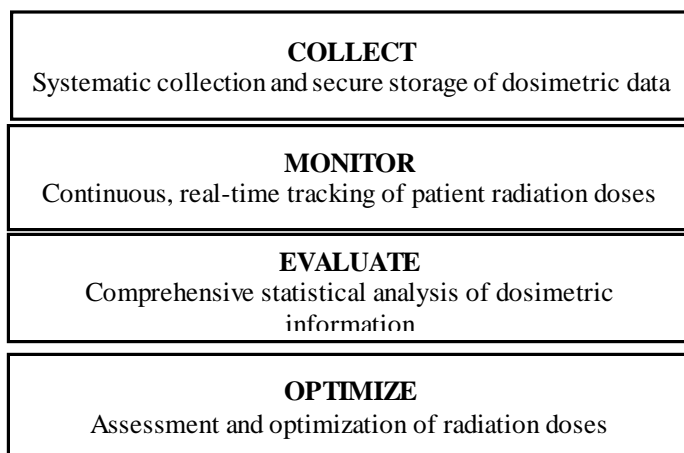

Fig. 1. Dose archiving and communication system objectives.

In conclusion, a robust network infrastructure is indispensable for creating a connected and technologically

advanced radiology department. By enabling seamless data management, integrating imaging systems, facilitating real-time monitoring, supporting telemedicine, implementing dose tracking systems, ensuring security and compliance, and fostering education programs, the network plays a pivotal role in enhancing radiation protection and dose control in medical imaging based on X-rays.

IV. X-RAY DOSE MANAGEMENT

According to our survey, users' specific needs vary depending on their roles and usage contexts. Radiologists and medical imaging technicians require effective tools to monitor and evaluate x-ray doses administered to patients while optimizing diagnostic image quality and controlling the doses absorbed by them. Similarly, radiation protection and safety professionals need dose management systems to ensure compliance with regulatory standards and worker safety. Current challenges encountered by professionals in this domain include the increasing complexity of imaging equipment, which makes dose management more challenging, as well as time and resource constraints that limit the ability to implement effective dose management practices. Additionally, compliance with regulatory standards and safeguarding patients' health data are critical considerations.

By conducting a comprehensive analysis of users' needs and the challenges faced by professionals in managing and analyzing X-ray doses, we have developed effective solutions tailored to their requirements. Fig. 2 illustrates an overall structure of our system application area.

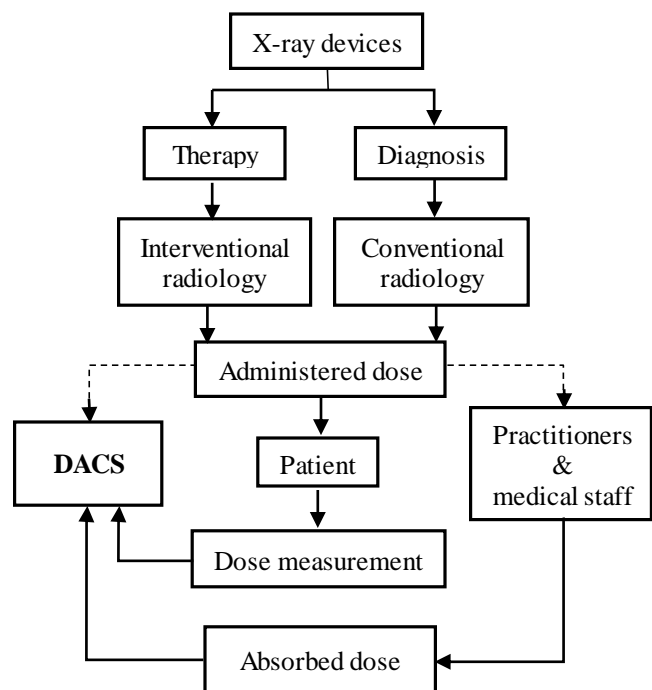

Fig. 2. General diagram and application area.

In the field of X-ray based medical imaging, two primary types of equipment are utilized: those employed in conventional radiology for diagnostic purposes and those utilized in interventional radiology for therapeutic interventions. Prior to conducting an examination, technicians program the dose of X-

rays to be administered to the patient based on various parameters such as the type of exam and patient anatomical characteristics. Following exposure, the patient absorbs a dose of X-rays, which is measured during image detection using radiographic or fluoroscopic imaging. Simultaneously, medical personnel present during the examination are also exposed to X-ray doses, which vary depending on their proximity to the radiation source and the protective measures employed, such as lead aprons. All these doses, both those administered to patients and those absorbed by medical personnel, are then transmitted to the Dose Archiving and Communication System for storage and analysis. Additionally, this system conducts equipment checks based on these doses and the utilized examination protocols, ensuring adherence to safety standards and the quality of radiological exams performed.

To understand the framework and components of our Dose Archiving and Communication System, we present a modeling overview (Fig. 3) including:

- **Data Acquisition and Integration:** This component is responsible for collecting dose data from x-ray devices, integrating it into a standardized format, and transmitting it to the central storage.
- **Central Dose Data Storage and Management:** This component stores and manages the dose data in a centralized database, facilitating efficient archiving, retrieval, and analysis.
- **User Interface:** The user interface provides a dashboard for visualizing dose data, and reporting functionalities.
- **Security and Compliance:** This component ensures data security through encryption, access control mechanisms, and maintains compliance with regulatory requirements.

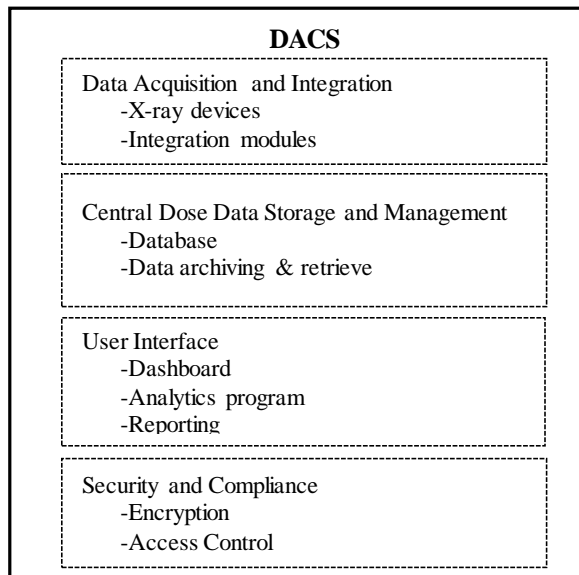

Fig. 3. Overview of DACS architecture.

Designing an effective architecture for a Dose Archiving and Communication System requires careful consideration to ensure both flexibility and security. An optimal approach involves the integration of modular components that can adapt to evolving requirements while maintaining robust security measures. Technologies such as cloud-based storage solutions offer scalability and accessibility, allowing for seamless data archiving and retrieval [23]. Additionally, blockchain technology [24-25] provides a secure and transparent framework for data communication and authentication, ensuring the integrity and traceability of dose data. Implementation of industry standard encryption protocols further fortifies data security, safeguarding sensitive information against unauthorized access. By leveraging these technologies synergistically, a DACS architecture can achieve the delicate balance between flexibility and security, laying the foundation for efficient dose management and analysis.

In the diverse landscape of medical imaging, a range of Dose Archiving and Communication Systems are available, each designed to address specific needs and requirements within healthcare facilities. Integrated Picture Archiving and Communication Systems (PACS) with dose monitoring capabilities offer a consolidated approach, allowing for the storage and management of both medical images and dose data within a single platform. While these systems provide basic dose tracking functionalities, they may lack the advanced analytics and reporting features found in standalone solutions. Standalone DACS, on the other hand, are dedicated platforms focused solely on dose monitoring and management. These systems offer comprehensive dose tracking, analysis, and reporting capabilities, enabling healthcare providers to perform in-depth assessments and trend analyses. Cloud based DACS leverage the scalability and accessibility of cloud computing technology, providing healthcare facilities with flexible and remotely accessible dose management solutions. By centralizing dose data in the cloud, these systems enable seamless collaboration and data sharing across multiple locations. Additionally, some medical imaging equipment vendors offer proprietary solutions tailored to their specific imaging systems. These vendor specific DACS are seamlessly integrated into the equipment's software and workflow, providing healthcare providers with specialized features optimized for their imaging modalities. However, they may lack the flexibility and interoperability of standalone or cloud based DACS. Healthcare providers must carefully evaluate the features, scalability, interoperability, and cost effectiveness of each solution to determine the most suitable option for their organization, considering factors such as existing infrastructure, budget constraints, and regulatory compliance requirements.

Our dose management system is a specialized platform designed to effectively manage, archive, and communicate dose data from medical imaging procedures and it provide several features as below (Fig. 4):

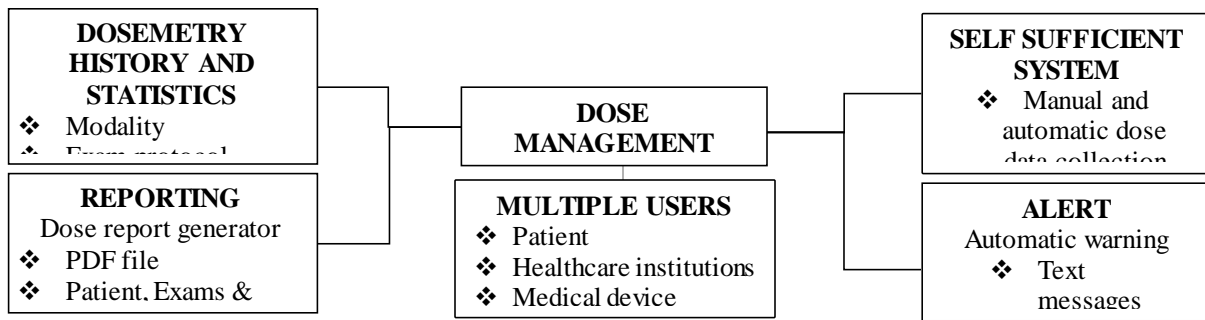

Fig. 4. Features of the DACS system.

A. Dosimetry History and Statistics

DACS facilitates the integration and comprehensive analysis of dose data across various imaging modalities. This section outlines its capabilities in documenting exam protocols and providing customizable statistical analysis over different time periods.

1) *Modality*: DACS seamlessly integrates with various imaging modalities, capturing dose data from x-ray, CT scans, and more.

2) *Exam protocol*: Detailed documentation of exam protocols used during imaging procedures, ensuring comprehensive data capture.

3) *Period*: Provides a comprehensive dose history and statistical analysis over customizable time periods, facilitating trend identification and dose optimization efforts.

B. Self Sufficient System

This section highlights the DACS features that ensure system autonomy and flexibility in dose data management.

1) *Manual and automatic dose data collection*: DACS supports both manual entry and automated collection of dose data, ensuring accuracy and flexibility.

2) *Remote access*: Enables secure remote access to dose data and system functionalities, allowing users to monitor and manage dose information from anywhere, at any time.

C. Multiple Users

This part describes how DACS accommodates various users, from patients to healthcare institutions and medical device suppliers, enhancing transparency, collaboration, and centralized dose management.

1) *Patient access*: Empowers patients to access their own dose history and reports, promoting transparency and patient engagement in their healthcare journey.

2) *Healthcare institutions*: Facilitates centralized dose management across healthcare facilities, allowing institutions to monitor dose levels, compliance, and performance across departments and modalities.

3) *Medical device suppliers*: Provides access to dose data for medical device suppliers, fostering collaboration and optimization of imaging equipment performance.

D. Reporting

This segment outlines DACS's capabilities in generating detailed and customizable dose reports for both healthcare providers and patients.

1) *Dose report generator*: Generates detailed and customizable reports in PDF format, incorporating patient information, exam details, and dose data for comprehensive documentation.

2) *Patient centric reports*: Delivers personalized dose reports to patients, enhancing communication and understanding of dose exposure and associated risks.

E. Alert System

This category details DACS's alert features, ensuring timely intervention and communication through automatic alerts and notifications.

1) *Automatic alerts*: DACS triggers automatic alerts for dose threshold breaches or abnormal dose patterns, ensuring timely intervention and dose optimization.

2) *Text messages and email notifications*: Alerts are disseminated via text messages or email to designated recipients, facilitating prompt action and communication among relevant stakeholders.

The Dose Archiving and Communication System streamlines dose management processes, enhances patient safety, and promotes collaboration among healthcare providers and stakeholders. With its advanced features and user-friendly interface, our solution empowers healthcare organizations to effectively manage dose data, optimize imaging practices, and deliver high-quality patient care.

V. RESULTS AND DISCUSSIONS

The dashboard of our Dose Archiving and Communication System is meticulously designed to offer the users a comprehensive snapshot of key statistics and metrics crucial for understanding the system's performance and ensuring patient safety. Upon accessing the system through secure login protocols, users are greeted with the main dashboard, where they can quickly grasp essential information. This includes the total number of patients, providing an overview of the volume of dosimetric data within the system, and the average dose per patient, offering insight into the typical radiation exposure experienced by individuals undergoing procedures. Additionally, a dose distribution chart visually represents the

spread of doses across different ranges, aiding in identifying any anomalies or trends.

The procedure statistics section presents users with valuable insights into the total number of procedures performed, segmented by procedure type, along with the average doses administered for each procedure category. A timeline graph depicting procedure volumes over time facilitates the tracking of procedural trends, enabling proactive decision-making and resource allocation. Real-time monitoring capabilities allow users to stay updated on current active procedures and receive prompt alert notifications for doses that exceed predefined safety thresholds, ensuring timely intervention and adherence to safety protocols.

The dashboard's analytical section offers in-depth analysis and historical perspectives, with features such as dose trends over time and patient specific dose histories presented in a user-friendly format. Compliance reports provide transparency regarding adherence to safety standards, while benchmarking facilitates performance comparison against industry norms, fostering a culture of continuous improvement and excellence. Finally, the optimization insights section leverages data driven recommendations derived from statistical analysis to enhance dose safety and efficacy, empowering users to make informed decisions aimed at improving patient outcomes and optimizing resource utilization. Through its intuitive interface and comprehensive feature set, our DACS dashboard facilitates seamless access to critical dosimetric data, empowering stakeholders with the insights needed to drive informed decision-making and deliver high-quality patient care.

The patient dose summary collected from different healthcare institutions provides a comprehensive overview of radiation exposure among of 350 patients over a year (Fig. 5). On average, each patient received a dose of 4.5 Gray (Gy), a unit measuring the absorbed radiation energy. The distribution of doses reveals that 40% of the patients fell into the low dose category, receiving between 0 and 2 Gy. The majority (about 50%) received a medium dose ranging from 2 to 5 Gy, while 10% were exposed to high doses exceeding 5 Gy. This summary highlights the variation in radiation exposure levels among the patients during this period and underscores the need

for careful monitoring and management of radiation doses in clinical settings.

Fig. 5. Patient dose summary and distribution.

The Table I provides a detailed breakdown of the dose absorbed by ten patients across various medical procedures. Each row corresponds to a patient, while the columns represent different procedures undertaken by them. The values within the table denote the dose of radiation absorbed by each patient during the respective procedures. This comprehensive overview allows for a comparative analysis of radiation exposure among patients undergoing different medical interventions. By examining the data within the table, trends in radiation dosage across procedures and variations among patients become apparent. Such insights are crucial for ensuring the optimization of radiation doses, minimizing unnecessary exposure, and enhancing patient safety in clinical settings. Furthermore, this information facilitates informed decision-making by healthcare professionals regarding the appropriate dosage levels for specific procedures based on individual patient characteristics and medical requirements.

To calculate the risk associated with X-ray doses, the first step is to determine the effective dose, which is measured in Sieverts (Sv). The effective dose accounts for the type of radiation and the varying sensitivity of different tissues and organs. This measure provides an overall risk estimate from radiation exposure [26]. The effective dose is calculated using the formula:

$$E = \sum(Dr \cdot Wr \cdot Wt) \tag{1}$$

TABLE I. DOSE ABSORBED FOR DIFFERENT PROCEDURES ACROSS 10 PATIENTS

Procedure \ Patient	Chest CT	Abdomen CT	Brain CT	Cardiac CT	Lumbar Standard	Extremity Standard	Chest Standard	Mammography	Dental
Patient 1	6.1	*	*	*	1.4	*	0.2	0.21	*
Patient 2	*	5.3	1.6	*	*	*	*	*	0.25
Patient 3	6	5.2	*	*	*	0.2	0.1	0.20	
Patient 4	*	*	1.5	1.6	*	*	0.2	*	0.23
Patient 5	6.2	*	*	1.5	*	0.1	*	*	0.3
Patient 6	*	5.4	1.4	*	1.3	*	*	0.22	*
Patient 7	*	*	*	*	1.2	*	0.2	*	0.31
Patient 8	*	5	*	1.4	*	0.3	0.1	*	*
Patient 9	6	4.8	*	*	*	*	*	*	0.2
Patient 10	7	*	1.8	*	1	*	0.12	0.3	*

Where:

E is the effective dose. D_t is the absorbed dose in tissue t , W_r is the radiation weighting factor (depends on the type of radiation, usually 1 for X-rays) and W_t is the tissue weighting factor (varies for different tissues).

Tissue weighting factors (W_t) are used to account for the varying sensitivity of different tissues to radiation. These factors, provided by the International Commission on Radiological Protection (ICRP) [27], help in calculating the contribution of each tissue or organ to the effective dose. By applying these factors (Table II), the effective dose calculation becomes more accurate, reflecting the differential risk of radiation exposure to various tissues.

TABLE II. TISSUE WEIGHTING FACTORS

Tissue or Organ	ICRP 60	ICRP 103
Gonads	0.20	0.08
Red bone marrow	0.12	0.12
Lung	0.12	0.12
Colon	0.12	0.12
Stomach	0.12	0.12
Breast	0.05	0.12
Bladder	0.05	0.04
Liver	0.05	0.04
Esophagus	0.05	0.04
Thyroid	0.05	0.04
Skin	0.01	0.01
Bone surface	0.01	0.01
Brain		0.01
Salivary glands		0.01

A comprehensive empirical investigation was conducted within healthcare institutions in Morocco to assess the implementation of radiation protection measures in both diagnostic and therapeutic procedures. The study's objectives encompassed evaluating adherence to the three fundamental principles of radiation protection and examining infrastructure, notably computer network connectivity, across services employing ionizing radiation sources. To accomplish this, a questionnaire was administered to over 1000 healthcare professionals, comprising radiology technicians, radiologists, surgeons, biomedical technicians, and biomedical engineers, representing diverse healthcare facilities across different regions of the kingdom. Key areas of inquiry included training in radiation protection, utilization of personal protective equipment, availability of individual dosimeters, effectiveness of control and monitoring systems, and comprehensiveness of dosimetry reports. Survey results encompass a broad spectrum of hospital structures spanning various regions in Morocco, with contributions from multiple healthcare institutions as delineated in Table III.

Professionals from various hospital services participated in the survey, with representation as follows: the biomedical department accounted for 13% (Fig. 6), where technicians and

engineers, serving as both internal and external interfaces, manage device-user interaction and liaise with suppliers. The radiology department accounted for 63% (Fig. 6), including radiology technicians and managers in the medical imaging department. The oncology department represented 7% (Fig. 6), comprised of radiation therapists and radiologists, while the surgery department contributed 17% (Fig. 6), involving traumatologists, neurologists, and other medical personnel.

TABLE III. HEALTHCARE INSTITUTIONS PARTICIPATING IN THE STUDY

Healthcare institutions	Number
University Hospital Center	5
Regional Hospital Center	14
Provincial Hospital Center	60
Military Hospital	4
Clinic	10
Radiology Center	15

Fig. 6. Participating departments.

In the array of healthcare institutions, a significant portion of healthcare professionals, totaling 58%, lack training in radiation protection and are unaware of the relevant standards (Fig. 7). This gap primarily stems from inadequacies in the academic curriculum of universities and higher education institutions, which fail to sufficiently cover radiation protection. Additionally, there is a dearth of coverage on this topic in the continuing education courses pursued by these professionals, exacerbating the issue. The study reveals that only 42% have received training on radiation protection and its critical implications for both patient well-being and healthcare practitioners (Fig. 7).

Fig. 7. Radiation safety-trained professionals.

Adhering to dose limits ensures that the radiation risk from all controllable sources of ionizing radiation remains sufficiently low to pose no concern to individuals. The emphasis lies not in solely controlling the radiological risk from one specific source, but in restricting individual risk arising from exposure to all sources. This underscores the necessity of utilizing both individual protective gear such as lead skirts, lead gowns, thyroid covers, X-ray gloves, and X-ray glasses, as well as collective protective measures like lead walls and X-ray screens [28-35]. According to the findings, 26% of practitioners utilize lead gowns (Fig. 8), 10% use both thyroid covers and lead gowns (Fig. 3), while a notable 64% do not employ any protective measures (Fig. 8).

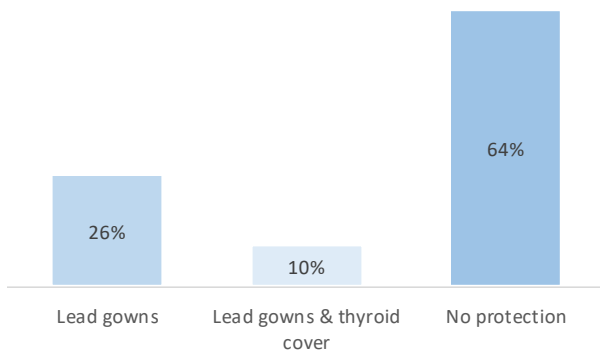

Fig. 8. Individual protection items.

Regulations stipulate the monitoring of external exposure to ionizing radiation in areas where individuals may encounter such risks, necessitating the use of individual dosimeters. This practice evaluates the radiation dose received by each person during their professional activities, ensuring ongoing safety measures and facilitating the early detection of any anomalies for timely intervention. It's essential to clarify that while this monitoring doesn't provide direct protection, its purpose is to maintain safety conditions. The associated risk with a specific radiation dose is determined by the likelihood of an individual experiencing particular radiation-induced effects upon exposure.

Within the purview of the National Center for Radiation Protection (NCRP), the dosimetry-monitoring department assumes responsibility for the provision and management of individual dosimeters used in medical settings, both private and public. Under the authority of the Ministry of Health, the NCRP oversees the monitoring of external exposure for individuals engaged in tasks involving ionizing radiation. Typically, this monitoring is reserved for medical and paramedical personnel operating within controlled areas, particularly those classified as category A, who are anticipated to be occupationally exposed to an effective dose exceeding 6 millisieverts over a 12-month period and directly involved in radiation-related tasks.

The primary objectives of individual dosimetry monitoring encompass several key aspects:

1) *Quantification of ionizing radiation levels:* The foremost purpose is to measure and quantify the doses of ionizing

radiation accumulated by an individual during their occupational activities. This data provides crucial information regarding the extent of radiation exposure experienced by workers.

2) *Empowerment of occupational physicians:* Individual dosimetry monitoring empowers occupational physicians to take necessary actions based on the radiation exposure levels detected. This may include implementing supplementary medical examinations or temporarily relocating individuals from high-risk areas to mitigate potential health risks associated with radiation exposure.

3) *Effective monitoring and regulation of working conditions:* By utilizing individual dosimetry data, employers can effectively monitor and regulate working conditions to ensure compliance with radiation safety standards and guidelines. This proactive approach aids in maintaining a safe and healthy work environment for employees exposed to ionizing radiation.

For all personnel exposed to ionizing radiation falling within categories A and B, the utilization of a passive dosimeter is obligatory. This dosimeter must be worn either at chest level or, if not feasible, on the belt beneath protective clothing (such as a lead gown) for the entire duration of work. At the end of the workday, the dosimeter is securely stored in a designated area, ensuring distance from any sources of radiation, heat, or humidity. Subsequently, it is dispatched to the relevant agency responsible for passive dosimetry either monthly or, exclusively for category B workers, on a quarterly basis. The measured results are quantified in millisieverts (mSv), and the outcome report is conveyed in an individualized and nominative manner to the occupational physician, who then communicates them to the healthcare professionals. The survey's results pertaining to this protocol are depicted in Fig. 9. The statistics indicating that 54% of healthcare professionals use passive dosimeters while 46% do not underscore the varying levels of adherence to radiation safety practices within healthcare settings. Those utilizing passive dosimeters benefit from continuous monitoring of radiation exposure, enabling them to proactively manage risks and adhere to regulatory requirements such as the ALARA principle. In contrast, those not using dosimeters may potentially overlook the cumulative effects of radiation exposure, highlighting a need for enhanced awareness and adherence to safety protocols across the healthcare field.

Fig. 9. Monitoring radiation exposure.

When X-rays interact with matter, they induce various effects primarily because of their capacity to ionize atoms and molecules [36-38]. These effects include ionization, where X-rays possess adequate energy to expel electrons from atoms, resulting in the formation of positively charged ions. This ionization process can disrupt chemical bonds, thereby impacting the structure and functionality of molecules. Furthermore, the ionizing nature of X-rays is central to their utility in medical imaging, but it can also inflict cellular damage by disrupting DNA strands within cells. This mechanism underlies their application in radiation therapy, where X-rays are employed to target and eradicate cancer cells. Additionally, high doses of X-rays can lead to radiation burns on the skin and underlying tissues, necessitating careful control of radiation doses in medical environments. Moreover, prolonged or repeated exposure to X-rays, particularly at elevated doses, heightens the risk of cancer, emphasizing the critical importance of radiation protection measures in both medical and industrial settings. Furthermore, X-rays can induce fluorescence in certain materials, causing them to emit light of characteristic wavelengths, a property exploited in X-ray fluorescence spectroscopy for elemental analysis. Finally, X-rays are extensively utilized in medical diagnostics, including diagnostic radiography, computed tomography (CT) scans, and fluoroscopy, facilitating the visualization of internal bodily structures for the detection and diagnosis of various medical conditions. It is crucial to acknowledge that while X-rays offer significant benefits in medical diagnostics and treatment, adherence to proper precautions and safety protocols is imperative to mitigate potential risks associated with their ionizing nature.

The importance of network infrastructure within radiology departments cannot be overstated, as it is fundamental for improving radiation protection and dose control measures. A resilient network infrastructure is instrumental in enabling the seamless integration of cutting-edge technologies and tools, thereby enhancing the overall safety and efficiency of radiological practices. However, the study findings (Fig. 10) reveal a concerning statistic: only 11% of diverse radiology department spaces have opted to incorporate a computer network, leaving a substantial 89% without such integration. This deficiency has emerged as a significant barrier to the adoption of new technologies that rely on a computer network for essential dose monitoring functionalities.

Fig. 10. Network infrastructure implementation.

The effective management of radiation exposure is paramount for both X-ray practitioners and patients alike. Implementing key practices such as utilizing personal dosimetry, maintaining safe distances from X-ray sources, proper collimation, emphasizing accurate positioning and technique, using shielding equipment, and adjusting imaging protocols based on patient parameters are essential steps in minimizing radiation doses while ensuring diagnostic quality. By adhering to these recommendations, X-ray practitioners can safeguard themselves from excessive radiation exposure and contribute to the overarching goal of optimizing patient care. Moreover, ongoing training, open communication, and stringent quality assurance protocols are vital components for maintaining a safe and effective radiological practice. By prioritizing radiation protection measures, X-ray practitioners play a crucial role in promoting both occupational safety and patient well-being within radiology departments.

VI. DACS IMPLEMENTATION APPROACH

Implementing a Dose Archiving and Communication System in Moroccan hospitals involves several key steps to ensure accurate radiation dose tracking, storage, and communication. This system will enhance patient safety, optimize radiology practices, and comply with regulatory standards. To initiate the implementation, it is crucial to conduct a thorough needs assessment and planning phase. Engage key stakeholders, including radiologists, medical physicists, IT specialists, hospital administrators, and regulatory authorities, to gather comprehensive requirements and understand existing workflows and challenges. Organize meetings and workshops to ensure all perspectives are considered. Evaluate the current radiology and IT infrastructure to identify gaps in radiation dose tracking, archiving, and communication processes. Once the needs assessment is complete, define the technical and functional requirements for the DACS. These requirements should include integration capabilities with existing Radiology Information Systems (RIS) and Picture Archiving and Communication Systems (PACS).

Developing the necessary infrastructure is a key step in implementing DACS. Upgrade or procure the required hardware, such as servers, storage systems, and network infrastructure, to support the new system. Ensure high-speed and secure network connectivity within and between hospitals to facilitate seamless data transfer. Install the DACS software on designated servers and configure it for integration with existing RIS and PACS systems. Proper infrastructure development ensures the system's reliability and performance, supporting efficient radiation dose management. With the infrastructure in place, focus on migrating existing dose records from legacy systems to the new DACS. This process involves validating the accuracy and completeness of the migrated data to ensure no critical information is lost. Integrate the DACS with RIS and PACS for automatic dose data capture and sharing, ensuring interoperability with other hospital systems. Successful data migration and integration are essential for maintaining continuity and accuracy in radiation dose tracking and management.

Implementing a new system requires comprehensive training and effective change management strategies. Develop

training programs for radiologists, technologists, IT staff, and administrative personnel, including hands-on training sessions and the provision of user manuals and support materials. Address potential resistance and concerns through regular communication, highlighting the benefits of the new system. By facilitating a smooth transition and ensuring all users are proficient with the new system, hospitals can maximize the benefits of the DACS. Before full-scale deployment, conduct a pilot implementation in a few selected hospitals to test the DACS in a real-world setting. Monitor system performance, user feedback, and data accuracy during this pilot phase. Validate the system's functionality, reliability, and compliance with regulatory standards, making necessary adjustments based on the pilot testing results. This step helps identify and resolve any issues, ensuring a smoother rollout across all hospitals.

Following a successful pilot, proceed with the full-scale deployment of the DACS to all targeted hospitals across Morocco. Provide continuous support and troubleshooting during the initial deployment phase to address any challenges promptly. Establish a monitoring system to track the performance and usage of the DACS, ensuring it meets operational needs and regulatory requirements. Regular monitoring and maintenance are vital to ensure the system operates optimally and continues to benefit the hospital's radiology practices. Post-deployment, regularly evaluate the system's impact on radiation dose management, patient safety, and operational efficiency. Collect and analyze feedback from users to identify areas for improvement. Implement an ongoing process for system enhancements based on evolving needs and technological advancements. Stay updated with international best practices and regulatory changes to ensure the system remains compliant and effective. Continuous evaluation and improvement will help maintain the DACS's relevance and utility in enhancing patient care and radiology workflows.

VII. CONCLUSION

In Morocco, legislation mandates regular dosimetry monitoring for medical personnel exposed to ionizing radiation, yet the current implementation of such measures remains inadequate, with a significant portion of healthcare professionals lacking training in radiation protection. To address this gap, comprehensive training and education programs must be prioritized, encompassing all personnel working with ionizing radiation. Concurrently, consistent utilization and maintenance of Personal Protective Equipment (PPE) are essential, alongside optimization of imaging procedures to minimize radiation doses while maintaining diagnostic quality. Furthermore, fostering a radiation safety culture within healthcare institutions is crucial, promoting open communication and awareness about safety concerns among healthcare professionals and patients alike.

Implementing a robust dose archiving and communication system offers numerous benefits in enhancing radiation protection efforts. Such a system enables systematic storage and retrieval of radiation dose data, facilitating comprehensive dose monitoring and timely identification of potential overexposure incidents. Additionally, it supports informed decision-making regarding patient care and radiation protection measures. Despite potential obstacles such as technological

limitations and concerns about data security and privacy, the benefits of a dose archiving and communication system justify continued efforts to promote its widespread adoption, ultimately ensuring the safety and well-being of both patients and healthcare professionals within radiology departments. However, several obstacles may hinder the successful implementation of a dose archiving and communication system. These may include technological limitations, such as compatibility issues with existing healthcare infrastructure and electronic health record systems. Additionally, concerns regarding data security and patient privacy may pose challenges in establishing trust and compliance with regulatory requirements. Furthermore, resource constraints, including financial limitations and staffing shortages, may impact the feasibility of implementing and maintaining such a system on a large scale. Despite these challenges, the benefits of a dose archiving and communication system in enhancing radiation protection efforts and ensuring the safety of both patients and healthcare professionals justify continued efforts to overcome obstacles and promote its widespread adoption in healthcare settings.

UTAUT Model for Digital Mental Health Interventions: Factors Influencing User Adoption

Mohammed Alojail

Management Information System Department, College of Business Administration, King Saud University, Riyadh, Saudi Arabia

Abstract—The impact of digital revolution on mental health therapies is examined in this research. As explained in the paper, the delivery of mental healthcare is being revolutionized by digital transformation, which is providing creative answers to the problems associated with mental health illnesses. But knowing and managing user approval is crucial to the effective integration of digital transformation approaches into mental health therapies. To investigate user's acceptance regarding digital transformation in Mental Health therapies, this study outlines a modeling-based method based on a well-established Unified Theory of acceptability and Use of Technology theory, abbreviated as UTAUT. This study delves into the base constructs of Expected Performance, Expected Effort, Social Influence, Conditions facilitating the use of proposed solution, Hedonic Motivation, and Value for Money, utilizing the UTAUT model as a framework. By employing Structural Equation Modelling (SEM) in a thorough study, the goal of this research is to identify statistical correlations that impact user acceptance dynamics. To offer context-specific insights, this article also delves into digital mental health solutions, including teletherapy platforms, mood monitoring smartphone applications, and virtual reality-based exposure therapy. This study enhances accessibility, engagement, and results for people seeking mental health care by providing a deeper knowledge of user acceptability, which aids in the creation and roll-out of digital mental health solutions.

Keywords—Digital transformation; mental health interventions; UTAUT model; TAM; SmartPLS; user acceptance; hypothesis testing

I. INTRODUCTION

The integration of digital technologies in healthcare represents a transformative shift, offering profound opportunities for enhanced patient care, improved clinical outcomes, and optimized healthcare delivery processes [1][2]. Within this realm of transformation, mental health interventions are at the forefront, leveraging various digital solutions to address the multifaceted challenges associated with mental health disorders [4]. Digital transformation in mental healthcare includes innovations such as teletherapy platforms, mobile applications for mood monitoring, virtual reality-based exposure therapy, and online support communities. These advancements hold significant promise in extending the accessibility of mental health services, reducing associated stigma, and empowering individuals to actively manage their mental health [4]. A central component of the success of digital mental health interventions is user acceptance, which reflects the degree to which individuals perceive a technology as useful, user-friendly, and worth adopting [3]. Navigating user acceptance dynamics is crucial for the effective implementation and uptake of these interventions across diverse user populations. Unified Theory of

Acceptance and Use of Technology (UTAUT) model offers a robust framework for testing factors which effect user acceptance within the context of digital transformation. The UTAUT model, proposed by Venkatesh et al. [6], integrates key constructs from various other new technology acceptance theories, like Technology Acceptance Model (TAM), Theory of Reasoned Action (TRA), and Innovation Diffusion Theory (IDT) [3]. According to this model, user acceptance is influenced by core constructs such as Performance expectation, Expected Effort, Influence of Social Life, Conditions facilitating the use of proposed solution, Hedonic Motivation, and Value for Money. These constructs encompass the usefulness through perception, ease of use, social norms, organizational support, and cost-effectiveness linked to adopting a technology.

While the UTAUT model has seen widespread application in various contexts, its utility within the domain of digital mental health interventions remains underexplored. This paper is written with an objective to bridge this gap by employing a UTAUT modeling-based approach to investigate user acceptance dynamics specific to digital transformation in mental healthcare. Utilizing Structural Equation Modeling (SEM), this study examines the connection between UTAUT constructs and user acceptance. The insights derived aim to inform the design, implementation, and evaluation of effective digital mental health strategies, ultimately advancing the delivery of evidence-based care to those in need.

A. Motivations and Contributions

Since mental health is a major subject of the current world. It is also seen that the world is moving towards the involvement of more digital transformation driven interventions in various facets of life. Therefore, it was felt prudent that, while the paper is developed diligently towards the development of the solutions – how well these solutions will be accepted by the user group. It was done, because ultimately, it is the users who decide the success or failure of the specific solution. This paper makes an endeavour to analyze the responses from a varied set of people to understand the following parameters:

- 1) How eager are people to employ a digital transformation driven mental health care intervention in their lives?
- 2) Is cost a driving factor in this?
- 3) Will people use the functionality under the peer pressure of friends, family or society?
- 4) How significant is the user friendliness of the solution to drive its usage?

The paper is divided into the following sections. Section I Lists the Introduction and Section II presents the Literature review followed by Proposed Research Model in Section III.

Section IV describes the Model Validation and Section V Presents the Results and last Section Concludes.

II. LITERATURE REVIEW

At the very onset of this paper, the paper reviews the previous works done on the premise of digital transformation implementation, then it delves into digital transformation acceptance and then into implementation of digital transformation methodologies in mental health scenario.

Digital transformation refers to the amalgamation of digital technologies, strategies, and capabilities into various aspects of an organization or industry in order to fundamentally alter its operations and value delivery to stakeholders [5]. It is not merely a matter of adopting new technologies, but rather a holistic reimagining and restructuring of an organization's culture, processes, and customer experiences to align with the evolving demands of the digital age. This phenomenon of digital transformation is not confined to any specific sector or industry. It has had a widespread impact, transforming diverse fields such as finance, healthcare, retail, and manufacturing [6]. While the potential benefits of digital transformation can be substantial, including enhanced competitiveness, customer satisfaction, and long-term sustainability, it also presents significant challenges. These challenges include the need for substantial investment, overcoming resistance to change, and addressing ethical and regulatory issues related to data use.

Conceptualizing Digital Transformation in Organizations the concept of digital transformation transcends the mere adoption of new technologies, encompassing a more holistic and strategic approach to fundamentally reshape how organizations operate and deliver value to their stakeholders [5]. This transformative process involves the integration of digital technologies, capabilities, and innovative strategies across various aspects of the business, from culture and processes to customer experiences [6]. By embracing digital transformation, organizations can reinvent themselves to better align with the evolving demands of the digital age.

While digital transformation has impacted a wide range of industries, from finance and healthcare to retail and manufacturing, the extent of its adoption and the challenges faced can vary significantly across sectors [6]. Organizations that navigate this transformation successfully can reap substantial benefits, including enhanced competitiveness, improved customer satisfaction, and long-term sustainability. However, the path to digital transformation is not without its obstacles, requiring substantial investment, overcoming resistance to change, and addressing complex ethical and regulatory issues related to data utilization [7].

One significant implementation case study of Digital Transformation is the Real Estate Sector.

Realizing the Full Potential of Digital Transformation in Real Estate The real estate sector has historically been slower to embrace the digital revolution compared to other industries, but there is growing recognition of the immense potential for growth and innovation through digital transformation [8]. This discrepancy can be attributed to the deeply entrenched processes and systems that have long defined the upstream and downstream segments of the real estate industry, as well as the

disruptive impact of digital technologies on conventional business practices.

Despite this initial hesitation, the real estate sector has witnessed a surge in the adoption of cutting-edge technologies, becoming a topic of increasing interest in relevant research studies [5]. Over the past decade, the pace and scope of innovation have accelerated, driven by a wave of technological advancements, such as cloud and mobile computing, as well as the rising prominence of platform-based business models that have attracted substantial venture capital investment [9].

The mental healthcare sector is undergoing a significant transformation driven by the integration of digital technologies. Digital transformation in this context refers to the adoption and implementation of innovative digital solutions to address the complex challenges associated with mental health disorders [10]. These digital interventions have the potential to revolutionize mental healthcare delivery, enhancing accessibility, engagement, and treatment outcomes for individuals seeking support.

However, the successful integration of digital technologies into mental health interventions is contingent upon understanding and navigating user acceptance. UTAUT model has emerged as a valuable framework for exploring the issues that influence user behaviour towards new technologies [11]. The UTAUT model identifies core constructs, such as Expected Performance, Expected Effort, Social Influence and Conditions facilitating the use of proposed solution, as key determinants of user acceptance and usage behavior.

Recent studies have further expanded the UTAUT model to include additional factors relevant to the context of digital mental health interventions. For instance, Hedonic Motivation, which refers to the intrinsic enjoyment and pleasure derived from using a technology, and Price Value, which considers the perceived cost-benefit ratio, have been incorporated to develop an understanding towards user acceptance dynamics [12].

Structural Equation Modeling (SEM) has emerged as a powerful analytical technique to explain the complex relationships between these UTAUT determinants and user acceptance. By employing SEM, researchers can uncover the intricate interplay between factors such as Expected Performance, Expected Effort, Social Influence and Conditions facilitating the use of proposed solution, and their collective impact on user acceptance and usage behavior.

The existing literature has highlighted the importance of context-specific insights when studying user acceptance of digital mental health interventions. Researchers have delved into the adoption and usage patterns of various digital mental health solutions, including teletherapy platforms, mobile applications for mood monitoring, and virtual reality-based exposure therapy [13]. These context-specific investigations provide valuable insights into the unique challenges and opportunities associated with the integration of digital technologies in mental healthcare.

By offering a nuanced understanding of user acceptance, this line of research contributes to the design, development and roll-out of effective digital mental health related strategies. Leveraging the insights gained from UTAUT-based studies can help mental healthcare providers and digital health innovators to

design and deploy digital interventions that are more aligned with user needs and preferences, ultimately enhancing accessibility, engagement, and treatment outcomes for individuals seeking mental health support.

Ensuring User Adoption is Key to Successful Digital Transformation. The success of digital transformation initiatives is fundamentally contingent upon user adoption and acceptance of the implemented technological solutions [12]. Recognizing the central role of end-users, organizations must prioritize understanding the factors that drive technology acceptance in order to effectively promote and sustain the usage of their digital innovations. To this end, researchers have developed several conceptual models that provide valuable frameworks for exploring the nuances of user acceptance behavior. These include the extended expectation-confirmation model (EECM), UTAUT and TAM [14]. The EECM is specifically insightful in relation of post-adoption technology usage. This model extends the TAM by integrating expectation-confirmation theory, suggesting that users' ongoing satisfaction and continued usage of a technology are influenced not only by their initial expectations, but also by the degree to which those expectations are confirmed through actual system usage.

Complementing the EECM, the UTAUT model provides a comprehensive perspective on the key indicators of acceptance of technology, including expected performance, expected effort, influence of social life, and conditions that facilitate the situation [6]. Similarly, the TAM focuses on the role of perceived usefulness and perceived ease of use in shaping user attitudes and behavioural intentions towards technology [17]. These frameworks can help organizations develop a more holistic realization of the multifaceted behaviour that influence user acceptance and adoption of mental health related digital innovations.

By leveraging these well-established theoretical models, organizations can design and deploy their digital transformation strategies in a manner that is more closely aligned with user needs, preferences, and ongoing experiences. This user-centric approach is crucial for fostering sustained engagement, driving long-term adoption, and ultimately, realizing the full potential of digital transformation initiatives. While the EECM, UTAUT, and TAM have similarities in studying user acceptance of technology, they also have distinct differences. After reviewing the literature on user acceptance of the system, it became evident that the TAM, UTAUT, and EECM are all relevant frameworks for understanding user acceptance of technology.

Building upon the well-established theory of reasoned action, TAM has emerged as a seminal framework for understanding and predicting user adoption of new technologies is demonstrated [15]. At the core of this model are two key constructs that shape an individual's attitudes, intentions, and ultimately, their usage behavior. The first construct, perceived ease of use (PEOU), reflects the degree to which a user expects the target system to be free of effort and user-friendly [17]. This factor speaks to the intrinsic motivations of the user, as individuals are more likely to embrace technologies that they perceive as intuitive and effortless to navigate. The second construct, perceived usefulness (PU), captures the user's subjective assessment of the likelihood that using a particular

system will enhance their performance or productivity within a given context [16]. This extrinsic motivation is a critical determinant of user acceptance, as individuals are more inclined to adopt technologies that they believe will tangibly improve their outcomes or experiences.

By integrating these two core determinants - PEOU and PU - the TAM provides a robust theoretical foundation for analyzing the complex interplay of cognitive, attitudinal, and behavioral factors that shape an individual's technology adoption decisions [15]. This model, grounded in the broader theory of reasoned action, acknowledges that user behavior is not solely driven by personal beliefs and attitudes, but is also influenced by subjective norms and social influences.

The versatility and predictive power of the TAM have made it a widely adopted framework for exploring user acceptance across a diverse range of technological innovations, from enterprise software and mobile applications to e-commerce platforms and smart home devices [6]. By leveraging the TAM, researchers and practitioners can gain valuable insights into the nuanced factors that drive technology adoption, enabling the design and deployment of more user-centric digital solutions.

It has been observed that the previous works done encircling the key words have done only a partial level of analysis, where either TAM, PU or any one acceptance factor is analyzed solely without any cohesion amongst other factors, this has deeply restricted the performance of the solutions in models shown in available literature review.

III. PROPOSED RESEARCH MODEL

In this paper, examination of the total acceptance model along with some modifications to handle mental health intervention specific tests in the system. In the extant scenario through the proposed models, it has been proposed to contribute a holistic approach towards UTAUT where various critical factors are analyzed in conjunction with other critical factors of the model, such as Societal Conditions, Attitude Towards Use etc. to come to a more effective conclusion at the end of the study.

In the instant case, the following is considered:

Behavioral Intention is taken as the base measure of TAM, which is a concept derived from base UTAUT architecture [6], System Quality (SQ) plays zero role in this solution, as the proposed research paper plays no role in this.

Therefore, a system is designed where the following are considered:

H1: Perceived Usefulness (PU)

H2: Perceived Ease of Use (PEOU)

H3: Social Influence/ Social Impact (SI)

H4: Facilitating Conditions (FC)

H5: Attitude Towards Use (ATT)

TAM is centered around two main constructs that shape an individual's acceptance and usage of technology, which are Perceived Usefulness (PU) which refers to "the degree to which a person believes that using a particular system would enhance

their job performance" and Perceived Ease of Use (PEOU) which is defined as "the degree to which a person believes that using a particular system would be free of effort" [17]. These two main units, PU and PEOU, are influenced by external variables and in turn affect the user's "attitude toward using (ATT)" and "behavioral intention to use (BI)". The model presumes that the perceived ease of use and usefulness mediate the relationship between these independent variables and the actual system usage behavior. The validity of the TAM model has been extensively demonstrated across a wide range of fields and disciplines, including healthcare, technology related to assistive care, social networking, e-shopping, internet, computer, online public services, and entertainment [17].

Notably, the TAM has been widely applied in the context of technology acceptance and adoption among the population. Researchers have explored the use of TAM in various technological contexts relevant to the youth, such as social network related works & digital well-being related interventions and more [18].

The versatility and predictive power of the TAM have made it a leading framework for understanding the factors that drive technology acceptance, enabling researchers and practitioners to design and deploy more user-centric digital solutions.

Fig. 1 shows a graphical representation of the proposed hypothesis.

Fig. 1. Research model.

Most crucial parameter for our proposed research model is Attitude to Use (ATT) and its subsequent factor Behavioral Intention to Use (BI). These factors help in influencing user experience with information technology, encompassing aspects like ease of use, accessibility, and reliability [19]. This study integrates BI as an independent variable within the TAM framework to explore its influence on perceived ease of use (PEOU) and perceived usefulness (PU) of the use case (U) of "Using Digital Transformation based interventions in Mental Health". Understanding this relationship is vital for assessing the impact of ATT and BI on both PEOU and PU, ultimately influencing user behavioral intentions towards user acceptance.

A. Hypothesis Development

The hypothesis formulated for this subject research model are as follows:

1) H1. Perceived usefulness of the use case "Using Digital Transformation based interventions in Mental Health" has a positive effect on the ATT & BI.

2) H2. Perceived Ease of Use of the use case "Using Digital Transformation based interventions in Mental Health" has a positive effect on the ATT & BI.

The degree to which an individual feels that utilizing a certain technology will enhance their quality of life is known as Perceived Usefulness (PU). Perceived Ease of Use (PEOU) is the degree to which a person believes that using a technology involves no effort.

Most studies employing the Technology Adoption Model (TAM) approach make the assumption that there is a relationship between a product's adoption and usage patterns and consumers' evaluations of its utility. This suggests that people are more likely to adopt new technology when they believe it to be beneficial or has clear advantages.

The Technology Acceptance Model (TAM) states that an individual's opinion of a technology's usefulness influences their assessment of its value. A thorough evaluation of the variables impacting healthcare professionals' adoption of information and communication technology (ICT) revealed that the PEOU and PU of the system were the two most crucial components. These two components made up the majority of the original TAM [20].

H3. Social Influence/Social Impact of the use case "Using Digital Transformation based interventions in Mental Health" has a positive effect on the ATT & BI.

The degree to which friends, family, peers, and carers feel something will affect someone's decision to use new healthcare technology, either favourably or unfavourably, is known as social influence [6].

Previous studies ([21] & [22]) have shown how important social impact is when deciding whether or not to utilise technology for ageing in place. Peers, relatives, kids, and professional caretakers for the elderly are all potential sources of social influence.

H4. Facilitating Conditions of the use case "Using Digital Transformation based interventions in Mental Health" has a positive effect on the ATT and BI.

The "facilitating conditions" are the extent to which people believe that an organisational and technological infrastructure is in place to support the information system and motivate users to use it. Previous studies have shown that encouraging surroundings, such as training programmes, technical support, and financial aid, have a beneficial influence on people's intents to use smart wearables and assist them in overcoming their reservations about utilising cutting-edge technology.

Using the effort expectation construct in the same model, researchers discovered that while facilitating conditions by themselves—that is, in the absence of any moderator—do not significantly predict intention to use the system, they do so with a strong effect on older workers with more experience when they are moderated by age and experience. Enabling aspects that are considered important for young people include accessibility, price, and the availability of technical assistance.

H5. Attitude towards use of the use case “Using Digital Transformation based interventions in Mental Health” has a positive effect on the BI.

"An individual's positive or negative feelings or appraisal about using a technology" is the definition of attitude factors (ATT) [6]. Prior research indicated that older adults with more favorable attitudes towards technology are more likely to utilize it. Though they may have a good attitude towards the relevant technology, older people may not want to utilize healthcare technology, according to a study, where the attitude towards technology utilization was not statistically significant.

Behavioural intention (BI) is a key component of technology acceptance models (TAM). It refers to the choice to adopt or

utilise a technology based on one's attitude towards using it. Research indicates that a person's behavioural desire to utilise technology positively effects how they actually use it. The first TAM referred to BI as "the degree to which an individual has formulated conscious plans to perform or not perform some specified behaviour in future". Therefore, behavioural intention to use technology has been the focus of various research studies in attempt to predict actual technology usage and adoption.

B. Research Methodology

In the healthcare sector, TAM is the most often used and well-liked model [23], and certain correlations found in TAM have consistently been shown to be significant.

TABLE I. MEASUREMENT ITEMS

Construct	Item	Measurements	Reference
	PU1	Medical Care Managing my health will be easier for me if I use a smart wearable.	
Perceived Usefulness	PU2	I believe that using an innovative wearable to track my mental wellbeing will make my daily life safer.	[6] & [17]
	PU3	By using a mental health tracker, I will live a better life.	
	PEOU1	I think using a smart mental health monitor will be easy to use.	
Perceived Ease of Use	PEOU2	Learning involved to use this app/technology will be easy.	[6] & [17]
	PEOU3	This app/technology will be convenient to use.	
	SI1	Family will approve of my use of a smart mental health monitor.	
Social impact/influence	SI2	My friends will recommend that I use a mental health monitor.	[6] & [17]
	SI3	My friends will approve that I use a mental health monitor.	
	FC1	I will know how to use the app/technology.	
Facilitating Conditions	FC2	Someone will always be there for help, if I encounter any problem during using the app/technology.	[6] & [17]
	FC3	I have sufficient financial means to use this app/technology.	
	ATT1	Using this will have a positive impact on my lifestyle	
Attitude towards use	ATT2	This app/technology will benefit my family life.	[6] & [17]
	ATT3	I feel positive about this app/technology	
	BI1	I would be happy to use a digital health monitor, if I get the opportunity	
Behavioural Intention to Use	BI2	I will use this app/technology for the betterment of my mental health	[6] & [17]
	BI3	I will use this app/technology to increase my quality of life	

Several research changed and added variables to improve the model's predicting ability in light of the pertinent circumstances for optimal results.

The TAM has a weakness in that it disregards social influence and subjective standards because it was designed based on individual ideas. As a result, the original Technology Acceptance Model (TAM), which included just the two predictive variables PU and PEOU, would not be sufficient to explain why older people embrace technology in a hospital setting.

Based on the suggested model, a structured survey was created to collect information from users who have been exposed to Digital medical/consultation for their medical needs on the variables impacting platform adoption. In order to evaluate important dimensions including perceived utility, perceived ease of use, social impact and facilitating conditions,

the survey made use of well-established metrics from earlier research (see Table I).

The concept measurement section uses a 5-point Likert scale, with 1 representing strongly disagree and 5 representing strongly agree. Demographic questions regarding age, gender, qualification, nationality, and user type are also included. Nineteen questions comprise the measure of independent and dependent variables, each specifically designed for the use case scenario.

In this section, all of the questions pertaining to the six variables that make up our suggested model were also accessible. Three measures each, derived from measuring items published ([6] and [17]), were used to test variables including perceived utility, perceived ease of use, and intention to utilise digital health wearables. Three questions each from the Venkatesh et al. measuring items were used to measure social influence and facilitating circumstances. To measure each

component of the research model, a five-point Likert scale ranging from strongly disagree to strongly agree was utilized.

Data was gathered using an online survey tool. The poll was sent to 500 people at random in Saudi Arabia, and 239 of them answered. Participation was completely optional. Three days later, a follow-up email reminder was issued in an attempt to increase participation. 56 valid replies—or a 23.3% response rate—were obtained after the data was cleaned to remove incomplete or incorrect responses as well as to detect and exclude biased respondents. Therefore, then total sample size is 295.

Male and female participants in the research sample showed comparable levels of involvement, according to Table II's findings. The age distribution of the participants was found to be variable, with 42.37% of the individuals lying between the 30- to 39-year-old age ranges. Moreover, 15.25% of the population was under 30, 10.17% was over 50, and 21.2% of the population was between the ages of 40 and 49.

TABLE II. DEMOGRAPHIC DATA

		N=295	%
Gender	Male	166	56.27%

The study model was validated using the partial least squares (PLS) method, which is based on structural equation modelling. First, the paper uses measurement analysis, which comprised factor loading, the average variance extracted (AVE), Cronbach

alpha, and path coefficient, to assess the internal consistency and validity of our study model.

This paper also confirmed the association between various variables. This paper uses SmartPLS 3 in our investigation to examine the information gathered.

The validity of the convergence and accuracy of the measurement model were evaluated. Internal reliability is verified using Cronbach's alpha test, and consistency of internal validity indication of >0.7 is deemed suitable. A summary of the loadings, SMC, composition reliability, AVE, and Cronbach's alpha can be seen in Table III.

IV. MODEL VALIDATION

The converging validity hypothesis was supported by the composite reliability coefficients (CR) and average variance extracted (AVE) values, both of which were more than 0.65. The loading, variance inflation factors (VIF) and AVE values of our variables meet the criteria for convergent validity, and Cronbach's alpha (CA) values show that they are internally consistent. A resampling technique called cross-validation is used to get almost unbiased estimates of model performance without compromising sample quantity.

The model validation findings at each of the measurement locations are shown in Tables III-V.

TABLE III. FACTOR LOADING AND RELIABILITY TEST

Construct	Item	Loading	VIF	SMC	CR	AVE	CA
Perceived Usefulness	PU1	0.871	2.37	0.8

One of the most often used methods for examining the discriminant validity of measurement models is the Fornell-Larcker criteria. This criteria states that a construct's square root of the average variance it extracts must be larger than the correlation it has with any other construct. Discriminant validity is proven once this requirement is met.

The evaluation of a scale's validity involves determining whether or not it captures the idea of what it is meant to capture. Convergent and discriminant validity are established in order to evaluate construct validity. Convergent and discriminant validity are proven in constructs that are reflectively assessed.

When items in a given measure converge to represent the underlying construct, this is known as convergent validity. The mean of the squared loadings of each indicator connected to a construct is how the AVE is computed. In terms of statistics, convergent validity is proven when the Average Variance Extracted (AVE) value is greater than 0.50.

Discriminant Validity: The purpose of discriminant validity is to determine how unique the study's constructs are. It

demonstrates that each research construct has a distinct identity and is not too connected with other study constructs. Three methods are used to establish discriminant validity in SMART-PLS.

Fornell and Larcker Criterion: When discriminant validity is proved, it means that the Sq. When it comes to a certain construct, the root of AVE is larger than its association with every other construct.

Cross Loadings: When compared to other research constructs, an item should have larger loadings on its own parent construct, according to cross loadings.

There are problems with discriminant validity when an item loads more favourably onto a different construct than it does onto its own parent construct. The item may be endangering discriminant validity if the difference in loading smaller than .10 also suggests that it is cross-loading onto the other construct.

The correlations between the constructs are shown by numbers outside of the diagonal, while values in bold indicate the square root of the variance extracted (AVE). PEOU: perceived usability; PU stands for perceived utility, SI for social impact, and FC for facilitating condition. ATT: Usage-related attitude; BI: Intention to utilize behavior.

"Discriminant validity is shown when each measurement item correlates weakly with another construct, except for the ones to which it is theoretically associated,". When analyzing cross-loadings, the researcher looks at each item to determine which ones load heavily on numerous constructions and which ones have high loadings on the same construct [24]. Consequently, to demonstrate discriminant validity at the item level, there must be a significant correlation between items that belong to the same concept and a relatively weak correlation between items that belong to different constructs. Despite its simplicity, this technique lacks empirical evidence and theoretical support [25].

A factor's square root of average variance for each latent variable needs to be greater than the other correlation coefficient in order for it to be deemed significant in terms of discriminant validity. Table V displays the detailed cross-loading data. In Table V, the construct that received the highest weight relative to all other constructs is denoted by bolded numerals.

The results of the investigation show that the conditions for discriminant validity are satisfied. The validity and reliability outcomes of our model are displayed in Tables III–V.

A. Hypothesis Testing and Evaluation

This paper used the Smart PLS 3's bootstrapping module (5000 epochs) to get the path coefficients and t values in order to evaluate our hypothesis. Using the bootstrap technique, subsamples from the observed data were selected at random to verify the data's stability. Perceived usefulness, perceived ease of use, social influence, and enabling condition are the four factors that predict 51.3% of the behaviour intention ($R^2 = 0.513$) and 67.6% of the attitude ($R^2 = 0.676$). The route coefficient (β) and t statistics were used to examine the association between the variables. Table VI displays the PLS findings for the hypotheses.

TABLE VI. HYPOTHESIS TEST

H	Route	β	t-Value	Comments

** $p < 0.001$

From the above, it is observed that the impact of Social Impact/Influence on the Attitude to Use of Digital Transformation driven interventions in mental health treatment is not supported, therefore, doesn't play any role.

V. RESULTS

This study's primary objective was to look at the elements that affect people' behavioural intention and acceptance of digital transformation-driven mental health therapies, such as wearables or mobile apps.

The two fundamental TAM components of perceived utility and perceived ease of use were supplemented by two additional dimensions in our study: social influence and enabling situation. In this study, which included a rather flexible targeting method for population selection, it is discovered that attitudes towards utilising digital mental health monitors are favourably impacted by perceived usefulness, ease of use, and enabling conditions.

It was demonstrated that attitudes regarding the adoption of digital mental health monitoring were positively impacted by the core TAM qualities of perceived usefulness and perceived ease of use.

In this study, the sample population's attitude towards digital mental health monitoring was strongly impacted by perceived usefulness ($\beta = 0.425$). Similarly, the sample set members' attitude towards utilising digital mental health monitors was positively impacted by their perception of the devices' ease of use ($\beta = 0.200$).

According to the findings, people's attitudes about using digital mental health monitors were favourably correlated with enabling conditions ($\beta = 0.200$), but social influence ($\beta = 0.090$) did not appear to play a significant role in fostering the population's favourable attitudes about using them.

In summary, the research outlines the role that perceived usefulness, perceived ease of use, and facilitating conditions have in supporting attitudes toward mental health support online. While social influence is less prominent, the success of digital transformation of mental health rests on how well these platforms demonstrate alignment with the end-user needs, as well as the ease of access and perceived ease of use associated with these digital technologies. This knowledge can effectively inform the future design and implementation of digital mental health interventions, by focusing on user-centered design, and provide the requisite supporting technical factors to allow for sustained use.

VI. CONCLUSION

Digital mental health monitors must live up to public expectations for usability and practicality in daily life in order to foster good attitudes toward these technologies and promote their usage, taking into account the first two results on perceived utility and perceived ease of use. Moreover, the third result suggests that the population's positive sentiments towards the use of digital wearables may not be significantly influenced by social influence. Friends, relatives, and acquaintances won't have a significant impact on the population's desire to utilise these digital mental health monitors unless they are willing to use the technology themselves.

The public is likely to utilise digital mental health monitors if they obtain technical support and recommendations whenever they require assistance utilising the application or technology, according to the fourth result about enabling conditions.

Finally, it is discovered that the sample population's behavioural intention to utilise digital mental health monitoring was significantly influenced by their opinions. These demonstrated that the population's behavioural intention to utilise digital mental health monitoring is higher among those with a more positive attitude towards using these devices.

Like any other research work, this study is also not free from flaws and is not without restrictions.

The data were gathered from Saudi Arabia, therefore the implementation of this study will require the survey to be done on a global scale. In addition, the sample size was modest given the size of the response received from our survey.

In the future, gathering data is advised should involve a bigger sample size. Furthermore, the term "mental health" is used significantly in the paper and in the survey conducted, therefore it may have acted as a deterrent while filling information as the same may have been a taboo subject. In addition to this, it is also necessary to bind the available principles of UTAUT with modern methodologies that revolve around AI based Surveying and Machin learning processes.

Future researchers are urged to consider other factors in order to present a more thorough and definitive view on the behavioural intention of Saudi Arabian youth to use digital mental healthcare wearables, including age-related characteristics, physical changes, digital literacy, technically savvy—experience with technology—and adoption. This will contribute to a more thorough comprehension of this research. In addition to the above, it is to be noted that, like any other research work, this study also has its own limitations, one major limitation is the usage of relatively old methodology for implementation of UTAUT and other is the geo-specific dataset used for the study which limits the overall effectiveness of the study.

Abstract—Humans use voice, gestures, and emotions to communicate with one another. It improves oral communication effectiveness and facilitates concept of understanding. Majority of people are able to identify facial emotions with ease, regardless of gender, nationality, culture, or ethnicity. The recognition of facial expressions is becoming more and more significant in a variety of newly developed computing applications. Facial expression detection is a hot topic in almost every industry, including marketing, artificial intelligence, gaming, and healthcare. This study proposes a novel hybrid model combining ResNet-50 and Gated Recurrent Unit (GRU) for enhanced Facial emotion recognition (FER) accuracy. The dataset for the study is taken from Kaggle repository. ResNet-50, a deep convolutional neural network, excels in feature extraction by capturing intricate spatial hierarchies in facial images. GRU, effectively processes sequential data, capturing temporal dependencies crucial for emotion recognition. The integration of ResNet-50 and GRU leverages the strengths of both architectures, enabling robust and accurate emotion detection. Experimental result on CK+ dataset demonstrate that the proposed hybrid model outperforms current methods, achieving a remarkable accuracy of 95.56%. This superior performance underscores the model's potential for real-world applications in diverse domains such as security, healthcare, and interactive systems.

Keywords—Deep convolutional neural network; ResNet-50; Facial Emotion Recognition; Gated Recurrent Unit

I. INTRODUCTION

Emotions play a major role during communication. A person's mental condition is one of the most important things that can reveal their facial expression. Humans are able to communicate nearly forty five percent of their information verbally and about fifty-five percent nonverbally [1]. Psychologist has defined seven basic emotions such as Disgust, Fear, Surprise Angry, Neutral, Unhappy and Happy [2]. In a broader sense, there are three emotional states of the person. First, neutral emotions, second, positive emotion comprising Happy and Surprise expressions and third, negative emotions comprising Fear, Disgust, Angry and Unhappy expressions. These are basic expressions and are independent of gender and ethnicity [3]. Humans also recognizes other emotions such as contempt, confusion, excitement, stress and desire. Darwin suggested that emotional facial expressions have evolved for a reason.

Nonverbal communication heavily relies on the understanding of facial emotions. Right now automatic face

expression recognition is the hardest task thus, there is a strong need for systems that can recognize the same in many different sectors. FER has several uses outside of analyzing behavior and keep track on emotions and mental health of people. It has applications in a variety of domains, including data-driven animation, medical diagnostics, human–robot communication, human–computer interfaces [4], education, robotics, entertainment, holography, smart healthcare systems, security systems, criminology [5], and stress detection [6–7]. Facial expressions are becoming increasingly significant in the medical sciences, especially for bipolar patients whose mood swings are frequent.

FER is also beneficial for applications like smart card readers, social robots, e-learning, criminal justice systems, and customer satisfaction identification [8-9]. The classic emotion identification system consists of three key blocks namely feature extraction, face detection, and emotion classification. Conventional methods of emotion detection have the disadvantage of mutually optimizing feature extraction and categorization. The automation of face emotion recognition and classification is a difficult task. A few fundamental emotions are used by the research community, including fear, anger, upset, and pleasure. However, machines find it extremely difficult to distinguish between a wide ranges of emotions. The major contributions of the proposed research work are follows:

- Developed an efficient Facial Emotion Recognition (FER) method utilizing a deep learning model.
- Implemented a hybrid deep learning approach by integrating ResNet 50 with Gated Recurrent Unit (GRU).
- Achieved enhanced accuracy in Facial Emotion Recognition.

The rest of the paper is organized as follows: In Section II, a summary of literature is provided, highlighting areas that indicate a need for more investigation. In Section III, the methodology is explained in depth. Section IV goes into great detail about the results that the suggested strategy produced. A discussion is provided in Section V and finally, a summary of the findings is included in Section VI, which gives a conclusion to the paper.

II. LITERATURE REVIEW

A framework that used a BiLSTM fusion network and simultaneously learned temporal dynamics and spatial information for FER was presented by Liang et al. [10]. Three benchmark databases—namely MMI, CK+, Oulu-CASIA, were used in the experiment. The technique learned discriminative spatial features and short-term dynamic features using two separate CNNs, and then combined them at the feature level. A comparison of the model's performance using the Oulu-CASIA dataset revealed an accuracy of 91.07%. Because there were only few training samples available for the study, the method's generalizability was constrained. A spatio-temporal feature representation learning method for FER that was resistant to changes in expression intensity was presented by Kim et al. [11]. Regardless of the intensity of the expression, the approach made use of representative expression described in face sequences. Using a CNN, spatial properties were learned. Long short-term memory of the face expression was used to learn the temporal property of the spatial feature representation. The studies were carried out using two datasets namely one for spontaneous micro-expression (CASME II) and the other for purposeful expression (MMI). The accuracy of the approach was found to be 72.83% and 78.61% in the intra- and inter-dataset evaluations.

A Transfer learning approach to emotion recognition was proposed by Chowdary et al. [12]. Pre-trained vgg19, Resnet50, and Mobile Net, Inception V3, networks were used in this work. The CK + database was used in the experiment and 94.2% accuracy was attained with the help of MobileNet. Using a CNN, Debnath et al.'s new facial emotional recognition model [13] identified seven distinct emotions from image data. The model attained an accuracy of 92.05% using the generalization strategy on the JAFFE dataset. A modular framework was presented by Alreshidi et al. [14] for the classification of facial emotions into seven distinct states. The authors failed to utilize geometric elements that could enhance the performance. The approach achieved 59.0% accuracy and might be used to treat and diagnose patients with emotional problems.

A Custom CNN Architecture was presented by Borgalli et al. [15] to do fundamental FER in static images. The three datasets utilized in the methodology to evaluate the model are FER13, JAFFE, and CK+. The CK+ datasets achieved an accuracy rate of 92.27% on fundamental emotions. The method's significant recognition error amount was one of its limitations. In order to circumvent the conventional feature extraction procedure, Bukhari et al. [16] created a CNN model that was utilized as a feature extractor for emotion identification using facial expression. Three pre-trained models were employed in this work by the authors: VGG-16, ResNet-50, and Inception-V3. The accuracy rates for CNN 92.91% on ck+ dataset, according to the experimental results.

CNN, which predict and assign probabilities to each emotion, were the basis of an efficient facial emotion identification system for the seven basic human emotions presented by Ghaffar et al. [17]. In order to improve prediction, the system applied a variety of preprocessing procedures to each image as deep learning models learn from data. To

include each image in the training dataset, the face detection algorithm was run on each one first. With the combined dataset, the method's maximum accuracy was 78.1%. In order to overcome the facial expression recognition (FER) problem, Kandhro et al. [18] proposed a CNN; in recent years, more and more significant efforts have been done in this area. This FER technique can be used to obtain facial expressions based on regularization settings, activations, and optimizations from databases such as CK+ and JAFFE. Numerous techniques, such as regularization, optimization, and activation, in addition to additional hyperparameters, were used to assess the model's performance. The authors obtained 71% test accuracy and 97% training accuracy using the FER2013 dataset. By utilizing several facial features with appropriate dimensions space reduction and applying a kernel filter as part of the preprocessing technique, Kumar Arora et al. [19] suggested the facial feature for emotional recognition using a deep learning algorithm.

A. Research Gap

Facial expression recognition heavily depends on facial landmarks in image-based approaches, which can be prone to errors in varying conditions. Model-based approaches, while accurate, rely on intense numerical computations due to the need for complex mapping functions, making them resource-intensive and time-consuming when training on large datasets. Current models exhibit good performance but require further improvement to handle real-world variations such as different lighting conditions, occlusions, and diverse facial expressions across various ethnicities and age groups. Existing methods often fall short in robustness and generalization, partly due to training on relatively small or biased datasets. Additionally, many FER systems are not optimized for real-time operation on edge devices with limited computational resources. Fourier transform techniques, commonly used in these systems, may miss important spatial features crucial for emotion detection as they focus primarily on frequency domain information. Addressing these gaps is essential for developing FER systems that are both efficient and applicable in diverse, real-world scenarios.

III. MATERIALS AND METHODS

The proposed methodology as shown in Fig. 1 comprises two main components: a pre-trained ResNet50 [20] for image feature extraction and a GRU [21] for capturing sequential patterns. ResNet-50 was chosen for its exceptional feature extraction capabilities, which are crucial for capturing the intricate spatial details of facial expressions, while GRU was integrated to leverage its strength in sequential pattern recognition, enabling the model to effectively analyze the temporal dynamics of emotions. Existing methods, such as those relying solely on Convolutional Neural Networks (CNNs) or Long Short-Term Memory (LSTM) networks, often fall short in either spatial feature extraction or temporal sequence modeling, making them less effective for FER tasks that require a holistic approach. The proposed method overcomes these limitations by combining the strengths of both architectures, making it more suitable for the complex pattern recognition required in accurately classifying emotions.

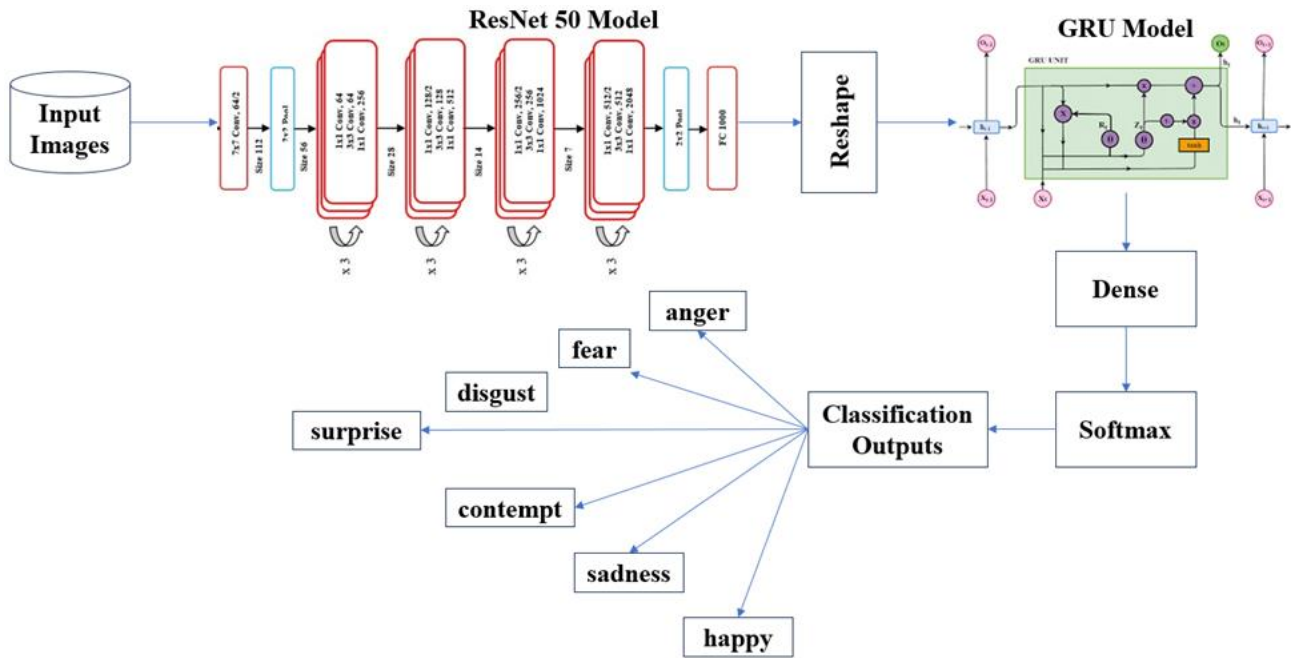

Fig. 1. Block diagram of the proposed model.

Following dataset collection, pre-processing and augmentation techniques are applied. The data generator resizes images to a target size of 224x224 pixels, rescale pixel value to the range [0, 1], and apply shear transformations, zoom in/out, horizontal and vertical flips, and rotations up to 30 degrees. The images are batched into groups of 32, and class labels are encoded in categorical format. This setup is crucial for training and evaluating the model on the CK+ dataset, enhancing generalization through data augmentation. The ResNet50 and GRU networks are integrated into a hybrid model by concatenating their outputs. The ResNet and GRU components are connected sequentially, with the GRU input reshaped to match its expected input shape. The performance of the model is evaluated on the several performance measures.

A. Dataset Description

Data is sourced from Kaggle repository <https://www.kaggle.com/davilsena/ckdataset/>. The sample images are shown in Fig. 2. Dataset Contains modified

data up to 920 images from 920 original CK+ dataset. Data is already reshaped to 48x48 pixels, in grayscale format and face cropped using haarcascade_frontalface_default. Noisy images were adapted to be clearly identified using Haar classifier.

B. Data Pre-processing and Augmentation

The preprocessing and data augmentation steps for the model involve several techniques to enhance training and evaluation on the CK+ dataset. Initially, the dataset is preprocessed by rescaling pixel values to the range [0, 1]. The data generator is then configured to apply various augmentation techniques, including shear transformations, zooming in and out, horizontal and vertical flips, and rotations up to 30 degrees. Images are resized to a target size of 224x224 pixels and batched into groups of 32. Additionally, class labels are encoded in categorical format. This comprehensive setup is crucial for improving the model's generalization capabilities through effective data augmentation.

Fig. 2. Sample images from the dataset.

C. ResNet 50 Architecture

Four main parts of the ResNet50 architecture are the identity block, fully connected layer, convolutional block, and convolutional layer. Fig. 3 shows the architecture of the ResNet 50 model. The features that the convolutional layers have extracted from the input image are being processed and transformed by the identity block and convolutional block. The identity block is a straightforward block that adds the input back to the output after passing it through several convolutional layers. The network is able to learn residual functions, which convert input into desired output. In the

convolutional layers of ResNet50, batch normalization and ReLU activation come after many convolutional layers. These layers are in charge of taking characteristics like edges, textures, and forms out of the input image. Max pooling layers, which minimize the spatial dimensions of the feature maps while maintaining the most crucial properties, come after convolutional layers. The fully connected layers make up the last section of ResNet50. The last classification is determined by these layers. The output of the final fully connected layer is fed into a softmax activation function to get the final class probabilities.

ResNet50 Model Architecture

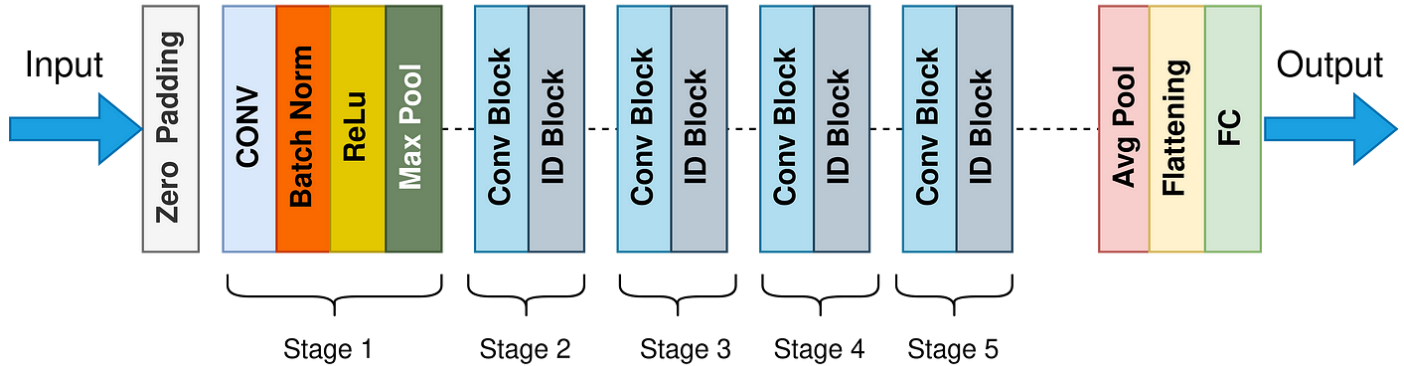

Fig. 3. Architecture of ResNet50 model.

When deep neural networks are trained, an issue known as "vanishing gradients" might arise. This is when the parameter gradients in the deeper layer get very small, which makes it harder for such layers to learn. The deeper the network, the more severe this issue gets. By enabling data to move straight from the network's input to its output and omitting one or more tiers, skip connections solve this issue. Instead of having to learn the complete mapping from scratch, the network can learn residual functions that convert input into the intended output. The residual block is depicted in Fig. 4. The output of the residual block is represented by Eq. (1).

$$Y = F(X, \{W_m\} + X) \tag{1}$$

Fig. 4. Block diagram of the residual block.

The input to the residual block is denoted by X, Y is the output of the block, W_m represents the weights of the convolutional layers within the block, and F is the residual function. In a residual block, the residual function F typically consists of two or three convolutional layers. For a three-layer residual block, the residual function can be expressed as in Eq. (2).

$$F(X, \{W_m\} = W_3\sigma(W_2\sigma(W_1X))F(X, \{W_m\}) = W_3\sigma(W_2\sigma(W_1X)) \tag{2}$$

σ denotes the ReLU activation function, W_1, W_2, W_3 are the weights of the convolutional layers. The identity mapping X sometimes be transformed using a linear projection to match the dimensions of $F(X, W_m)$ when necessary. This can be done using a 1x1 convolution as depicted in Eq. (3).

$$Y = F(X, \{W_m\}) + W_5X \tag{3}$$

where W_5 is the weight matrix of the 1x1 convolution used for matching dimensions. The activation function used is typically the Rectified Linear Unit (ReLU), expressed as in Eq. (4).

$$\sigma(x) = \max(0, x) \tag{4}$$

Batch normalization as expressed in Eq. (5) is applied after each convolution and before the activation function:

$$BN(x) = \frac{x-\mu}{\sigma^2+\epsilon} * \gamma + \beta \tag{5}$$

Where μ and σ^2 are the batch mean and variance, γ and β are learnable parameters, and ϵ is a small constant to prevent division by zero.

D. Gated Recurrent Unit

By allowing information to be selectively retained or lost over time, GRU is intended to mimic sequential data. Because GRU has fewer parameters and a simpler architecture, it may be easier to train and use less computing power. The update gate and the reset gate are the two distinct gates that are part of the GRU architecture as shown in Fig. 5. The distinct functions of each gate greatly add to the high efficiency of the GRU. Long-term connections are recognized by the update gate, whereas short-term ties are identified by the reset gate.

The computation steps of a GRU in the Reset Gate, update gate, candidate hidden state, as are the following.

$$R_t = \sigma(A_{x,z}X_t + A_{H,z}H_{t-1} + B_z) \quad (6)$$

$$Z_t = \sigma(A_{x,z}X_t + A_{H,z}H_{t-1} + B_z) \quad (7)$$

$$\hat{H}_t = \tanh(A_{H,H}R_tH_{t-1}) + A_{x,H}X_t + B_H \quad (8)$$

$$H_t = (1 - Z_t)H_{t-1} + Z_t\hat{H}_t \quad (9)$$

where, \hat{H}_t is the candidate hidden state that is incorporated proportionately to the hidden state, R_t is the reset gate value, and Z_t is the update gate.

E. Proposed ResNet 50-GRU Hybrid Model

The proposed hybrid model for FER integrates a pre-trained ResNet-50 and a GRU. The model architecture of the proposed hybrid model is depicted in Fig. 6. The model takes an image input of shape (224, 224, 3), with the ResNet and GRU components connected sequentially, reshaping the GRU input to match its expected input shape. The ResNet-50, configured as a feature extractor by removing its top layers and applying global average pooling, reduces spatial dimensions and is followed by a dense layer and ReLU activation to enhance feature representation. Concurrently, a GRU network with 128 units is constructed, also followed by a dense layer with 256 units and ReLU activation. These two networks are

then integrated by concatenating their outputs, and the final output layer is a dense layer with softmax activation, which produces probability distributions over seven emotion classes.

F. Hardware and Software Setup

The computational setup for this research utilized a machine with robust specifications, featuring an Intel Core i7 processor. 32GB of RAM, and the formidable NVIDIA GeForce GTX 1080Ti GPU. Model implementation was seamlessly carried out through the Keras library, functioning as a prototype built upon the Tensorflow framework and executed using the versatile Python language. Keras, known for its user-friendly interface and powerful capabilities, proved instrumental in crafting intricate Neural Network architectures. This framework ensures efficient utilization of computing resources, seamlessly accommodating CPU, GPU, and TPU environments. To leverage extensive computational capabilities and streamline model training, the deployment was orchestrated on Google Colab. This cloud-based Python notebook environment not only provides complimentary access to robust computational resources but also facilitates collaborative development, making it an optimal choice for training models.

Hyper parameters are essential configuration settings that define the behaviour and characteristics of a machine learning framework throughout the training process. Unlike the parameters of the model, which are learned from the data itself, hyper parameters are set by the user before training begins. The neural network model uses the Adam optimizer. The training process is guided by the Categorical cross-entropy loss function. During training, the model processes input data in batches of 32 samples per iteration. The training is carried out over 50 epochs, signifying the number of times the entire training dataset is processed by the model. These hyper parameter choices, such as the optimizer, loss function, batch size, and number of epochs, collectively define the configuration for training the neural network model, aiming to optimize its performance on the proposed emotion detection. The model configuration of the suggested approach is tabulated in Table I.

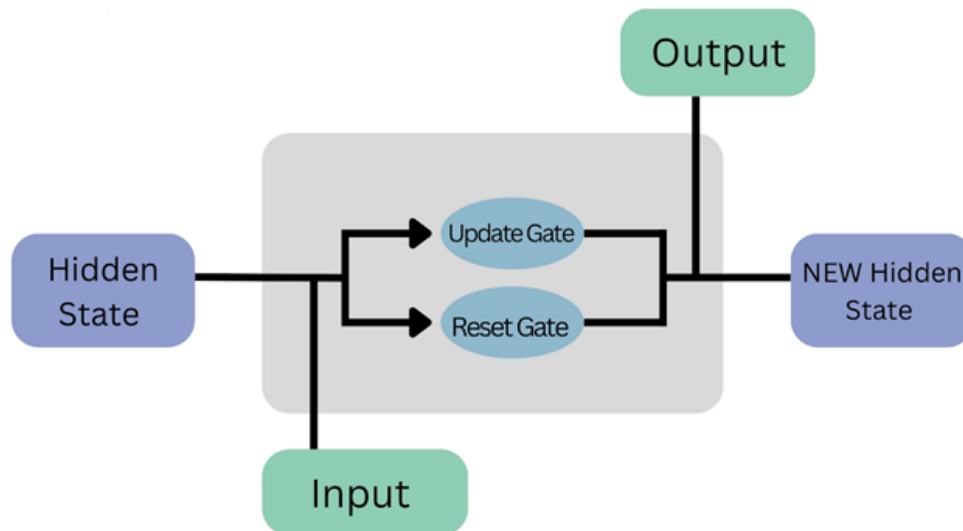

Fig. 5. Architecture of Gated Recurrent Unit.

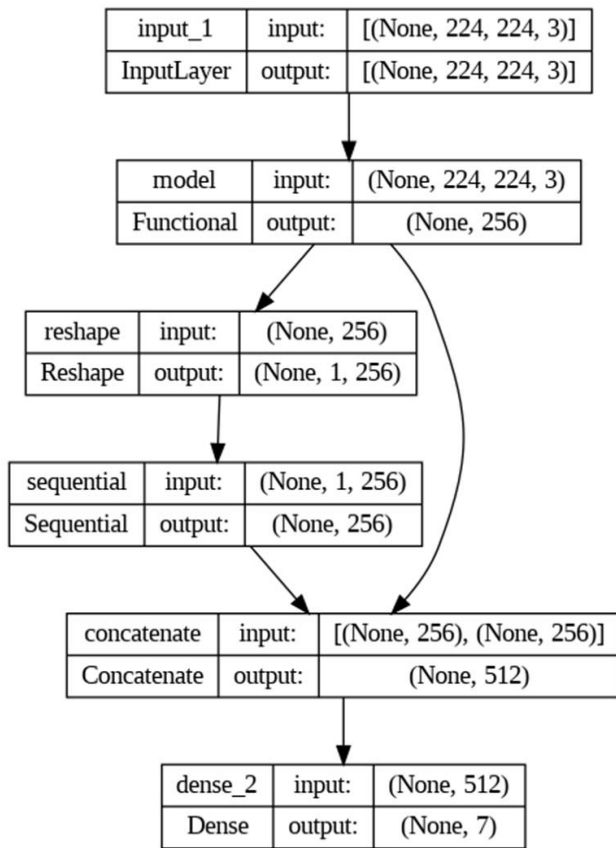

Fig. 6. Proposed model architecture.

TABLE I. MODEL CONFIGURATIONS

Hyper parameter	Values
Optimizer	Adam
Loss Function	Categorical crossentropy
No. of epochs	50
Batch Size	32
Activation Function	ReLU, Softmax

IV. EXPERIMENTAL RESULTS

The accuracy and loss plots are essential tools for assessing the performance and learning dynamics of the proposed emotion classification model. The accuracy plot visually depicts how accurately the model predicts the emotional labels of the data across training iterations for both the training and validation datasets. This plot tracks the consistency between the model's predictions and the actual emotional labels, serving as a crucial indicator of the model's performance throughout the training process. The accuracy plot highlights the model's ability to effectively distinguish between different facial emotions during training. Ideally, in the early epochs, both training and validation accuracies rise simultaneously, demonstrating the model's ability to generalize its knowledge beyond the training dataset.

The accuracy plot of the model is shown in Fig. 7. In the initial epochs of training, the proposed system demonstrates high accuracy, starting at 98.74% in epoch 1. This strong initial

performance indicates the model's rapid learning capacity. As the training progresses, accuracy consistently remains high, reaching 99.20% by epoch 2 and continuing to show incremental improvements. However, some fluctuations in accuracy occur between epochs 13 and 16, where accuracy drops from 98.40% to 94.04%, reflecting a temporary period of instability. Despite these fluctuations, the model quickly recovers, achieving a perfect accuracy of 100% by epoch 10 and maintaining this level through the final epochs, from epoch 48 to epoch 50. These fluctuations are typical in deep learning training processes, often due to batch variance or learning rate adjustments.

Fig. 7. Accuracy plot of the proposed system.

The difference between the predicted emotions and the true labels is quantified as the model's loss, which is illustrated in the loss plot. Throughout the training process, the objective is for the loss to decrease steadily, reflecting that the model is improving its predictions and reducing errors with each iteration, as depicted in Fig. 8.

Fig. 8. Loss plot of the proposed system.

In the initial epochs, the loss decreases steadily from 0.0329 to 0.0010, and the accuracy increases from 0.9874 to 1.0000. By epoch 22, the loss decreases to 0.0911 with the same accuracy, but in epoch 23, the loss increases to 0.1567, and accuracy slightly drops to 95.53%, showing some initial fluctuation. In the final epochs, the loss significantly decreases, with epoch 48 showing a loss of 0.0021 and 100% accuracy, continuing to epoch 49 with a loss of 0.0011 and epoch 50 reaching the lowest loss of 0.0010, both maintaining 100% accuracy. This indicates that the model is learning well and improving its performance over time. However, there are fluctuations in the loss and accuracy throughout the epochs, such as a slight increase in loss during epochs 11 and 12, followed by a decrease. Overall, the fluctuations seem relatively minor, and the model achieves a very low loss and high accuracy by the final epoch, suggesting that it has effectively learned the patterns in the data and generalized well.

A valuable method for assessing the effectiveness of the proposed emotion classification system is the use of a confusion matrix. This matrix offers a structured overview of the model's performance by comparing its predicted emotional categories with the actual labels across various classes. It organizes the outcomes into a table format, where the rows correspond to the true emotional labels and the columns correspond to the predicted labels, as illustrated in Fig. 9. Each cell within the matrix displays the count of instances where the model's predictions either match or deviate from the true emotional labels. The confusion matrix is divided into four quadrants, with the diagonal elements representing correct predictions and the off-diagonal elements indicating misclassifications.

Performance metrics derived from the confusion matrix offer a thorough evaluation of the proposed model's efficacy in classifying emotions. The performance of the system is mainly evaluated on four parameters accuracy, precision, recall, F1-

score. These measures, which are based on the concepts of False Positive (FP), False Negative (FN), True Negative (TN), and True Positive (TP), are essential for assessing the model's performance. The calculation of accuracy involves dividing the total number of predictions by the number of right predictions.

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \quad (10)$$

The exactness of a prediction is measured by its precision, or the number of true positives. Instead, recall quantifies completeness, or the number of real positives that were anticipated as positives.

$$Precision = \frac{TP}{TP+FP} \quad (11)$$

$$Recall = \frac{TP}{TP+FN} \quad (12)$$

$$F1 - Score = 2 * \left(\frac{Precision*Recall}{Precision+Recall} \right) \quad (13)$$

Fig. 9. Confusion matrix.

Fig. 10. Performance metrics.

The performance metrics of the proposed emotion classification system are detailed in Fig. 10, illustrating its effectiveness in accurately classifying emotions. The accuracy metric stands at 95.56%, indicating the overall correctness of the model's predictions compared to the total number of predictions made. Precision, measured at 94.58%, reflects the model's capability to correctly identify specific emotions among those predicted. Recall, which measures at 96.05%, signifies the model's ability to accurately retrieve all instances of a particular emotion from the dataset. The F1-score, calculated at 95.07%, harmonizes precision and recall into a single metric, offering a balanced assessment of the model's performance in emotion classification tasks. These metrics collectively demonstrate the system's high accuracy and

reliability in recognizing and distinguishing between different emotional states, underscoring its potential for practical applications requiring nuanced emotion detection.

The prediction results of the proposed emotion classification system are illustrated in Fig. 11. This figure provides a comprehensive visual representation of the model's performance, showcasing how effectively it can identify and classify various emotional expressions. By examining the prediction results, one can assess the accuracy and reliability of the model in real-world scenarios. The figure highlights the model's capability to distinguish between different emotions, demonstrating its potential effectiveness and practical application in emotion recognition tasks.

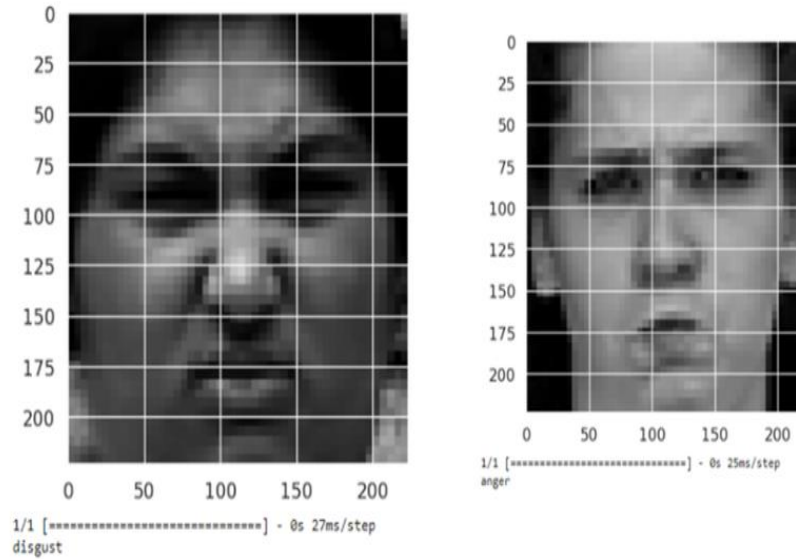

Fig. 11. Prediction output.

V. DISCUSSION

Comparing the performance of the proposed hybrid emotion classification network against existing methods primarily based on machine learning and deep learning is a pivotal aspect of this study. Table II and Fig. 12 provides a comparative analysis that highlights the effectiveness of the hybrid model by carefully evaluating outcomes in contrast to established approaches. This model addresses the challenges of accurately recognizing and classifying emotions from facial expressions, which is critical in fields such as human-computer interaction, healthcare, and security. This evaluation rigorously examines a range of metrics and parameters to assess how well the proposed method performs compared to traditional methodologies used in emotion recognition. The aim is to demonstrate the superiority and robustness of the hybrid approach in accurately classifying emotions, showcasing its potential to outperform conventional techniques in real-world applications.

The comparison report presents various state-of-the-art models and their corresponding methodologies and results in a certain task, likely classification or prediction. Liang et al. employed a Bidirectional Long Short-Term Memory (BiLSTM) model achieving an accuracy of 91.07%. Kim et al.

utilized a CNN-LSTM hybrid model, attaining a slightly lower accuracy of 78.61%. Debnath et al. deployed a CNN achieving a higher accuracy of 92.05%, while Borgalli et al. introduced a custom CNN with a slightly higher accuracy of 92.27%. Bukhari et al. implemented a ResNet-50 model, achieving an accuracy of 92.91%. Finally, the proposed model in the report, a hybrid of ResNet-50 and GRU, demonstrated the highest accuracy of 95.56%. This comparison highlights the effectiveness of different architectures and demonstrates the superiority of the proposed hybrid model, which integrates both convolutional and recurrent neural network components, achieving the highest accuracy among the compared methods.

TABLE II. COMPARISON OF PROPOSED MODEL WITH EXISTING METHODS

Authors	Methodology	Result
Liang et al [10]	Bi-LSTM	91.07%
Kim et al [11]	CNN-LSTM Hybrid model	78.61%
Debnath et al [13]	CNN	92.05%
Borgalli et al [15]	Custom CNN	92.27%
Bukhari et al [16]	ResNet -50	92.91%
Proposed model	Hybrid model ResNet 50 and GRU	95.56%

Fig. 12. Performance comparison.

Moreover, the robustness of the proposed model in handling diverse and complex emotional expressions demonstrates its potential for real-world applications where emotion recognition must be accurate and reliable. The comparison study underscores the model's capability to outperform conventional techniques, making it a promising solution for advancing the field of emotion recognition. This hybrid approach not only achieves higher accuracy but also offers a more nuanced understanding of emotional expressions, paving the way for more sophisticated and effective emotion recognition systems.

VI. CONCLUSION

Facial expressions are a vital tool for determining human emotions since they are reflections of those emotions. The majority of the time, a person's facial expressions are a nonverbal means of expressing their emotions. These emotions can be used as concrete evidence to determine whether or not someone is telling the truth. This study aimed to classify facial expressions into one of seven emotions using the CK+ dataset. The study successfully demonstrates the efficacy of a hybrid model combining a pre-trained ResNet50 and a GRU for FER. By leveraging the powerful feature extraction capabilities of ResNet50 and the sequential pattern recognition strengths of GRU, the proposed model achieves an accuracy of 95.56% in classifying emotions. When compared to cutting-edge outcomes, the developed model provides good accuracy. This hybrid approach not only validates the integration of ResNet 50 and GRU for complex pattern recognition tasks but also sets a robust framework for future research in FER and related fields.

While the proposed model has shown promising results, there are several areas for future work to further enhance the

performance and applicability of FER systems. First, expanding the dataset to include more diverse and real-world scenarios could improve the model's generalizability, making it more robust in different environments and cultures. Additionally, exploring the integration of other advanced deep learning architectures, such as Transformer-based models, could potentially enhance the model's ability to capture complex dependencies in facial expressions. Moreover, incorporating multimodal data, such as voice and physiological signals, alongside facial expressions could lead to more comprehensive emotion recognition systems.

Department of Computer Science-Faculty of Graduate Studies for Statistical Research, Cairo University, Giza, Egypt³

Abstract—Fuzzy Formal Concept Analysis (FFCA) is a robust mathematical tool for analyzing data, particularly where uncertainty or fuzziness is inherent. FFCA is utilized across various domains, including data mining, information retrieval, and knowledge representation. However, fuzzy concepts extraction is a crucial yet computationally intensive task. This paper addresses the challenge of time efficiency in extracting single-sided fuzzy concepts from large datasets. A parallel algorithm is proposed to reduce computational time and optimize resource utilization, thus enabling the scalable analysis of expanding datasets. By computing fuzzy concepts across multiple threads in parallel, each thread processes an attribute independently to extract fuzzy concepts, which are then merged in the final step. The proposed algorithm extracts fuzzy-crisp concepts, which are more concise than other types of fuzzy concepts. Experiments were conducted to evaluate the performance of the proposed parallel algorithm against existing sequential methods. Experimental results demonstrate significant gains in computational efficiency, with the algorithm achieving an average time reduction of 68% compared to the attribute-based algorithm and up to 83%-time reduction compared to the fuzzy ChO algorithm across various types of datasets, including binary, quantitative, and fuzzy.

Keywords—Fuzzy Formal Concept Analysis; single-sided fuzzy concept; fuzzy-crisp concepts; parallel algorithm; fuzzy concepts extraction; knowledge representation

I. INTRODUCTION

Formal Concept Analysis (FCA) is a mathematical framework that involves the systematic study of formal concepts and their interrelationships, providing a structured approach to analyzing complex data sets [1] [2]. Therefore, FCA has found diverse applications across various domains, including linguistics [3], information retrieval [4], bioinformatics [5], Text classification [36], and beyond [6][34]. Traditional FCA algorithms can process only binary datasets [15], namely formal context, to extract formal concepts, constituting logical clusters of related objects and attributes [7]. This framework is based on the principles of crisp set theory, which categorizes objects as either fully belonging to a set or completely outside of it, emphasizing clear boundaries in the conceptual space [35]. Besides, classical FCA algorithms use the crisp scaling method to handle quantitative or qualitative data (many-valued contexts MVC) [8]. As a result, the crisp boundary problem in crisp scaling introduces challenges in accurately defining the boundaries between sub-attributes, affecting the precision of the analysis [9].

Fuzzy Formal Concept Analysis (FFCA) effectively addresses the limitations of handling many-valued and fuzzy contexts by managing ambiguity and uncertainty similarly to human cognition[10]. It represents data on a spectrum rather than in binary terms, allowing for nuanced and accurate analysis of large datasets. FFCA captures the complexity of real-world data, leading to more meaningful insights and clear, interpretable results. Its flexibility allows adaptation to various data mining tasks, making it ideal for applications like customer feedback analysis, where understanding human sentiment is essential. Additionally, FFCA's ability to represent imprecise data aligns with subjective user views, making it suitable for everyday data handling [11] [28]. For example, in the education domain, a university using FFCA to analyze student course evaluations can handle nuanced feedback such as "somewhat satisfied", "mostly satisfied," and "highly satisfied", rather than just "satisfactory" or "unsatisfactory." This deeper understanding of student opinions allows for more targeted improvements in teaching methods and course content, enhancing the overall educational experience.

Extracting the entire set of fuzzy concepts from large datasets is a time-consuming task, recognized as a #P-complete problem [12]. However, if the relationship between object and attribute sets is sparse, even in large datasets, the complexity of this process can be reduced [11]. The generation time of classical formal concepts is often notably shorter than the extraction time of fuzzy concepts. This discrepancy arises due to the inherent complexity involved in computing fuzzy concepts, which typically requires additional computational resources and processing steps [13]. FCA primarily deals with crisp binary relations, leading to relatively faster computations, whereas FFCA involves handling fuzzy relations, which require more complex calculations to derive fuzzy concepts. Therefore, while FFCA handles different data types effectively, it requires extensive time than the traditional FCA that hinder its applicability across various domains. Addressing this research gap, the proposed algorithm significantly enhances the efficiency of generating fuzzy concepts by leveraging parallel processing techniques.

The proposed algorithm differs from In-Close4b [32], bit-close4 [30], and FPCbO [31] in its ability to effectively process a variety of data types. While these algorithms are limited to handling binary data, real-world applications typically involve heterogeneous datasets. In contrast, the proposed algorithm leverages fuzzy set theory, enabling it to process diverse data types, including crisp, vague, and quantitative.

FuzzyInClose4b algorithm [24] generates concepts where both the extent and intent are fuzzy, resulting in an excessive number of fuzzy concepts. This abundance hinders its practical application in data-intensive domains such as association rule extraction, semi-automatic ontology construction, and information retrieval [16]. Conversely, the proposed algorithm generates fuzzy concepts with fuzzy extents and crisp intents, reducing the number of extracted fuzzy concepts. Additionally, the proposed algorithm leverages parallel processing to significantly reduce execution time. These enhancements improve the algorithm's applicability and efficiency.

Through this research, a time-efficient algorithm is proposed for extracting fuzzy concepts from large datasets utilizing parallel processing. The main contributions of this work are summarized as follows:

- 1) The proposed algorithm utilizes fuzzy logic in extracting fuzzy-crisp concepts from various data types, unlike existing crisp algorithms such as In-Close4b [32], bit-close4 [30], and FPCbO [31], which only process binary data.
- 2) The proposed algorithm generates more concise fuzzy concepts compared to FuzzyInClose4b [24], facilitating the practical application of FFCA in real-world scenarios.
- 3) The proposed algorithm reduces the computational time of extracting fuzzy concepts by leveraging multithreading in processing multiple attributes simultaneously to extract fuzzy concepts in parallel, thereby enhancing efficiency and performance. Therefore, it utilizes the available resources for faster computation of fuzzy concepts.

The remainder of this paper is organized as follows: Section II offers a comprehensive review of fundamental notions and definitions concerning formal concept analysis (FCA) and its fuzzy variant. Subsequently, Section 0 takes a closer look at the related algorithms employed in the derivation of formal concepts. Next, Section IV presents the proposed parallel algorithm for generating fuzzy formal concepts, clarifying its operation. Section V introduces a practical case that utilizes the proposed algorithm to see how well it performs in practical in comparison to other algorithms. Section VI evaluates the proposed algorithm across different types of data, presenting a comparative study with other related algorithms. This section highlights the superior performance of the proposed algorithm through detailed analysis. Lastly, Section TABLE IX. provides a summary of the main findings, highlights the key contributions, and discusses avenues for future research and development.

II. PRELIMINARIES

This section provides an overview of the basic definitions and notions related to classical Formal Concept Analysis (FCA) and its fuzzy variant FFCA. Further definitions and foundations can be found in the references [14] for FCA and [17], [18] for FFCA [17].

A. Classical Formal Concept Analysis

Formal concept analysis primarily aims to identify groupings of entities and their associated attributes within a given dataset. Typically, FCA operates on binary formal contexts as its input, wherein a crisp relation I outlines the

associations between entities G and their attributes M . Accordingly, a formal context can be concisely characterized as a tabular representation comprising rows denoting entities and columns representing attributes (or vice versa).

Definition 1: A formal context is delineated as a triple $\mathbb{K} = (G, M, I \in \{0, 1\})$, where G signifies the set of objects, M denotes the set of attributes, and I denotes a crisp relation among objects and attributes, where $I \subseteq G \times M$. If an object $g \in G$ and an attribute $m \in M$ are related in I , it is expressed as the pair $(g, m) \in I$ or $(g I m)$.

Definition 2: A formal concept is denoted as a pair (A, B) of the formal context $\mathbb{K} = (G, M, I)$ iff $A \subseteq G$, $B \subseteq M$, $A \uparrow = B$, and $B \downarrow = A$, where A and B the concept extent and intent, respectively. And $A \uparrow$, $B \downarrow$ are given by Eq. (1) and Eq. (2):

$$A \uparrow := \{ m \in M \mid (g, m) \in I \ \forall g \in A \} \quad (1)$$

Such that $A \uparrow$ represents the set of characteristics in M that are shared by all objects in A .

$$B \downarrow := \{ g \in G \mid (g, m) \in I \ \forall m \in B \} \quad (2)$$

Given that $B \downarrow$ is set of objects having all features in the set B .

Classical FCA is typically proficient in processing crisp binary contexts, a scenario that may not align with the inherent complexity of real-world datasets. One challenge encountered pertains to specifying sharp boundaries within scaled attribute intervals, thus posing limitations in effectively addressing the many valued contexts inherent in many datasets.

Fuzzy Formal Concept Analysis (FFCA), in contrast, offers a versatile framework capable of accommodating various types of data, thereby addressing the limitations associated with classical FCA. Unlike its crisp counterpart, fuzzy FCA embraces the inherent uncertainty and vagueness present in real-world datasets by allowing for graded membership degrees. FFCA can handle different types of data (continuous, discrete, or hybrid) types without needing strict boundaries between attribute intervals. Consequently, FFCA offers a more robust and adaptable approach for analyzing complex datasets characterized by imprecision and ambiguity.

B. Fuzzy Formal Concept Analysis

Fuzzy Formal Concept Analysis (FFCA) is a mathematical framework designed to analyze and extract meaningful patterns from datasets characterized by uncertainty and imprecision. Fuzzy sets [33] in FFCA replace the conventional binary representation of relationships between objects and attributes where a value in the range $[0, 1]$ represents the degree of membership of an object to an attribute.

Definition 3: a fuzzy formal context is a triple $\hat{\mathbb{K}} = (G, M, \hat{I} \in [0, 1])$, where G is a set of objects, M is a set of attributes, \hat{I} is a fuzzy relation between objects and attributes each with membership μ that gives each pair (g, m) in $G \times M$ a degree of membership. This membership degree shows how strongly objects and attributes are linked.

FFCA extends traditional FCA by allowing for the representation of graded relationships, enabling a more flexible

and nuanced analysis of complex datasets. One-sided FFCA involves the fuzzification of either the extent or the intent of a formal concept while maintaining a crisp definition on the other side [10][17].

As depicted in Fig. 1, various viewpoints and formal definitions for fuzzy concepts exist. Fuzzy concepts can be categorized into single-sided fuzzy concepts and full-sided fuzzy concepts. In single-sided fuzzy concepts, only the intent or extent of the fuzzy concept is fuzzy, not both [26]. On the other hand, full-sided fuzzy concepts have both extent and extent represented as fuzzy sets [24]. This paper proposes a parallel algorithm for extracting single-sided fuzzy concepts in which extents are fuzzy and intents are crisp. The rest of this section presents the formal definitions and notions for this type of FFCA.

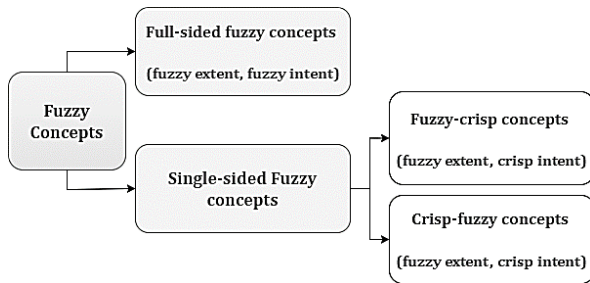

Fig. 1. Fuzzy concepts' taxonomy.

Definition 4: In a fuzzy context $\mathbb{K} = (G, M, \mathbb{I})$, a fuzzy-crisp concept is represented by a pair (A_f, B) , where $A_f \subseteq G$ denotes the fuzzy extent of the concept, $B \subseteq M$ represents the crisp intent, and $A_f \uparrow = B$ and $B \downarrow = A$. The definitions of $A_f \uparrow$ and $B \downarrow$ are provided by Eq. (3) and Eq. (4) [17]:

$$A_f \uparrow = \{ b \in B \mid \forall a \in A: \mu_I(a, b) \geq \mu_A(a) \} \quad (3)$$

$$B \downarrow := \{ a \mid \mu_A(a) = \min_{\{b \in B\}} (\mu_I(a, b)) \} \quad (4)$$

In this context, $A_f \uparrow$, denoted as A_f' , delineates the crisp intent of the object set A_f , while $B \downarrow$, denoted as B' , delineates the fuzzy extent of the attribute set B . A confidence threshold α is utilized where $\alpha < 1$. The user can adjust the threshold α according to their requirements for generating fuzzy concepts from a provided fuzzy context [20]. This threshold aids in filtering out fuzzy relations that fall outside the interval $[\alpha, 1]$ from the given fuzzy formal context, thereby facilitating knowledge discovery and representation [19] [21] [28]. Alternatively, the threshold interval is denoted as α -cut of the fuzzy context.

Example 1: Table I shows a fuzzy context example that refers to a part of the employee's dataset. According to Def. 3, the attribute set M is $\{A, B, C, D, E, F\}$, and each attribute corresponds to the properties: A : low salary, B : moderate salary, C : high salary, D : young, E : youth, and F : old. Moreover, the object set $G = \{O_0, O_1, O_2, O_3, O_4\}$ represents five different employee instances. Applying an α -cut of 0.4 to the fuzzy context in Table I produces the fuzzy context in Table II. Eliminated relationships are highlighted in gray background in Table II. Applying the threshold clearly produces a sparser context and can effectively eliminate unwanted relationships.

TABLE I. EXAMPLE FUZZY CONTEXT

Obj	A	B	C	D	E	F
O_0	1	0	0	1	0	0
O_1	0.22	0.78	0	1	0	0
O_2	0	0.33	0.67	0.73	0.27	0
O_3	0	0	1	0	0.36	0.64
O_4	0	0	1	0	0	1

TABLE II. FUZZY CONTEXT WITH α -cut = 0.4

Obj	A	B	C	D	E	F
O_0	1	0	0	1	0	0
O_1	0	0.78	0	1	0	0
O_2	0	0	0.67	0.73	0	0
O_3	0	0	1	0	0	0.64
O_4	0	0	1	0	0	1

For more clarity, Table III illustrates the fuzzy concepts extracted from the fuzzy context in Table II after applying the threshold $\alpha = 0.4$. As shown in Table III, there are ten fuzzy concepts, each consisting of a fuzzy extent and a crisp intent.

TABLE III. FUZZY CONCEPTS GENERATED FROM THE FUZZY CONTEXT IN TABLE II

#	Fuzzy Extent	Crisp Intent
C_1	$\{O_0: 1, O_1: 1, O_2: 1, O_3: 1, O_4: 1\}$	$\{\}$
C_2	$\{O_0: 1\}$	$\{A, D\}$
C_3	$\{\}$	$\{A, B, C, D, E, F\}$
C_4	$\{O_1: 0.78, O_2: 0.33\}$	$\{B, D\}$
C_5	$\{O_2: 0.33\}$	$\{B, C, D\}$
C_6	$\{O_2: 0.67, O_3: 1, O_4: 1\}$	$\{C\}$
C_7	$\{O_2: 0.67\}$	$\{C, D\}$
C_8	$\{O_3: 0.36\}$	$\{C, E, F\}$
C_9	$\{O_3: 0.64, O_4: 1\}$	$\{C, F\}$
C_{10}	$\{O_0: 1, O_1: 1, O_2: 0.73\}$	$\{D\}$

A fuzzy extent consists of a set of objects and their corresponding memberships in the form of $\{O_i: \mu_{o_i}\}$, such that O_i refers to the object number i and μ_{o_i} is the membership of O_i to the corresponding crisp intent. For instance, fuzzy concept (4) is $(\{O_1: 0.78, O_2: 0.33\}, \{B, D\})$ where $(\{O_1: 0.78, O_2: 0.33\})$ is the fuzzy extent consisting of objects O_1 and O_2 with membership degrees of 0.78 and 0.33, respectively. These membership degrees determine to what extent the objects possess the attributes in the crisp intent $\{B, D\}$.

III. RELATED WORKS

Extracting formal concepts from formal contexts has gained a significant interest in classical algorithms that handle binary datasets using crisp set theory. In-Close4b [32], bit-close4 [30], and FPCbO [31] algorithms identify crisp concepts through depth-first search and pruning techniques. With a mix of arrays and bitsets, In-Close4b balances memory usage and speed,

making it suitable for large datasets. Bit-Close4 enhances performance for sparse data by optimizing memory efficiency with bitset data structures. FPCbO [31] has improved the classical CbO algorithm [23] by reducing computational redundancy and employing a canonical direct basis representation to generate only canonical concepts. Regarding optimizations, these algorithms differ in the following ways: In-Close4b balances resources; Bit-Close4 emphasizes memory efficiency; and FPCbO focuses on redundancy reduction.

Compared to the proposed algorithm, these crisp algorithms are less adaptable to diverse data types and cannot handle fuzzy or imprecise data, limiting their applicability in real-world scenarios where data uncertainty is common. While In-Close4b balances memory usage and speed, it struggles with extremely large or dense datasets, and its complexity makes it harder to implement. Bit-Close4's reliance on bitsets enhances performance for sparse matrices but can reduce flexibility and efficiency in dense datasets. FPCbO's strict canonicity minimizes redundancy but introduces significant computational overhead and increased memory consumption, making it less efficient for complex datasets. Overall, these limitations highlight the need for more versatile and scalable algorithms, offered by fuzzy concept extraction algorithms.

Fuzzy FCA algorithms gained less popularity due to its extensive time requirement despite its capability to process diverse data types, including fuzzy and imprecise data. This section reviews current fuzzy algorithms, identifying key limitations that the proposed algorithm aims to address.

Fuzzy CbO [22] presents an algorithm to extract fuzzy-crisp concepts. Therefore, fuzzy CbO can process fuzzy and vague data effectively. In addition, this recursive algorithm exploits canonicity tests to discover new fuzzy concepts, demonstrating superior efficacy in fuzzy concept generation when compared to the fuzzy NextClosure algorithm[25]. Despite its effectiveness in processing fuzzy data, the fuzzy CbO algorithm faces limitations such as significant computational overhead from canonicity tests, high memory consumption due to its recursive nature, and potential challenges in handling large and diverse datasets. These limitations are efficiently handled by the proposed parallel algorithm.

The attribute-based algorithm [27] excels with symmetrically correlated attributes, outperforming fuzzy CbO in execution time under these conditions. However, in other scenarios, both algorithms demonstrate similar performance, limiting the attribute-based algorithm's effectiveness in handling diverse datasets and asymmetric correlations. On the contrary, the proposed algorithm leverages parallel processing techniques to handle multiple attributes at the same time, which results in efficient processing of fuzzy concepts. Unlike sequential algorithms like Fuzzy CbO and attribute-based algorithm, the proposed algorithm excels in handling large, dense datasets and produces compact fuzzy-crisp concepts efficiently.

FuzzyInClose4b algorithm[24] utilizes incremental closure and matrix searching techniques to extract full-sided fuzzy concepts. It computes each closure incrementally, only once per concept, to prevent repeated closure calculations. Compared to the proposed algorithm, FuzzyInClose4b[24] generate more

fuzzy concepts. Therefore, it requires plenty of time and storage space. But it may be more suitable when the intent's membership values are essential. But for Ontology construction applications and association rule mining, it can be sufficient to use fuzzy-crisp concepts algorithms like the proposed algorithm.

To the best of knowledge, all existing algorithms for generating fuzzy-crisp formal concepts operate sequentially, failing to leverage parallel computation. This limitation significantly impacts execution time, particularly with large datasets. This work addresses this gap by proposing a parallel algorithm to accelerate the generation of fuzzy concepts.

IV. PROPOSED PARALLEL ALGORITHM FOR COMPUTING FUZZY-CRISP CONCEPTS

This section introduces the proposed parallel fuzzy concept (PFC) algorithm to generate fuzzy-crisp concepts from a fuzzy formal context in parallel, leveraging multi-threading to improve efficiency. The algorithm accesses the fuzzy context and eventually returns fuzzy concepts as pairs of fuzzy extents and crisp intents.

Algorithm: PFC()

Input: A fuzzy formal context $\mathbb{K} = (G, M, \hat{I} \in [0, 1])$

Output: The set of FC of all fuzzy concepts of \mathbb{K}

Begin

```
1 Initialize FC  $\leftarrow \{(G \uparrow, G), (M \downarrow, M)\}$ 
2 With ThreadPoolExecutor() as executor:
3   For each  $i$  from 0 to  $|M| - 1$  do
4     executor.map( ProcessAttribute, i)
5   End for
6 Return FC
```

Procedure: ProcessAttribute ($attr_i$)

```
1 F_extent  $\leftarrow attr_i \downarrow$ 
2 intent  $\leftarrow F\_extent \uparrow$ 
3 If intent  $\notin FC.intents$  then:
4   FC  $\leftarrow FC \cup (F\_extent, intent)$ 
5   With threading.lock():
6     For  $c$  in  $FC \setminus \{(F\_extent, intent) \cup (G, G) \cup (M \downarrow, M)\}$ 
7       Inters = Fextent  $\wedge$  c.extent
8       If Inters  $\downarrow \notin FC.intents$  then:
9         FC  $\leftarrow FC \cup (Inters, Inters \downarrow)$ 
10      End If
11    End For
12  End If
End Procedure
```

The Parallel Fuzzy Concept (PFC) algorithm begins by initializing the global fuzzy concepts set with the bottom and top concepts (line 1). The top concept is a set of all objects G and their shared intent $G \uparrow$ evaluated using Eq. (3). The bottom concept is a set of whole intent M and all objects that assess M , given by $M \downarrow$ provided using Eq. (4), and represents the fuzzy extent in the form $ext: \mu_{ext}$. Subsequently, a thread pool is employed to process attributes in parallel (Lines 2–5), where each thread is responsible for computing all fuzzy concepts discoverable using a particular attribute. Therefore, the algorithm ensures efficient computation of fuzzy concepts using multiple threads.

To identify all new fuzzy concepts given an attribute, the ProcessAttribute() procedure is invoked. First, lines 1 – 2 calculate the fuzzy extent using Eq. (4) and the crisp intent using Eq. (5). Next, line 3 verifies that the concept intent is new and not present in the FC set, thereby storing the new fuzzy concept in FC (line 4). In line 5, a locking mechanism ensures thread safety during updates. Lines 6–9 then uncover all other fuzzy concepts that arise from intersections between the new fuzzy extent (F_extent) and the existing concepts' extents. Therefore, line 6 presents a loop that iterates over all existing concepts except all fuzzy concepts that cannot produce new concepts via the fuzzy intersection (i.e., the newly generated concept $\{F_extent, intent\}$, the top concept ($G, G \uparrow$), and the bottom concept ($M \downarrow, M$). In line 7, Zadah's intersection, as stated in definition (5), evaluates the fuzzy intersection between the extent of the new concept and the extent of the existing concept. If the intent of an intersection is not in FC , it adds the new concept to FC (lines 8 and 9).

Definition 5: The intersection of two fuzzy sets A and B with membership functions $\mu_A(x)$ and $\mu_B(x)$, respectively, results in a fuzzy set C , denoted as $C = A \cap B$. The membership function of C is defined as $\mu_C(x) = \text{Min}[\mu_A(x), \mu_B(x)]$ for all $x \in X$ in the universe of discourse X . This can also be represented as $C = A \wedge B$.

The proposed algorithm significantly enhances efficiency by leveraging parallel processing technique (multi-threading), making it well-suited for large datasets. The combination of parallel attribute processing and intersection checking ensures the identification of all fuzzy concepts within the fuzzy context.

Unlike existing algorithms for extracting full-sided fuzzy concepts, such as FuzzyInClose4b [24], the proposed algorithm generates fuzzy-crisp concepts that are more compact and suitable for information retrieval, ontology construction and association rule mining. Additionally, the parallel nature of the proposed algorithm makes it more efficient in extracting fuzzy-crisp concepts from large dense datasets, a feature that is not present in existing sequential fuzzy-crisp concept generation algorithms like Fuzzy CbO [22], Fuzzy NextClosure [25], and attribute-based algorithm [27].

V. CASE STUDY AND DISCUSSION

This section demonstrates the practical application of the proposed PFC algorithm in analyzing a fuzzy keyword-document context. This context involves eight keywords (k_1 to k_8) and four documents (d_1 to d_4), where fuzzy values represent the strength of relationships between keywords and documents. Keywords are treated as fuzzy extents, and documents as crisp intents, quantified by fuzzy membership values ranging from 0 to 1, as shown in Table IV.

Using the proposed PFC algorithm, this fuzzy context is systematically analyzed to extract fuzzy-crisp concepts, detailed in Table V. These concepts are characterized by fuzzy extents, indicating the strength of associations between keywords and

documents, and crisp intents, describing documents based on keywords.

TABLE IV. KEYWORD-DOCUMENT FUZZY CONTEXT

	d_1	d_2	d_3	d_4
k_1	0	1	1	0
k_2	0.2	0.6	1	0.2
k_3	1	0	0	0
k_4	0.3	0.6	0.7	0.3
k_5	1	0	0	1
k_6	0	1	0	0
k_7	0.1	0.5	0.5	0.1
k_8	0.5	0.3	0	0.5

TABLE V. FUZZY-CRISP FUZZY CONCEPTS EXTRACTED BY THE PROPOSED ALGORITHM

#	Fuzzy Extents (keywords)	Crisp Intents (documents)
C1	$\{k_0: 1, k_1: 1, k_2: 1, k_3: 1, k_4: 1, k_5: 1, k_6: 1, k_7: 1\}$	{ }
C2	$\{k_1: 0.2, k_3: 0.3, k_6: 0.1\}$	$\{d_1, d_2, d_3, d_4\}$
C3	$\{k_1: 0.2, k_2: 1, k_3: 0.3, k_4: 1, k_6: 0.1, k_7: 0.5\}$	$\{d_1\}$
C4	$\{k_0: 1, k_1: 0.6, k_3: 0.6, k_5: 1.0, k_6: 0.5, k_7: 0.3\}$	$\{d_2\}$
C5	$\{k_1: 0.2, k_3: 0.3, k_6: 0.1, k_7: 0.3\}$	$\{d_1, d_2, d_4\}$
C6	$\{k_0: 1, k_1: 1, k_3: 0.7, k_6: 0.5\}$	$\{d_3\}$
C7	$\{k_0: 1, k_1: 0.6, k_3: 0.6, k_6: 0.5\}$	$\{d_2, d_3\}$
C8	$\{k_1: 0.2, k_3: 0.3, k_4: 1, k_6: 0.1, k_7: 0.5\}$	$\{d_1, d_4\}$

Fig. 2 illustrates the steps of the PFC algorithm. Initially, the top and bottom fuzzy concepts (C1 and C2) are added to the fuzzy concepts set (line 1 of the algorithm). According to line 2, four threads are utilized to process different attributes (d_1, d_2, d_3, d_4) in parallel. Each thread independently processes its assigned attribute by calculating the fuzzy extent and corresponding crisp intent and checks if the newly formed concept's intent is not in the set of fuzzy concepts (FC). If it's unique, it adds a new concept to FC. Additionally, each thread performs fuzzy intersections of extents with existing concepts and ensures that new intersection concepts, if unique, are also added to FC. For example, processing attribute d_1 results in a concept with the fuzzy extent $\{k_1: 0.2, k_2: 1, k_3: 0.3, k_4: 1, k_6: 0.1, k_7: 0.5\}$ and the crisp intent $\{d_1\}$.

This process is repeated for all attributes, ensuring systematic extraction of all fuzzy concepts. This tracing highlights the algorithm's parallel behavior, where multiple threads execute concurrently to process different attributes, significantly speeding up the concept generation process by leveraging parallel computation. By analyzing these fuzzy concepts, the varying strengths of relationships between keywords and documents can easily be demonstrated.

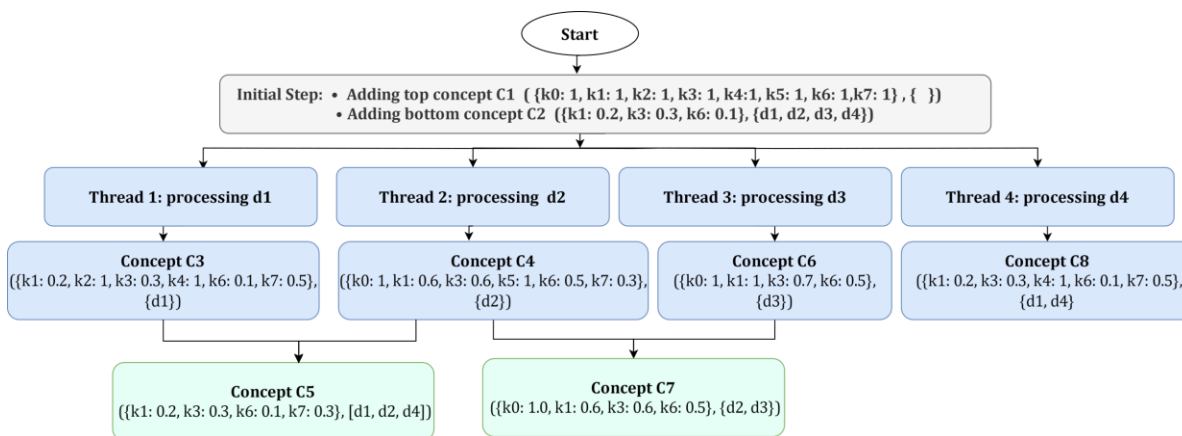

Fig. 2. Steps by the proposed PFC algorithm for extracting fuzzy concepts from fuzzy context in Table IV.

This analysis helps identify documents with strong, weak, or similar associations to multiple keywords. For instance, fuzzy concept C8 highlight that document d_1 and d_4 have a strong association with keyword k_4 and moderate to weak associations with other keywords. These keywords serve as a linking set for these two documents. Information from fuzzy-crisp concepts is valuable for tasks like information retrieval, as it improves search accuracy by highlighting documents strongly associated with the user query. The FuzzyInClose4b [24] algorithm generated 43 fuzzy concepts from Table IV in which both extent and intent are fuzzy. Example fuzzy concepts are: $(\{k_2, k_4, k_7, k_8: 0.3\}, \{d_1: 0.1, d_2: 0.5, d_4: 0.1\})$ and $(\{k_2, k_4, k_7: 0.1, k_8: 0.3\}, \{d_1: 0.2, d_2: 0.6, d_4: 0.2\})$ which are very similar concepts.

In this case study, fuzzy-crisp concepts extracted by the proposed PFC algorithm, which use fuzzy extents for keyword relevance and crisp intents for document associations, provide an efficient and nuanced approach. This method captures keyword importance precisely while maintaining clear document associations, leading to effective and context-aware search results. For example, in a search for "renewable energy sources," relevant keywords can be weighted, and documents are crisply linked, enhancing search efficiency. In contrast, full sided fuzzy concepts extracted by FuzzyInClose4b [24] offer more detailed relationships by representing both keywords and documents with varying degrees, but they introduce higher computational complexity and interpretation challenges with the existence of very similar fuzzy concepts. Thus, the fuzzy-crisp concepts extracted by the proposed PFC algorithm balance complexity and precision, delivering relevant and personalized search outcomes efficiently.

VI. RESULTS AND DISCUSSION

This section shows the efficiency and scalability of the proposed PFC algorithm through experiments on synthetic and benchmark datasets. The aim of these experiments is to show that the proposed PFC algorithm significantly reduces computation time, making FFCA feasible for large-scale data analysis. Table VI provides an overview of the datasets utilized in the experiments. The Iris and red-wine datasets are benchmarks from the UCI Repository [29]. To further assess the robustness of the proposed algorithm, we synthesized three variations of a fuzzy dataset with different densities (20%, 30%

and 40%) and a size of $(20,000 \times 15)$, so the performance of the proposed algorithm under various conditions can be assessed.

TABLE VI. DATASETS USED IN THE EXPERIMENTS

Dataset	G	M	Density	Description
Fuzzy Red Wine	1600	36	66.2%	Multivariate (fuzzified)
Fuzzy Iris	150	15	58%	Multivariate (fuzzified)
Synthetic Fuzzy Dataset	20,000	15	20%, 30%, 40%	Synthetic Fuzzy
Car	1,728	25	28%	Crisp

To maintain consistency with the fuzzy setting, all quantitative attributes are fuzzified using three linguistic labels per attribute: low, moderate, and high. Trapezoidal membership functions are employed to represent the low and high linguistic labels, while a triangular membership function is used for the moderate label. The proposed PFC algorithm is implemented in Python, and the experiments are carried out on a Windows machine equipped with an Intel Core i7 processor running at 2.60 GHz and 32 GB of RAM.

Before exploring experiments, Table VII presents feature comparisons between the proposed PFC algorithm and the related algorithms: In-Close4b [32], bit-close4 [30], FPCbO [31], FuzzyInClose4b [24], fuzzy CbO [22], attribute-based algorithm [27].

TABLE VII. FEATURES COMPARISON

Algorithms	Data Types	Parallel	Concept Extent	Concept Intent
In-Close4b [32]	Binary	x	Crisp	Crisp
bit-close4 [30]		✓		
FPCbO [31]		✓		
FuzzyInClose4b[24]	Fuzzy	x	Fuzzy	Fuzzy
fuzzy CbO [22]		x		
attribute-based [27]		x		
PFC algorithm	Fuzzy	✓	Fuzzy	Crisp

The algorithms In-Close4b [32], bit-close4 [30], and FPCbO [31] can only extract formal concepts from binary data, such as Car dataset. They can't process other types of data, such as multivariate and fuzzy datasets. In contrast, the proposed PFC algorithm can process these data by utilizing fuzzy set theory in computing fuzzy concepts.

The FuzzyInClose4b algorithm [24] extracts full-sided fuzzy concepts, which are more numerous than fuzzy-crisp concepts, extracted by the proposed PFC algorithm. Table VIII compares the number of fuzzy concepts extracted by the FuzzyInClose4b algorithm with those extracted by the proposed PFC algorithm for the fuzzy Iris dataset considering different α -cuts. Due to the larger count of concepts, the FuzzyInClose4b algorithm is computationally intensive and demands significant storage resources.

TABLE VIII. COMPARISON OF FUZZY CONCEPTS BETWEEN FUZZY IN CLOSE4B AND PROPOSED PFC ALGORITHMS ON FUZZY IRIS DATASET

α - cut	full-sided fuzzy concepts	Fuzzy-crisp concepts
0.8	844	73
0.7	2,738	87
0.6	8,438	110
0.5	16,843	160
0.4	46,514	252

All of fuzzy CbO [22], attribute-based algorithm [27], and the PFC algorithm extract fuzzy-crisp concepts. However, both fuzzy CbO and attribute-based algorithms operate sequentially and are computationally intensive. In contrast, the proposed PFC algorithm leverages parallel processing of attributes, significantly enhancing its efficiency. Experiments are conducted to compare the computational time (in seconds) required by fuzzy CbO, the attribute-based algorithm, and the PFC algorithm at different α -cut values applied to the dataset.

Fig. 3–6 demonstrate the persistent effectiveness of the suggested parallel algorithm in comparison to other algorithms. For all algorithms, the computation times decrease as the α -cut threshold increases. Aside from that, the proposed PFC algorithm consistently outperforms the other algorithms, achieving the shortest calculation times across all thresholds.

Fig. 3 demonstrates a performance comparison over the fuzzy Iris dataset, indicating that the suggested PFC algorithm consistently takes the least amount of time to compute all fuzzy concepts for all α -cuts applied to the dataset. Although the sequential attribute-based approach and the PFC algorithm behave similarly on this dataset, the difference in performance between them becomes more apparent when the α -cut decreases. This indicates that the suggested parallel algorithm is especially suitable for datasets with a high density.

Fig. 4, 5, and 6 display the efficiency for the synthetic fuzzy dataset with densities of 20%, 30%, and 40%, respectively. The proposed PFC algorithm consistently outperforms the fuzzy CbO and attribute-based algorithms on synthetic fuzzy datasets with different densities. It also has a stable and efficient

execution time of 5 to 40 seconds, which doesn't change depending on the α -cut thresholds. On the other hand, the density of the dataset significantly influences the Fuzzy CbO and attribute-based algorithms. Regardless, they both show a decrease in execution time with increasing α -cut values but remain inefficient. The proposed parallel algorithm is always efficient, even when datasets are very dense.

Fig. 3. Performance comparison of algorithms on fuzzy Iris dataset.

Fig. 4. Performance of algorithms on the synthetic fuzzy dataset with 20% density.

Fig. 5. Performance of algorithms on the synthetic fuzzy dataset with 30% density.

TABLE IX. EXPERIMENTS OVER DIVERSE DATASETS

Expr #	dataset	α -cut	Concepts#	Fuzzy CbO algorithm	Attribute based algorithm	Proposed parallel algorithm	Time reduction w. r. t. attribute-based algorithm	Time reduction w. r. t. Fuzzy CbO algorithm

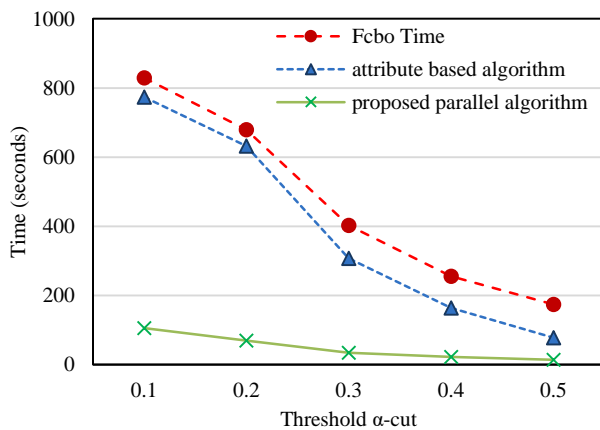

Fig. 6. Performance of algorithms on the synthetic fuzzy dataset with 40% density.

Table IX compares the proposed parallel algorithm's efficiency across diverse datasets, showing significant time reductions compared to the attribute-based and Fuzzy CbO algorithms. For instance, in the synthetic fuzzy dataset with 20% density, the proposed algorithm achieved an average time reduction of 55% compared to the attribute-based algorithm and 92% compared to the Fuzzy CbO algorithm, demonstrating its robustness and superior performance.

VII. CONCLUSION

Fuzzy formal concepts are essential to reveal the fundamental structures and patterns in heterogeneous datasets, thus enabling efficient decision-making in several fields. However, due to the complexity and ambiguity inherent in fuzzy datasets, extracting fuzzy concepts is computationally intensive. This inefficiency can hinder the practical application of fuzzy concepts in the real world. To address this challenge, the

proposed novel parallel algorithm optimizes the extraction of fuzzy-crisp concepts from fuzzy datasets, exploiting the resources at disposal. The proposed PFC algorithm utilized multi-threading to process attributes in parallel, then merge extracted fuzzy concepts. Experiments witness that the proposed algorithm reduces computation times and improves scalability, making it more suitable for handling dense and complex data structures. Besides, performance evaluation of the proposed PFC algorithm against other fuzzy algorithms across multiple datasets has demonstrated the algorithm's consistent superiority, achieving the shortest processing times across all α -cuts, with notable efficiency improvements as the α -cut decreases.

Future research should enhance the algorithm's applicability in various computational environments, including big data processing frameworks like Apache Spark, and explore its adaptation for distributed computing environments, allowing workload division and reduced computation times. Besides, a comprehensive evaluation of the algorithm's performance across a wider range of datasets and use cases will provide deeper insights into its strengths and limitations, guiding future enhancements and adaptations. Besides, the algorithm's efficient fuzzy concept extraction could revolutionize applications in data processing and decision-making, including online recommendation systems and dynamic risk assessment.

Abstract—With technology innovations such as Artificial Intelligence (AI) and Internet of Things (IoT), unprecedented applications and solutions to real world problems are made possible. Precision agriculture is one such problem which is aimed at technology driven agriculture. So far, the research on agriculture and usage of technologies are at government level to reap benefits of technologies in crop yield prediction and finding the cultivated areas. However, the fruits of technologies could not reach farmers. Farmers still suffer from plenty of problems such as natural calamities, reduction in crop yield, high expenditure and lack of technical support. Plant diseases is an important problem faced by farmers as they could not find diseases early. There is need for early plant disease detection in agriculture. From the related works, it is known that deep learning techniques like Convolutional Neural Network (CNN) is best used to process image data to solve real world problems. However, as one size does not fit all, CNN cannot solve all problems without exploiting its layers based on the problem in hand. Towards this end, we designed an automatic plant disease detection system by proposing an advanced CNN model. We proposed an algorithm known as Advanced CNN for Plant Disease Detection (ACNN-PDD) to realize the proposed system. Our system is evaluated with PlantVillage, a benchmark dataset for crop disease detection result, and real-time dataset (captured from live agricultural fields). The investigational outcomes showed the utility of the proposed system. The proposed advanced CNN based model ACNN-PDD achieve 96.83% accuracy which is higher than many existing models. Thus our system can be integrated with precision agriculture infrastructure to enable farmers to detect plant diseases early.

Keywords—Plant disease detection; advanced CNN; Artificial Intelligence (AI); deep learning; precision agriculture

I. INTRODUCTION

Agricultural sector in the world is crucial for growing food required by humanity. This field makes the highest contribution towards food and the economy as well. Farmers spend their lives in agricultural activities and work hard in production of different food items besides other commercial products like cotton. However, farmers are suffering from high expenditure involved in cultivation and also plant diseases. Particularly certain crop diseases lead to significant losses to farmers leading to crisis in agricultural domain [1]. Technology innovations such as AI are shaping unprecedented solutions in different real world applications. ML and DL techniques could improve state of the art in solving problems

[2]. However, technological innovations in several countries are helping governments and organizations but actual benefits of technologies could not reach farmers. In other words, in spite of innovations in agriculture, technology benefits are not really changing the lives of farmers. To state it differently, at the farmer level the technologies are not exploited. In this paper, our endeavour is to build a system that helps farmers to have automatic detection of plant diseases in a user-friendly fashion.

There are many existing methods dealing with the problem of automatic plant disease detection. PlantVillage [26] is the dataset widely used to have machine learning based approaches for disease detection. An excerpt from the dataset is shown in Fig. 1 reflecting some healthy leaves and diseased ones. Many of the existing methods such as [3], [5], [16] and [21] are based on CNN model. Sardogan *et al.* [3] proposed a hybrid DL technique using CNN and quantization to detect diseases in Tomato crop. Marzougui *et al.* [5] used ResNet model along with data augmentation for automatic disease detection. Hassan *et al.* [16] used pre-trained techniques like InceptionV3 and MobileNet with transfer learning to improve prediction performance. Suma [21] proposed a system for disease prediction and also incorporated a provision to give suitable recommendations on detection of specific crop disease. Andrew *et al.* [25] used models such as Inception v4, VGG16, ResNet50 and DenseNet121 to deal with automatic leaf disease detection process more efficiently. From the review of related works, it is ascertained that most of the existing models are built on CNN. Nevertheless, there is necessity for improving accuracy further and also work with live data collected from agricultural fields. Here are important contributions of the paper.

1) We designed an automatic plant disease detection system by proposing an advanced CNN model.

2) We proposed an algorithm known as Advanced CNN for Plant Disease Detection (ACNN-PDD) to realize the proposed system.

3) Our system is evaluated with PlantVillage [26], a benchmark dataset for crop disease detection result, and real-time dataset (captured from live agricultural fields).

4) The experimental results showed the utility of the proposed system. The proposed advanced CNN model

ACNN-PDD achieve 96.83% accuracy which is higher than many prior models.

Fig. 1. Leaf samples from plantvillage dataset.

The rest of the paper covers more details of our research. Prior works are reviewed in Section II. Preliminaries is given in Section III while Section IV throws light on the materials and methods associated with our work. Our investigational observations are provided in Section V. Our research is concluded in Section VI.

II. RELATED WORK

This section analyses related works on deep learning based methods for plant disease detection. Ferentinos et al. [1] used many variants of CNN models for disease prediction. They opined that CNN based models are widely used and they are more suitable for image analysis. It is found that various CNN variants are available for processing imagery data. Shruthi et al. [2] reviewed many DL models used for plant disease diagnosis. Their research showed that CNN is the preferred deep learning model. The rationale behind this is that, CNN has power to have discrimination towards efficient predictions. Sardogan et al. [3] defined a hybrid deep learning model using CNN and LVQ to detect diseases in Tomato crop. They found that when LVQ is combined with CNN, it could perform better in disease detection. Kumar et al. [4] explored region based approaches based on CNN models. Their methodology includes feature selection prior to using a supervised learning approach. With region approach, they found that there is increased probability in accurate predictions. Marzougui et al. [5] used ResNet model along with data augmentation for automatic disease detection. It is observed that the ResNet is a model that has provision towards transfer learning leading to better performance. Mishra et al. [6] used Corn crop for disease detection using CNN based model deployed into Raspberry Pi. They could test leaf images collected through mobile phone camera. Thus their system is found to be useful in collecting new samples and detect diseases. Chowdhury et al. [7] used U-Net model for segmentation process while EfficientNet model is used for automatic disease classification. The usage of dual models in their research they found that division of labour led to improved performance. Militante et al. [8] designed a DL based system for disease detection considering agricultural crops. They explored an image pre-processing method for

performance enhancement. It is observed that DL modes are better used for image data analytics.

Kannan et al. [9] defined a CNN based methodology along with data augmentation to improve disease detection process using Tomato crop. They also used transfer learning with ResNet50 model and found its utility. With such reuse in the model has improved chances of accuracy in predictions. Gui et al. [10] used background replacement technique along with an improved CNN for disease recognition using uncontrolled field conditions and controlled laboratory conditions. With the mixture of field conditions, the evaluation of the models became more comprehensive. Kumar et al. [11] investigated on Coffee plants using a CNN based architecture for disease detection. Their study revealed the utility of DL models for solving problems in agriculture. Tugrul et al. [12] followed a systematic review approach to explored different CNN variants. Their investigation has resulted in set of CNN variants and their modus operandi besides capability in predictions. Yan et al. [13] proposed an improved CNN model detect diseases such as cedar rust, frogeye spot and scab using Apple leaves. Apart from this, they used several pre-trained models such as VGG16 as well. Their inception model is found to have better performance. When compared with baseline models, their model was performing better significantly. Gajjar et al. [14] incorporated a trained CNN model into an embedded system in order to have automatic detection of leaf diseases. Their ideal of having an embedded system is to provide a solution in hand-held devices. Zeng and Li [15] proposed a method based on CNN by improving it using self-attention in the form of BaseNet architecture. This architecture is found better than its counterparts devoid of self-attention mechanism. Hassan et al. [16] used advanced models like InceptionV3 and MobileNet with transfer learning to improve prediction performance. Their findings are important towards making comparison between baselines and their models. Lu et al. [17] made a review on CNN models for leaf disease detection. Their findings are in affirmative on the capability of CNN in agricultural research. Raina and Gupta [18] studied many models used for disease detection in agricultural crops. Those models could establish the significance of learning based approach to solve problems in agriculture. Ahmad et al. [19] combined stepwise transfer learning and CNN models on imbalanced datasets for disease detection. This research could throw light on dealing with datasets that exhibit imbalance. Panchal et al. [20] investigated on different deep models for image based disease prediction. Their findings revealed that deep models have better opportunities in learning and prediction procedures.

Suma [21] proposed a system for disease prediction and also incorporated a provision to give suitable recommendations on detection of specific crop disease. Such recommendations provide another layer of knowledge to farmer community. Venkataramanan et al. [22] used YOLOv3 technique to obtain leaf from given image. Then that leaf is subjected to a learned CNN model for disease detection. Learning based approach is thus found to be scalable and more useful. Li et al. [23] explored different techniques used for disease detection. Their research has come up with several insights, challenges and current trends in leaf disease

detection. Their work insights could trigger further research in the area of disease prediction. Nagasubramanian et al. [24] used hyperspectral imagery for their research. Moreover, they incorporated explainable 3D learning into their methodology for disease identification. Andrew et al. [25] used pre-trained models such as Inception v4, VGG16, ResNet50 and DenseNet121 to deal with automatic leaf disease detection process more efficiently. From the review of related works, it is ascertained that most of the prior models are based on CNN [29]. Nevertheless, there is necessity for improving accuracy further and also work with live data collected from agricultural fields.

III. PRELIMINARIES

DL is a neural networks based advanced ML meant for improving learning process and accuracy in solving real world problems. CNN is a DL technique widely used for image analysis. CNN has multiple layers as presented in Fig. 2.

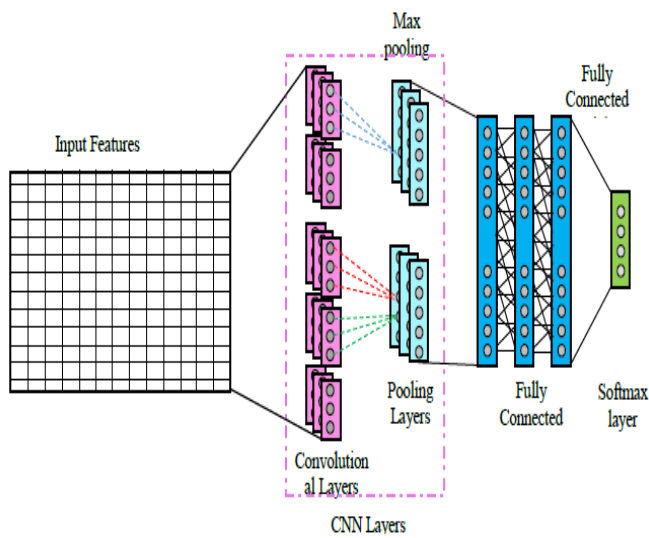

Fig. 2. Overview of baseline CNN architecture.

From the given image, convolutional layers are designed to extract features through correlation of local information. Pooling layers on the other hand perform sub-sampling and reduce feature space. A fully connected layer exploits the outcome of the convolutional and pooling layers and enables the prediction of class labels, while the soft max layer is meant for producing the final output in terms of different classes.

The convolution process is illustrated in Fig. 3. It places a kernel on input and gets pixel values. Then the pixel values are multiplied with kernel values. The result is summarized besides adding bias. The pooling in CNN can be of two types such as max pooling and average pooling as illustrated in Fig. 4. Max pooling is the process of dividing image into many regions and get max value for each region. Whereas average pooling does the same but takes average of each region. Generally, convolution and pooling layers are used in CNN architectures. In the fully connected layer, there is integration of multi-dimensional features and converting them into one-dimensional features eventually.

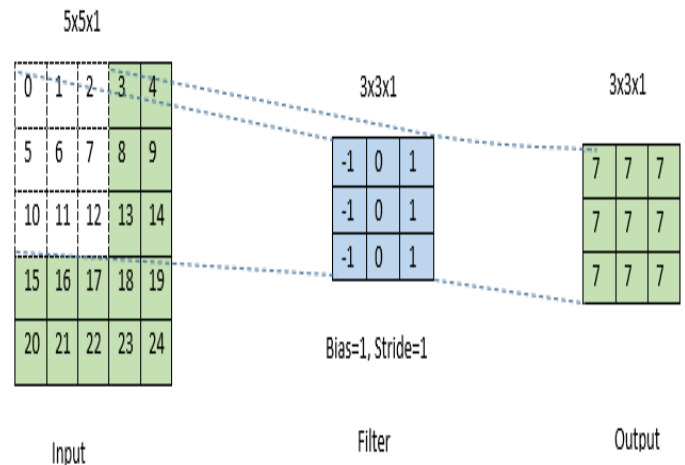

Fig. 3. Illustrates convolution process involved in CNN model.

Fig. 4. Illustrates max pooling (a) and Average pooling (b) Operations of a CNN model.

IV. PROPOSED SYSTEM

This research proposed an automatic plant disease detection system using DL approach. Towards this end, we considered the base line CNN model described in Section III and improved it to have advanced CNN model. With empirical study, we made different configurations of the layers to be more suitable for the purpose. As presented in Fig. 5, the proposed system is based on learning based phenomena. The proposed advanced CNN model is used to train the system. In other words, our CNN model learns from given training images and labels taken from PlantVillage dataset. We preferred CNN model for our research for many reasons. CNN is found to be most suitable for analysing image content. Its convolutional layers are designed to extract feature maps that reflect the underlying content of images. Moreover, the CNN model's pooling layers are designed to optimize feature maps so as to reduce in size without compromising the discriminative capabilities. CNN has capability to extract features without human intervention [26]. The configuration of CNN is designed such that its computational complexity is relatively less than other deep learning models. Strength of CNN lies in its ability to solve the problem known as "curse of dimensionality" in image data analytics. Its dense nature of the network has its influence in improving accuracy in prediction process [27]. Adjustment of filters in different layers of CNN has its impact on influencing accuracy. Adjustment of kernel size and stride can improve performance of CNN model.

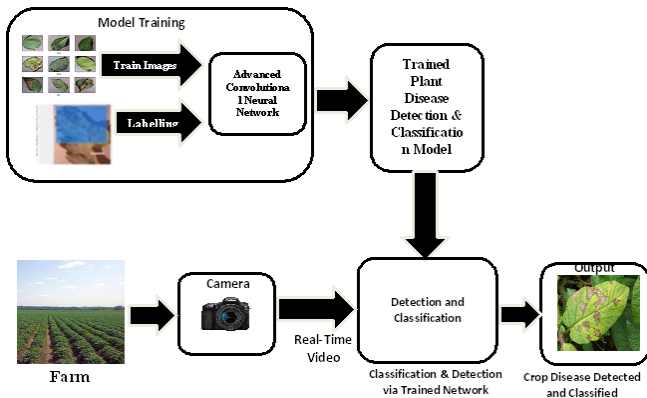

Fig. 5. Proposed automatic plant disease detection system.

The proposed advanced CNN model training set images and also corresponding ground truth. With the given inputs, the CNN model is trained to gain the knowledge pertaining to crop disease detection. After the training process, the learned CNN model has capability to discriminate healthy samples from the ones affected with diseases. In the process of training, convolutional layers are meant for collecting feature maps and pooling layers are meant for optimization of feature maps. The optimized feature maps play an important role in ascertaining knowledge about training samples along with their ground truth. The ground truth of training and testing samples play crucial role in evaluation of the proposed system. Then the knowledge model created is saved to persistent storage for using it later in the plant disease detection process [28]. The proposed system supports readily available test (unlabelled) images from PlantVillage dataset and also real

time images captured live from agricultural field using a camera. When a new image is given to the trained model, it is able to detect disease and classify it. In fact, the ability to detect any newly collected test sample is the important characteristic of the proposed system. This will enable farmers to take photo of their crop and use the proposed system to detect possible diseases. The given input image is subjected to convolution operation where it computes feature map as in Eq. (1).

$$x_j^\lambda = \sum_{i \in M_j} x_i^{\lambda-1} \times k_{ij}^\lambda + b_j^\lambda \quad (1)$$

The extracted feature map is denoted as x_j^λ . The kernel used by the convolutional layer is denoted as k_{ij} while λ denotes layers. The input feature map is represented by M_j and bias is denoted by b_j . Then the max pooling performs efficient sampling and results in reduction of feature map. The max pooling process is expressed as in Eq. (2).

$$s_j = \max_{i \in R_j} \alpha_i \quad (2)$$

In the proposed system, there is need for multiple classes in the classification outcome. For this reason, a softmax utility is used and its proposition is expressed as in Eq. (3).

$$h_\theta(x) = \frac{1}{1 + \exp(-\theta^T x)} \quad (3)$$

ReLU, as activation utility improves learning capability. In other words, it is used to handle over-fitting problem and enable speed in the prediction process. The functionality of activation function is stated in Eq. (4).

$$f(x) = \max(0, x) \quad (4)$$

An algorithm known as Advanced CNN for Plant Disease Detection (ACNN-PDD) is proposed to realize the proposed system.

Algorithm 1: Advanced CNN for Plant Disease Detection (ACNN-PDD).

Algorithm: Advanced CNN for Plant Disease Detection (ACNN-PDD)

Inputs:

D, n, m
(PlantVillage Dataset, number of epochs, batch size)

Outputs:

R, P
(Plant disease detection results, performance statistics)

1. Start
2. Initialize training set vector T1
3. Initialize testing set vector T1
4. (T1, T2) ← SplitDataset(D)
5. Create CNN model
6. Add convolutional 2D layers (5 layers are used)
7. Add max pooling 2D layers (5 layers are used)
8. Add fully connected layers (2 layers are used)
9. Add dropout layer (used one layer)
10. F ← FeatureSelection(T1) // using conv and pooling layers
11. M = TrainTheModel(F)
12. For each epoch e in n

13.	For each batch b in m	
14.	Update the model M	
15.	End For	
16.	End For	
17.	M' = FitTheModel(M)	
18.	R = Detect(M')	
19.	P = PerformanceEvaluation(M')	
20.	Print R	
21.	Return P	
D	dataset	n number of epochs
m	number of batches	T1 training set
T2	test set	R detection results
P	performance statistics	e one epoch
b	one batch	M trained model
F	Optimized feature map	M' updated model

Algorithm 1 takes PlantVillage Dataset, number of epochs and batch size as input and produce results of disease detection besides performance statistics. The proposed algorithm is evaluated using the procedure as described here. It is based on confusion matrix presented in Fig. 6.

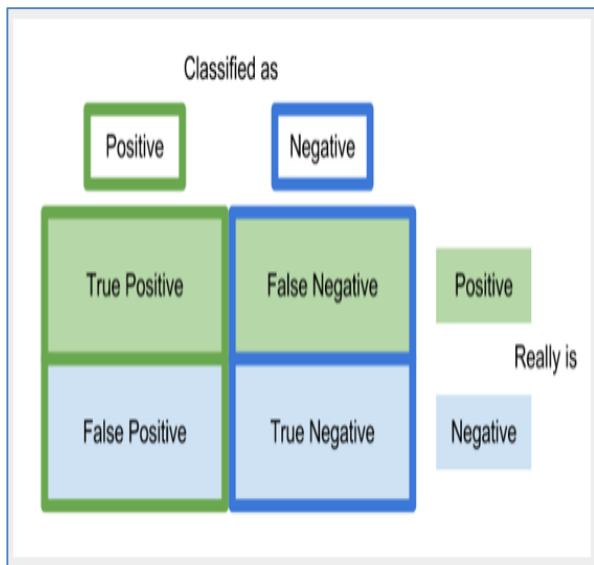

Fig. 6. Illustrates ground truth and predictions through confusion matrix.

Confusion matrix helps in understanding number of correct and incorrect predictions with regard to disease detection. Correct positive prediction is known as True Positive (TP), correct negative prediction is known as True Negative (TN). Opposite to these two (wrong predictions) are known as False Positive (FP) and False Negative (FN) respectively. Accuracy is the metric derived from confusion matrix.

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \quad (5)$$

Accuracy is metric used to evaluate performance of the proposed model as expressed in Eq. (5).

V. EXPERIMENTAL RESULTS

Experiments with both PlantVillage dataset [26] and also real time dataset captured from agricultural field are provided

here. Then the accuracy of the proposed method is evaluated and compared against prior works.

TABLE I. HYPER PARAMETERS SET IN THE PROPOSED MODEL

Hyper parameter	Value
batch size	128
dropout rate	0.8
learning_rate	1e-3
Loss	categorical_crossentropy
number of epochs	40
Optimizer	adam

As presented in Table I, the hyper parameters used in the proposed CNN model and its values are provided. Batch size indicates that the training process needs to be done in batches. In our research it is set to 128. Dropout rate refers to the fact that contribution of certain neurons is not considered in the learning process. Sometimes, the dropout layer enables the CNN to improve its efficiency by ignoring some inputs. The learning rate is set to control the training process in the proposed system. In our research number of epochs is set to 40 and it does mean the CNN is trained for 40 cycles. Adam is the optimizer used to adjust weights and learning rate in order to minimize loss and improve accuracy in prediction.

A. Results with PlantVillage Dataset

First, we tested the proposed model with test data taken from Plant Village dataset. The results are with two test samples are shown in Fig. 7. The first sample has “yellow leaf curl virus” disease and the proposed system is able to detect it correctly. The second sample also has same disease but with different severity level. The proposed system could detect it also correctly.

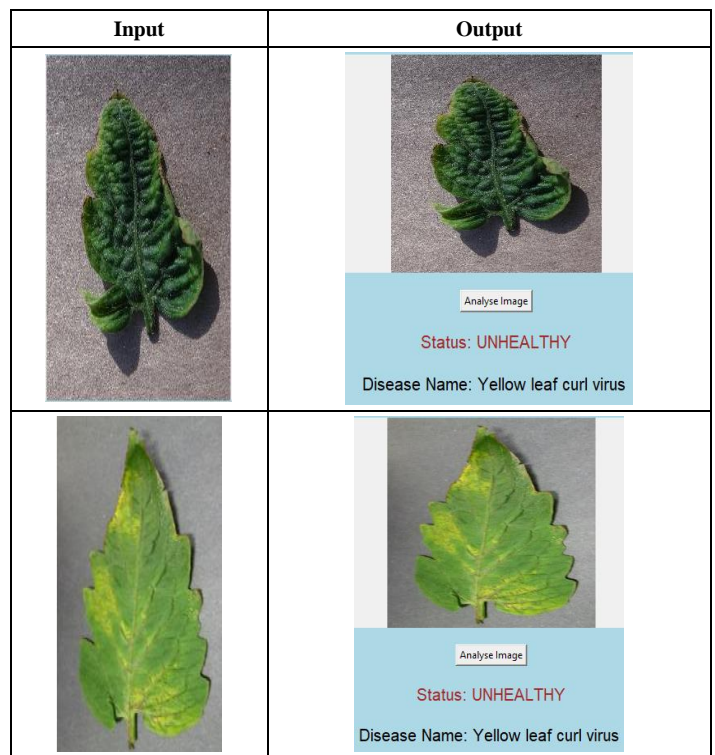

Fig. 7. Plant disease detection results using benchmark dataset.

As shown in Fig. 6, the test data is taken from the PlantVillage dataset and the detection results are provided. These results are observed with the test images available in the PlantVillage dataset. Since the dataset has plenty of test samples, the system is initially tested with the readily available samples. Section V(B) presents our empirical study with newly acquired test samples.

B. Results with Real-Time Dataset

We also tested the proposed model with test data captured live from agricultural field. The results are shown in Fig. 8.

Fig. 8. Plant disease detection results using benchmark dataset.

As shown in Fig. 8, the test data is taken from the real time dataset collected live from agricultural field and the detection

results are provided. Since the proposed system works for any crop for whom training data is available in PlantVillage dataset, we did experiments with newly acquired leaves of Tomato crop. Test results for three such samples are provided here. The first sample is detected as “tomato bacterial spot”. The second sample is detected as “tomato late blight” while the third one is detected as “tomato late blight”. These results are validated and found to be accurate.

C. Performance Evaluation

In this paper compared the detecting performance of our proposed model with many existing deep learning models.

As presented in Table II, the plant disease detection models and their performance in terms of accuracy are provided.

TABLE II. SHOWS PLANT DISEASE DETECTION ACCURACY OF DIFFERENT MODELS

Method	Accuracy
AlexNet	90.46048
GoogLeNet	94.92448
ResNet-20	92.01792
VggNet-16	95.54944
ACNN-PDD (proposed)	96.83904

Fig. 9. Performance comparison among plant disease detection models.

As presented in Fig. 9, performance of the models is evaluated in terms of detection accuracy. The detection accuracy is computed by comparing ground truth with predicted values. Different deep learning models showed varied detection performance due to their internal functionality and configuration of layers. Though all the models are based on CNN, their performance is different due to different architecture of the models. Least accuracy is exhibited by AlexNet model with 90.46%. ResNet-20 showed 92.01% accuracy. GoogLeNet has achieved 94.92% accuracy. VGG16 showed 95.54% accuracy. Highest plant disease

detection accuracy is exhibited by the proposed ACNN-PDD model with 96.83% accuracy. In summary, our research has resulted in better accuracy as it incorporates layers of the DL model appropriately. Moreover, the model is found robust with both test images from benchmark dataset and also the newly collected samples live from agricultural fields.

VI. CONCLUSION AND FUTURE WORK

In this paper, we designed an automatic plant disease detection system by proposing an advanced CNN model. We proposed an algorithm known as Advanced CNN for Plant Disease Detection (ACNN-PDD) to realize the proposed system. Our algorithm has an iterative process that learns from given training samples and ground truth. Then the model is evaluated with test samples. The prediction of ACNN-PDD for each test sample is compared against ground truth to arrive at confusion matrix reflecting efficiency of the model. Our system is evaluated with PlantVillage, a benchmark dataset for crop disease detection result, and real-time dataset (captured from live agricultural fields). The experimental results showed the utility of the proposed system. The proposed advanced CNN based model ACNN-PDD achieves 96.83% accuracy which is higher than many existing models such as AlexNet, GoogLeNet, ResNet-20 and VGG16. Though the proposed model provides better performance, it could be improved further with feature selection enhancements. In future, therefore, we intend to improve our system with further enhancement in CNN model along with feature engineering.

Towards Secure Cloud-Enabled Wireless Ad-Hoc Networks: A Novel Cross-Layer Validation Mechanism

Zhengu LIU

Shandong University of Political Science and Law, Jinan, Shandong, China, 250014

Abstract—Network security tackles a broad spectrum of damaging activities that threaten network infrastructure. Addressing these risks is essential to keep data accurate and networks running. This research aims to detect and prevent blackholes and wormholes in cloud-based wireless ad-hoc networks. A new Cross-Layer Validation Mechanism (CLVM) is introduced to detect and counter these dangerous attacks. CLVM boosts network security and ensures data travels through cross-layer interactions. CLVM is tested using NS2 software by performing several simulations and comparing the results with previous methods. The results show that CLVM effectively defends against blackhole and wormhole attacks, which makes it a crucial extra service for cloud computing. CLVM provides a strong defense against new security threats, making sure the network stays reliable and safe.

Keywords—Network security; wireless ad-hoc networks; cloud environments; cross-layer validation; blackhole and wormhole attacks

I. INTRODUCTION

Wireless networks play a key role in modern communication technology, enabling worldwide communication [1, 2]. Over the last two decades, progress in wireless communication has transformed our world, offering a range of wireless technologies such as Bluetooth, Wi-Fi, WiMAX, HSPA, 3G, 4G, 5G, ZigBee, Satellite, and NFC [3]. These wireless methods support different uses, from home networking to real-time multimedia and surveillance, adding to energy-saving designs on portable devices. We can split these networks into two main types: infrastructure-based wireless networks and infrastructure-less or Wireless Ad-hoc Networks (WANs) [4].

Infrastructure-based wireless networks rely on a fixed infrastructure in which nodes transmit data to a base station over predetermined routes [5]. Although these networks are reliable, they are typically expensive and unsuitable for hostile environments such as proactive disaster management or military applications where fixed infrastructure may not be available [6]. On the other hand, WANs function without predefined infrastructure. Nodes in these networks can connect to other nodes within their communication range, creating a dynamic, self-configuring, and self-organizing network [7]. They use shared radio channels and enable data forwarding between nodes.

Unlike traditional wireless networks with fixed configurations, cloud-based WANs face unique issues that

make their design and operation difficult. These networks must cope with changing layouts where nodes frequently connect or disconnect, resulting in constant shifts in routing paths. Additionally, the sprawling nature of WANs, as well as limited resources such as battery life and processing power, increase the risk of security threats. In cloud environments, these problems are exacerbated as data must be moved and processed across distributed nodes without central control. This setup is vulnerable to smart attacks such as blackhole and wormhole tricks, which can compromise network reliability and access. To address these problems, we need new ideas that increase security and keep the network running. This is the main objective of the Cross-Layer Validation Mechanism (CLVM) that we propose in this study.

Key distinguishing characteristics of ad hoc networks include lack of fixed infrastructure, dynamic topology, multi-hop routing, node heterogeneity, connection variability, scarce resources (power, storage, computing power), and limited physical security [8]. Nodes in WANs can be either mobile or fixed, resulting in two main categories based on mobility: Mobile Ad-hoc Networks (MANETs) and Wireless Sensor Networks (WSNs). MANETs are mobile nodes with no fixed location, while WSNs consist of non-mobile nodes deployed at specific locations [9]. The main differences between these networks are summarized in Table I.

TABLE I. WSN vs. MANET

Feature	WSNs	MANETs
Optimization focus	Power optimization	Both QoS and performance optimization
Communication	Many-to-one	Point-to-point
Routing	Data-centric	Address-centric
Destination	The final destination is known	The final destination is unknown
Power source	Not possible to change or recharge	Can be changed or recharged
Network type	Homogeneous	Heterogeneous
Topology	Static	Dynamic

While WANs offer significant advantages, they present several design and implementation challenges due to node mobility, limited resources, and decentralized network structures. These challenges span different protocol stack layers and increase the complexity of WAN development. In addition, WANs have specific vulnerabilities compared to other traditional networks, which are described below:

- Infrastructure absence: Nodes in these networks lack prior security association and can dynamically join or exit without notice, necessitating mutual trust among participating nodes within the protocol design.
- Wireless links: The unsecured nature of wireless links allows potential adversaries to access the network, lacking the equivalent protection level of wired links, making the network vulnerable to attacks from various directions.
- Limited physical protection: Nodes in WANs are often either minimally protected or entirely unprotected, intensifying network vulnerability due to their dynamic and mobile nature, facilitating easier insertion of malicious nodes.
- Lack of central management: The absence of a central authority enables adversaries to devise new attacks, exploiting the cooperative algorithm present in WANs. Security mechanisms must be adaptive and scalable to cope with dynamic topology changes and node increases.
- Resource constraints: Nodes in these networks have limited computational and power resources, making them susceptible to Denial-of-Service (DoS) attacks that exhaust the limited power source through excessive transmissions or computations.

In ad hoc networks, the absence of a central security system allows bad actors, both inside and outside the network, to put network security and privacy at risk [10]. We can split security attacks into two types based on how they work: passive and active [11]. Passive attacks try to break data privacy by listening in on conversations to gather useful info for future bad actions. This makes them hard to spot [12]. Active attacks go after data integrity and privacy by changing, blocking, repeating, or getting rid of packets being sent. They use different network functions to pull off these attacks [13]. We group these attacks into internal and external based on where they come from. Internal attacks happen when compromised nodes within the same network cause trouble and mess up how the system or network works. External attacks, on the other hand, come from unauthorized outsiders who don't belong to the network [14].

Security mechanisms for ad hoc networks include two main approaches. To prevent security attacks, cryptographic techniques are used as the first line of defense against external attacks to ensure the authenticity and integrity of the data source. However, this mechanism can fail if internal attackers have valid cryptographic keys to launch an attack. Security attack detection and response serves as a secondary line of defense, identifying abnormal activity on the network before it causes damage. The defense offers effective countermeasures against detected attacks.

The rest of this paper follows the following structure. A review of related work in the field of secure WANs is presented in Section II. CLVM is discussed in detail in Section III. The simulation results are presented in Section IV. The paper

concludes with a summary of key findings and research directions in Section V.

II. RELATED WORK

Compressive Sensing (CS) data collecting systems may efficiently decrease the transmission cost of WSNs by using the sparsity of compressible signals. While there have been explanations of CS as a symmetric cryptosystem, CS-based data-gathering systems still encounter security risks because of the intricate deployment environment of WSNs. Zhang, et al. [15] developed two viable attack methods for certain applications. They introduced a secure approach for collecting data using compressive sensing. The proposed method improves data privacy through the use of an asymmetric semi-homomorphic encryption technique and minimizes computational costs by utilizing a sparse compressive matrix. To be more precise, the asymmetric approach decreases the complexity of distributing and managing secret keys. Homomorphic encryption enables in-network aggregation in the cipher domain, thereby improving security and achieving network load balancing. The sparsity of the measurement matrix decreases both the computational and transmission costs, therefore offsetting the rising costs associated with homomorphic encryption.

Al-Shayegi and Ebrahim [16] designed a robust and energy-efficient system that minimizes energy use while ensuring privacy. The security strategy employs a customized version of the sharing-based method with a precision-enhanced and encryption-mixed privacy-preserving data aggregation procedure. The first protocol provides authentication and encryption via XOR gates, while the second protocol is a secure data aggregation method that improves security and energy efficiency. An approach to reduce energy usage is presented, which involves asynchronous scheduling duty cycling depending on location, priority, and pre-configuration. The findings indicate that the performance of the system is influenced by factors such as the sensing rate, data transmission frequency, data size, sensor placement and quantity, and smartphone battery capacity. For infrequent use and smaller amounts of data, the energy consumed by operations accounts for just 1% of the total battery capacity of the mobile device. When sensors are placed near the sink, the cost is decreased by more than 70% compared to an unsecured network, but there is an extra cost of 20%. The simulations demonstrate that the expense of encryption decreases with an increase in the quantity of sensors. In addition, as the number of sensors increases, the proximity between nodes reduces, resulting in more sensors entering sleep mode.

Wang, et al. [17] suggested a hierarchical trust system based on fog computing to address security vulnerabilities in cloud-enabled WSNs. This tiered approach has two components: confidence in the foundational framework and trust between cloud service providers (CSPs) and sensor service providers (SSPs). Monitoring behavior is built and executed inside WSNs to ensure confidence in the fundamental framework. At the same time, the intricate and detailed data analysis component is shifted to the fog layer. To establish trust between CSPs and SSPs, it is crucial to prioritize the real-time comparison of service parameters, the collection of exception information in

WSNs, and the focused quantitative assessment of entities. The experimental findings demonstrate that the fog-based topology effectively conserves network energy, swiftly detects malicious nodes, and promptly recovers misjudgment nodes within an appropriate timeframe. Moreover, the dependability of edge nodes is effectively ensured by data analyses conducted in the fog layer, and an assessment approach that relies on comparable service records is proposed.

Hsiao and Sung [18] developed an innovative method to bolster the data security of WSNs by using blockchain technology. They used blockchain technology and data transmission to provide a safe framework for WSNs based on the Internet of Things (IoT) architecture. The research employs embedded microcontrollers such as Raspberry Pi and Arduino Yun to construct a portable database node that gathers sensor data and hash values from preceding blocks. The transaction ledger is converted into a sensor data record, thereby improving the dependability of the WSN structure. The system can process data from a private cloud and display sensor data. The wireless network design is constructed utilizing embedded devices, facilitating the creation of a web server using Python or JavaScript programming languages. The research examines the efficacy of conventional methods against new data transmission methods, concluding that using innovative methods using blockchain technology renders it very difficult for operators to manipulate sensor data.

Haseeb, et al. [19] proposed a protocol for safe data collection in mobile WSNs, which utilizes cloud services. The technique aims to efficiently distribute information in dynamic networks by employing mobile sensors with little loss and power consumption. Furthermore, it guarantees the continuous presence and uniformity of the gathered data inside the cloud organizations while enhancing the routing reliability. The

simulation results and their analysis demonstrate the substantial efficacy of the suggested approach.

Sharmila, et al. [20] introduced a hybrid key management system for WSNs linking edge devices. This system utilizes Elliptic Curve Cryptography (ECC) and a hash function to create pre-distribution keys. The key setup is accomplished by simply broadcasting the node identity. The primary purpose of implementing a hybrid technique in the key pre-distribution method is to achieve mutual authentication between the sensor nodes during the installation phase. The suggested solution decreases computing complexity while enhancing security, making it suitable for implementation in sensor nodes with limited resources.

Ensuring the reliable and secure functioning of WSNs necessitates the identification of anomalies. Maximizing resource efficiency is essential for minimizing energy use. Gayathri and Surendran [21] introduced two methods for anomaly detection in WSNs: Ensemble Federated Learning (EFL) with cloud integration and Online Anomaly Detection with Energy-Efficient approaches (OAD-EE) using cloud-based model aggregation. Cloud-integrated EFL uses ensemble approaches and federated learning to improve detection accuracy and safeguard data privacy. OAD-EE, using a cloud-based model aggregation approach, employs online learning and energy-efficient strategies to save energy on sensor nodes. A complete and efficient system for anomaly detection in WSNs is established by integrating EFL and OAD-EE. The experimental findings indicate that adopting cloud technology in EFL leads to the best accuracy in detection. On the other hand, OAD-EE, which utilizes cloud-based model aggregation, exhibits the lowest energy consumption and the shortest detection time among all algorithms. Consequently, OAD-EE is well-suited for real-time applications.

TABLE II. AN OVERVIEW OF RELATED WORKS

Reference	Methodology	Key features	Results

The reviewed related works, as outlined in Table II, address various security and efficiency challenges in wireless sensor networks (WSNs) and mobile ad-hoc networks (MANETs) using diverse methodologies, such as compressive sensing, blockchain technology, and fog computing. However, these approaches encounter specific limitations. For instance, while Zhang, et al. [15] leverage semi-homomorphic encryption to enhance data privacy, the rising costs of this encryption remain a challenge. Similarly, Al-Shayegi and Ebrahim [16] focus on energy efficiency, yet their method incurs an additional 20% cost for security enhancements. Addressing these challenges, the current study introduces a novel mechanism that synergistically integrates the strengths of various approaches to bolster network security and data integrity while minimizing computational and transmission costs. Through extensive NS2 simulations, the proposed method demonstrates superior performance in detecting and mitigating blackhole and wormhole attacks, offering a robust defensive mechanism for cloud-enabled WSNs. This study's main contributions include the development of an efficient, cost-effective security framework that ensures reliable and secure data transmission, thus advancing the state-of-the-art in network security for WSNs and MANETs.

III. PROPOSED MECHANISM

This paper proposes a novel CLVM framework to identify and eliminate malicious activities within network routing protocols. CLVM aims to improve network reliability and data security by setting trust values for individual network elements. This trust scoring helps to find and remove wormhole nodes, making sure data moves over trusted routes. CLVM's main goal is to keep the network secure by spotting and containing harmful activities before they cause trouble. It does this in two ways. The framework has ways to detect and stop harmful activity in the network. This includes picking trusted paths to send data, which helps avoid potential threats. CLVM gives trust scores to network parts based on a full evaluation. This lets the framework prioritize data transfer across reliable and trustworthy nodes. Fig. 1 shows how CLVM works overall. The framework spots harmful activity by looking at how individual nodes in the network behave. During route discovery, nearby nodes are picked, and each node confirms it got and sent on data packets.

Fig. 1. Workflow of the cross-layer validation mechanism.

The Round-Trip Time (RTT) associated with data packet communication is a key anomaly detection metric. The framework leverages the Request-To-Send (RTS)/Clear-To-Send (CTS) handshake mechanism within the Media Access Control (MAC) layer to determine RTT. Significant variations in RTT can indicate the presence of a blackhole node, where a node along the designated route discards incoming packets instead of forwarding them. Fig. 2 depicts a typical blackhole attack scenario. In this example, data is transmitted from source node S to destination node D via nodes 7 and 8. However, node 2, acting maliciously, accumulates all incoming data packets without forwarding them. The extended RTT caused by this behavior can be identified through the RTS/CTS mechanism, exposing the blackhole node.

Fig. 2. Blackhole attack scenario in a WAN.

The IEEE 802.11 standard defines the Media Access Control (MAC) layer protocol for wireless local area networks (WLANs). This protocol leverages Carrier Sense Multiple Access with Collision Avoidance (CSMA/CA) to minimize collisions during data transmission. CSMA/CA mandates that nodes listen for ongoing transmissions before initiating their own, significantly reducing the likelihood of packet collisions.

In CSMA/CA, the Request-To-Send/Clear-To-Send (RTS/CTS) handshake process offers a way to cut down on collisions even more when hidden terminals are involved. This method works like this: A node that wants to send data first transmits an RTS frame to the receiver it's aiming for. When the receiver gets this RTS frame, it sends back a CTS frame, which sets aside the channel for the upcoming data transmission. Other nodes in the area pick up on this CTS frame and hold off on sending anything during this reserved time slot, which stops collisions from happening.

While the RTS/CTS handshake solves the hidden terminal problem, it adds extra work because of the RTS and CTS frame exchange. This extra work can have a big impact on network speed when many nodes are active in a small area. Researchers have looked into other ways to reduce this extra work, but the possible benefits haven't been worth the added complexity these changes would bring.

Another consideration for WLANs is the power consumption associated with RTS/CTS frames and data packets. The Power Control Mechanism (PCM) can adjust transmission power levels based on specific needs. Typically, RTS/CTS frames are transmitted at a higher power level (Pmax) to ensure wider reception, whereas data packets might utilize a lower power level to conserve energy. However, PCM might occasionally raise the transmission power of data packets to Pmax to overcome potential signal degradation. Acknowledgment (ACK) packets are generally transmitted at a lower power level.

The importance of minimizing collisions in the MAC layer stems from the power consumption associated with retransmissions. Retransmissions not only waste bandwidth but also deplete battery life in mobile devices. While RTS/CTS-based protocols offer advantages, they do not eliminate the hidden terminal and exposed terminal problems, especially in high-density networks. Furthermore, migrating such protocols to cloud-based environments introduces additional challenges that must be addressed. This paper proposes a secure routing protocol designed to establish reliable communication paths within a network while mitigating the risks of wormhole nodes. The protocol operates under the following assumptions:

- Transmission range: All participating nodes are confined within a predefined transmission range (R).
- Node mobility: Nodes are considered stationary for routing calculations. Real-world deployments might involve mobile nodes, requiring adjustments to the protocol.
- Neighbor discovery: Nodes can discover and communicate with neighboring nodes within their transmission range.

The core objective of the protocol lies in identifying a secure path between a source node (S) and a destination node (D). The distance between these nodes (d) is calculated using Eq. (1), which factors in the transmission range (R) and the average node speed (V). The transmission range can be dynamically adjusted within a predefined threshold based on the varying distances between nodes. A weighted average

distance is also employed as a stopping condition for route discovery.

$$Dist_{SD} = \frac{R - d}{V(R - D)} \quad (1)$$

To enhance security, each node maintains a counter variable initialized to zero. This counter is incremented whenever a designated operator node retrieves data from a particular node. The operator node can connect and disconnect from any node within the network. The counter reflects the number of interactions a node has had with the operator. If multiple operators collect data from the same node (node-S), the data on the destination node stored by the operator with the higher counter value takes precedence. The counter range is also configurable, with a minimum value of zero and a maximum value determined by the network's reach.

Unique identifiers are assigned to each node to facilitate secure communication. Data packets transmitted within the network encompass various fields, including a packet ID, distance traveled, counter value, and potential information regarding intermediate nodes. The validity of these parameters, including details about intermediate nodes, is verified at each network layer until the data reaches its intended destination.

Route discovery and data transmission processes leverage a routing table (R-table) that stores information about nodes and established routes. This information is constantly compared against the data packets to ensure validity. Since source nodes are assumed to be geographically close, any node can access details on neighboring nodes. Data is then forwarded to the nearest available node along the designated path.

The paper highlights a potential security concern: a wormhole attack scenario. In this scenario, a malicious node (node-S) intercepts data packets from the source node and transmits them to another colluding node (node-8) closer to the destination. Node-S then impersonates node-7, the intended recipient of the data from the source, by altering its ID to match node-7's. Consequently, the source node is deceived into believing it communicates directly with node-7, establishing a wormhole connection. The proposed protocol must have mechanisms to identify and counteract such wormhole attacks.

Unlike traditional routing protocols, where multiple nodes might operate on the same radio frequency, this approach assigns unique channels to individual nodes. This distinctiveness allows the source node to verify the legitimacy of neighboring nodes by transmitting on a randomly chosen channel.

The core principle assumes a legitimate neighboring node can detect a message transmitted on its designated channel. In contrast, a wormhole node lacking knowledge of the correct channel will miss the transmission. The probability of a source node failing to detect a wormhole node through a single random channel test can be calculated using Eq. (2). In this equation, 'n' represents the total number of neighbors, and 'S' represents the number of suspected wormhole nodes within the set of neighbors.

$$\begin{aligned}
 P_r &= \sum_{all\ S,M,G} P_r(S, M, G) P_r(detection|S, M, G) \\
 &= \sum_{all\ S,M,G} \frac{\binom{S}{S} \binom{m}{M} \binom{g}{G} S - (m - M)}{\binom{n}{c} c} \quad (2)
 \end{aligned}$$

The channel frequency diversity approach can be extended to enhance detection accuracy by conducting multiple rounds of random channel tests (denoted by 'r' in Eq. (3)). With each round, the source node selects a random subset of neighbors and a random channel for transmission. Eq. (3) calculates the probability of failing to detect a wormhole node after 'r' rounds of testing.

$$\begin{aligned}
 P_r(decontt) &= 1 - P_r(nondetection)_{1round}^r \\
 &= 1 - (1 - P_r((P_r))_{1round}^r \\
 &= 1 - \left(1 - \sum_{all\ S,M,G} \frac{\binom{S}{S} \binom{m}{M} \binom{g}{G} S - m - M}{\binom{n}{c} c} \right)^r \quad (3)
 \end{aligned}$$

This technique assumes a network scenario where a node's neighbors might encompass 'S' wormhole nodes, 'M' malicious nodes of other types, and 'G' legitimate nodes. Due to practical constraints, the source node can only test a limited number of neighbors at a time. Eq. (2) factors the possibility of encountering a wormhole node, a malicious node of a different type, or a legitimate node within the chosen subset of 'C' neighbors. By analyzing the probability ratio derived from Eq. (2) and Eq. (3), it can be concluded that the channel frequency diversity approach offers a viable solution for detecting wormhole nodes within various Wide Area Network (WAN) topologies.

IV. RESULTS AND DISCUSSION

The CLVM was implemented and evaluated using the NS-2.5 network simulator. Table III summarizes the simulation parameters employed in the evaluation process. The primary objective of this evaluation was to assess the efficiency of CLVM relative to an existing approach, LBIDS [22]. The simulations were conducted in a 1000 x 1000 m network area, simulating a typical wireless ad hoc network environment. The nodes were randomly distributed across this area, with the number of nodes varying between 10 and 50 over five rounds of simulation, increasing by ten nodes per round. Node mobility was simulated using the random waypoint mobility model, with node speeds ranging from 1 to 15 m/s, reflecting the dynamic nature of real-world ad hoc networks.

The radio propagation model used was the two-ray ground reflection model, which takes into account both direct and ground-reflected paths of signal propagation, allowing for a more realistic simulation of wireless communications. The transmission range of each node was set to 250 meters, with the MAC layer using the IEEE 802.11 standard. Traffic was generated using a constant bit rate (CBR) application with packet sizes of 50 bytes, simulating a typical data transfer scenario. Energy consumption was modeled based on the remaining energy level of nodes after each round, using

mechanisms such as RTS/CTS handshakes and distance checking to save energy.

TABLE III. SIMULATION PARAMETERS AND VALUES

Parameter	Value
Simulation area	1000m x 1000m
Malicious node ID count	2
Malicious node percentage	Up to 5%
Node placement	Random
Simulation duration	100 seconds
Packet size	50 bytes
Traffic type	CBR, 100 – 500
MAC protocol	802.11
Total nodes	20 – 750
Transmission range	250 m
Propagation model	Two-ray ground reflection
Node Speed	1 – 15 m/s

A. Transmission Delay Analysis

Fig. 3 compares the average transmission delay incurred by each approach across the five rounds. The results demonstrate that CLVM consistently exhibits lower transmission delay compared to LBIDS. In the case of round five with 50 nodes, LBIDS exhibits a transmission delay of 46 milliseconds (ms), whereas CLVM achieves a delay of only 24 ms. This improvement can be attributed to the efficiency gains introduced by CLVM's mechanisms, such as trust value evaluation and route selection.

Fig. 3. Average transmission delay comparison.

B. Throughput Analysis

Throughput, measured by the successful transmission and reception of data packets, serves as another key performance metric. Fig. 4 depicts the throughput achieved by both CLVM and LBIDS across the five rounds. The results indicate that CLVM consistently delivers superior throughput compared to LBIDS. This can be primarily explained by CLVM's ability to mitigate malicious activities that disrupt data transmission within the network. For example, in round five, LBIDS achieves a throughput of 6123 packets, whereas CLVM delivers a higher throughput of 6400 packets.

Fig. 4. Average throughput comparison.

C. Energy Consumption Analysis

The remaining energy level of network nodes after each round was evaluated to assess the energy efficiency of both approaches. Fig. 5 presents the results, indicating that CLVM nodes conserve more energy than LBIDS nodes. This is a consequence of CLVM's strategies for reducing unnecessary communication and data transmissions. Mechanisms like RTS/CTS handshakes and distance verification contribute to this energy conservation. Nodes are unable to transmit data if they fail to provide valid IDs or adhere to the RTS/CTS protocol and distance requirements. This helps to preserve node energy. The simulations reveal that in round five, the remaining energy level for LBIDS nodes is 95%, whereas CLVM nodes retain a higher energy level of 96%.

Fig. 5. Remaining energy comparison.

D. Malicious Activity Detection Analysis

The simulations also evaluated the effectiveness of both approaches in detecting malicious activities within the network. CLVM's algorithm leverages a long-established foundation and incorporates node behavior analysis for comprehensive malicious node identification. Fig. 6 compares the number of malicious activities detected using LBIDS and CLVM. The results demonstrate that CLVM significantly reduces the number of malicious activities within the network. This

improvement stems from CLVM's verification of critical parameters like node ID, RTS/CTS compliance, and transmission distance during data exchange. Additionally, CLVM maintains a database for comparison purposes, enabling it to identify nodes that deviate from expected behavior and potentially block them. While LBIDS focuses on detection, CLVM prioritizes prevention by proactively identifying and mitigating potential threats.

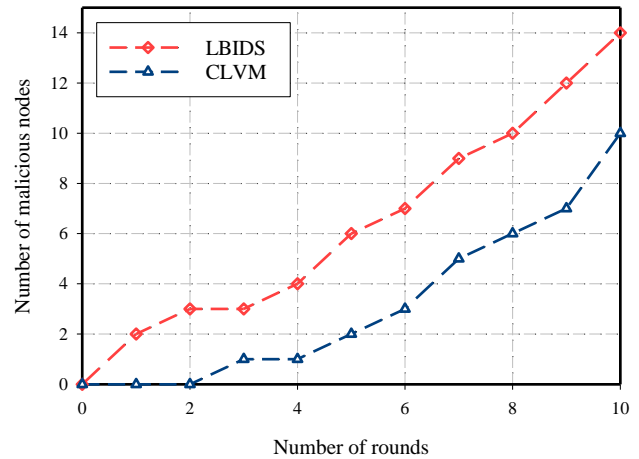

Fig. 6. The number of malicious activities comparison.

The obtained results clearly show that CLVM not only outperforms the existing LBIDS approach in practical metrics such as transmission delay, throughput, and energy consumption but also embodies significant theoretical advances. CLVM's integration into existing network protocols is achieved through its trust-based validation process, which improves route selection and mitigates malicious activity more effectively than traditional methods. By prioritizing trust assessment at multiple levels, CLVM eliminates the limitations of LBIDS, which focuses primarily on detection rather than prevention. This cross-layer approach allows CLVM to reduce transmission delays and energy consumption while maintaining high throughput, providing a more holistic and efficient network security solution. CLVM's theoretical robustness, combined with its practical effectiveness, makes it a superior alternative to existing security mechanisms in cloud-enabled wireless ad hoc networks.

The simulation setup was designed to closely mimic real-world scenarios by incorporating widely used models such as random waypoint mobility and two-ray ground reflection. These models simulate the unpredictable movement of nodes or realistic signal propagation in an open environment. The range of node speeds and the random distribution of nodes reflect the dynamic and decentralized nature of cloud-enabled wireless ad hoc networks. However, it is important to note that certain simplifications were made in the simulation. For example, environmental factors such as obstacles and interference, which can significantly impact signal propagation and network performance in real-world scenarios, have not been fully modeled. In addition, the simulations assumed idealized conditions for node operations and communications, which may differ from the more complex and variable conditions encountered in actual operations.

V. CONCLUSION

This study introduced CLVM as an innovative solution to enhance the security and efficiency of cloud-enabled wireless ad-hoc networks. Extensive evaluations demonstrated that CLVM significantly outperforms the existing LBIDS approach in key performance metrics, including transmission delay, throughput, energy consumption, and malicious activity detection. CLVM achieves a remarkable reduction in transmission delay, evidenced by a delay of only 24 milliseconds in a 50-node network compared to LBIDS's 46 milliseconds. Additionally, CLVM consistently delivers higher throughput, with a notable increase to 6400 packets in the same network configuration. Energy efficiency is another critical advantage, as CLVM nodes retain 96.59% of their energy compared to LBIDS's 95.1%, thanks to effective strategies like RTS/CTS handshakes and distance verification protocols. Moreover, CLVM excels in detecting and mitigating malicious activities, leveraging comprehensive node behavior analysis and a proactive approach to threat prevention. These improvements underscore the robustness and reliability of CLVM in securing data transmission and maintaining network integrity.

Looking forward, future research will focus on several key areas to build on the findings of this study. One possible path is to extend the CLVM to other types of wireless networks, such as Vehicular Ad-hoc Networks (VANETs) or industrial IoT environments, where security challenges are even more pronounced. Additionally, optimizing CLVM for larger deployments with hundreds or thousands of nodes is critical to ensure its scalability and efficiency in various network scenarios. Further research could also include integrating CLVM with advanced machine learning algorithms to improve its ability to detect and adapt to new types of security threats in real-time. These future efforts aim to refine and expand CLVM's capabilities, ensuring its relevance and effectiveness in the ever-evolving network security landscape.

Abstract—The deployment of ultra-wideband (UWB) technology offers enhanced capabilities for various Internet of Things (IoT) applications, including smart cities, smart buildings, smart aggregation, and smart healthcare. UWB technology supports high data rate communication over short distances with very low power densities. This paper presents a UWB printed antenna design with multiple input and output (MIMO) capabilities, specifically tailored for Routed Satellite Sensor Systems (SRSS) to enhance IoT applications. The proposed UWB printed antenna, designed for the 2–18 GHz frequency band, has overall dimensions of 14.5 mm x 14.5 mm, with an efficiency exceeding 70% and a gain ranging from 2 to 6.5 dB. Both simulated and measured reflection parameters ($|S_{11}|$) at the antenna input show strong agreement. Furthermore, a compact MIMO system is introduced, featuring four closely spaced antennas with a gap of 0.03λ , housed in a 60 mm x 48 mm module. To minimize coupling effects between the antennas, the design incorporates five Split Ring Resonator (SRR) elements arranged linearly between the radiating elements. This arrangement achieves a mutual coupling reduction to -35 dB at 8 GHz, compared to -20 dB isolation in systems without SRR. The results demonstrate that the proposed MIMO antenna system offers promising performance and meets the requirements for effective space communication within satellite sensor networks.

I. INTRODUCTION

UWB technology was originally developed for military applications but began to be used in civilian applications. Arousing growing interest within the scientific and industrial community, it was transferred to telecommunications applications [1-12]. This technology is used in other applications, such as structural health monitoring (SHM) for large structures, and in particular in the aeronautics and space fields are under development [13].

Other applications of wireless sensor networks operating using UWB spectrums appear in smart homes, the biomedical field, natural disaster detection, intrusion detection, pollutant detection, agriculture, and many other fields [14]. They provide great ease of use and reduce the cost and time of deployment. One can't talk about UWB without mentioning Internet of Things (IoT), the concept of connected devices, continues to show promising progress, and now, with the re-emergence of UWB technology, IoT devices that require location and

movement data are performing better than ever for the cost and time of deployment [15]. Thanks to UWB interoperability, this communication protocol can be used to take advantage of smart technologies such as Bluetooth, WiFi, and the IoT's. UWB can play a key role in redesigning the IoT devices already available and in introducing more sophisticated networks of interconnected devices in the future [16]. In wireless communication systems, antennas play a very important role as it is the backbone of any wirelessly communicating system. To meet the emerging requirements of the smart IoT devices an enhanced performance antenna is required [17]. Moreover, to meet the requirements of the MIMO system a compact yet low mutual coupling antenna has become essential for communication systems.

Thus, the researcher puts a lot of effort to design compact size UWB antenna for IoT devices [18–28]. For instance, a metamaterial inspired circular split ring resonator shaped antenna is designed for UWB application in study [18]. Although the antenna offers a UWB operational band with a notch band ranges 7 – 8 GHz it had a setback of bigger dimension along with lower cutoff frequency around 3.4 GHz. In study [19] a dual stub loaded antenna having dual reconfigurable notch band is proposed for UWB applications. However, the insertion of the diodes and biasing circuit causes the degrading of antenna performance resulting in a low gain throughout the band of interest. Likewise, in [20] a rectangular monopole antenna exhibiting broad bandwidth is converted into a UWB antenna by initially modifying the ground plane, then by truncating the radiating structure and finally loading some parasitic elements. The resulting antenna offers UWB ranges 2.5–18 GHz at the cost of complex structure along with low gain and large physical size. The study in [21– 22] present the conversation of circular and semi-circular monopole antenna into UWB antenna by truncating the radiating structure along with ground plane. Resistor loaded anti-spiral shaped UWB antenna is presented in [24], where flexible antenna is designed by compromising the size of antenna along with partial covering the UWB spectrum. Moreover, the work reported in study [26–28] has a relatively big size as compared to other literary works. Furthermore, none of the discussed can be used for IoT applications due to their SISO nature.

Considering the requirements of IoT and future networks that require MIMO antenna, there is a dire need to design UWB MIMO antenna with low mutual coupling in study [29–35]. A

compact size two-port UWB antenna is presented in study [29] where two open ended stubs are loaded, and their structure is modified to achieve a mutual coupling of -15 dB between adjacent elements. On the other hand, a truncated corner shaped UWB antenna is utilized to design a 4-element UWB MIMO antenna. The antenna elements are placed orthogonal to each other to achieve low mutual coupling along with defected ground structure to further reduce the mutual coupling to < -20 dB. A flower shaped semi-fractal antenna is proposed in study [31], which is converted into 4-element MIMO antenna. Four-open ended stubs were loaded to reduce the mutual coupling among MIMO elements; however, the MIMO antenna system only offers the mutual coupling of < -18 dB. Likewise, in study [32] a hollow ground plane and inverted L-shaped stub loaded UWB MIMO antenna is presented. The antenna offers UWB ranges 2.84 – 15.88 GHz having a overall size of 58 x 58 mm² along with a setback of high mutual coupling. Another MIMO antenna for UWB application is proposed in study [33] in which the orthogonal placement of MIMO element is utilized to achieve a low mutual coupling while compromising the overall size of antenna. A tapered-fed circular shaped MIMO antenna is designed for UWB applications while neutralization lines along with DGS and inverted L-shaped open stubs are utilized to reduce the mutual coupling [34]. On the other hand, a pair of C-shaped parasitic patches are loaded at the back of antenna to reduce the mutual coupling [35]. However, both the works have the disadvantage of bigger size along with complex geometrical structure.

All of the aforementioned works either lack in covering complete UWB spectrum or have large physical dimension along with most of them suffering from complex geometrical structure. Therefore, this study focuses on the design of geometrically simple yet UWB MIMO antenna having low mutual coupling along with high gain is given in Section II. The antenna design methodology is discussed in Section III, afterward the results will be discussed in Section IV, and the manuscript is concluded in Section V.

II. ANTENNA DESIGN

The design methodology started from designing a conventional rectangular patch antenna that resonates at central frequency of 10 GHz, as depicted in Fig. 1. The length and width of the rectangular patch along with microstrip feedline can be estimated using the equations provided in [36]. The setback of conventional microstrip antenna, the narrow bandwidth, is nullified using the partial ground plane technique along with truncated corners, as shown in Fig. 1 (a). This helps in achieving a broad $|S_{11}| < -10\text{dB}$ impedance bandwidth ranging 4–9.5 GHz, as illustrated in Fig. 1(b). Although there is significant improvement observed in bandwidth, still the antenna didn't cover the entire UWB spectrum ranges 3-10.3 GHz. Therefore, to further improve the performance of the antenna another iteration is performed by truncating the lower corners of radiators along with implementing the DGS, as shown in Fig. 1(a). After optimizing the results, the antenna again offers wide operational bandwidth ranges 5–15.7 GHz, as shown in Fig. 1(b). It is important to note here that although the bandwidth of the antenna increases but operational spectrum shifted toward higher frequency.

Thus, there is need to shift the lower end of the resonating band. For said purpose two u-shaped slots were utilized, they are etched from the radiator and by optimizing the parameters of the slots the antenna resonance can be shifted toward lower side. The other parameters of the proposed antenna are also optimized which results in UWB spectrum ranges 2 – 18 GHz, covering UWB, extended UWB and Ku-band, as shown in Fig. 1(b).

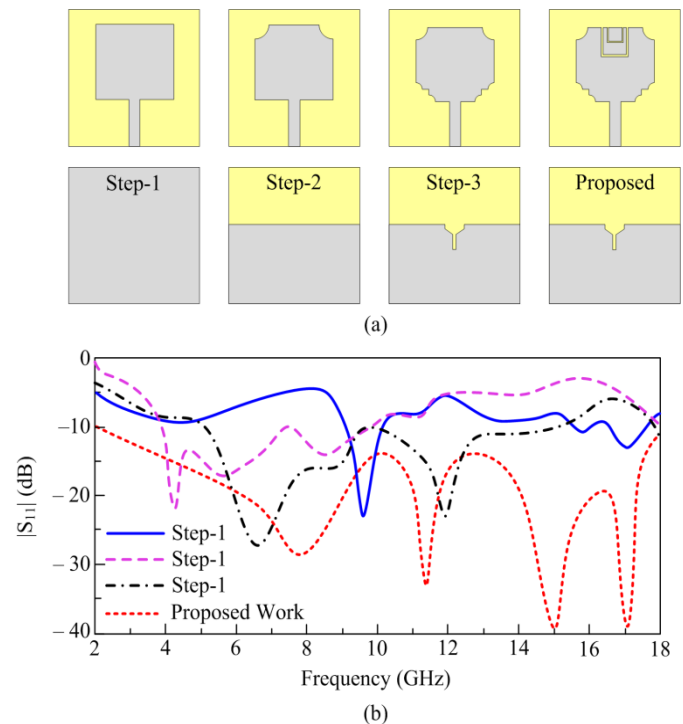

Fig. 1. (a) Geometrical configuration (b) Reflection coefficient of various modifications in radiator and ground plane.

Fig. 2 depicts the geometrical configuration of the proposed ultra-wideband antenna, while Table I summarizes the optimal parameters obtained by simulation.

For in-depth understanding of UWB behavior of antenna, Fig. 3 depicts the impedance characteristics of the antenna. It can be observed that the proposed antenna offers real impedance value around 50Ω while the imaginary value stays around 0Ω which also proves the ultra-wideband behaviour of the antenna.

Fig. 2. Final geometry of the proposed antenna: (a) the front view, (b) backside view.

TABLE I. PROPOSED ANTENNA DIMENSIONS IN DETAIL

Elements	Parameters	Values(mm)
Patch	$r_1=r_2$	2.5
	W_1	3.4
	L_1	7.5
	$r_3=r_4=r_5=r_6$	1.5
	W_3	6.17
	L_f	13.5
	W_f	3
	W_2	7.2
	F	0.3
Dielectric substrate	W_s	25
	L_s	30
	H_s	1.6
	ϵ_r	4.4
Ground Plane	L_g	12.5
	W_g	3.5
	n	2.4
	i	0.75
	k	2.3

The gain of the proposed UWB antenna is shown in Fig. 4. The antenna offers a minimum gain of 2.4 dBi around 2 GHz, it tends to start increasing for higher frequency and reach up to the maximum value of 5.8 dBi around 17.7 GHz. Thus, the gain results strength the potential of the proposed work for UWB and Ku-band applications.

Fig. 3. Proposed antenna impedance characteristics.

Fig. 4. Peak gain of proposed work.

The radiation pattern of the proposed antenna at the selected frequencies of 8 and 15 GHz is shown in Fig. 5. The antenna offers a nearly omni directional radiation pattern in E-plane for both selected frequencies, while for H-plane the antenna offers a dual beam like structure. Moreover, Fig. 6 illustrates the radiation efficiency in the operational band, where antenna offers a minimum efficiency of 80% throughout the band of interest.

The distribution of the current at 8 GHz and 15 GHz of the proposed antenna is shown in Fig. 7. It can be seen that additional paths for surface currents are formed when slits are present. This results in a second resonance, increasing the bandwidth.

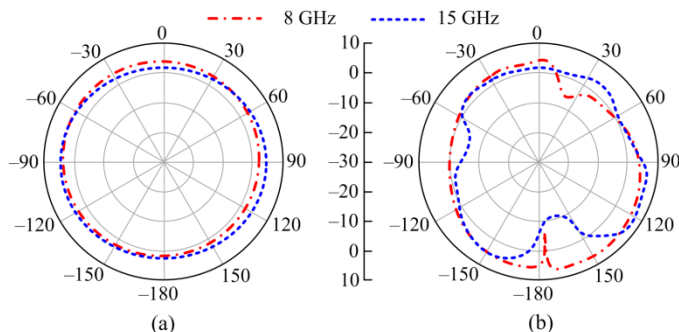

Fig. 5. Radiation pattern of proposed antenna in (a) E-plane and (b) H-plane.

Fig. 6. Efficiency variation of proposed work.

Fig. 7. Current distribution of proposed UWB antenna.

To validate the various performance parameters of the proposed UWB antenna a sample prototype is fabricated and later used for measurements, as shown in Fig. 8. Various parameters including $|S_{11}|$ and radiation pattern were measured and compared with simulated results. The comparison among estimated and measured $|S_{11}|$ results of proposed UWB antenna is shown in Fig. 9. A strong comparison among both results is found having identical wideband operation, a little deviation is observed in values of return loss which may be due to inaccuracy of measurement setup or due to fabrication tolerance.

Fig. 8. Fabricated Antenna: (a) Top view and (b) Bottom view.

Fig. 9. Comparison of reflection coefficient among simulated and measured results.

For the selected frequency of 8 GHz, the comparison among the radiation patterns found using the EM tool and measurement is presented in Fig. 10. A strong correlation is observed, with nearly identical patterns in both cases. Thus, in terms of all performance parameters, strong results are observed among the simulated and measured values, which illustrates the performance stability of the proposed antenna.

Fig. 10. Radiation pattern at 8 GHz: (a) E-plane and (b) H-plane.

III. COMMON TECHNIQUES TO REDUCE MUTUAL COUPLING AMONG MIMO ANTENNA ELEMENTS

Diversity and MIMO systems require good isolation between antennas. Much research has been done over the years to find techniques to reduce mutual coupling and increase isolation between antenna elements. In this part, a short explanation of various major techniques is done to better understand the working and then utilized a combination of them to reduce mutual coupling of proposed MIMO antenna system.

A. Structural Change of Ground Plane

This method is well known as DGS and consists of modifying the structure of the ground plane to change the current distribution [37]. MIMO systems use the effect of notch filters to minimize mutual coupling between radiating elements. In fact, a common use of the DGS method is to insert a slot in the ground plane [38]. The DGS solution is very easy to implement because its operation depends on the resonant frequency and not on the antenna type. However, the main drawback of this method is mainly integration issues on mobile phones.

B. Use of EBG (Electromagnetic Band Gap) Structure

Generally, in antenna decoupling, the EBG structure is similar to a notch filter [39]. In fact, a typical EBG cell has a mushroom-shaped structure containing patches and grounded vias. Moreover, the EBG structure can be used as a magnetic wall through which the phase of the reflection coefficient becomes zero for an incident wave. Therefore, surface wave propagation will be suppressed [40]. On the other hand, this method requires considerable space, especially for low frequencies [41]. Moreover, this solution is not commonly used in practice due to its complexity and large size [42]. In study [43], four rows of fork-shaped EBG patches were inserted between the E-plane coupling antennas to reduce mutual coupling. A mutual coupling reduction of 6.51 dB was achieved at 5.2 GHz when using the EBG structure.

C. Use of the Neutralization Line

This approach is generally used to ensure better isolation between two PIFA (Planar Inverted-F Antenna) antennas [44]. Indeed, it is a question of introducing a simple suspended metal line, integrated between the power supplies or the short circuits of the PIFA antennas. In addition, the neutralization line supports strong currents so that the direction of the current is radiated towards the antenna itself and not towards the power connector of the second antenna. It is also possible to cut all path couplings (OTA (over the air) couplings and ground plane power couplings) by changing the dimensions of the neutralization lines. For example, in study [45], the authors inserted an interrupted neutralization wire physically connected to two PIFA elements (operating in the UMTS band of 1920–2170 MHz).

The introduction of neutralizing lines was used to cancel pre-existing mutual coupling. This is because the line stores a certain amount of current that is fed from one antenna element to the other. In other words, the antenna achieved less than -18 dB of mutual coupling at a frequency of 2 GHz because an additional path was created to compensate for the antenna-to-antenna current on the circuit board. Recently, a new print diversity monopole antenna for WiFi and WiMAX applications was

presented in study [46]. It's based on the same concept, but with a much more complex kill line integration. The antenna consists of two crescent-shaped radiators placed symmetrically about a faulty ground plane, with neutralizing lines to achieve a bandwidth of 2.4 to 4.2 GHz and mutual coupling of less than -17 dB connected between them.

D. Using an Isolation Network

This method aims to reduce the mutual impedance or transmission coefficient between the radiating elements to zero while maintaining good impedance matching in each element [47]. In the literature, we have found various antenna array configurations based on 180° hybrid couplers or RF switches.

E. Use of Parasitic Resonators

This is similar to neutralizing wire-based solutions in that the parasitic resonator is integrated in the middle of the two antennas to minimize mutual coupling between them. In other words, this solution artificially creates an additional coupling path between antennas. However, simply changing the spacing between the radiating elements requires changing the structure of the resonator to ensure good isolation. This limitation then hinders the serial application of the parasitic resonator [48].

Although the above solutions overcome the coupling effect between the antennas, there are other innovative and more efficient means. In fact, recently, the development of metamaterials to design and optimize antenna characteristics has shown great importance, not only to minimize antenna size, but also to provide better isolation and reduce the spacing between elements radiating [49].

At this stage of our research, part of the solutions developed within the framework of the study of multi-antenna systems intended for wireless communications or intended to be used in applications of the diversity or MIMO type have been presented [50-53]. These solutions have been investigated with the aim of covering several wireless communication standards and improving the isolation between the antennas that make up these systems. Consequently, having antennas very close to each other and operating in neighboring or even identical frequency bands is an ever-present challenge because communication systems must have increasingly new, numerous, and innovative functionalities.

In the proposed study the EBG structure along with DGS is utilized to reduce the mutual coupling and explain in forthcoming sections.

IV. RESULTS AND DISCUSSIONS

Increasing the number of transmit and receive antennas without increasing radiated power can improve communication quality and channel capacity. The MIMO antenna design proposed in this article has four identical radiating elements, extracted by already designed unit element, as shown in Fig. 11. The overall dimensions of MIMO antenna system are $L_{sub} \times W_{sub}$ ($60 \times 48 \text{ mm}^2$), having edge to edge distance between all elements is 5mm, as depicted in Fig. 11.

Fig. 11. UWB-MIMO antenna system without decoupling structure.

A. Initial Prototype Simulation Results

The simulated S-parameters of the 4-element MIMO antenna without any decoupling structure are shown in Fig. 12. Due to the symmetry in structure, the S-parameter analysis can be easily performed. The $|S_{11}|$ of the MIMO antenna remain almost identical to the unit element having $|S_{11}| < -10\text{dB}$ bandwidth ranges 2–18 GHz. On the other hand the transmission coefficient $|S_{ij}|$, where $i,j=1,2$, offers a high value of more than -10 dB. This high value of transmission coefficient is not acceptable for present and future MIMO systems. The easiest way to reduce the value of $|S_{ij}|$ is to increase the edge-to-edge distance, however, it will increase the size of the antenna and thus compactness will vanish.

According to Fig. 13, the surface current circulation in the radiating element is high which leads to strong coupling as already indicated by the high values of $|S_{ij}|$. Surface currents generated by the excited antenna flow to the other non-excited elements, as shown in Fig. 13.

Fig. 12. S-parameters of UWB-MIMO antenna system.

Fig. 13. Effect of the current distribution of antenna 1 on the three other antennas at frequencies: (a) 8 GHz (b) 15 GHz.

Only one element of the MIMO antenna is energized (antenna 1), but we can see currents in the other three components that are not energized. As a result, without excitation, hot spots occur on at least one additional radiating element (2, 3 or 4). Although the maximum current on the unexcited antenna does not equal the maximum current on the excited antenna, it is sufficient to increase coupling between the components. However, compared to the minimum frequency in the operating band (2 GHz), the distance between them is only 0.03λ .

The mutual coupling comes from the capacitive coupling between the radiating elements and the current flowing on the PCB. Because the isolation value obtained is insufficient for a powerful multi-antenna system, thus a more effective way is required to reduce the coupling while leaving the four elements in their original places, i.e., to have a compact size MIMO antenna.

B. Design of SRR Unit Cells

A two small rectangular square split ring resonator (SRR) unit cells operating at frequencies corresponding to well-defined bands WiMAX and X-Band. Afterwards, a rectangular strip is loaded to widen the band of coverage by the SRR unit cell, as shown in Fig. 14.

Fig. 14. (a) Geometry of proposed SRR (b) Reflection and transmission coefficients of the proposed SRR.

For ease of understanding the S-parameter-based method is adopted and used to analyze the performance of the Metamaterial unit cell. The designing approach is based on a systematic approach to unit cell design, for this reason, the overall cell size should be smaller than the wavelength ($d\lambda$) (approximately $\lambda/11$ in presented case). The geometrical structure along with respective S-parameters is shown in Fig. 14. The unit cell of the metamaterial operates from 2.2–16.7 GHz band, covering almost the entire band offered by proposed unit element of the MIMO antenna. The metamaterial cell is mounted on an FR4 type epoxy dielectric substrate with a dielectric constant of 4.4, a loss factor of 0.02, and a thickness of 1.6mm. This SRR square has an outside side of 2 mm, a track width of 0.2 mm, and a 0.3 mm gap cut on one of these sides. It is two concentric rings with a spacing of 0.15 mm between them and an inner ring measures 1.3 mm on the outside. Before starting the simulation, an electric and magnetic wall was installed in a $2.5 \times 2.5 \times 5 \text{ mm}^3$ radiation box, these dielectric walls must be used to verify the SRR's requisite excitation conditions. The magnetic field must be positioned along the ring's axis to provide greater magnetic excitation and circulation of the induction current. To do this, two domain walls parallel to the XY- and XZ-plane and an electric wall are provided. The electric field is parallel to OY-axis and the propagation vector is

along the OX-axis to ensure a symmetrical current distribution. The optimized dimensions of the unit element are enlisted in Table II.

TABLE II. DIMENSIONS OF SRR UNIT CELL

Parameters	Values(mm)

L	0.75

C. Improved Insulation by Loading SRR and DGS

Initially, to improve the separation of this initial structure by known methods based on MTM applied to MIMO systems [54]. Therefore, four chains consisting of five SRR unit elements are inserted between the four excitation-radiating elements of the MIMO system. The UWB MIMO antenna configuration is illustrated in Fig. 15(a), the MIMO antenna design is the same as the previously design MIMO antenna with edge-to-edge gap of 5 mm, except that four strings of SSRs on the top layer of the substrate are added to improve the isolation between the antenna elements, (1-2, 2-3, 3-4 and 1-4). SRRs can act as a reflector and decrease the surface current between antenna elements which consequently reduce the mutual coupling between MIMO antenna elements. Furthermore, a t-shaped like dual slots were also etched in the ground plane which helps in further decrement of mutual coupling between elements placed side by side (1-2, 3-4), as depicted in Fig. 15(b).

Fig. 15. Proposed four-element MIMO UWB antenna configuration with decoupling network.

A fabricated prototype is used to verify the results of the MIMO antenna loaded with SRR and DGs, as depicted in Fig. 16. Comparison among $|S11|$ of the MIMO antenna loaded with decoupling structure is shown in Fig. 17. It can be observed that a good comparison between simulated and measured results is offered while covering the entire band spectrum globally allocated for UWB and Ku-band applications.

The mutual coupling of the MIMO antenna loaded with decoupling structure is depicted in Fig. 18. The antenna offers a low mutual coupling of less than -20 dB in the entire bandwidth having a good relationship among simulated and measured results.

Fig. 16. Manufactured MIMO UWB antenna system with decoupling structure.

Fig. 17. |S11| of MIMO antenna system with SRRs.

Fig. 18. |S12| (Simulated and measured) of 4-element MIMO UWB antenna system with isolation based on SRRs.

The other performance parameters that characterize the MIMO antenna are the envelope correlation coefficient (ECC) and diversity gain (DG). These parameters are analyzed and their impact on the overall performance of the antenna is considered. As already mentioned, the ECC measures the correlation between the radiating elements. It is also important to note that it is better to have the minimum possible ECC to crystallize the good performance of our MIMO system. In a MIMO system, the signals received must be sufficiently decorrelated to have good diversity. The parameter that describes the independence of the signals is called the correlation envelope. It is zero in the ideal case and must be less than 0.5 in order to obtain good diversity. In a 4-port MIMO

system, ECC can be determined between ports 1, 2, 3, and 4 using the expression (1) and (2).

$$ECC = \frac{\left| \int \int_{4\pi} (B_i(\theta, \phi)) \times (B_j(\theta, \phi)) d\Omega \right|^2}{\int \int_{4\pi} |(B_i(\theta, \phi))|^2 d\Omega \int \int_{4\pi} |(B_j(\theta, \phi))|^2 d\Omega} \quad (1)$$

$B_i(\theta, \phi)$ is the 3D radiation pattern when the i^{th} antenna is excited, $B_j(\theta, \phi)$ is the 3D radiation pattern when the j^{th} antenna is excited, Ω is the solid angle [55].

The disadvantage of this formula is to require a very precise estimation of the radiation patterns and therefore to lead to heavy calculations [56]. Another simplified solution is to calculate the correlation envelope using the S parameters [57]. Therefore, for a system with N antennas, equation (2) allows us to use:

$$ECC = \frac{\left| \sum_{n=1}^N S_{i,n}^* S_{n,j}^* \right|^2}{\prod_{k=i,j} \left[1 - \left| \sum_{n=1}^N S_{i,n}^* S_{n,j}^* \right| \right]} \quad (2)$$

N: Number of antennas, i and j denote antennas i and j

To use this formula (2), it is however necessary to satisfy certain conditions. When one of the antennas is powered, the others are loaded with a reference impedance (usually 50 Ω). The antenna system must be lossless, therefore with very high radiated efficiency [58], and low mutual coupling (< -6 dB).

To ensure that the signal-to-noise ratio (SNR) of the combined signal is better than the signal-to-noise ratio received from a single antenna in a MIMO system, the diversity gain (DG) should also be set to its recommended value should be inspected against value of about 10 dB.

The comparison among simulated and measured ECC and DG is shown in Fig. 19. The ECC offered by proposed work is less than 0.125 while the diversity gain > 9.9 dB is found, as shown in Fig. 19(a) and (b), respectively.

Table III shows a comparison of the UWB MIMO antenna with other existing antennas in the literature for similar applications. It can be observed that work presented in [32 – 33] offers large size as compared to proposed work along with setback of low mutual coupling and high ECC value. On the other hand, although the antenna proposed in [29-31, 34-35] offers a relatively compact size but most of the antennas are 2-port MIMO along with that they have set back of not covering the lower cut off frequency of UWB spectrum and high value of mutual coupling. Thus, it is evident from the comparison with recent works that proposed work offers a good combination of 4-port compact size MIMO antenna having UWB spectrum along with low mutual coupling and ECC values.

TABLE III. COMPARISON OF UWB MIMO ANTENNA

Ref	Dimensions (mm xmm)	Element Number	Band With (GHz)	Mutual Coupling (dB)	Gain Range (dBi)	Radiation Efficiency(%)	ECC
[29]	30 x 18	2	4.3 – 15.6	< -15	2.5 – 5.35	89	< 0.05
[30]	35 x 35	4	3.8 - 15	< -20	3 – 5	Not given	< 0.07

V. CONCLUSION

In this work, a novel technique was developed to enhance isolation between two antennas in MIMO systems for 5G networks and IoT applications. This approach involved incorporating Split Ring Resonators (SRRs) between the MIMO elements, which led to excellent simulation results for interconnection. We analyzed various simulation parameters and constructed a physical system to measure factors such as S-parameters. The system demonstrated impressive diversity performance, with an envelope correlation coefficient (ECC) of less than 0.07 across the relevant frequency bands. The proposed design features four resonators arranged in an anti-parallel configuration, achieving over 17 dB isolation throughout the operating range. We evaluated both simulation and experimental data for gain, S-parameters, isolation, ECC, and radiation patterns. The results validate that using decoupling SRRs effectively reduces inter-element coupling and provides a strong diversity response. These findings suggest that the proposed MIMO antenna design is promising for ultra-wideband (UWB) applications. Future work could explore its potential in wireless communication systems, such as base station terminals.

Novel Data-Driven Machine Learning Models for Heating Load Prediction: Single and Optimized Naive Bayes

Fangyuan Li*

Zhejiang Business Technology Institute, Ningbo, Zhejiang, 315012, China

Abstract—Numerous approaches can be employed to create models for assessing the heat gains of a building arising from both external and internal sources. This modeling process evaluates effective operational strategies, conducts retrofit audits, and projects energy consumption. These techniques range from simple regression analyses to more intricate models grounded in physical principles. A prevalent assumption underlying all these modeling techniques is the requirement for input variables to be derived from authentic data, as the absence of realistic input data can lead to substantial underestimations or overestimations in energy consumption assessments. In this paper, eight input parameters, including relative compactness, orientation, wall area, roof area, glazing area, overall height, surface area, and glazing area distribution, are employed for training proposed Naive Bayes (NB)-based machine learning models. Utilizing a novel approach, this research explores the application of Beluga Whale Optimization and the Coot Optimization algorithm for optimizing the Naive Bayes model in heating load prediction. By harnessing the collective intelligence of Beluga Whales and drawing from the cooperative behavior of coots, the research aims to improve the model's predictive capabilities, which is of paramount importance in building energy management. Based on the comparative analysis between developed models (NB, NBCO, and NBBW), it is attainable that NBCO and NBBW, as two optimized models, have 2.4% and 1.3% higher R^2 values, respectively. Also, the RMSE of the NBCO was, on average, 19-33% lower than that of the two other models, confirming the high accuracy of NBCO. This innovative integration of bio-inspired optimization techniques with machine learning demonstrates a promising avenue for optimizing predictive models, offering potential energy efficiency and sustainability advancements in the built environment.

Keywords—Prediction models; heating load demand; building energy consumption; Naive Bayes; metaheuristic optimization algorithms

I. INTRODUCTION

In contemporary facility management, a critical challenge managers face revolves around assessing and predicting a building's energy requirements, particularly those equipped with air conditioning systems. This challenge stems from the notable variability exhibited in the energy feeding patterns generated by these systems. These fluctuations can be attributed to changes in external climate situations, the ebb and flow of occupants throughout the day, and internal loads incorporated within the building [1]. A holistic understanding of building performance is imperative to address this challenge and optimize building energy consumption. This begins with the initial identification

of energy resources and the principal end-uses within the building. Energy resources typically natural gas, encompass electricity, and district heating supply, while the major end-uses comprise heating, ventilation, and air-conditioning (HVAC) systems, domestic hot water, lighting, plug-loads, elevators, kitchen equipment, ancillary appliances, and various equipment [2]. Such an integrated approach can enhance energy management and sustainability in the built environment.

Scholars have developed diverse assessment systems and modeling methodologies to propose an optimal predictive tool for estimating building energy consumption [3, 4]. Within this framework, two conventional devices for evaluating the Energy Performance of Buildings (EPB) through modeling and simulation have been highlighted in lectures [5]. Historically, the physical attributes of buildings, such as their geometry, were used as the basis for energy performance simulations. However, using such predictors has limitations, as it entails controlling factors that are challenging to manipulate in practical applications [6]. This can be considered a drawback of these traditional approaches. The primary challenge in advancing simulation and modeling techniques is the accurate estimation of EPB, a time-consuming process demanding meticulous attention due to including many influencing factors.

Furthermore, using various simulation programs may yield assessments with varying degrees of accuracy [7]. These methods can be relied upon to calculate the impact of individual factors on EPB when all other variables remain constant. Notably, there are established computer software tools like Designer's Simulation Toolkit (DeST) [8], Energy Plus [9], and DOE-2 [10] that facilitate these modeling and simulation endeavors.

Engineers have proposed using inverse (data-driven) modeling to remedy the limitations associated with simulation tools to explore EPB [11]. In this approach, a robust assessment of the impact of significant factors (e.g., roof area, relative compactness, and orientation) on EPB can be achieved by ensuring a sufficient quantity of data samples [12–15]. Various Machine Learning (ML) models, due to their ease of implementation and high-performance speed [16–18], were highly regarded by scholars.

For instance, Kalogirou and Bojic [19] employed a recurrent neural network to predict the energy feasting of a passive solar building. Pao [20] compared various models and concluded that ANN models are well-suited for forecasting building energy

consumption, effectively capturing complex non-linear relationships. Ben – Nakhi and Mahmoud [21] used *ANN* models to predict building cooling loads, achieving a strong fit to experimental data and optimizing thermal energy storage in public and office buildings.

In addition to Artificial Neural Networks (*ANNs*), various other artificial intelligence (AI) tools, including Support Vector Machine (*SVM*) [22] regression, neuro–fuzzy systems [23], and random forests [24], have been applied to address EPB challenges. For instance, Li et al. [25] conducted a qualified study on cooling load calculations, demonstrating the effectiveness of *SVM* and General Regression Neural Network (*GRNN*) compared to conventional *ANNs*. Moreover, researchers [26] have integrated *SVM* and wavelet transforms with Partial Least Squares Regression (*PLS*) to model office building heating and cooling loads, yielding precise insights. While AI has proven valuable in EPB, computational challenges have prompted the use of metaheuristic algorithms like Genetic Algorithm and Particle Swarm Optimization [27, 28, 38], which this study further explores, focusing on Beluga Whale Optimization (*BWO*) [29] and the Coot Optimization algorithm (*COA*) [30] for optimizing the Naive Bayes (*NB*) [31] model in heating load prediction.

The *NB* model is a widely used machine learning (*ML*) algorithm known for its simplicity and effectiveness in classification tasks in many applications similar to this study [32–34]. It is based on Bayes' theorem and chin independence assumption, making it particularly suited for applications where the independence assumption holds. It calculates the likelihood of a particular instance belonging to a specific class based on the probabilities of its features occurring in each class. This study embarks on developing *NB*-based models for predicting heating loads (*HL*) in buildings. Two distinct optimizers, as mentioned above (*BWO* and *COA*), were employed to optimize the training process. The predicted results of the *three* models were subjected to comparison utilizing performance metrics, including R^2 , *RMSE*, *MSE*, *U95*, and *IOA*. Afterward, the most optimal hybrid model for predicting *HL* in buildings was identified.

The choice of Naive Bayes (*NB*)--based machine learning models is particularly appropriate for addressing this type of problem due to several reasons. Firstly, *NB* models are known for their simplicity and computational efficiency, making them well-suited for handling large datasets and multiple input variables, such as those involved in predicting building heating loads. Secondly, *NB* models assume conditional independence between input features, which, despite being a simplification, often works well in practice, especially in complex systems where interactions between variables may not be easily discernible. This makes *NB* models robust and less prone to overfitting compared to more complex algorithms. Additionally, the probabilistic nature of *NB* models allows for clear interpretability of the results, providing insights into the contribution of each feature to the prediction, which is valuable in the situation of building energy management. Finally, the integration of bio-inspired optimization techniques like *BWO*

and *COA* further enhances the model's ability to fine-tune its parameters, leading to improved accuracy and reliability in heating load predictions. This combination of simplicity, efficiency, and optimization makes *NB*-based models an effective choice for tackling the challenges of energy modeling in buildings. The paper is organized into five sections. The Abstract provides a concise summary of the study's objectives, methods, and key findings. The Introduction in Section I outlines the research background, related works, and significance. Materials and Methods in Section II details the dataset, machine learning models, and the hybrid optimization algorithms used, along with the evaluation metrics. The Results in Section III presents the outcomes of the modeling process. Discussion in Section IV offers a validation of present study, compares their performance, and addresses the study's limitations. Finally, the Conclusion in Section VI summarizes the findings, discusses implications for energy management, and suggests avenues for future research.

II. MATERIALS AND METHODS

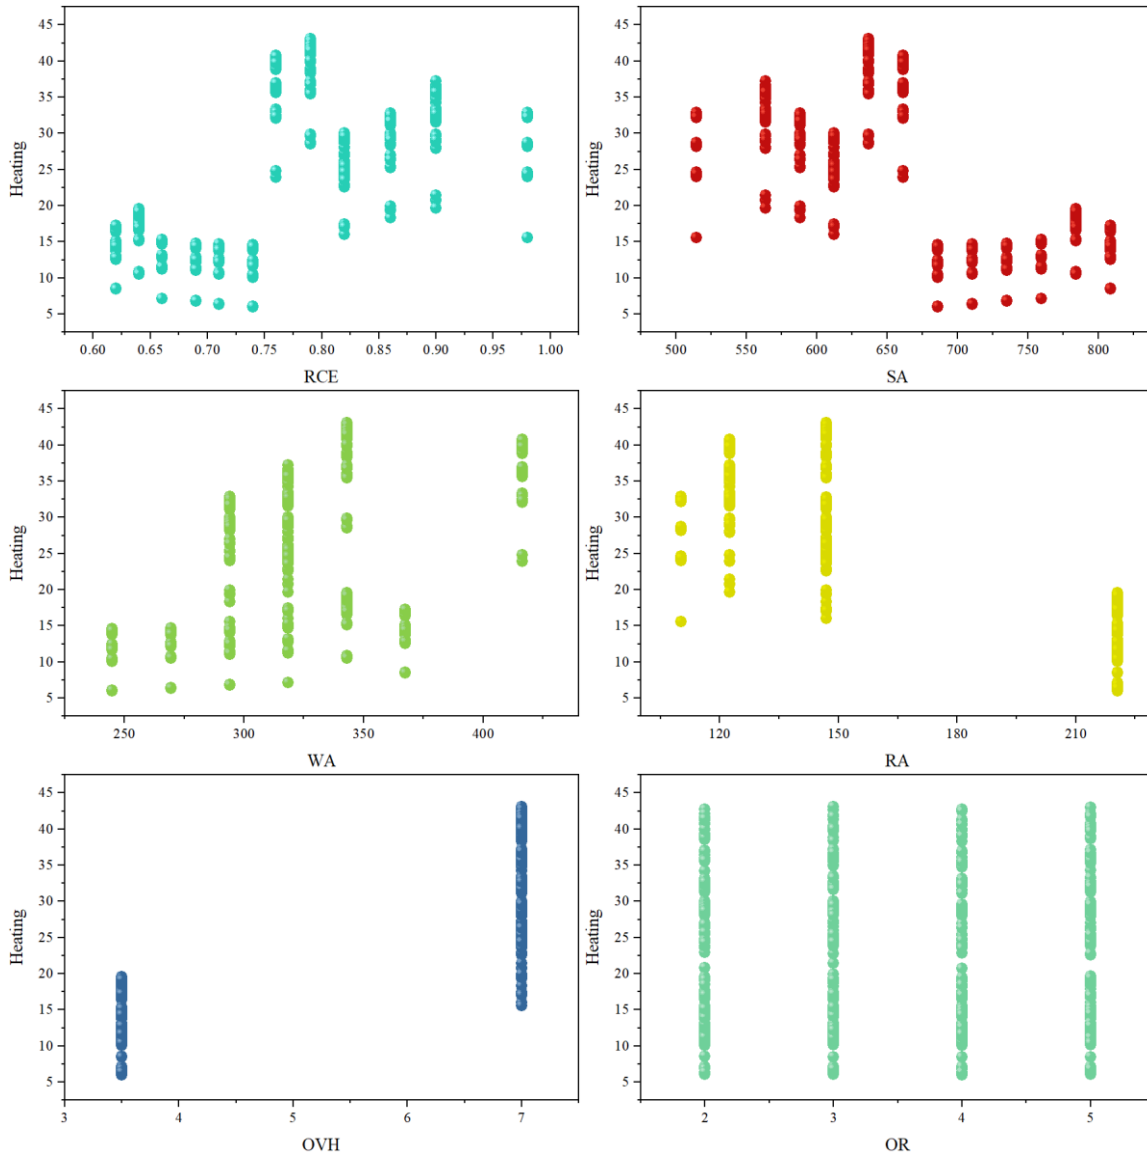

A. Dataset Description

The primary aim of this study is to predict *HL* in buildings by utilizing data that captures energy consumption patterns. A simulation approach involving the *NB* model is employed to accomplish this objective, with the training process incorporating two distinct optimizers designed to optimize *NB* hyper parameters. The inputs provided to the predictive model encompass various parameters, including relative compactness (*RCE*), surface area (*SA*), overall height (*OVH*), roof area (*RA*), glazing area (*GA*), wall area (*WA*), orientation (*OR*), and glazing area distribution (*GAD*). The data relating to the input and output parameters, including minimum, maximum, average, standard deviation, Median, and Skewness, is reported in Table I. Minimum and maximum values identify the lowest and highest data points, establishing the data's range. The average, also known as the mean, provides a central measure to understand the typical value in the dataset. Standard deviation quantifies the dispersion of data points, indicating how closely they cluster around the mean. Conversely, the median represents the middle value when the data is ordered, making it robust to outliers. Skewness measures the asymmetry of the data distribution, indicating whether it is skewed to the left or right.

The scatter plot in Fig. 1 demonstrates the correlation among input and output parameters. The data distribution related to the *RCE*, *SA*, and *WA* input parameters is vertically highly asymmetric with the highest skewness values (*RCE* and *WA* skewed right of the average and *SA* skewed left of the average). Data points of *OVH* are located in two values (3.5 and 7) where *OVH* = 3.5 is related to lower heating values (below 20), and *OVH* = 7 corresponds to the heating values higher than 20. The *OVH* and *OR* data points' distribution is highly symmetric, with skewness values approximately equal to zero and their median and average values the same. *GA* and *GAD* are the only parameters with zero values, indicating that their effect is neglected in some samples.

TABLE I. THE STATISTICAL PROPERTIES OF THE INPUT ADJUSTABLE OF HEATING

Variables	Category	Indicators					
		Min	Max	Median	Avg	Skew	St.Dev.
RCE	Input	0.62	0.98	0.75	0.764	0.496	0.106
SA	Input	514.5	808.5	673.75	671.708	-0.125	88.09
WA	Input	245	416.5	318.5	318.5	0.534	43.63
RA	Input	110.25	220.5	176.604	176.604	-0.163	45.17
OVH	Input	3.5	7	5.25	5.25	-2.9E - 19	1.751
OR	Input	2	5	3.5	3.5	2.68E - 18	1.119
GA	Input	0	0.4	0.234	0.235	-0.060	0.133
GAD	Input	0	5	2.813	2.813	-0.089	1.551
Heating	Output	6.01	42.96	22.307	22.307	0.361	10.09

B. Machine Learning Model and Hybrid Optimization Algorithms

1) *Naive bayes (NB)*: The NB is a robust probabilistic classification method grounded in Bayes' theorem, streamlining the modeling process by assuming input variable independence. When integrated with kernel density approximations, NB exhibits promise for significant enhancements in predictive accuracy, as indicated in previous studies [35, 36]. Notably, NB stands out due to its scalability, characterized by a need for only a few input parameters that increase linearly with the number of predictors. This differentiates it from computationally demanding classifiers. The closed-form training methodology of NB is remarkably efficient, ensuring swifter performance compared to more intricate computational techniques.

The NB classifier represents an advanced system seamlessly incorporating the *NB* probability model into its decision-making framework. Its foundation lies in applying the *max* a posteriori (*MAP*) choice rule, a proven approach for selecting the most likely supposition from a set of possible choices. Furthermore, it is worth noting the existence of a closely linked classifier known as the Bayes classifier. This formidable algorithm plays a pivotal role in assigning class labels $y = C_k$, with k ranging from 1 to K , a process involving an intricate assessment of multiple factors and variables to classify data points into predetermined categories.

$$y = \operatorname{argmax}_p(C_k) \prod_{i=1}^n p((x_i | C_k)) \quad (1)$$

2) *Beluga whale optimization (BWO)*: The BWO method simulates beluga whale (*BW*) behaviors for optimization, with two phases: exploration and refinement, using beluga whales as search agents updating candidate solutions within a specified area. The matrix maps the positions of these search agents (Zhong, Li, und Meng 2022):

$$X = \begin{bmatrix} x_{1,1} & x_{1,2} & x_{1,d} \\ x_{2,1} & x_{2,2} & x_{2,d} \\ x_{n,1} & x_{n,2} & x_{n,d} \end{bmatrix} \quad (2)$$

Within this framework, 'n' signifies the people size of *BW*, and 'd' denotes the dimensionality of design variables, with the fitness values of each individual within this population being meticulously recorded as follows:

$$F_X = \begin{bmatrix} f(x_{1,1}, x_{1,2}, \dots, x_{1,n}) \\ f(x_{2,1}, x_{2,2}, \dots, x_{2,d}) \\ f(x_{n,1}, x_{n,2}, \dots, x_{n,d}) \end{bmatrix} \quad (3)$$

The changeover from examination to exploitation in the BWO algorithm is determined by the mathematical representation of the balance factor B_f .

$$B_f = B_0(1 - T/2T_{max}) \quad (4)$$

Throughout each iteration, random fluctuations within the range of (0, 1) are experienced by the value of B_0 , with the current iteration being denoted by T , and the *max* allowable number of iterations being represented by T_{max} . The exploration stage is initiated when the balance factor (B_f) surpasses the threshold of 0.5, while the exploitation stage is engaged when B_f is either less than or equal to 0.5. As the number of iterations (T) escalates, the variability in B_f is observed to diminish from the initial span of (0, 1) to the narrower interval of (0, 0.5). This transformation underscores a conspicuous alteration in the probability of transitioning between the exploitation and exploration stages, with the likelihood of entering the exploitation phase being augmented as the iteration count progressively increases.

- Exploration phase

The exploration phase in *BWO* is inspired by observed synchronized swimming behaviors of captive beluga whales, influencing the search agents' coordinates and subsequent position modifications.

$$\begin{cases} X_{i,j}^{T+1} = X_{i,pj}^T + (X_{r,p1}^T - X_{i,pj}^T)(1 + r_1)\sin(2\pi r_2), & j = \text{even} \\ X_{i,j}^{T+1} = X_{i,pj}^T + (X_{r,p1}^T - X_{i,pj}^T)(1 + r_1)\cos(2\pi r_2), & j = \text{odd} \end{cases} \quad (5)$$

Within this equation, the current iteration count, denoted as T , establishes the framework. The expression $X_{i,j}^{T+1}$ represents the newly adjusted location for the i -th beluga whale along the j -th dimension. Concomitantly, pj (with j spanning from 1 to d) is symbolic of a value randomly selected from the d -dimensional space. Moreover, $X_{i,pj}^T$ designates the i -th *BW* position along the pj dimension at iteration T . Furthermore, both $X_{i,pj}^T$ and $X_{r,pj}^T$ serve to depict the prevailing positions of the i -th *BW* and a stochastically chosen r -th beluga whale, where r is selected randomly. Additionally, r_1

and r_2 are arbitrary values within the range of (0, 1). It is of significance to note that the sine (\sin) and cosine (\cos) functions, applied to $(2\pi r_2)$, delineate the alignment of the mirrored BW fins toward the water's external. The selection of dimensions using odd or even numbers determines the reflection of synchronized or mirrored behaviors exhibited by BW during swimming or diving in the updated position. To enhance the stochastic components within the exploration stage, two random values identified as r_1 and r_2 , are utilized.

- Exploitation Phase

The exploitation stage in BWO is inspired by BW cooperative foraging and adaptive movement patterns, involving sharing positional information and coordination, utilizing the Levy flight strategy for convergence enhancement (Mantegna 1994), which has been integrated into the exploitation phase of BWO . It is postulated that these whales employ the Levy flight strategy for capturing prey, and this strategy is expressed mathematically as follows:

$$X_i^{T+1} = r_3 X_{best}^T - r_4 X_i^T + C_1 \cdot L_F \cdot (X_r^T - X_i^T) \quad (6)$$

In the context of the current iteration designated as " T ," the following elements are encompassed: X_i , which serves as a representation of the current position of the i -th beluga whale and " X_r ," which represents the current position of a beluga whale that has been randomly selected. Furthermore, " X_i^{T+1} " denotes the updated position of the i -th beluga whale, and " X_{best} " designates the optimal position among all the beluga whales. Additionally, " r_3 " and " r_4 " signify randomly generated numbers that fall from 0 to 1. Lastly, " C_1 " is ascertained utilizing a calculation involving " r_4 ," specifically it determines the value of r_4 multiplied by the expression " $C_1 = 2r_4(1 - T/T_{max})$ " thereby representing the random jump strength that quantifies the magnitude of a Levy flight [37].

The Levy flight function, denoted as L_F , is computed according to the following procedure.

$$L_F = 0.05 \times \frac{u \times \sigma}{|v|^{1/\beta}} \quad (7)$$

$$\sigma = \left(\frac{\Gamma(1+\beta) \times \sin(\pi\beta/2)}{\Gamma((1+\beta)/2) \times \beta \times 2^{(\beta-1)/2}} \right) \quad (8)$$

In this context, β , the default constant set to 1.5, is accompanied by normally distributed random numbers u and v .

- Whale fall

In BWO iterations, whale falls are simulated to mimic the beluga whale population changes. Assuming that some whales relocate or descend to the ocean floor, positions and step magnitudes are adjusted to maintain population size, resembling the natural process of whale fall decomposition.

$$X_i^{T+1} = r_5 X_i^T - r_6 X_r^T + r_7 X_{step} \quad (9)$$

" X_{step} " is the step size of whale fall, which is determined as follows: where r_5 , r_6 , and r_7 are random numbers within the range of (0, 1)."

$$X_{step} = (u_b - l_b) \exp(-C_2 T / T_{max}) \quad (10)$$

In this context, the parameter C_2 is possessed, functioning as the step factor and being linked to the probability of a whale fall event, along with the population size ($C_2 = 2W_f \times n$). Furthermore, the variables u_b and l_b are present, signifying the *upper* and *lower* boundaries of variables, respectively. It is observable that the extent of the step size is influenced by a range of factors, encompassing the constraints established by the design variables, the ongoing iteration, and the *max* permissible number of iterations.

This model calculates the probability of a whale falling (W_f) as a linear function:

$$W_f = 0.1 - 0.05T/T_{max} \quad (11)$$

The decrease in the probability of a whale falling from 0.1 in the initial iteration to 0.05 in the final iteration indicates a trend in which, as the food source is approached more closely by beluga whales during the optimization process, the risk to beluga whales is mitigated.

3) *Coot optimization algorithm (COA)*: The COA is influenced by the group behaviors of Coots, a water bird species, and utilizes a metaheuristic optimization strategy. Coots exhibit various movements on water as they seek food sources or specific destinations, including chain, random, leader-driven, and leader-adjusted motions. The COOT algorithm integrates these behaviors into its structure. In its application, the algorithm commences by randomly establishing a population, following the guidelines of Eq. (12) as specified in (Naruei und Keynia 2021):

$$CootPos(i) = rand(1, N) \times (UB - LB) + LB \quad (12)$$

$CootPos(i)$ signifies the geographical coordinates of an individual Coot, where N matches the dimensionality of issues or the count of involved variables. UB and LB , on the other hand, represent the *upper* and *lower* confines of the search space in which the pursuit is performed.

$$UB = [UB_1, UB_2, \dots, UB_N], LB = [LB_1, LB_2, \dots, LB_N] \quad (13)$$

After the initial population setup, four different crusade designs are used to adjust the coots' situations.

- Random Movement

Following the equation described in Eq. (14) below, position Q is first randomized for this particular movement:

$$Q = rand(1, N) \times (UB - LB) + LB \quad (14)$$

To avoid becoming trapped in local optima, the position is updated in line with the equation presented in Eq. (15):

$$CootPos(i) = CootPos(i) + A \times R_2 \times (Q - CootPos(i)) \quad (15)$$

To determine A , the R_2 is a random number that exists within the range [0, 1], and its value is calculated by an equation given in Eq. (16):

$$A = 1 - L \times \left(\frac{1}{iter} \right) \quad (16)$$

In this case, $Iter$ is the highest achievable number of iterations, and L is a reference to currently recorded numbers.

- Chain Movement

The regular location of two chick birds may be calculated by applying the formula in Eq. (17) to execute chain movements.

$$CootPos(i) = \frac{CootPos(i-1) + CootPos(i)}{2} \quad (17)$$

In this case, $CootPos(i - 1)$ indicates the placement of another coot in the arrangement.

- Adjusting Location Giving to the Leader

A coot bird's place in each group is adjusted according to the leader's location, which causes the follower to move closer to the leader. The method given in Eq. (18) is used to estimate the leader's designation:

$$K = 1 + (i \text{ MOD } NL) \quad (18)$$

$$LeaderPos(i) = \begin{cases} B \times B_3 \times \cos(2\pi R) \times (gBest - LeaderPos(i)) + gBest & B_4 < 0.5 \\ B \times B_3 \times \cos(2\pi R) \times (gBest - LeaderPos(i)) - gBest & B_4 \geq 0.5 \end{cases} \quad (20)$$

In this specific scenario, $gBest$ characterizes the optimal possible site, and B_3 and B_4 are haphazardly generated figures within the break $[0, 1]$. The value B is calculated using the equation provided in Eq. (21):

$$B = 2 - L \times \left(\frac{1}{Iter}\right) \quad (21)$$

a) Performance evaluation metrics: In the evaluation of the performance of a regression model, it is customary to employ the following metrics:

- Coefficient of Determination (R^2): Commonly represented as R^2 , measures the percentage of inconsistency in the reliant on variable that can be attributed to the sovereign variables within a statistical model. The following formula demonstrates it:

$$R^2 = \left(\frac{\sum_{i=1}^n (t_i - \bar{w})(v_i - \bar{v})}{\sqrt{[\sum_{i=1}^n (v_i - \bar{w})^2][\sum_{i=1}^n (v_i - \bar{v})^2]}} \right)^2 \quad (22)$$

- Error evaluation metrics (RMSE, MSE): $RMSE$ (Root Mean Square Error) and MSE (Mean Square Error) are statistical metrics that quantify the average magnitude and accuracy of errors among predicted and observed values in a model, with $RMSE$ emphasizing the root of the squared differences. These metrics are mathematically represented in Eq. (23) and (24) as follows:

$$RMSE = \sqrt{\frac{1}{n} \sum_{i=1}^n (v_i - w_i)^2} \quad (23)$$

$$MSE = \frac{1}{n} \sum_{i=1}^n (v_i - w_i)^2 \quad (24)$$

- Uncertainty 95% (U95): This metric illustrates the range in which 95% of the predicted values correspond to the actual observed values. It provides valuable insights into

K represents the index of leaders, i refers to the supporter coot bird's sequence, and NL indicates the total total of leaders in the group.

Following the formula in Eq. (19), a coot's position will be modified during this specific motion.

$$CootPos(i) = LeaderPos(K) + 2 \times R_1 \times \cos(2R\pi) \times (LeaderPos(K) - CootPos(i)) \quad (19)$$

$CootPos(i)$ refers to the present location of the coot bird, and $LeaderPos(K)$ stands for the chosen leader's position. R_1 is a randomly generated number within the range of $[0, 1]$, and R is another random number within the range of $[-1, 1]$. These parameters are utilized in the location update calculation outlined in Eq. (19).

- Leader Movement

The leadership roles experience modifications as outlined in Eq. (20), aiming to shift from locally optimal positions to globally optimal ones.

the correctness and dependability of a model's predictions, particularly when evaluating its variation and level of uncertainty. The mathematical expression of this metric can be found in Eq. (25).

$$U95 = \sqrt{\frac{\sum_{i=1}^n (v_i - \bar{v})^2}{(n * (n - 1))}} \quad (25)$$

- Index of Agreement (IOA): IOA is a metric used to evaluate the agreement or accuracy of model predictions compared to observed data, typically expressed as a value between 0 and 1. The Eq. (26) represents it below:

$$IOA = 1 - \frac{\sum_{i=1}^n |w_i - v_i|}{\sum_{i=1}^n (|w_i - \bar{w}| + |v_i - \bar{v}|)} \quad (26)$$

In all equations:

n : quantity of samples,

v_i : denotes the individual predicted cost,

\bar{v} : indicates the mean of the predicted morals,

w_i : stands for the experimentally measured cost,

\bar{w} : represents the average of the experimentally measured values.

III. RESULTS

In this research paper, the assessment of heating energy consumption relies on utilizing a Naive Bayes (NB) model. Two optimization algorithms, COA and BWO, have been employed to assess the model's performance and training procedure. To create the requisite datasets for training, validation, and testing, a partitioning scheme of 70% for training, 15% for validation, and 15% for testing has been implemented.

In Table II, it is evident that the R^2 values exhibit a range, with the lowest value of 0.947 (corresponding to the NB model) and the highest value of 0.987 (associated with the NBCO

model). Interpreting the R^2 , it is apparent that the NBCO model, with the highest R^2 , indicates superior model performance. The NBBW model, which achieved a R^2 of 0.975, closely follows as the second-best performer.

RMSE and MSE represent the amount of error according to their definitions. The smaller values of these metrics indicate better model performance. For the NB model, the highest values of RMSE and MSE are 2.050 and 4.204, respectively. In contrast, for the NBCO model, these values are significantly lower at 1.377 and 1.896, demonstrating the superior performance of the NBCO model.

U95, representing data uncertainty, shows that a model's performance improves as this value decreases. According to Table II, the U95 values for models NBCO, NBBW, and NB are 3.747, 4.676, and 5.677, respectively.

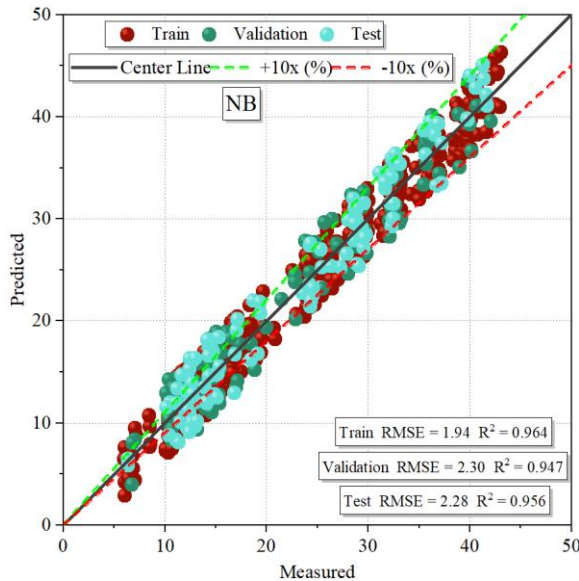

The metric IOA indicates the agreement or accuracy of the model predictions associated to the practical data, and its value falls within the range of 0 to 1. NBCO, with an IOA of 0.995, ranks the highest, demonstrating superior performance. NBBW and NB models are second and third in model quality, respectively.

TABLE II. THE RESULT OF THE DEVELOPED MODELS

Model	Phase	Index values				
		RMSE	R2	MSE	U95	IOA
NB	Train	1.940	0.964	3.764	5.375	0.991
	Validation	2.298	0.947	5.282	6.354	0.986
	Test	2.278	0.956	5.188	6.278	0.988
	All	2.050	0.960	4.204	5.677	0.990
NBCO	Train	1.325	0.985	1.757	3.598	0.996
	Validation	1.491	0.978	2.222	4.104	0.994
	Test	1.490	0.980	2.219	4.034	0.994
	All	1.377	0.983	1.896	3.747	0.995
NBBW	Train	1.605	0.975	2.575	4.429	0.994
	Validation	1.880	0.967	3.536	5.115	0.991
	Test	1.914	0.964	3.662	5.276	0.991
	All	1.698	0.972	2.882	4.676	0.993

Fig. 2. displays a scatter plot for hybrid models, illustrating the variation among predicted and measured values. This scatter plot is generated using RMSE and R^2 values, which primarily influence data dispersion. A decrease in RMSE corresponds to an increase in data density. Furthermore, a higher R^2 value indicates a more precise fit of the line to the data. Based on the visual representations in the plots, it is evident that three primary lines can be identified: a central line, a line representing a 10% overestimation, and a line depicting a 10% underestimation.

After explicit consideration, it is apparent that the minimum R^2 value, at 0.947, is associated with model NB, whereas model NBCO exhibits the highest value, 0.985. Furthermore, the highest RMSE is observed in model NB, which is equal to 2.30, and the lowest value for model NBCO is 1.33, representing a 47% reduction in error. Based on these findings, it can be concluded that NBCO is the superior choice for predicting heating load.

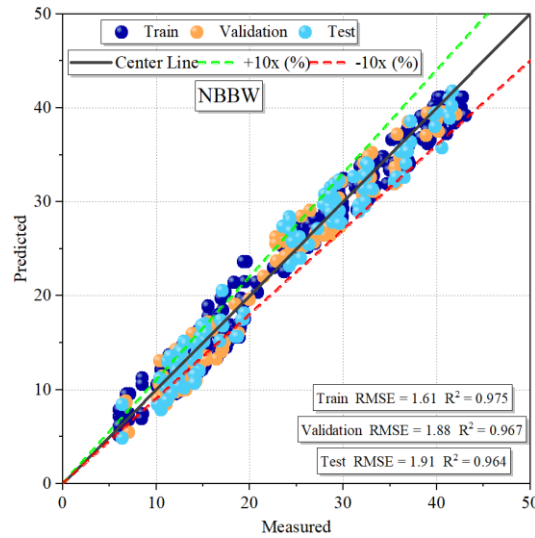

Fig. 2. The hybrid model's created scatter plot.

Fig. 3 illustrates the variations in error metrics ($RMSE$ and MSE) and R^2 values across the three models in this study. According to the trend lines for $RMSE$ and MSE , it is observed that errors in all models initially increase during the train phase. However, there is a noticeable decrease from the validation phase to the test. In summary, after comparing the error rates of $RMSE$ and MSE , it can be deduced that NBCO, with values of

1.377 and 1.896, is the most accurate prediction model, while NBBW and NB are the second and third-ranking models, individually. In all phases, the value of R^2 for NBCO is higher than NBBW and NB by approximately 1.13% and 2.396%, which again shows the superiority of the NBCO.

Fig. 3. Comparison between models corresponding $RMSE$, R^2 , MSE .

The histogram distribution diagram, depicting the error percentages of models, is presented in Fig. 4. The horizontal axis displays the percentage of errors, while the vertical axis represents the frequency of occurrences for each model during the training, validation, and test phases. In the basic *NB* model, the error percentage falls within the range of approximately -40 to 40, with the highest frequency around 90. In the case of the

two subsequent hybrid models, the error ranges for *NBCO* and *NBBW* are approximately -20 to 20 and -30 to 30, correspondingly. The highest frequencies of error values near zero percent for *NBCO* and *NBBW* are 100 and 120, respectively.

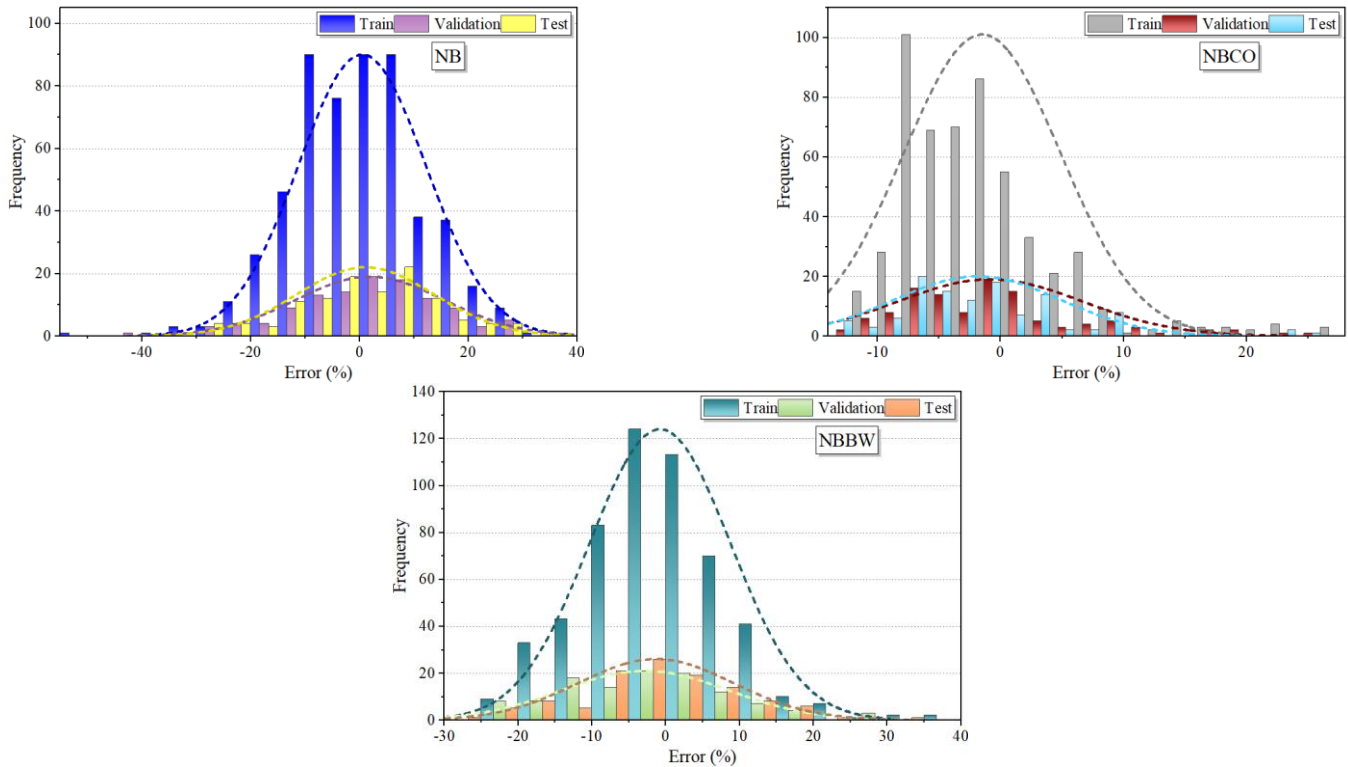

Fig. 4. The error ratio for the hybrid models is created on the Histogram distribution plot.

The multi-line diagram illustrating the error percentages of the models is presented in Fig. 5. The horizontal axis represents the number of samples, and the vertical axis is divided into three components: the blue axis represents the error rate of model *NB*. At the same time, the brown and pink axes correspond to models *NBCO* and *NBBW*, respectively. It should

be noted that the error percentage range for the *NB* model spans approximately from -40 to 40 during the train, validation, and test phases. In contrast, for the *NBCO* model, the range extends from -20 to just above 20, while for the *NBBW* model, it falls within the range of approximately (-30 to 30).

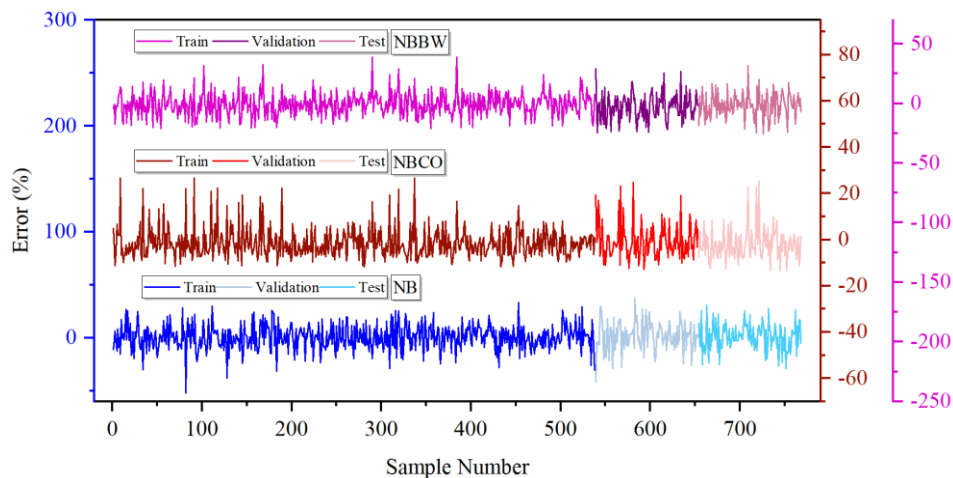

Fig. 5. The Multi-line plot for errors of the developed models.

IV. DISCUSSION

A. Validation of Present Study

The validation of the developed NBCO model in this study demonstrates its superior performance compared to existing models. Table III presents a comparison among the NBCO model from the present study and the PSO-MLP model by Zhou et al. (Zhou u. a. 2020). The NBCO model achieves an R^2 value of 0.985, significantly higher than the 0.9126 obtained by the PSO-MLP model. This indicates that the NBCO model explains a larger proportion of the variance in heating load predictions, showcasing its enhanced predictive power. Additionally, the RMSE of the NBCO model is 1.325, which is substantially lower than the 2.9736 RMSE reported for the PSO-MLP model. A lower RMSE reflects higher accuracy in the predictions, further validating the effectiveness of the NBCO model in accurately forecasting heating loads. These results highlight the advantages of the bio-inspired optimization techniques employed in this study, particularly the Coot Optimization Algorithm, in refining the Naive Bayes model. The validation confirms that the NBCO model outperforms existing approaches, making it a valuable tool for improving energy efficiency and sustainability in building energy management.

TABLE III. THE VALIDATION OF DEVELOPED MODEL

Article	Model	Evaluator	
		R^2	RMSE
Zhou et al. (Zhou u. a. 2020)	PSO-MLP	0.9126	2.9736
Present study	NBCO	0.985	1.325

B. Comparison

Table IV presents a comparative analysis of the best-performing models from the present study alongside similar models from relevant literature, focusing on their ability to predict HL. The models compared include Support Vector Regression (SVR), Multi-Parameter Moving Ridge (MPMR), Light Gradient Boosting Machine (LGBM), and the Naive Bayes optimized with Coot Optimization Algorithm (NBCO) developed in the current study. The SVR model by Moradzadeh et al. (Moradzadeh u. a. 2020) achieved an impressive RMSE of 0.4832 and an R^2 value of 0.9979, indicating a high level of accuracy and predictive power. Similarly, Roy et al. (Roy u. a. 2020) reported an MPMR model with an RMSE of just 0.059 and an R^2 of 0.99, making it one of the most accurate models for heating [39] load prediction. Gong et al. (Gong u. a. 2020) employed the LGBM model, which also performed well, achieving an RMSE of 0.1929 and an R^2 value of 0.9882. In comparison, the NBCO model from the present study produced an RMSE of 1.325 and an R^2 value of 0.985. While the NBCO model's R^2 value is close to those reported in the literature, indicating strong predictive accuracy, its RMSE is notably higher. This suggests that while NBCO captures the overall variance in heating loads [40] effectively, there may be room for improvement in reducing the prediction errors to match or surpass the accuracy levels of the models reported in other studies. Despite this, the NBCO model still offers significant advantages, particularly in its innovative use of bio-inspired optimization techniques. The model's relatively high R^2 value demonstrates its ability to serve as a reliable tool for heating [41] load prediction, with the added potential for further refinement

to improve its RMSE. This comparison underscores the value of continuing to explore and optimize machine learning models in the pursuit of enhanced energy efficiency in building management.

TABLE IV. THE COMPARISON OF THE BEST PERFORMED MODELS RESULTS OF PRESENT STUDY WITH SOME RELATED LITERATURES

Articles	Index values			
	Target	Models	RMSE	R^2
Moradzadeh et al. (Moradzadeh u. a. 2020)	HL	SVR	0.4832	0.9979
Roy et al. (Roy u. a. 2020)	HL	MPMR	0.059	0.99
Gong et al. (Gong u. a. 2020)	HL	LGBM	0.1929	0.9882
Present Study	HL	NBCO	1.325	0.985

C. Limitation

Despite the promising results, this study has several limitations that should be acknowledged, both in the context of the Naive Bayes (NB) model and the broader modeling approach. First, the NB model's inherent assumption of conditional independence among input features may not fully capture the complex interdependencies in building systems, potentially leading to inaccuracies when strong correlations exist between variables such as orientation, glazing area, and thermal performance. This limitation could result in suboptimal predictions, particularly in scenarios where these interactions play a significant role. Additionally, the optimization techniques employed Beluga Whale Optimization (BWO) and Coot Optimization Algorithm (COA) though effective, are relatively novel and less established than traditional methods. Their efficacy in various contexts remains to be thoroughly validated, and there may be cases where these optimizers do not provide substantial improvements over more conventional approaches. Moreover, the study focuses exclusively on predicting heating loads, overlooking other critical aspects of building energy management, such as cooling loads and ventilation. This narrow focus limits the comprehensiveness of the model and its applicability in broader energy efficiency strategies. Finally, the existing model does not account for real-time data integration or adaptive learning, which are increasingly important in dynamic energy management systems. The absence of these features may restrict the model's effectiveness in responding to changing conditions and optimizing performance over time.

V. CONCLUSION

The contemporary challenge of effectively managing building energy consumption, particularly in structures equipped with air conditioning systems, necessitated a holistic understanding of energy resources and end-uses within buildings. Achieving energy efficiency and sustainability in the built environment demanded the development of optimal predictive tools for estimating building energy consumption. Various modeling methodologies, including traditional approaches based on building geometry and advanced machine

learning models like ANNs, SVM, and random forests (RF), were explored for this purpose. Additionally, integrating metaheuristic algorithms emerged as a promising avenue for optimizing these models.

This study extended these efforts by applying the Naive Bayes (NB) model to predict heating loads in buildings and optimize the train process using the Beluga Whale Optimization (BWO) and Coot Optimization Algorithm (COA). Comparative analysis revealed that the optimized NB models outperformed traditional NB, demonstrating the potential for these bio-inspired optimization techniques to enhance predictive models and contribute to greater energy efficiency and sustainability in the built environment. Based on comparative analysis based on numerical values obtained for each evaluation metric corresponding to the developed models, the NBCO hybrid model attained a maximum coefficient of determination of 0.985, surpassed NBBW and NB by 1.03% and 2.2%, respectively, and exhibited minimal performance RMSE error of 1.325, which are notably 17.4% and 31.7% lower than those observed in NBBW and NB. This research served as a significant step toward addressing the energy challenges faced by contemporary facility management, presenting a promising path for future developments in the field.

Facial Expression Real-Time Animation Simulation Technology for General Mobile Platforms Based on OpenGL

Mingzhe Cao

Department of Tourism and Arts, Yangzhou University Guangling College, Yangzhou, 225000, China

Abstract—With the popularization and development of mobile devices, the demand for image processing continues to increase. However, the limited hardware resources of mobile devices make traditional CPU computing unable to meet the requirements of real-time image processing. In response to the limited rendering resources of mobile platforms, this study adopts OpenGL for graphic interface design and animation simulation of facial expressions to control the changes of facial expressions in real-time, achieve facial expression animation simulation, and develop effective expression fusion methods. By combining rich rendering effects such as particle effects, facial expressions can be expressed more realistically and interestingly in 3D models. The results indicated that the research method only required less than 50 MB of memory, and the average accuracy of facial expression recognition had significantly improved. The final normalized average error level was close to 4%, with higher accuracy. The processing speed of each image was around 19.4ms, which could achieve animation simulation of facial expressions and had strong universality and flexibility. This method optimizes the real-time performance, stability, and user experience of facial expression real-time animation simulation, which can meet the needs of different application scenarios.

Keywords—OpenGL; mobile platform; facial expressions; animation simulation; rendering

I. INTRODUCTION

In computer graphics, due to the emergence of OpenGL technology, graphics has entered a new era. OpenGL is widely used in 3D animation, Computer-Aided Design (CAD), visual simulation, and other fields. Its high quality and high-performance characteristics enable developers to create high-quality 2D and 3D graphics. Whether for broadcasting, CAD/computer-aided manufacturing/computer-aided engineering, entertainment, medical imaging, or virtual reality development, OpenGL provides outstanding graphics quality and performance. OpenGL can make full use of the functions of modern graphics hardware, such as Graphic Processing Units (GPU) parallel computing, and texture mapping, to provide higher graphics rendering performance and effect. This hardware-accelerated support makes OpenGL excellent at handling complex graphic effects, such as shadow, reflection, anti-aliasing, etc. Therefore, OpenGL has become one of the ideal choices for graphics rendering due to its high-quality graphics rendering, cross-platform compatibility, rich development tools and resources, and hardware acceleration support. In traditional graphics, rendering is the process of texturing the surface of an object. OpenGL provides a new

texture mapping method, which maps textures to the real world through a transformation matrix [1]. A transformation matrix can transform a 3D object into a 2D image, which can then be displayed on the screen. The transformation matrix can realize the 3D model view transformation, model transformation, clipping, projection transformation, and viewport transformation. OpenGL is a cross-language and cross-platform application programming interface for rendering 2D and 3D vector graphics. Whether it is 3D animation, CAD, or visual simulation, visual computation programs take advantage of OpenGL's high graphics quality and high-performance characteristics. OpenGL has a good structure, intuitive design, and logical commands. Compared to other graphics packages, OpenGL has very little code and therefore high execution speed. In addition, OpenGL encapsulates information about the basic hardware, so that developers do not need to design for specific hardware characteristics. OpenGL-based graphics applications can run on many systems, including a variety of user electronics, PCS, workstations, and supercomputers. As a result, OpenGL applications can be adapted to various target platforms chosen by the developer [2-3].

With the popularization and development of mobile devices, the demand for mobile image processing is increasing. However, due to the limited hardware resources of mobile devices, traditional CPU computing cannot meet the requirements of real-time image processing. A review of the relevant mainstream products on the market reveals that the majority of video special effects and facial expression simulations are based on the display of 2D animation. In contrast, the expression of 3D animation requires a significant amount of computing resources, making real-time performance difficult to achieve, and it is rarely promoted or applied in products. At present, most of the algorithms based on data structures and mathematical methods are used in research work, but such methods require computers to have a high computing speed, and the running speed on mobile platforms is slow [4-5]. The objective of this research is to develop a Facial Expression Animation Simulation (FEAS) system that can drive a virtual 3D model through facial expression unit parameters based on face key point detection through the front camera on a universal mobile platform. The system will then be encapsulated into operational applications that meet the requirements of real-time performance, low cost, practicality, stability, and maintainability. To adapt to the characteristics of the mobile platform and achieve the real-time goal, a universal real-time FEAS system based on OpenGL technology is developed.

OpenGL is used for graphic interface design, which can be run on the mobile platform, and the 3D Max model file format is adopted. The 3D model is drawn by OpenGL, and then the texture mapping is carried out by OpenGL to realize the real-time simulation of facial expression animation.

The article conducts research through six sections. Section II is a review of the research status of OpenGL in real-time FEAS applications. Section III is the research on 3D facial expression animation methods based on OpenGL. Section IV is performance validation of the proposed model. Results and discussion is given in Section V. Section VI is the conclusion.

II. RELATED WORKS

Bossér L et al. developed an underwater target echo signal strength prediction method based on image processing technology. By injecting code into the segment shader stage of the OpenGL graphics pipeline, the light reflection problem was transformed into an acoustic reflection problem. Compared to the Kirchhoff method, this method had higher computational accuracy [6]. Calabuig B E et al. improved the 3D engine used for real-time CAD geometric representation by using OpenGL Shaders to make ray tracing and radiation rendering techniques more realistic. It improved computing power by solving visualization problems and optimizing data. After verification, the model provided correct results for both computer-optimized 3D engines and network environment 3D engines [7]. Yin J et al. proposed a new lattice Boltzmann method to reduce the computational time, memory allocation, and complexity of existing algorithms for high-precision graphics processing units. It used OpenGL-based Compute Shaders GPGPGPU technology to accelerate and avoid the storage of distribution function components to reduce memory allocation size. The spatial accuracy was tested through 2D and 3D lid drive cavity benchmark cases, with high accuracy [8]. Rémi F et al. proposed a new method based on the OpenGL4 framework to achieve GPU-based high-order mesh rendering and almost pixel-accurate rendering of high-order solutions. This method used OpenGL fragment shaders to calculate precise solutions for each pixel by transferring degrees of freedom and shape functions to GPUs with textures. Compared to standard techniques, it eliminated linear interpolation steps, reduced memory usage, and improved rendering accuracy and speed [9].

Pham H X et al. proposed using Recurrent Neural Networks (RNNs) to achieve time-varying contextual nonlinear mapping between audio streams and facial micro movements, to drive 3D mixed-shape facial models in real-time. It depicted different speech generation actions in the form of lip movements, automatically estimating the speaker's emotional intensity with high accuracy [10]. Berson et al. proposed a generative RNN to make facial animation editing faster and easier for non-experts. It generated realistic movements in designated parts of existing facial animations based on user-provided guidance constraints. The experiment showed that the system had strong usability in scenarios such as motion filling, expression correction, semantic content modification, and noise filtering during occlusion [11]. Pumarola et al. proposed a weakly supervised strategy to train the model to describe the anatomical facial movements that define human expressions using continuous manifolds. This strategy annotated images through activated

action units and utilized a new self-learning attention mechanism to make the network robust to constantly changing backgrounds, lighting conditions, and occlusion, with high performance [12]. Paier W et al. developed an interactive animation engine using deep learning to achieve more realistic rendering in difficult areas such as the mouth and eyes of animated faces. It described an automatic pipeline for generating training sequences composed of dynamic textures and consistent 3D facial model sequences through simple and intuitive facial expression editing visualization. It also trained a variational auto-encoder to learn the low dimensional latent space of facial expressions for interactive facial animation [13]. Huang Z et al. proposed a real-time simulation method for humanoid robot facial expression imitation based on a smooth constrained inverse mechanical model by combining deep learning models with motion smoothing constraints to improve the spatio-temporal similarity and motion smoothness of facial expression imitation. This method sent the generated optimal position sequence to the hardware system, making it consistent with the performer's spatio-temporal characteristics, with a deviation of less than 8% [14].

In summary, although researchers have proposed many methods to improve real-time FEAS performance and achieved certain results, the optimization scheme still needs improvement. Therefore, this study aims to achieve facial animation simulation in different application scenarios through the OpenGL platform.

III. A 3D FACIAL EXPRESSION ANIMATION METHOD BASED ON OPENGL

This study is based on the OpenGL ES computational shader, which accelerates image processing algorithms through GPU parallel computing for different memory access and computational characteristics to achieve higher performance. Detailed implementation steps for face detection, facial keypoint localization, and tracking are introduced.

A. Design and Optimization of Facial Expression Capture Algorithm Module

There are many types of facial expression capture devices, and traditional devices are mostly bulky and have larger machine sizes. Due to the popularity of mobile Internet and mobile devices, this study selects the video camera attached to mobile devices as the capture device. The facial expression capture module consists of various algorithms, including image-based facial detection and facial key point localization [15]. Facial detection is achieved by obtaining image data from videos or cameras, normalizing the image data, and tracking the position of key points. In addition, for some more complex expressions, specially trained classifiers such as blinking and sticking out the tongue are used to improve the richness of the expressions. Finally, the entire tracking result is filtered to generate and extract facial expression unit parameters.

Facial expression collection includes face detection, key point localization and tracking, and solving the motion parameters of expression primitives. The key point tracking adopts an image denoising method based on median filtering, which significantly reduces computational complexity while ensuring tracking accuracy. Kalman filtering is used for facial

key points to filter and process the key point information generated in each frame. By calculating the key point information, the parameters of facial expressions are obtained. The specific process is shown in Fig. 1.

In OpenGL ES computing shaders, it is necessary to fully tap into the hardware resources of the GPU to create a sufficient number of threads, ensuring that all processors on the GPU are in the operational state of data processing, that is, to partition tasks as finely as possible. Fine partitioning of GPUs can improve their computational efficiency and effectively suppress latency. In the OpenGL ES rendering program, different tasks have different requirements for the size of the thread workgroup. To maximize the bandwidth usage of memory access, the size of the thread team can be set to be a full multiple of the block size to ensure that each thread can continuously access memory and avoid access conflicts.

This study proposes an image denoising method based on median filtering. This method is a non-linear filtering technique based on statistics, which replaces noise with the median in the median filtering window. The median filtering window traverses the entire image and calculates the median of all values within the filtering window as new pixels. The median calculation formula of the median filtering algorithm is Eq. (1).

$$g(x, y) = \text{median}\{f(x - i, y - j), i, j \in H \times W\} \quad (1)$$

In Eq. (1), $f(x, y)$ and $g(x, y)$ are the substitution values of the original image and the output image, respectively. $H \times W$ is the size of the filtering window (usually $H = W$ and odd, such as 3×3 , 5×5 , 7×7 , etc.). Due to the fact that median filtering belongs to nonlinear filtering, its mathematical analysis becomes more complex when dealing with images containing random noise. For a normally distributed image with zero mean filtering noise, the noise variance of the median filtering can be approximately expressed as Eq. (2).

$$\sigma_{med}^2 = \frac{1}{4nf^2(\bar{n})} \approx \frac{\sigma_i^2}{n + \frac{\pi}{2} - 1} * \frac{\pi}{2} \quad (2)$$

In Eq. (2), σ_i^2 represents the size of the incoming noise,

n represents the median, and $f(\bar{n})$ represents the noise density function. The variance of mean filtering is expressed as Eq. (3).

$$\sigma_0^2 = \frac{1}{n} \sigma_i^2 \quad (3)$$

The performance of median filtering depends on one factor, which is the size of the filtering window. At the same time, due to the different data types of images, a single algorithm cannot solve the corresponding problem. The Image Histogram (IH) represents the image distribution by quantifying the pixel numbers in each brightness value. For instance, in grayscale images, the IH algorithm calculates the quantity of pixel values (from 0 to 255) in the image and produces a histogram array with 256 elements. This study uses IH equalization to change the original IH by dispersing pixels that were previously existed in specific pixel values. For the original histogram $H(i)$, the calculation of the equilibrium distribution $H'(i)$ is Eq. (4).

$$H'(i) = \sum_{0 \leq j < i} H(j) \quad (4)$$

Finally, the final output image is calculated using Eq. (4), as exhibited in Eq. (5).

$$\text{equalized}(x, y) = H'(src(x, y)) \quad (5)$$

To solve the representation problem of 3D face acquisition, this study introduces the grid sampling operator and defines the downsampling and upsampling of grid features. Fig. 2 shows the grid sampling operation. Vertices shrink during downsampling operations. The downsampled vertices are a subset of the original mesh vertices. Each weight represents whether the Q -th vertex is retained during downsampling. Due to the infeasibility of lossless downsampling and upsampling for general grid surfaces, the upsampling matrix is constructed during the downsampling period. The vertices retained during downsampling are convolved, while these vertices are retained during upsampling. During downsampling, discarded vertices are mapped onto the downsampled mesh surface using centroid coordinates.

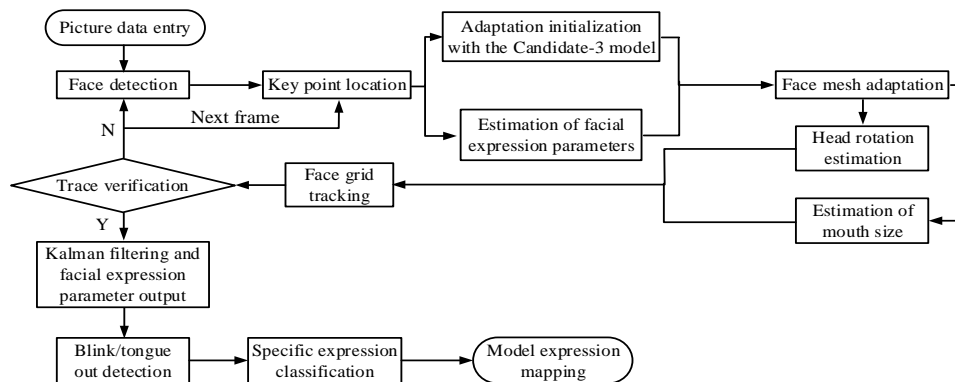

Fig. 1. Flow chart of facial expression capture.

Fig. 2. 3D grid sampling operation.

In OpenGL ES computational shaders, data type optimization is an important optimization. This study aims to use low-precision data types as much as possible based on the actual needs of calculations. When precision is not high, use single-precision floating-point instead of double-precision floating-point to avoid using type conversion operations in shaders. Type conversion requires additional computational resources, especially for low-end devices. The advantage of integral filtering is that its computational complexity is

independent of the filtering radius, so it can quickly process large-sized filtering templates and achieve filtering effects of different radii through multiple integral filtering. The localization and tracking of facial key points adopt a Supervised Descent Method (SDM)-based facial key point localization and tracking algorithm. Image information is extracted based on the current facial shape and position, and the shape is updated, as shown in Fig. 3.

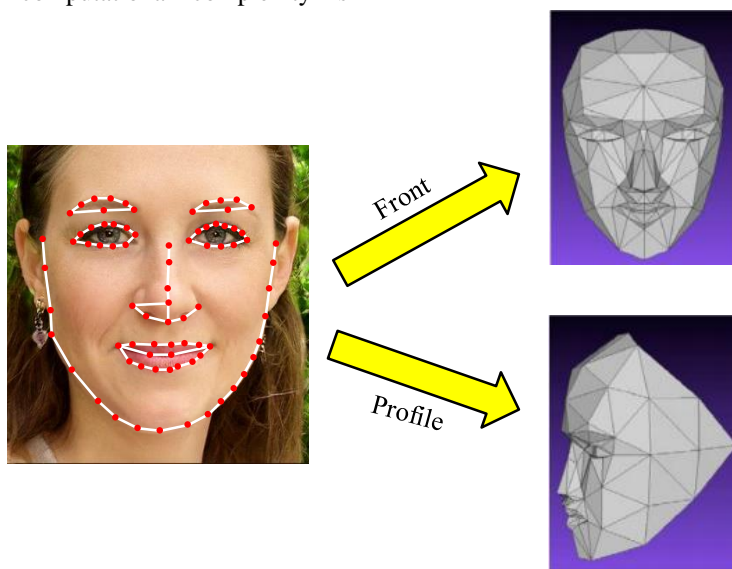

Fig. 3. Face key points.

The algorithm of integral filtering is simple to implement, fast in calculation speed, and widely used in image processing fields, such as face recognition, object detection, etc. $I(x, y)$ is the integral image, which is the sum of the original $i(x, y)$ on the left and top of point (x, y) . The calculation formula is Eq. (6).

$$I(x, y) = \sum_{x'}^x \sum_{y'}^y i(x', y') \quad (x' \leq x, y' \leq y) \quad (6)$$

Once the integral image is calculated, the pixel sum in any rectangular area composed of the upper-left point $(x1, y1)$ and the lower-right point $(x2, y2)$ can be found with the time

complexity of $O(1)$. Calculating the rectangular range in the left image requires eight summation operations, and the computational complexity increases with the expansion of the matrix area. The process is given in Eq. (7).

$$S(x_1, y_1, x_2, y_2) = \sum_{y=y_1}^{y_2} \sum_{x=x_1}^{x_2} i(x, y) \quad (7)$$

In facial detection, features are decomposed into integral filter algorithms based on row and column directions. The algorithm for row direction is an exclusive scanning operation, as shown in Eq. (8).

$$\lfloor a_0, a_1, \dots, a_{n-1} \rfloor \rightarrow \left[0, a_0, (a_0 + a_1), \dots, \sum_{i=0}^{n-2} a_i \right] \quad (8)$$

B. Design and Implementation of Animation Synthesis and Rendering Module

3D facial expression animation is mainly used to model models. Model modeling requires determining what kind of model to create and some basic facial expressions of the model. In the process of modeling and fusion, it is necessary to receive the basic expression parameter sizes transmitted by facial capture for linear fusion, to render the requirements of different models and enrich the expression of facial expressions [16].

Expression fusion P_{expr} is Eq. (9).

$$P_{expr} = p_{neur} + \sum_i \beta_i \times \Delta p_i \quad (9)$$

In Eq. (8), β_i represents the expression parameter weight passed by the face capture module. P_{neur} represents the vertex

coordinates of the 3D model in its natural state, and P_i represents the distance between the basic expression vertex of the 3D model and the natural expression vertex. By performing this linear calculation and overlaying all expression parameter weights, the final 3D model expression vertex position can be obtained, without the need for special processing in texture mapping. Based on considerations of computational complexity and effectiveness, this study chooses the Phong lighting model for calculation, as shown in Eq. (10).

$$light\ color = emissive + ambient + diffuse + specular \quad (10)$$

This model defines light as composed of self-illumination, diffuse reflection, ambient light, and mirror light, as shown in Figure 4. Self-luminous *emissive* is used to simulate the light source information emitted by objects such as the sun. *ambient* often simulates ambient light and low light on a global scale. In practical applications, diffuse reflection *diffuse* is the most important, combined with the calculation of the incident angle of light rays, which has the strongest performance on the direction of light rays. The calculation method is Eq. (11).

$$diffuse = light\ color \times \max(N \cdot L, 0) \quad (11)$$

In Eq. (11), N represents the normal and L represents the inverse of the incident vector. P represents the current vertex, while $N \cdot L$ is mainly used to determine whether the points on the face are facing or facing away from the light source.

Fig. 4. Schematic diagram of diffuse and specular light.

Mirror light mainly simulates the reflection effect, calculated as Eq. (12).

$$specular = light\ color \times facing \times (\max(N \cdot H, 0))^{shininess} \quad (12)$$

In Eq. (12), H is the centerline of the line of sight reversal V and L . *shininess* is the light intensity parameter. *facing* represents a Boolean value. If $N \cdot L$ is greater than 0 and takes a value of 1, it indicates that the light source vector L is facing the surface. The final color value can be expressed as Eq. (13).

$$output_{color} = texture_{color} \times (material_k \times light_{color}) \quad (13)$$

In Eq. (13), $material_k$ can simulate different materials by adjusting the coefficient. Finally, the color output is obtained through Eq. (14).

$$light_{color} = K_e + K_a \times ambient + K_d \times diffuse + K_s \times specular \quad (14)$$

In Eq. (14), K_e , K_a , K_d , and K_s represent vec4. If it is a model with fur, it needs to enable blending before rendering the transparency map. The mixing in OpenGL is achieved through Eq. (15).

$$C_{result} = C_s \times F_s + C_d \times F_d \quad (15)$$

In Eq. (15), C_s is the color vector of the texture. C_d

represents the color vector currently stored in the color buffer. F_s and F_d are the source and target factor values, specifying the impact of alpha values on the C_s color and target color.

This study also utilizes the MG2 algorithm in OpenCTM software to store and compress 3D model files. OpenCTM files are a simple format that can be well applied to modern 3D image rendering pipeline programs like OpenGL. In a 3D model, the minimum required information is the vertex

coordinates of the model and the patch composed of coordinate points. OpenCTM simply includes these two prerequisites and also supports adding more options. An OpenCTM file only contains one Mesh, which is mainly divided into two parts: vertex information and patch information. Among all Vertex, Normal, UV, and Attrib, Vertex is mandatory. Table I shows the subscript $(0, 1, 2, \dots, N)$ of the vertex to ensure the correspondence of the data in secret.

TABLE I. MODEL DATA STORAGE ARRANGEMENT

Index	0	1	2	3	4	...	N
Vertex	v0	v1	v2	v3	v4	...	vN
Normal	n0	n1	n2	n3	n4	...	nN
UVCoord1	t10	t11	t12	t13	t14	...	t1N
UVCoord2	t20	t21	t22	t23	t24	...	t2N

IV. ANALYSIS OF REAL-TIME FEAS

This study compares various algorithms on a scale of 1024x1024 and selects several excellent algorithms in recent years for comparison. Except for the code not implemented in the OpenCV library, performance comparisons are made with the corresponding algorithms in the OpenCV library.

A. Analysis of Facial Capture Performance

This study uses Xcode to compile static libraries, and then

calls mobile platform camera data through the Object c interface to transfer image data to the C interface to test the performance of the proposed face capture method. This study performs timestamp operations on each specific module, and after running for 10 minutes, the statistical results are obtained as shown in Table II. In Table II, the entire process achieves ultra real-time processing speed on both iPhone 12 and Galaxy S8, requiring less than 50 MB of memory.

TABLE II. FACE CAPTURE PERFORMANCE STATISTICS

Face capture module	IPhone12(iOS 9.5.3)			Galaxy S8 (Android 8.0.1)		
	GPU (%)	Memory (MB)	Time (ms)	GPU (%)	Memory (MB)	Time (ms)
Camera recording	12.2	48.6	/	13.6	51.3	/
Face detection and key location tracking	5.4	2.1	4.9	6.6	2.6	6.5
3D mesh adaptor	1.3	1.7	0.4	1.5	1.6	1.3
Eye classifier	1.2	0.4	0.7	1.4	1.4	3.2
Tongue sticking out classifier	1.0	1.2	0.4	1.1	1.3	3.2
Expression computing output	2.2	1.8	0.4	2.9	2.7	3.0
All functions	23.3	55.8	6.8	27.1	60.9	17.2

To objectively and accurately detect the recognition performance under different expressions, this study used the data from the expression fusion library as the basis to achieve data balance, and used the basic parameters in the model to adjust the corresponding penalty coefficients. The larger the parameter, the longer it took to identify the error. Therefore, it was necessary to determine a higher mean for this type of parameter. This study adjusted the parameters to predict the expressions to be tested for classification using the trained classifier, and compared the recognition rate with the pre-imbalanced expression data classifier. Fig. 5 shows the confusion matrix of six facial expressions. After data balancing, the recognition accuracy on the test sample increased from 87.69% before data balancing to 91.26%.

This study also conducted sample detection experiments on

traditional texture features, Active Appearance Model (AAM), and proposed fusion feature extraction methods, and compared their results. Table III shows the average recognition rate of six types of expressions using three feature extraction methods. In Table III, compared to the other two methods, the research method had a better recognition rate on facial expressions than traditional and AAM algorithms. The recognition accuracy of Happy, Neutral, and Surprised facial expressions was relatively high, but the recognition accuracy of Anger, Sad, and Distorted facial expressions was not as good as the above three types. There were two main reasons for this situation. One reason is that each person has different ways of expressing sadness and disgust, and there are also significant differences. Therefore, the results of identifying such expressions are relatively scattered and may be recognized as various types of expressions. When

recognizing anger, it is easy to identify it as a surprise because when extracting features from the eye area, both types of expressions are prone to eye enlargement, which can confuse recognition. The second is that the three types of expressions, Anger, Distorted, and Sad, have certain similarities in themselves, and people may find it difficult to distinguish these

three types of expressions in real life. Therefore, the recognition accuracy of these three types of expressions is lower than that of other expressions, but experiments have shown that the average accuracy of expression recognition in the research method still has a significant improvement.

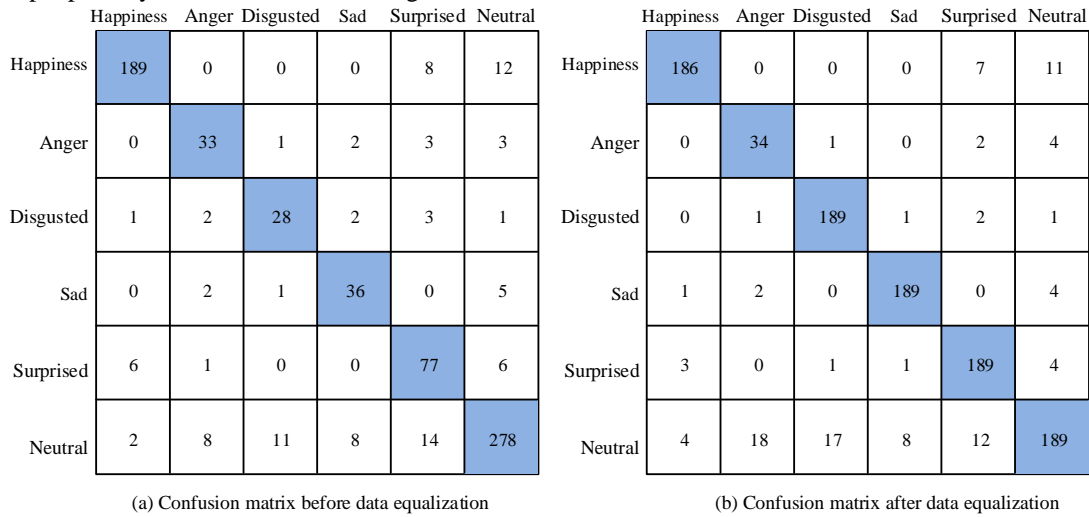

Fig. 5. Confusion matrix of six facial expressions.

TABLE III. COMPARISON OF FACIAL EXPRESSION RECOGNITION RESULTS

Method	Traditional texture feature	AAM feature	Research proposed fusion features
Happiness	72.13%	83.62%	92.43%
Anger	75.32%	81.75%	91.65%
Sad	76.32%	80.69%	93.47%
Surprised	74.19%	79.42%	89.62%
Disgusted	73.58%	83.66%	86.78%
Neutral	71.96%	84.51%	90.33%
Average	74.37%	80.42%	91.76%

B. Analysis of Facial Animation Rendering Effects

To comprehensively evaluate the facial rendering performance of research methods, multiple excellent algorithms in recent years were selected for comparison, including 2DASSL [17], DCN [18], 3DDFA [19], SDM [20] and other algorithms. The Normalized Mean Error (NME) was selected as the evaluation metric, which represents the average error value of normalized feature points. The normalized size corresponds to the square value of the product of the length and width of the face border to ensure that face alignment was not affected by external factors. Fig. 6 (a), (b), and (c) show the cumulative alignment errors of 68 2D face key points (2D-KP), all 2D face key points (A2D-KP), and all 3D face key points (A3D-KP) for face alignment. Among the 68 cumulative errors of 2D-KP, 2DASSL and research methods performed similarly, demonstrating excellent performance. 3DDFA is stable and efficient, and also performs well. The research method achieved optimal NME on 68 2D-KP, A2D-KP, and A3D-KP datasets.

This study evaluated the impact of loss functions on alignment using three commonly used loss functions: PDC, VDC, and WPDC, based on MATLAB. The performance of

models trained with different loss functions on the dataset is Fig. 7. PDC could not fit the model well, and the convergence of errors was poor. It basically converged when the NME reached around 8%. VDC performed better than PDC, but was affected by pathological curvature during the convergence process, so fitting errors might occur during the fitting process, resulting in poor visualization results. Compared to other methods, WPDC had better error performance and could quickly reduce NME. However, overall, the loss function of the research method combined key point loss, resulting in better performance and the fastest reduction of NME. The final error level was close to 4%, and the accuracy was significantly higher.

The proposed facial animation rendering method consumes a time proportional to the image size, as shown in Fig. 8. In a size of 200×300, the processing speed of each image was around 19.4 milliseconds, which was extremely fast. After testing, it could reach about nine milliseconds at a size of 120×120, but due to the small window, it was not suitable for real-time input of facial images. If face detection was performed by scaling images, sometimes the detection efficiency might be affected due to the small size of the face.

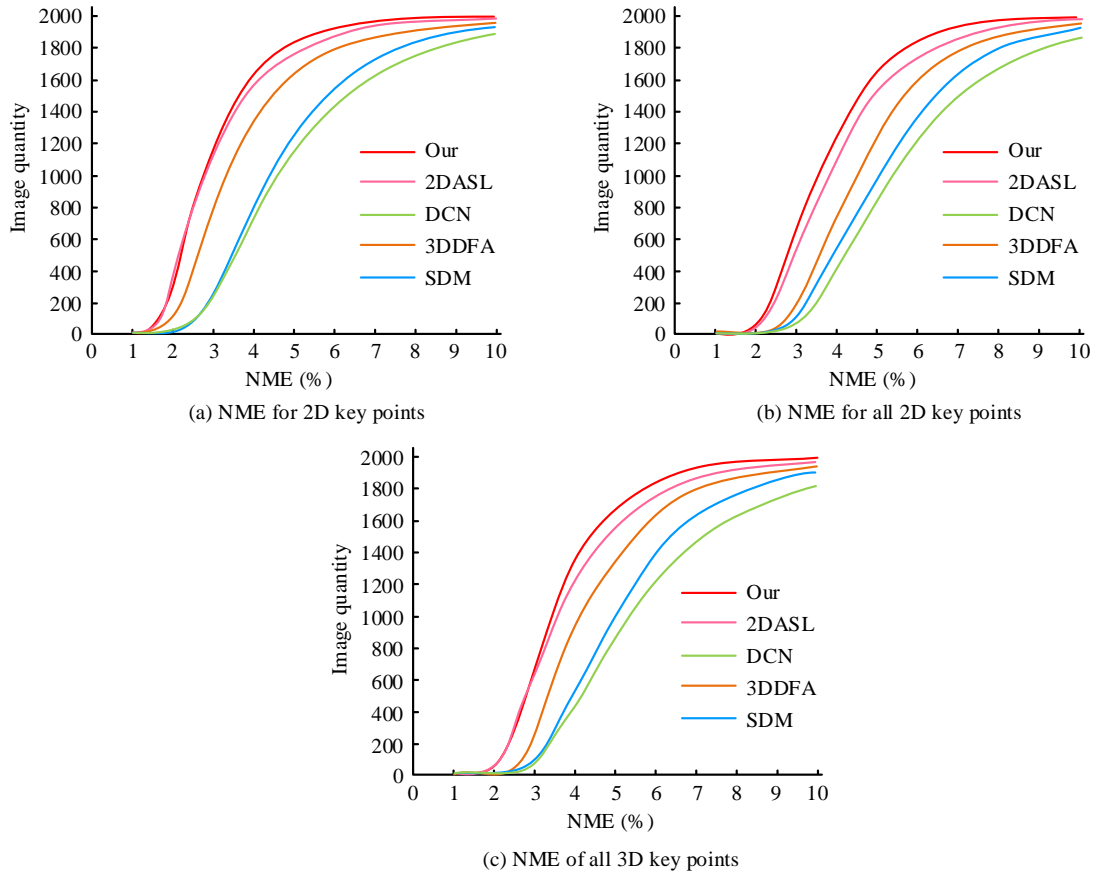

Fig. 6. Comparison of NME results.

Fig. 7. Error function results in face alignment.

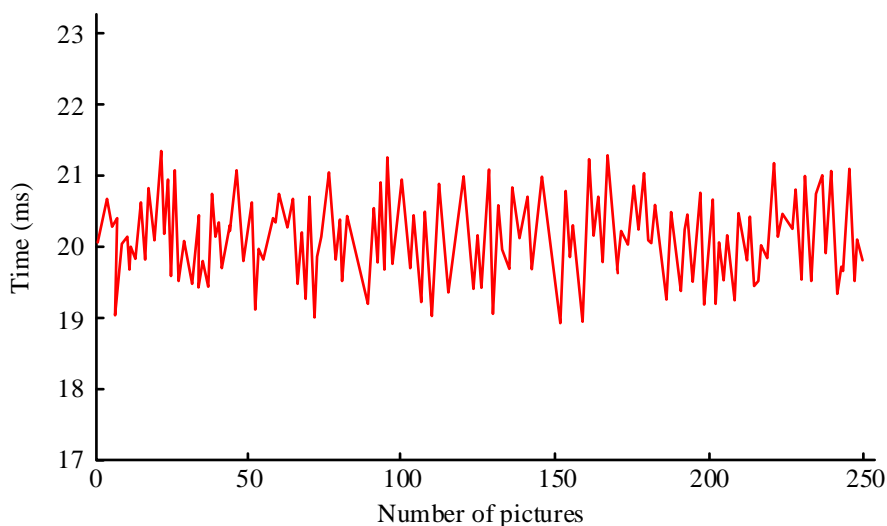

Fig. 8. Runtime of the image enhancement method on 200 images.

To better explore the impact of video frame preprocessing algorithms, speech features of speech driven networks, and lip animation results on expression and posture networks, this study divides each part and obtained six variants by considering one or more component parts. Method 1 is the benchmark method. Method 2 is to crop each frame separately. Method 3 is to add speech features from the speech network as inputs to the expression and posture network for feature fusion. Method 4 uses speech driven network prediction of lip animation as the basis. Method 5 adds the speech features of the speech network as input to the expression and posture network for feature fusion, and also uses the lip animation predicted by the speech driven

network as the basis. Method 6 uses the proposed rendering method.

Table IV shows the objective evaluation results of various situations on the dataset. It can be found that the proposed rendering method can bring certain results in improving the expression posture. Among them, video frame preprocessing has the best effect on VER reduction, surpassing the combination of speech features and lip animation. In addition, it also has a good decrease in WER and VWER, surpassing individual speech features or lip animation.

TABLE IV. RESULTS OF ABLATION EXPERIMENT

Serial number	Video frame preprocessing	Ocular features	Lip animation	CER	WER	VER	VWER
1				68.7	98.1	61.0	97.6
2	√			67.5	96.2	59.1	94.4
3		√		67.0	96.4	60.0	94.8
4			√	67.8	97.0	60.3	95.7
5		√	√	66.4	95.0	59.4	93.7
6		√	√	65.0	92.7	57.5	91.0

V. RESULTS AND DISCUSSION

The process of face detection and face feature point detection is conducted on the collected ordinary images with the objective of determining the face region. Subsequently, facial expression recognition and face reconstruction are carried out on the cropped face region aiming to obtain the 3D model data of the corresponding 2D face image. Finally, 3D animation can be realized by using the renderer. However, when face image 3D modeling is applied in mobile devices, higher requirements are put forward for computing time. In regard to graphical rendering, OpenGL employs hardware acceleration technology, thereby enabling direct access to the GPU to accelerate the graphical rendering process, thus markedly enhancing the efficiency of the rendering process [21]. Furthermore, OpenGL employs a dual-cache system to process the computing scene, generated image, and display image

separately. This approach significantly enhances the computing power and display speed of the computer, thereby improving the user experience and greatly reducing processing time. The proposed method was validated on iPhone 12 and Galaxy S8, and it was found that the entire process achieved ultra real time processing speed with less than 50 MB of memory required. In addition, the processing speed of each image in the 200×300 size was about 19.4 milliseconds, which is extremely fast. Wang B et al. proposed a face feature extraction algorithm based on deep learning, which adopted C++ and OpenGL for rendering simulation, and has good performance in accuracy and speed [22]. The results are consistent with the results of this study, indicating that the mobile platform FEAS technology based on OpenGL can meet the real-time requirements.

Face images contain some very complex information and content. Typical facial features include the eyes, mouth,

eyebrows, and the face as a whole. Additionally, there is a great deal of information present within the face, composed of these parts [23]. Based on face detection, the key facial feature points are automatically located according to the input face image, such as the eyes, nose tip, corners of the mouth, eyebrows, and contour points of the face parts, etc. The input is the face appearance image and the output is the set of face feature points. Due to the combination of key point loss, the proposed method can rapidly reduce the normalized average error, and the final error level is close to 4%. The error performance on 68 2D key points, all 2D face key points, and all 3D face key points is optimal. 3D DFA and 2D ASL are messy in the 3D spatial error distribution. It indicates that there are some defects in the face estimation, which reduces the accuracy and visibility of model fitting. With the help of OpenGL, 3D model can be quickly mapped to 2D space and 3D effect can be displayed in 2D space. The 3D face data acquisition based on OpenGL is extremely efficient, which can ensure a high frame rate, achieve continuous animation effect, and effectively improve the adaptability of face reconstruction to the scene.

VI. CONCLUSION

This study was based on the OpenGL platform and utilized the OpenGL ES computational shader to develop a GPU version of a high-performance image algorithm, providing a real-time facial animation processing solution for mobile devices. By combining a series of architecture and resource optimization strategies, the cross-platform application of Android and iOS systems on mobile devices has been implemented, and the stable performance of the entire solution on mobile platforms has been guaranteed. The results indicated that the research method achieved ultra real-time processing speed on two different operating systems and only required less than 50 MB of memory. After data balancing, the recognition accuracy increased from 87.69% before data balancing to 91.26%, and there was a significant improvement in the average accuracy of facial expression recognition. The loss function of the research method combined key point loss, resulting in better performance and the fastest reduction of NME. The final error level was close to 4%, and the accuracy was significantly higher. In a size of 200×300, the processing speed of each image was around 19.4 modes. This method has the characteristics of simple operation, powerful functionality, high realism, and strong real-time performance. However, this study only optimized high-performance image processing algorithms for a single architecture and efficient computation cannot be performed when the algorithms are ported to other platforms. In the future, high-performance facial animation simulation processing algorithms for other architecture processors can be optimized.

Noise Reduction Techniques in ADAS Sensor Data Management: Methods and Comparative Analysis

Ahmed Alami, Fouad Belmajdoub

Faculty of Science and Technology of Fez, University of Sidi Mohammed Ben Abdellah, Fez, Morocco

Abstract—This review examines noise reduction techniques in Advanced Driver Assistance Systems (ADAS) sensor data management, crucial for enhancing vehicle safety and performance. ADAS relies on real-time data from conventional sensors (e.g., wheel speed sensors, LiDAR, radar, cameras) and MEMS sensors (e.g., accelerometers, gyroscopes) to execute critical functions like lane keeping, collision avoidance, and adaptive cruise control. These sensors are susceptible to thermal noise, mechanical vibrations, and environmental interferences, which degrade system performance. We explore filtering techniques including KalmanNet, Simple Moving Average (SMA), Exponential Moving Average (EMA), Wavelet Denoising, and Low Pass Filtering (LPF), assessing their efficacy in noise reduction and data integrity improvement. These methods are compared using key performance metrics such as Signal-to-Noise Ratio (SNR), Mean Squared Error (MSE), and Root Mean Squared Error (RMSE). Recent advancements in hybrid filtering approaches and adaptive algorithms are discussed, highlighting their strengths and limitations for different sensor types and ADAS functionalities. Findings demonstrate the superior performance of Wavelet Denoising for non-stationary signals, SMA and EMA's effectiveness for smoother signal variations, and LPF's excellence in high-frequency noise attenuation with careful tuning. KalmanNet showed significant improvements in noise reduction and data accuracy, particularly in complex and dynamic environments. Extended Kalman Filter (EKF) and Unscented Kalman Filter (UKF) were especially effective for RADAR sensors, handling non-linearities and providing accurate state estimation. Emphasizing Hardware-in-the-Loop (HIL) bench testing to validate these techniques in real-world scenarios, this study underscores the importance of selecting appropriate methods based on specific noise characteristics and system requirements. This research provides valuable insights for ADAS and autonomous driving technologies development, emphasizing precise signal processing's critical role in ensuring accurate sensor data interpretation and decision-making.

Keywords—ADAS; sensor data management; noise reduction; KalmanNet; Wavelet Denoising; RADAR; SMA; EMA; LPF; HIL bench testing

I. INTRODUCTION

The evolution of automotive technology is rapidly transforming with the integration of Advanced Driver Assistance Systems (ADAS) and Autonomous Driving (AD) technologies, which are set to redefine vehicle safety and efficiency standards. Central to the success of these systems is the precise and reliable processing of sensor data from a variety of sources, including wheel speed sensors (WSS), inertial measurement units (IMUs), and radar systems. These sensors

collectively enable the vehicle to perceive its environment, make decisions, and execute safe driving maneuvers [1], [2]. However, the performance of ADAS and AD is critically dependent on the quality of the sensor data, which can be severely compromised by noise and interference, posing significant challenges to system reliability [3]. As vehicle systems become increasingly interconnected through Vehicle-to-Everything (V2X) communication and the rollout of 5G networks, the demand for real-time, robust, and low-latency data processing solutions has intensified, underscoring the necessity for efficient noise reduction algorithms.

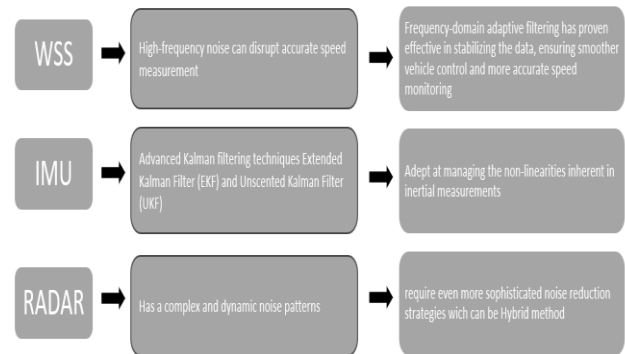

Fig. 1. Challenges encountered by each sensor type.

As shown in the Fig. 1 and in order to mitigate these challenges, cutting-edge signal processing techniques have been developed to enhance sensor data quality, each tailored to the unique characteristics of different sensors. For instance, in WSS, where high-frequency noise can disrupt accurate speed measurement, frequency-domain adaptive filtering has proven effective in stabilizing the data, ensuring smoother vehicle control and more accurate speed monitoring [4]. IMUs, which are essential for maintaining vehicle dynamics and stability, benefit from advanced Kalman filtering techniques—particularly the Extended Kalman Filter (EKF) and Unscented Kalman Filter (UKF)—which are adept at managing the non-linearities inherent in inertial measurements [3], [12]. Meanwhile, RADAR systems, tasked with obstacle detection and environmental mapping, require even more sophisticated noise reduction strategies, including multi-sensor fusion and machine learning-based methods, to effectively manage the complex and dynamic noise patterns encountered in real-world scenarios [5], [6].

To address the challenges posed by dynamic environments in ADAS applications, this Fig. 2 illustrates the increasing

necessity for advanced noise reduction techniques tailored to specific driving situations.

Fig. 2. The need for enhancing sensor noise reduction based on the driving situation identified.

As ADAS technology continues to advance, the integration of more complex sensor systems, such as radar and lidar, has heightened the need for innovative noise reduction techniques. These systems operate in dynamic environments filled with clutter, where conventional noise reduction approaches may fall short. To overcome these limitations, researchers are developing more sophisticated signal processing algorithms and exploring alternative modulation schemes, specifically designed to enhance data acquisition accuracy and reliability [7]. For RADAR systems, advanced Kalman filtering methods, such as the Unscented Kalman Filter (UKF), have demonstrated exceptional performance in tracking applications, particularly where noise is non-Gaussian and non-linear [12]. Simultaneously, multi-sensor fusion strategies, which integrate data from radar, lidar, and cameras, have become increasingly vital in providing a comprehensive perception of the vehicle's surroundings, compensating for the limitations of individual sensors [8]. However, the success of these approaches hinges on precise data synchronization and the development of sensor-specific noise reduction strategies, making them a critical area of ongoing research.

This Fig. 3 highlights the range of noise reduction techniques evaluated in this study, with a focus on those specifically selected for their effectiveness in various sensor types.

Recent advances in noise reduction techniques reflect a growing recognition of the need for tailored solutions across different sensors. For WSS, techniques like Simple Moving Average (SMA) and Exponential Moving Average (EMA) remain popular for their simplicity and computational efficiency, though Enhanced Simple Moving Average (ESMA) methods have emerged to address the limitations of initialization periods and stability [9], [10], [11]. IMUs, on the other hand, continue to benefit from the Kalman filtering

family, with the EKF and UKF providing robust solutions for handling non-linear dynamics and improving measurement accuracy [13]. In RADAR systems, wavelet denoising has proven to be a powerful tool for managing non-stationary signals, while innovations like KalmanNet—which merges neural networks with Kalman filtering—offer significant advancements in reducing noise and enhancing signal clarity in complex operational environments [14], [15]. These innovations are critical not just for improving sensor data quality but also for enabling the high levels of performance demanded by modern ADAS and AD systems.

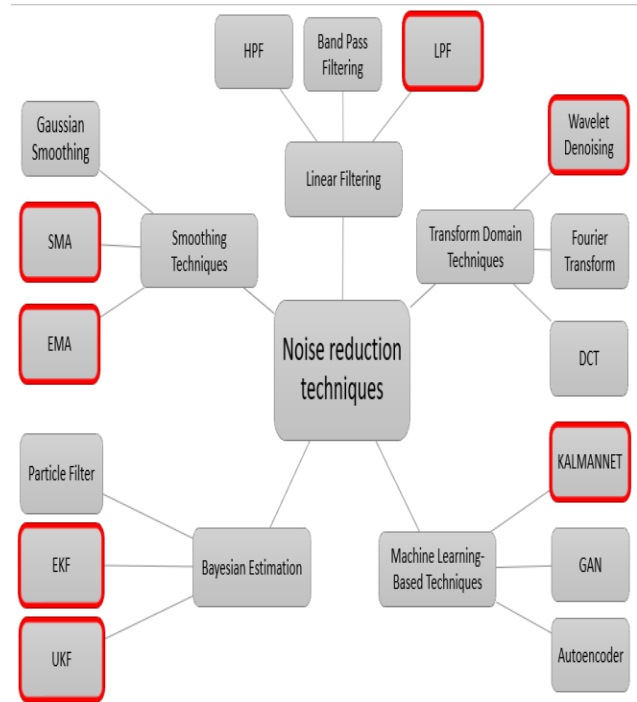

Fig. 3. Noise reduction techniques and chosen techniques shape outline are in red.

Effective noise reduction techniques are essential across WSS, IMUs, and RADAR systems, as they directly influence the reliability and safety of ADAS and AD applications. For WSS, methods like SMA and EMA continue to provide efficient solutions for mitigating speed-related noise, ensuring smoother control and accurate speed data [9], [10]. In IMUs, the advanced filtering techniques of EKF and UKF are crucial for maintaining vehicle stability by effectively handling the non-linearities in inertial data [16], [17]. RADAR systems, operating in complex environments, benefit significantly from wavelet denoising and hybrid methods like KalmanNet, which enhance signal clarity and improve the detection of critical obstacles [14], [15]. These tailored approaches are not only vital for current applications but also lay the groundwork for future advancements in automotive safety and sensor technology [18], [19], [20].

To validate the effectiveness of these advanced noise reduction techniques, we conducted a comprehensive empirical study using synthetic datasets that closely mimic the noise characteristics encountered by automotive sensors such as WSS, IMUs, and RADAR. By systematically introducing a

range of noise types and levels, we rigorously evaluated the performance of each noise reduction method across key metrics, including Mean Squared Error (MSE), Root Mean Squared Error (RMSE), Signal-to-Noise Ratio (SNR), and Peak Signal-to-Noise Ratio (PSNR). This approach ensured a robust assessment of each technique's ability to enhance data accuracy and reliability under real-world conditions.

The Fig. 4 shows a summary of the key findings from existing literature, emphasizing the importance of tailored noise reduction approaches for enhancing sensor data accuracy in ADAS applications.

Fig. 4. Key findings of the existing literature.

The findings of this study strongly support the hypothesis that a tailored, sensor-specific approach to noise reduction can significantly improve data accuracy and system performance across various ADAS and AD applications. KalmanNet and hybrid techniques showed the greatest improvements in SNR and significant reductions in MSE and RMSE for RADAR data, while SMA, EMA, and Wavelet Denoising effectively reduced noise in WSS and IMU data, with Low Pass Filtering (LPF) providing broad applicability across all sensor types [21], [22]. These results underscore the critical importance of selecting the right noise reduction techniques based on the specific operational requirements and noise characteristics of each sensor, paving the way for enhanced automotive safety and efficiency.

In the introduction, the critical role of Advanced Driver Assistance Systems (ADAS) and Autonomous Driving (AD) technologies in enhancing vehicle safety and efficiency is examined, with an emphasis on the importance of accurate sensor data processing. The challenges associated with noise and interference in key sensors—such as wheel speed sensors (WSS), inertial measurement units (IMUs), and radar systems—are highlighted, particularly given their integral role in ADAS and AD system performance. The methodology section discusses the application of advanced noise reduction

techniques, specifically tailored to the unique characteristics of these sensors, while also considering the demands of Vehicle-to-Everything (V2X) communication and 5G networks. Techniques such as Simple Moving Average (SMA), Exponential Moving Average (EMA), Wavelet Denoising, Low Pass Filtering (LPF), KalmanNet, Extended Kalman Filter (EKF), and Unscented Kalman Filter (UKF) are evaluated for their efficacy in noise reduction, with an additional focus on the necessity of real-time processing and the preference for simpler, computationally efficient algorithms over more complex ones. The results provide a detailed analysis, demonstrating the effectiveness of these methods in enhancing Signal-to-Noise Ratio (SNR) and reducing Mean Squared Error (MSE) and Root Mean Squared Error (RMSE), while also considering the practical implications of implementing these techniques in real-time V2X and 5G environments. The discussion elaborates on these findings, underscoring the importance of sensor-specific noise reduction strategies and their implications for the future development of ADAS. The conclusion synthesizes the key contributions of the study, proposing directions for future research aimed at further optimizing these techniques and ensuring their seamless integration into comprehensive, real-time ADAS frameworks, thereby advancing the reliability and performance of automotive safety systems.

Given the critical role that precise noise reduction techniques play in the effectiveness of ADAS, it is essential to explore and build upon existing research that has laid the groundwork in this field. The following section reviews the advancements and challenges documented in recent literature, providing a context for the methodologies employed in this study.

II. RELATED WORK

Recent research has focused extensively on developing data-driven frameworks for diagnostics and prognostics across various domains, including automotive and aerospace. These frameworks typically involve sophisticated data acquisition processes from sensors and control units, often leveraging machine logs and CAN bus networks to enhance system monitoring and fault detection [23], [24]. Advanced data processing techniques, such as feature selection and extraction, have been employed to improve diagnostic accuracy, but their application in real-time systems remains a challenge due to computational limitations [23], [24].

The Fig. 5 provides an overview of the testing and validation activities critical to ensuring the reliability and performance of automotive systems, especially in the context of noise reduction.

The adoption of machine learning algorithms, including Random Forests, Bayesian estimation methods, and Cox proportional hazards models, is widespread for fault detection and remaining useful life (RUL) prediction; however, these approaches often require significant computational resources, limiting their applicability in real-time environments [25]-[26]. Despite these advancements, there is a clear need for further research into hybrid models that can efficiently balance predictive accuracy with real-time processing demands,

particularly in safety-critical systems where data availability may be limited [25].

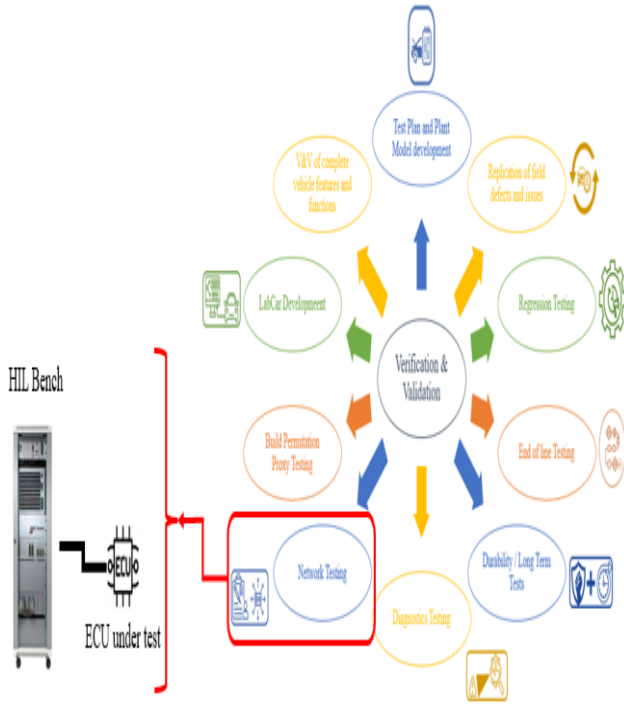

Fig. 5. Testing and validation activities in the automotive field [40].

The Fig. 6 below presents a comparison of advanced fault detection and diagnostic techniques, highlighting those selected for this study due to their relevance in noisy environments.

In the context of noise reduction in data acquisition systems, particularly for automotive applications and Hardware-in-the-Loop (HIL) testing, various noise sources have been identified, including thermal fluctuations, mechanical vibrations, and environmental interferences [27], [28]. Although conventional noise mitigation techniques, such as proper cabling, shielding, and signal modulation, provide baseline improvements, they fall short in addressing the complex, high-frequency noise patterns encountered in modern vehicle systems, especially under dynamic conditions [27], [29]. Emerging machine learning approaches, like ensemble LSTM and Random Forest, have been proposed for fault detection in noisy conditions, showing promise in controlled environments but requiring further validation under real-world conditions [30]. Moreover, the impact of noise on sensor performance, particularly in automotive camera sensors and object detection systems, has underscored the necessity for simultaneous analysis of multiple noise factors to ensure robust performance [31].

This Fig. 7 illustrates the various sources of noise and interference that impact sensor data quality in automotive systems, underscoring the need for robust noise reduction strategies.

Fig. 6. Advanced techniques for fault detection and diagnostics and selected ones for the current study in red [41].

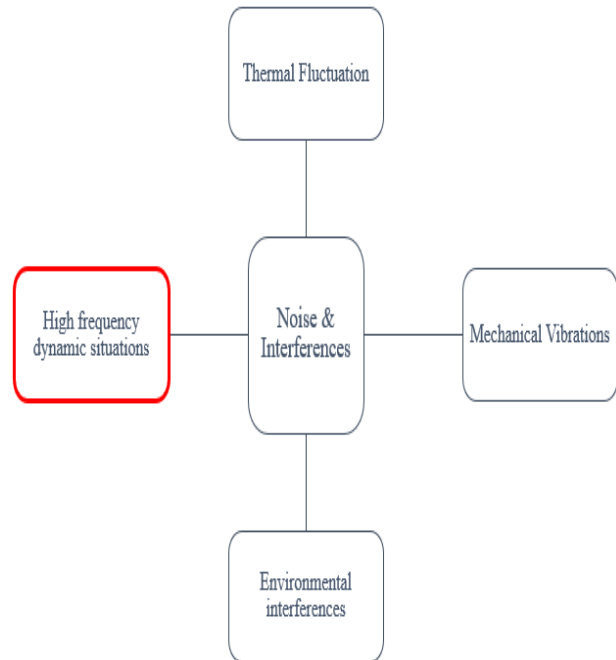

Fig. 7. Noise and interferences.

This body of work highlights the critical importance of noise reduction in the automotive and aerospace industries. Researchers have explored a wide array of techniques to minimize aerodynamic, vibroacoustic, and communication noise, yet the integration of these techniques into real-time systems remains an ongoing challenge [32], [33]. Advanced methods, such as compressive sensing-based noise radar and hybrid active noise control systems, have been developed to improve sensor performance, but their high computational requirements often hinder their implementation in embedded systems [34], [35]. As the industry moves towards more complex and interconnected systems, such as those enabled by V2X and 5G technologies, there is an increasing demand for noise reduction techniques that are both highly effective and computationally efficient [36], [28]. This demand is further amplified by the exponential growth in sensor data volume and complexity, necessitating the development of novel algorithms that can operate within the stringent constraints of modern embedded systems [37].

The Fig. 8 below compares existing noise reduction methods with the current demands of modern automotive systems, highlighting gaps that this study aims to address.

Fig. 8. Comparison between the existent method in the literature and the current need.

In summary, the need for effective noise reduction in automotive sensor data acquisition is well-established in recent research. However, as vehicle connectivity and automation continue to expand, the challenges associated with noise in sensor systems grow more complex [37]. While existing studies have made significant strides in addressing these issues, particularly through HIL testing and the development of robust sensor models, there remains a critical need for further research that focuses on the integration of real-time noise reduction techniques within the context of V2X and 5G environments [38]-[39]. This integration is essential not only for meeting current safety standards but also for advancing the capabilities of future Advanced Driver Assistance Systems (ADAS) and autonomous driving technologies [36], [37]. Future research should prioritize the development of scalable, adaptive noise reduction strategies that can efficiently process the vast

amounts of data generated by modern vehicle systems, ensuring both reliability and real-time performance [37].

III. CONTEXT AND OBJECTIVES

Hardware-in-the-Loop (HIL) testing has become a cornerstone in the validation process of complex automotive and aerospace systems. By accurately simulating real-world conditions, HIL testing serves as a critical bridge between theoretical models and practical applications, ensuring that systems perform reliably and efficiently under operational constraints. Recent advancements in this domain have been pivotal in overcoming key challenges, such as the bandwidth limitations of Electronic Control Units (ECUs), while significantly enhancing diagnostic capabilities. These advancements are particularly vital as the integration of next-generation technologies, including advanced communication networks like 5G and Vehicle-to-Everything (V2X), becomes increasingly prevalent in automotive systems.

This Fig. 9 showcases a typical Hardware-in-the-Loop (HIL) test bench setup, demonstrating its critical role in validating the performance of noise reduction techniques under real-world conditions.

Fig. 9. An example of HIL bench test bench with an ECU [42].

The primary objectives of this research are:

- Enhancing the precision of data collection and testing through the development and implementation of advanced HIL testbeds.
- Improving fault detection and noise reduction by integrating sophisticated signal processing techniques, tailored to the unique demands of modern sensor systems.
- Optimizing HIL testing frameworks to effectively manage the complexities introduced by the integration of 5G and V2X technologies, ensuring robust performance and reliability.

Addressing these objectives is crucial for refining real-time performance in HIL testing and ensuring that simulation outcomes closely mirror real-world conditions. As HIL testing methodologies evolve, these efforts will drive the development of more reliable, efficient, and safe automotive and aerospace systems, positioning them to meet and exceed the rigorous demands of contemporary engineering challenges. This study emphasizes the strategic selection of noise reduction techniques based on sensor-specific and operational requirements, highlighting their impact on the performance and

reliability of Advanced Driver Assistance Systems (ADAS). Future research should focus on further optimizing these techniques and exploring their seamless integration into comprehensive ADAS solutions, thereby advancing the frontier of automotive safety and operational efficiency.

IV. METHODOLOGY

A. General Approach

To validate the hypothesis that tailored noise reduction techniques enhance the accuracy and reliability of sensor data in Advanced Driver Assistance Systems (ADAS), a comprehensive study was conducted. This study involved the generation of synthetic datasets for Wheel Speed Sensors (WSS), Inertial Measurement Units (IMU/GYRO), and RADAR sensors, reflecting the typical data volume and noise complexity encountered in real-world scenarios. This approach ensures that the study replicates the diverse and challenging conditions that ADAS must effectively manage for enhanced performance and safety.

The following figure shows the proposed method followed for this paper:

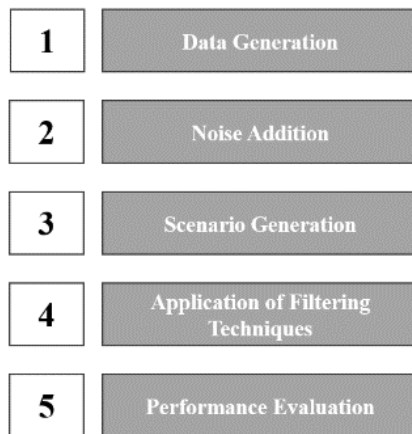

Fig. 10. Proposed method for filtering.

Fig. 10 illustrates the structured approach followed in this research, highlighting the key stages of data generation, noise addition, and performance evaluation.

The methodology followed a systematic approach as explained below:

1) *Data generation*: Synthetic datasets were generated to simulate sensor data under various driving scenarios. For WSS and IMU/GYRO sensors, 10 signals were created for each sensor type, capturing rapid changes in speed, motion, and orientation. For RADAR sensors, 100 signals were generated to account for the increased complexity and variability in noise patterns encountered in dynamic environments. These datasets were designed to replicate the typical challenges faced by ADAS systems, ensuring the relevance and applicability of the findings.

2) *Noise addition*: To replicate real-world conditions, various types and levels of noise were systematically introduced to the synthetic datasets. For instance, Gaussian noise was added to mimic thermal fluctuations, and periodic spikes simulated electromagnetic interference (EMI). The noise levels were varied to assess the robustness of each filtering technique across different conditions. Different levels of noise intensity were applied to test the robustness and adaptability of each filtering technique, ensuring comprehensive evaluation under varied conditions.

3) *Scenario simulation*: The study simulated a range of high-risk and typical driving scenarios, including urban intersections, highway lane changes, and emergency braking. These scenarios were derived from real-world conditions commonly tested in ADAS and Vehicle-to-Everything (V2X) systems, ensuring that the simulation covered a broad spectrum of challenges that ADAS must handle effectively. This comprehensive scenario simulation provides a rigorous testing environment, closely mirroring the operational challenges encountered in actual driving situations.

4) *Filtering techniques exposition*: The following Table I present a presents a comparative analysis of the noise reduction methods for WSS data in ADAS, highlighting their advantages, disadvantages, and performance metrics. This analysis is crucial for understanding the trade-offs associated with each technique, particularly in terms of computational complexity and real-time applicability.

The following Table I presents a comparative analysis of noise reduction methods specifically tailored for wheel speed sensor (WSS) data in advanced driver assistance systems (ADAS). It provides critical insight into the constraints associated with their application in real-time environments by highlighting the advantages, disadvantages and performance metrics of each method.

5) *Performance evaluation criteria*: The performance of each filtering technique was rigorously evaluated using metrics such as Signal-to-Noise Ratio (SNR), Mean Squared Error (MSE), and Root Mean Squared Error (RMSE). The analysis provided detailed insights into the scenario-specific performance and computational complexity of each method, with an emphasis on practical implications for ADAS development. The metrics used in this study are critical for quantifying the effectiveness of each noise reduction technique, offering a clear comparison of their relative strengths and weaknesses.

To quantify the effectiveness of the noise reduction techniques evaluated in this study, the following Table II outlines the performance evaluation criteria, focusing on key metrics such as Signal-to-Noise Ratio (SNR), Mean Squared Error (MSE), and Root Mean Squared Error (RMSE). This comparison is essential for understanding the impact of each technique on data integrity and system reliability.

TABLE I. COMPARATIVE ANALYSIS OF NOISE REDUCTION METHODS FOR WSS DATA IN ADAS

Method	Advantages	Disadvantages	Performance
Simple Moving Average (SMA)	- Easy to implement	- Introduces lag - Less effective for complex noise patterns	- Significant noise reduction - Improves SNR - Higher MSE and RMSE compared to other methods during rapid signal changes
Exponential Moving Average (EMA)	- More responsive to recent changes - Smoother transition and less lag compared to SMA	- More complex to implement than SMA - May still lag in highly dynamic scenarios	- Better noise reduction than SMA - Higher SNR improvement - Lower MSE and RMSE than SMA, suitable for timely signal changes
Wavelet Denoising	- Handles non-stationary signals well - Effective at separating noise from the actual signal	- Computationally intensive - Requires careful selection of wavelet type and decomposition level	- Outperformed SMA and EMA - Highest SNR improvements - Lowest MSE and RMSE, effective for varying noise characteristics
Low Pass Filtering	- Simple and effective for high-frequency noise - Preserves low-frequency components of the signal	- Can distort signal if cutoff frequency is not appropriately set - May not be effective for low-frequency noise	- Significant high-frequency noise reduction - Improved SNR - Potential signal distortion indicated by MSE and RMSE, requires careful tuning
KalmanNet	- Neural network-aided Kalman filtering to enhance noise reduction capability using learned patterns	- Computationally intensive - Requires training data	- Demonstrated significant improvements in noise reduction and data accuracy compared to traditional Kalman filters
Extended Kalman Filter (EKF)	- Suitable for non-linear systems - Incorporates system dynamics into the filtering process	- Requires accurate system models - Computationally demanding	- Significant noise reduction - Improved SNR - Lower MSE and RMSE, effective for non-linear RADAR data
Unscented Kalman Filter (UKF)	- Superior performance for highly non-linear systems - Does not require linearization of the system model	- High computational complexity - Sensitive to initial conditions	- Outperforms EKF in highly non-linear applications - Highest SNR and lowest MSE and RMSE for complex noise patterns

TABLE II. METRICS CRITERIA EVALUATION

Metric	Increase	Decrease
Signal-to-Noise Ratio (SNR)	- Indicates improved signal quality: → A higher SNR means the signal is clearer relative to the noise, suggesting that the filtering technique effectively reduces noise and enhances the signal's clarity.	- Indicates poorer signal quality: → A lower SNR implies that the signal is more contaminated by noise, suggesting that the filtering technique is less effective at noise reduction.
Mean Squared Error (MSE)	- Indicates poorer filtering performance: → An increase in MSE means the difference between the filtered signal and the original clean signal is larger, suggesting that the filtering technique introduces significant error or fails to effectively reduce noise.	- Indicates better filtering performance: → A decrease in MSE means the filtered signal is closer to the original clean signal, indicating that the filtering technique effectively reduces noise with minimal distortion.
Root Mean Squared Error (RMSE)	- Indicates poorer filtering performance: → An increase in RMSE suggests that the filtering technique is less effective, as there is a larger average magnitude of error between the filtered signal and the original clean signal.	- Indicates better filtering performance: → A decrease in RMSE indicates that the filtering technique performs well, reducing the average magnitude of error and closely approximating the original clean signal.

B. Scope and Limitations of the Research

Fig. 11 shows the ADAS driving scenarios for which we limit the current study to identify the adequate filtering method for each situation accordingly. This focused approach ensures that the findings are directly applicable to the most critical real-world challenges faced by ADAS systems.

The scenarios used for generating WSS signals represent various high-risk and typical driving situations encountered in Advanced Driver Assistance Systems (ADAS). These include:

- 1) *Urban intersection*: Simulates driving at different speeds within an intersection, capturing low, moderate, slow, and high-speed phases.
- 2) *Rear-end collision avoidance*: Captures high-speed driving followed by rapid deceleration to avoid a rear-end collision.

3) *Pedestrian crossing*: Models stopping and starting for pedestrian crossings, with periods of driving and stopping.

4) *Emergency braking for cyclist*: Demonstrates deceleration and rapid acceleration to avoid a collision with a cyclist.

5) *Blind spot detection*: Simulates consistent speed with noise to represent challenges in detecting vehicles in blind spots.

6) *Highway lane change*: Depicts the process of lane changing on a highway, with distinct phases of driving in a lane and the lane change itself.

7) *Cut-in vehicle*: Illustrates a vehicle cutting into the lane, requiring a deceleration phase followed by a return to normal speed.

8) *Roadworks zone navigation*: Depicts navigation through a roadworks zone with varying speeds and obstacles.

- 9) *Traffic jam assist*: Represents slow driving and stopping typical of traffic jam conditions.
- 10) *Left Turn Across Path (LTAP)*: Models the approach, turn, and acceleration phases of making a left turn across another path.

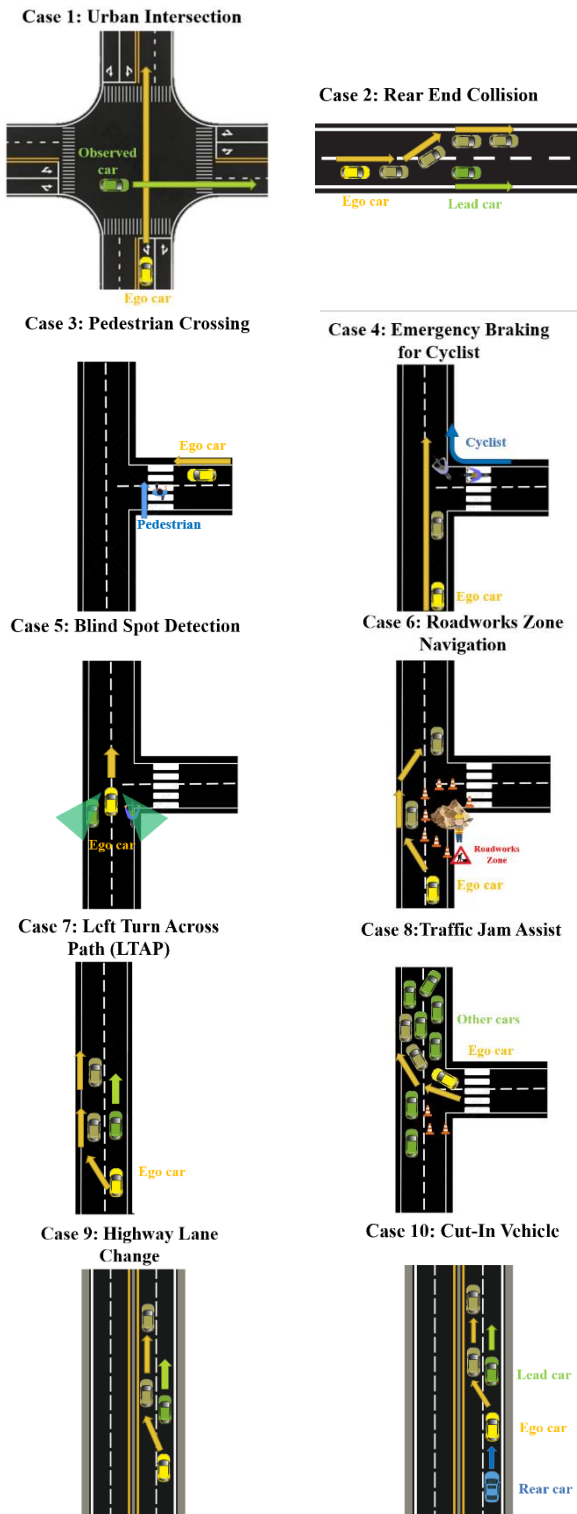

Fig. 11. ADAS driving scenarios.

These scenarios are derived from real-world situations commonly tested in ADAS and V2X (Vehicle-to-Everything) systems, as outlined in safety protocols like the European New Car Assessment Programme (Euro NCAP). The selection of these scenarios ensures the simulation of diverse and challenging conditions that ADAS must handle effectively for enhanced safety and performance. The rigorous selection and simulation of these scenarios are critical for validating the effectiveness of the noise reduction techniques in realistic and high-pressure environments.

C. Detailed Proposed Method

Below the detailed Method followed during this research:

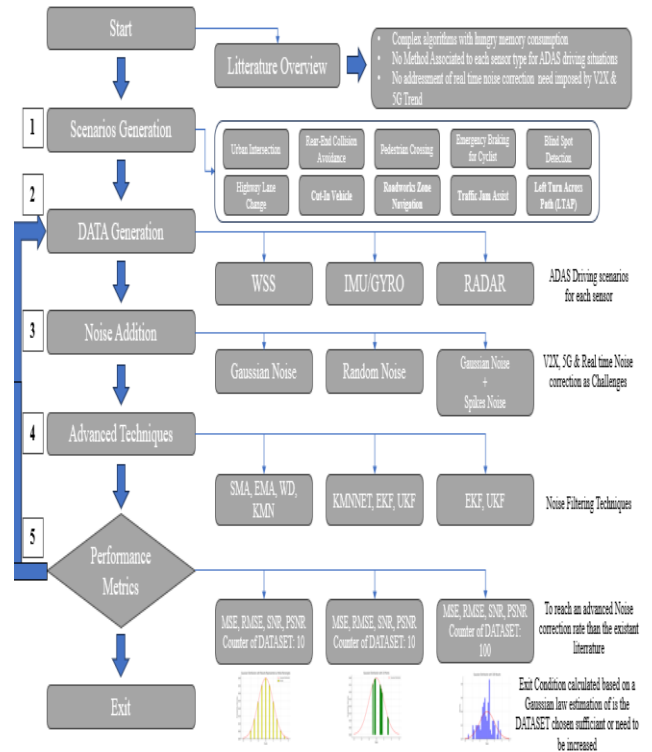

Fig. 12. Proposed method for noise filtering in the context of V2X & 5G challenges.

The proposed method (Fig. 12) is illustrated in the schema above, showcasing the systematic process of data generation, noise introduction, filtering, and evaluation across diverse driving scenarios. This approach ensures that the study addresses the specific challenges posed by V2X and 5G integration in ADAS systems.

1) *Data generation and noise addition*: The synthetic datasets were designed to replicate the sensor data from various automotive sensors under realistic driving conditions. For instance, WSS data was generated at high frequencies to capture rapid speed changes, while accelerometers and gyroscopes produced data representing motion and orientation in dynamic environments. This detailed approach ensures that the study comprehensively addresses the unique challenges posed by each sensor type, particularly under varied driving conditions, thus providing a robust basis for noise reduction

analysis. Noise was systematically introduced to these datasets, including Gaussian noise to simulate thermal fluctuations and periodic spikes to represent electromagnetic interference (EMI). The varied noise levels ensure a comprehensive evaluation of each filtering technique's effectiveness and resilience across diverse conditions.

The filtering techniques applied in this study were selected for the ability to address the specific challenges posed by each sensor type. The selection was guided by the specific operational contexts and the complexity of the noise characteristics encountered in real-world scenarios:

2) *Identification of the convenient filtering techniques:*

Based on the Fig. 4, the filtering techniques applied in this study were selected for their ability to address the specific challenges posed by each sensor type:

- **Simple Moving Average (SMA) and Exponential Moving Average (EMA):** These methods are computationally efficient and suitable for reducing short-term fluctuations and high-frequency noise in relatively stable environments. Their simplicity makes them ideal for real-time processing in scenarios where computational resources are limited, ensuring they meet the performance requirements of ADAS systems.
- **Wavelet Denoising:** This technique excels in handling non-stationary signals, making it effective for complex and dynamic noise patterns. Its ability to separate noise from actual signal components ensures high accuracy, especially in environments where signal integrity is critical.
- **Low Pass Filtering (LPF):** Simple yet effective for attenuating high-frequency noise, with careful tuning to avoid signal distortion. Although computationally lighter, LPF requires careful parameter selection to maintain signal fidelity and effectiveness.
- **KalmanNet:** A neural network-aided Kalman filtering technique designed to enhance noise reduction capability by learning patterns within the data. This advanced method is particularly effective in dynamic environments but requires significant computational resources and training data.
- **Extended Kalman Filter (EKF) and Unscented Kalman Filter (UKF):** These filters are particularly effective for non-linear systems, with the UKF offering superior performance without requiring linearization of the system model. Their robustness in handling non-linearities makes them indispensable for accurate sensor data processing in complex ADAS scenarios.

The methodology outlined provides a structured approach to evaluating and enhancing noise reduction techniques for automotive sensors in ADAS applications. By simulating diverse driving scenarios and introducing various noise types, the study identifies the most effective methods for improving sensor data integrity and reliability. This approach ensures that the findings are robust and applicable to real-world conditions,

contributing to the advancement of noise reduction strategies in automotive systems.

V. RESULTS

A. Study Overview and Hypothesis Testing

To rigorously evaluate the hypothesis that tailored noise reduction techniques enhance the accuracy and reliability of sensor data in Advanced Driver Assistance Systems (ADAS), this study conducted a comprehensive analysis across various driving scenarios. The analysis involved the generation of synthetic datasets for Wheel Speed Sensors (WSS), Inertial Measurement Units (IMU/GYRO), and RADAR sensors, reflecting the data volume and noise complexity typically encountered in real-world conditions. Various noise types and levels were systematically introduced, and multiple noise reduction techniques were applied. Their performance was measured using key metrics: Mean Squared Error (MSE), Root Mean Squared Error (RMSE), Signal-to-Noise Ratio (SNR), and Peak Signal-to-Noise Ratio (PSNR). Fig. 13 illustrates the flow of the results section, providing a clear roadmap of the steps and analysis undertaken.

The results section is organized systematically to ensure a thorough evaluation of noise reduction techniques across various driving scenarios. Fig. 13 outlines the flow of this section, detailing each step of the analysis, from data generation to performance evaluation.

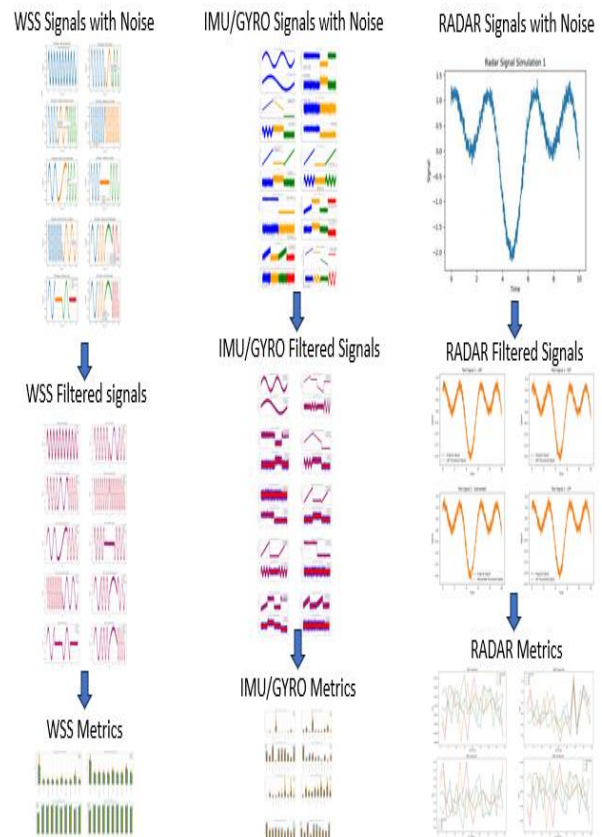

Fig. 13. Results flow chart.

This flow chart helps readers navigate the structure of the results, ensuring clarity and coherence in the presentation of the findings.

B. Synthetic Data Generation and Noise Modeling

Synthetic datasets were generated to mimic sensor data from WSS, IMU/GYRO, and RADAR sensors under diverse driving scenarios, including urban intersections, highway lane changes, and emergency braking situations. These datasets serve as the foundation for evaluating the effectiveness of various noise reduction techniques.

1) *WSS signals*: Fig. 14 shows the generated datasets for WSS signals with introduced noise across different ADAS scenarios.

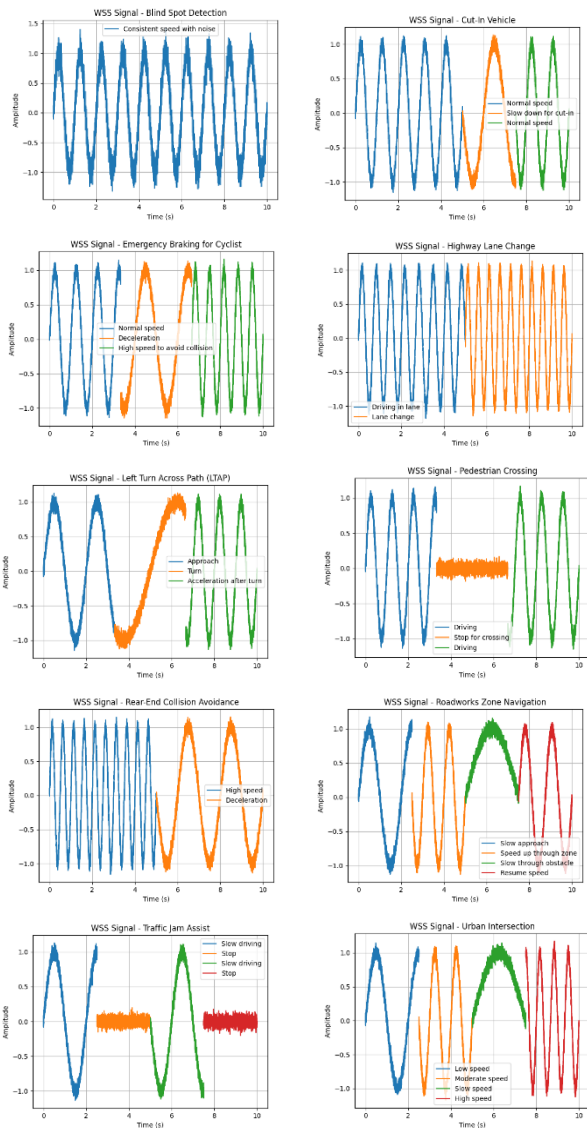

Fig. 14. DATA set generated for WSS signals with noises for each ADAS scenario.

The noise profiles depicted in this figure are crucial for assessing the robustness of the filtering techniques applied later in the analysis. Noise introduction involved adding Gaussian

noise to simulate thermal fluctuations and periodic spikes to replicate electromagnetic interference (EMI). Noise levels were varied to evaluate the robustness of each filtering technique under different conditions, ensuring a comprehensive assessment across all simulated scenarios.

2) *IMU/GYRO signals*: The IMU/GYRO signals, as shown in Fig. 15, were generated with various noise levels to replicate real-world conditions experienced by these sensors.

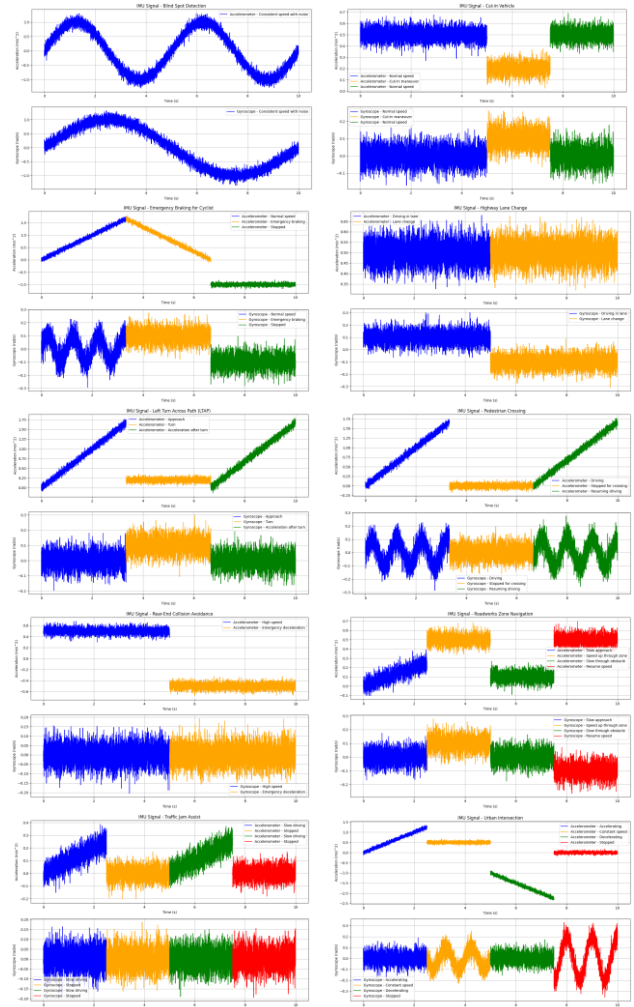

Fig. 15. DATA set generated for IMU/GYRO with noises for each ADAS scenario.

These datasets are essential for testing the effectiveness of noise reduction techniques on motion and orientation data in dynamic driving scenarios.

3) *RADAR Signals*: Fig. 16 presents the generated RADAR signals, highlighting the complexity of noise patterns in dynamic environments.

Given the importance of RADAR in obstacle detection and localization, this dataset plays a critical role in evaluating noise reduction techniques tailored for such complex signals. RADAR signals are dependent on obstacle localization rather than specific ADAS scenarios. Therefore, this study did not cover them under ADAS scenarios. The generation focused on

real-time noise reduction with minimal time consumption to emphasize pattern recognition and the application of the appropriate noise reduction technique based on the ADAS situation encountered. For RADAR signals, the dynamic environment necessitates a different noise reduction approach than simpler sensors like WSS and IMU/GYRO.

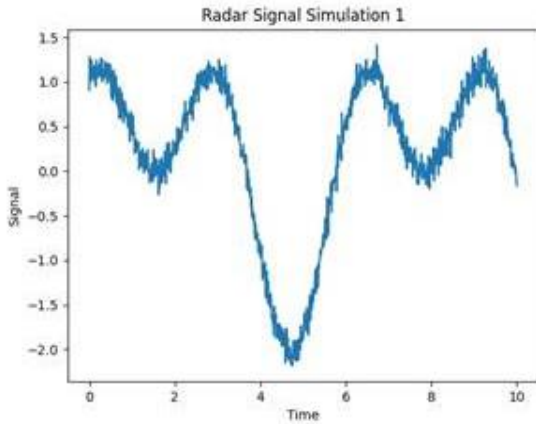

Fig. 16. DATA set for RADAR signals with noises.

C. Filtering Technique Performance on Sensor Data:

The effectiveness of the applied filtering techniques is illustrated in the following figures, showcasing the filtered outputs for each sensor type.

1) WSS Filtered signals: Fig. 17 displays the filtered WSS signals after applying the various noise reduction techniques, highlighting their impact on signal clarity.

This figure provides a visual comparison of how each technique improved the WSS data quality, making it easier to evaluate their relative effectiveness.

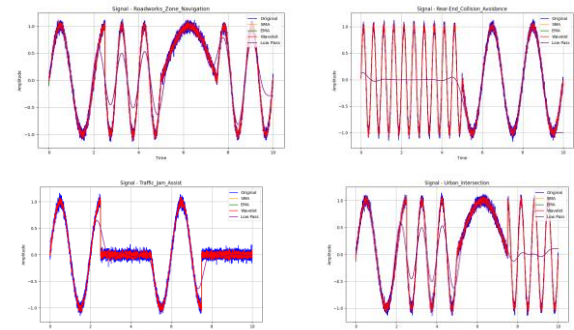

Fig. 17. Filtered signals for WSS.

2) IMU/GYRO filtered signals: The filtered signals for IMU/GYRO sensors are shown in Fig. 18, demonstrating the performance of different noise reduction methods.

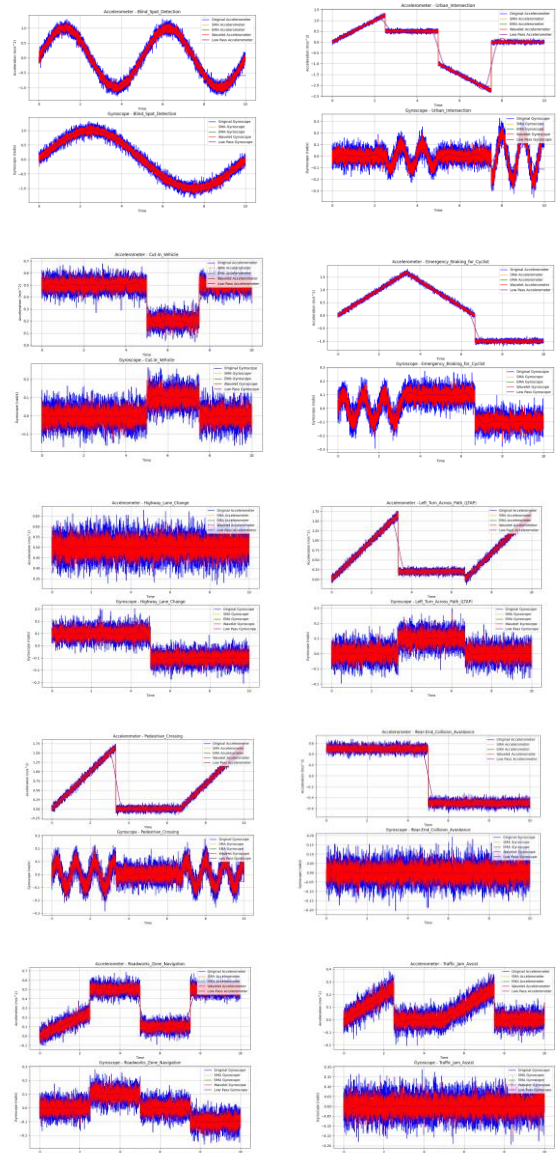

Fig. 18. Filtered signals for IMU/GYRO.

This visual representation underscores the importance of choosing the right technique based on the specific noise characteristics and sensor type.

3) *RADAR filtered signals*: Fig. 19 illustrates the filtered RADAR signals, reflecting the challenges and successes in noise reduction for these complex sensor types.

Fig. 19. Filtered signals for RADAR signals.

This figure is crucial for understanding the effectiveness of noise reduction techniques in preserving the integrity of RADAR data, which is vital for accurate obstacle detection.

D. Comparative Performance Analysis Across ADAS Scenarios

The effectiveness of each filtering technique is further analyzed across the ten scenarios, including Urban Intersection, Highway Lane Change, Pedestrian Crossing, and Rear-End Collision Avoidance, among others.

1) *WSS metrics evaluation*: Fig. 20 presents the metrics evaluation for WSS across various ADAS scenarios, providing insights into the performance of each filtering method.

Fig. 20. WSS metrics evaluation across ADAS scenarios.

This analysis highlights how well each technique maintained signal integrity while reducing noise under different driving conditions.

2) *IMU/GYRO metrics evaluation*: Fig. 21 shows the metrics evaluation for IMU/GYRO signals, offering a detailed comparison of the noise reduction techniques applied.

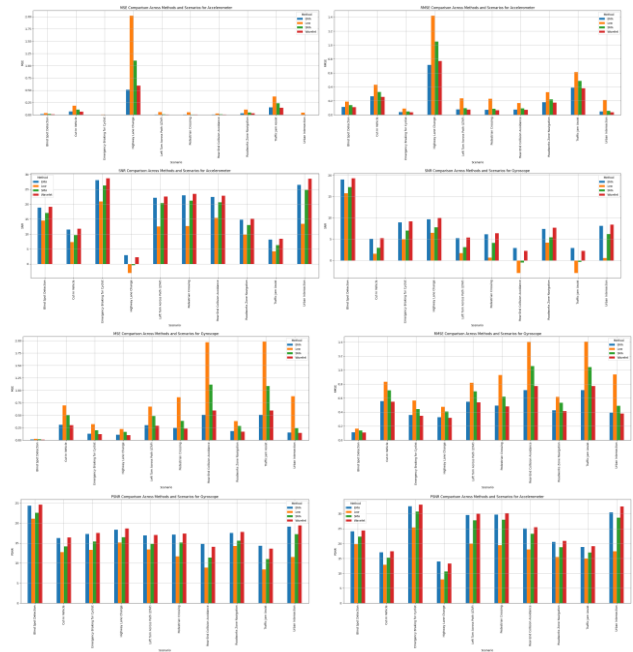

Fig. 21. IMU/GYRO metrics evaluation across ADAS scenarios.

This figure is key to understanding the effectiveness of filtering methods in handling the complexities of motion and orientation data.

3) *RADAR metrics evaluation*: Fig. 22 displays the metrics evaluation for RADAR signals, focusing on the ability of each technique to manage noise in dynamic environments.

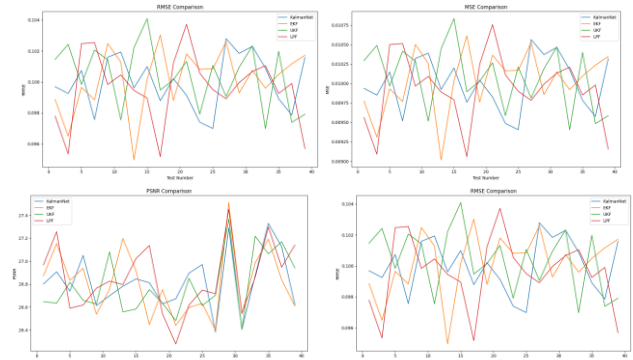

Fig. 22. RADAR metrics evaluation across ADAS scenarios.

The results from this figure are essential for determining the best noise reduction approach for RADAR data, crucial for obstacle detection and avoidance in ADAS.

The performance of each filtering technique was evaluated across the ten scenarios, focusing on how well each method reduced noise and preserved signal integrity, with a detailed analysis provided for each scenario.

The Table III summarizes the performance and results of various filtering methods across multiple ADAS scenarios, such as Urban Intersection and Highway Lane Change. It details the specific performance of each noise reduction technique, highlighting key metrics that demonstrate their

effectiveness in reducing noise and preserving signal quality under different driving conditions.

TABLE III. FILTERING METHODS PERFORMANCE AND RESULTS ANALYSIS

Noise Reduction Technique	Scenario	Performance	Key Metrics
Wavelet Denoising	Urban Intersection	Achieved the highest SNR and lowest MSE/RMSE, demonstrating robust noise reduction and signal preservation. Ideal for environments with non-stationary noise, making it suitable for dynamic urban settings.	High SNR, Low MSE/RMSE
	Highway Lane Change	Performed exceptionally well in handling high-frequency noise and rapid lane changes, with significant improvements in PSNR.	High PSNR
Simple Moving Average (SMA) and Exponential Moving Average (EMA)	Pedestrian Crossing	Offered balanced performance with smoother transitions and reduced signal lag. EMA slightly outperformed SMA in SNR, especially in scenarios involving frequent stop-start motions.	Smoother transitions, Reduced signal lag, Higher SNR for EMA
	Emergency Braking for Cyclist	Provided effective noise reduction during rapid deceleration phases, though introduced some lag in more dynamic environments.	Effective noise reduction, Some signal lag
Low Pass Filtering (LPF)	Blind Spot Detection	Effective in high-frequency noise attenuation but required careful tuning to prevent signal distortion. Showed consistent results in steady-state signal processing scenarios, such as Blind Spot Detection.	Effective high-frequency noise attenuation, Requires careful tuning
	Highway Lane Change	Demonstrated substantial high-frequency noise reduction but occasionally introduced residual errors, as indicated by higher MSE/RMSE values.	High-frequency noise reduction, Higher MSE/RMSE
KalmanNet	Emergency Braking for Cyclist	Showed superior noise reduction and signal preservation capabilities, particularly in	High SNR, Low MSE/RMSE

		complex, dynamic scenarios. Achieved high SNR and low MSE/RMSE, effective in real-time applications where accuracy is critical.	
Extended Kalman Filter (EKF) and Unscented Kalman Filter (UKF)	Cut-In Vehicle	UKF outperformed EKF in handling the non-linearities associated with sudden vehicle maneuvers, achieving the highest SNR and lowest error metrics in this scenario.	Highest SNR, Lowest error metrics
	Roadworks Zone Navigation	EKF provided robust performance in varying speeds and obstacle-rich environments, with moderate improvements in SNR and RMSE.	Moderate SNR/RMSE improvements

VI. DISCUSSION

A. Practical Implications for Real-Time ADAS Implementation

The findings underscore the importance of selecting appropriate noise reduction techniques based on specific driving scenarios and sensor characteristics. While advanced techniques like Wavelet Denoising and KalmanNet offer superior performance, their computational complexity poses challenges for real-time implementation. Conversely, simpler methods like SMA and EMA provide adequate noise reduction with lower computational demands, making them suitable for real-time processing in less dynamic environments.

B. Trends, Relationships, and Generalizations

The results from the experiments demonstrated clear trends in the performance of various adaptive signal-processing algorithms. KalmanNet and hybrid methods consistently showed the highest improvement in Signal-to-Noise Ratio (SNR) and the most significant reduction in Mean Squared Error (MSE) and Root Mean Squared Error (RMSE). These results underscore the effectiveness of combining traditional and machine learning techniques in handling both random and systematic noise, enhancing the accuracy of sensor data in dynamic automotive environments.

C. Scenario-Specific Performance Insights

The scenario-specific analysis revealed distinct strengths and limitations of each filtering technique:

This Table IV provides an evaluation of the noise reduction methods based on scenario-specific performance, offering a detailed analysis of their suitability in various ADAS environments. The advantages and disadvantages of each technique are listed, helping to identify the most effective approaches for dynamic, high-noise, and less dynamic conditions.

TABLE IV. METHODS EVALUATION BASED ON SCENARIO PERFORMANCE EVALUATION

Noise Reduction Technique	Performance Environment	Key Scenarios	Advantages	Disadvantages
Wavelet Denoising	Dynamic, high-noise environments	Urban Intersections, Highway Lane Changes	Superior noise reduction, ideal for dynamic settings	Potentially higher computational complexity
SMA and EMA	Less dynamic conditions	General ADAS applications requiring real-time processing	Simplicity, computational efficiency	Less effective in highly dynamic environments
KalmanNet and UKF	Non-linear dynamics, high uncertainty	Emergency Braking, Cut-In Vehicle	Best for complex scenarios, accurate signal preservation	Higher computational demands

Table I summarizes the comparative analysis of noise reduction methods across all scenarios, highlighting key metrics such as SNR, MSE, and RMSE.

The following table V offers a comprehensive comparative analysis of the noise reduction techniques discussed, focusing on their application to WSS data in ADAS. It examines their overall performance, including their ability to improve Signal-to-Noise Ratio (SNR) and reduce Mean Squared Error (MSE) and Root Mean Squared Error (RMSE), thereby providing a clear overview of their strengths and limitations.

TABLE V. COMPARATIVE ANALYSIS OF NOISE REDUCTION METHODS FOR WSS DATA IN ADAS

Method	Advantages	Disadvantages	Performance
Simple Moving Average (SMA)	- Easy to implement	- Introduces lag - Less effective for complex noise patterns	- Significant noise reduction - Improves SNR - Higher MSE and RMSE compared to other methods during rapid signal changes
Exponential Moving Average (EMA)	- More responsive to recent changes - Smoother transition and less lag compared to SMA	- More complex to implement than SMA - May still lag in highly dynamic scenarios	- Better noise reduction than SMA - Higher SNR improvement - Lower MSE and RMSE than SMA, suitable for timely signal changes
Wavelet Denoising	- Handles non-stationary signals well - Effective at separating noise from the actual signal	- Computationally intensive - Requires careful selection of wavelet type and decomposition level	- Outperformed SMA and EMA - Highest SNR improvements - Lowest MSE and RMSE, effective for varying noise characteristics

Low Pass Filtering	- Simple and effective for high-frequency noise - Preserves low-frequency components of the signal	- Can distort signal if cutoff frequency is not appropriately set - May not be effective for low-frequency noise	- Significant high-frequency noise reduction - Improved SNR - Potential signal distortion indicated by MSE and RMSE, requires careful tuning
KalmanNet	- Neural network-aided Kalman filtering to enhance noise reduction capability using learned patterns	- Computationally intensive - Requires training data	- Demonstrated significant improvements in noise reduction and data accuracy compared to traditional Kalman filters
Extended Kalman Filter (EKF)	- Suitable for non-linear systems - Incorporates system dynamics into the filtering process	- Requires accurate system models - Computationally demanding	- Significant noise reduction - Improved SNR - Lower MSE and RMSE, effective for non-linear RADAR data
Unscented Kalman Filter (UKF)	- Superior performance for highly non-linear systems - Does not require linearization of the system model	- High computational complexity - Sensitive to initial conditions	- Outperforms EKF in highly non-linear applications - Highest SNR and lowest MSE and RMSE for complex noise patterns

The Table V summarizes the performance of various noise reduction techniques across different driving scenarios, highlighting the strengths and limitations of each method in terms of key metrics like SNR, MSE, and RMSE, and providing clear insights into their suitability for specific ADAS applications. The comprehensive analysis across ten scenarios—Urban Intersection, Pedestrian Crossing, Emergency Braking for Cyclist, Highway Lane Change, Cut-In Vehicle, Rear-End Collision Avoidance, Blind Spot Detection, Traffic Jam Assist, Left Turn Across Path (LTAP), and Roadworks Zone Navigation—provided detailed insights into the suitability of each filtering technique under varied dynamic conditions. This detailed insight is crucial for tailoring noise reduction strategies to the specific operational contexts of ADAS, ensuring optimal performance under varied driving conditions.

D. Effectiveness of Wavelet Denoising

Wavelet Denoising was found to be the most effective method for non-stationary signals because it decomposes the signal into its frequency components, allowing for precise separation of noise from the actual signal. This method preserves important signal features while effectively attenuating noise, leading to improved SNR and lower MSE. However, the primary challenge is the computational complexity of the wavelet transform, which can be resource-intensive and may not meet the real-time processing requirements of ADAS. Optimizing the algorithms and leveraging efficient hardware solutions are necessary to address these challenges and implement Wavelet Denoising effectively in real-time applications.

E. Advantages of Kalmannet

KalmanNet integrates neural networks with traditional Kalman filtering, enhancing its capability to learn and adapt to complex, dynamic environments. This results in better noise reduction and data accuracy. In ADAS applications, KalmanNet provides robust performance in scenarios with high non-linearities and varying noise characteristics, making it suitable for handling the complex data from sensors like RADAR.

F. Importance of Hardware-in-the-Loop (HIL) Testing

HIL testing is crucial as it allows for the simulation of real-world driving conditions and noise patterns in a controlled environment. This ensures that the noise reduction techniques are tested under realistic scenarios, validating their effectiveness before deployment in actual vehicles. In our study, HIL testing was used to simulate various ADAS scenarios and noise conditions, providing a comprehensive evaluation of each filtering method's performance.

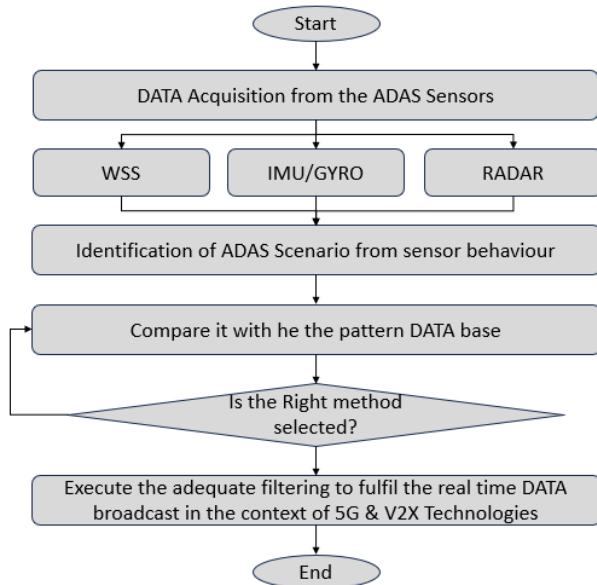

Fig. 23. Testing approach from HIL bench perspective.

Fig. 23 presents the testing approach from the HIL Bench perspective, showcasing how real-world driving conditions and noise patterns are simulated to rigorously evaluate and validate the performance of noise reduction techniques before their deployment in actual vehicles.

G. Practical Viability of SMA and EMA

Simple Moving Average (SMA) and Exponential Moving Average (EMA) provided effective noise reduction in scenarios with smoother signal variations. These methods, due to their computational simplicity, are highly viable for real-time applications where computational resources are limited. Although they introduce lag and are less effective in highly dynamic conditions, they provide reasonable noise reduction in scenarios with smoother signal variations. Combining these methods with other techniques can help mitigate their limitations and enhance overall performance.

H. Exceptions and Outlying Data

During the experiments, certain scenarios presented exceptions and outlying data points that deviated significantly from the expected performance metrics. For instance, in highly dynamic scenarios like emergency braking for cyclists, SMA and EMA struggled to adapt quickly enough, resulting in higher MSE and RMSE values. Additionally, Low Pass Filtering occasionally introduced signal distortions in scenarios with mixed frequency noise patterns, highlighting the need for precise tuning. These outliers emphasize the importance of scenario-specific adjustments and the potential for hybrid approaches to address diverse noise conditions more effectively.

I. Comparison with Previous Studies

The findings of this study align with previous research on noise reduction in ADAS sensor data management. Similar to the work by [1] and [5], our results confirm the effectiveness of advanced filtering techniques like KalmanNet and Wavelet Denoising in enhancing data accuracy and reliability. However, our study extends the existing literature by providing a more detailed comparative analysis across multiple driving scenarios and sensor types, offering practical insights for real-world applications. Furthermore, the integration of HIL testing in our methodology provides a robust validation framework, addressing a gap identified in earlier studies regarding the need for realistic testing environments.

J. Future Research Directions

Future research should focus on developing hybrid noise reduction methods that combine the strengths of traditional and advanced techniques, optimizing them for real-time applications. Expanding the dataset to include more diverse scenarios and sensor types will further validate the robustness and generalizability of these methods. Additionally, integrating machine learning algorithms and adaptive filtering techniques will be crucial in enhancing the adaptive capabilities of noise reduction methods in evolving technological environments.

Method applicability

Fig. 24. Method applicability and possibility for extension on car and HIL bench.

Fig. 24 illustrates the potential for extending the proposed noise reduction methods to both automotive applications and Hardware-in-the-Loop (HIL) Bench testing, highlighting the adaptability and scalability of these techniques for broader use cases and real-time environments.

K. Consolidated Findings and Recommendations

Overall, this study provides a detailed comparison of noise reduction techniques across various ADAS scenarios, offering valuable insights for their application in real-world systems. The results highlight the necessity of a tailored approach to noise reduction, considering both the operational context and the computational resources available.

VII. CONCLUSION

This study demonstrated that adaptive signal processing algorithms significantly enhance the accuracy and reliability of sensor data in embedded automotive systems. The introduction highlighted the need for advanced techniques to manage the increasing complexity and volume of sensor data in modern vehicles. The experimental simulations confirmed that KalmanNet effectively reduces noise and improves data accuracy, showing the highest improvement in SNR and significant reductions in MSE and RMSE. The study also found that methods like Wavelet Denoising excel in dynamic environments with non-stationary noise, making them suitable for complex urban driving scenarios. The implications of these results are significant for the automotive industry, as implementing these adaptive algorithms can enhance the performance and safety of vehicle systems by ensuring robust and reliable sensor data handling.

Future research should focus on further optimizing these algorithms, particularly in the context of real-time processing constraints, and exploring their integration into broader automotive applications, including autonomous driving and complex sensor fusion tasks.

The integration of 5G, V2X, and IoV technologies into automotive systems significantly enhances the capabilities and performance of Advanced Driver Assistance Systems (ADAS). This study rigorously evaluated the effectiveness of various noise reduction techniques on Wheel Speed Sensors (WSS) and Inertial Measurement Units (IMUs) across a range of urban and dynamic driving scenarios. The findings underscore the necessity of selecting noise reduction techniques that are tailored to specific driving conditions and sensor characteristics, ensuring that ADAS systems can operate effectively under the diverse and challenging conditions encountered in real-world driving.

Abstract—Multimodal medical image fusion leverages the correlation between different modal images to enhance the information contained within a single medical image. Existing fusion methods often fail to effectively extract multiscale features from medical images and establish long-distance relationships between deep feature blocks. To address these issues, we propose DMMFnet, an encoder-decoder fusion network that utilizes shared and private encoders to extract shared and private features. DMMFnet is based on super token sampling and channel-spatial attention. The shared encoder and decoder use a transformer structure with super token sampling technology to effectively integrate information from different modalities, improving processing efficiency and enhancing the ability to capture key features. The private encoder consists of invertible neural networks and transformer modules, designed to extract local and global features, respectively. A novel transformer module refines attention distribution and feature aggregation to capture superpixel-level global correlations, ensuring that the network effectively captures essential global information, thereby enhancing the quality of the fused image. Experimental results, comparing DMMFnet with nine leading fusion methods, indicate that DMMFnet significantly improves various evaluation metrics and achieves superior visual effects, demonstrating its advanced fusion capability.

Keywords—Medical image fusion; channel-spatial attention; super token sampling; encoder-decoder

I. INTRODUCTION

Rapid advancements in medical imaging technology have allowed for the integration of multimodal medical pictures into clinical diagnosis, surgical guidance, and medical research in recent decades [1]. However, different medical images emphasize distinct aspects. For example, Computer Tomography (CT) scans yield accurate images of the bones, they do not capture the fine details of soft tissues. In contrast, Magnetic Resonance Imaging (MRI) offers finely detailed images of the organs' soft tissues, providing substantial clinical diagnostic value [2]. Positron Emission Tomography (PET) images reflect metabolic changes and functional states of lesions through the ingestion of imaging agents. Single Photon Emission Computed Tomography (SPECT) images diagnose a broad spectrum of diseases using varying depth colors to mark affected areas [3, 4]. The usage of the medical images one by one modality to diagnose diseases is not only time-consuming but also requires extensive experience. Therefore, the goal of

multimodal medical image fusion techniques is to create a single multimodal image from two modalities, and the outcomes can preserve the meaning, unique characteristics, and information from the original images, such as high-resolution structural data from CT, tissue textures from MRI [5]. Fused images have a richer texture structure and more pronounced lesion areas compared to single-modality medical images [6]. This greatly helps physicians analyze the diseases that are challenging to observe, reducing the misdiagnoses rate and surgical errors.

Usually, there are two types of image fusion tasks: supervised learning fusion and unsupervised learning fusion. Supervised learning is predominantly applied in the domain of multi-focus image fusion [7, 8]. Unsupervised learning is considered unsuitable for medical image fusion (MMIF) tasks due to the unique nature of medical images [9]. Moreover, due to the characteristics of medical images, the fusion methods designed for other types of images cannot be directly applied to multimodal medical image fusion tasks. According to different computational approaches, medical image fusion methods can be divided into traditional methods and deep learning methods.

Historically, among the traditional fusion methods, multi-scale transform (MST)-based methods, such as wavelet transform [10], pyramid transform [11], and subspace transform [12], have been commonly used. While the tower-based decomposition laid the groundwork for MST-based image fusion research with relatively simple implementation, it lacks directionality and is sensitive to noise, leading to redundancy between the pyramid levels. Wavelet transform offers good time-frequency locality and directionality without information redundancy, but it lacks directional selectivity and translation invariance, failing to fully extract edge information in images. Choosing the appropriate subspace mapping methods for specific fusion tasks remains a significant challenge in MST-based fusion methods.

For image fusion tasks, Pulse-Coupled Neural Networks (PCNN) [13] have received the most attention. Yin et al. proposed a fusion method combining NSST with PCNN (NSST-PAPCNN) for multimodal image fusion tasks. In this approach, NSST is used for feature extraction from multiple levels [14]. Tan et al. developed NST-MSMG [15]. It fuses high-frequency data using PCNN and boundary measurements and fuses low-frequency features utilizing an energy-based fusion rule set. However, PCNN-based approaches nevertheless follow the

*Corresponding Author.

fundamentals of multi-scale transform (MST) methods, which are needed for well-crafted decomposition and fusion rules.

The sparse representation (SR) [16] is widely utilized for image fusion, employing a mechanism that optimizes an extensive dictionary and generates sparse coefficients to achieve effective fusion. Liu et al. integrated multi-scale decomposition with convolutional sparse representation (CSR) [17]. However, methods based on SR have high computational demands, generally employing a complete and redundant dictionary for adaptive sparse representation of images. Furthermore, applying the same decomposition operations to different modalities of the source images may result in unexpected artifacts. In addition, the manual construction of the decomposition strategies and fusion rules make the fusion process complex and time-consuming [18, 19].

Recent advances have seen the adoption of deep learning techniques for multimodal image fusion, aiming to address the shortcomings of conventional fusion methods, all of which can be classified into three main types according to the network architectures: the Auto-encoder-based image fusion, the Convolutional Neural Network [20] (CNN)-based image fusion, and the Generative Adversarial Network [21] (GAN)-based image fusion.

The CNN-based image fusion methods are effective in processing spatial and structural information within image neighborhoods. Although CNN-based models are proficient in extracting local details and inductive biases from images, they lack a comprehensive understanding and learning of global semantic information in images. Additionally, due to their limited receptive field, CNNs inherently find it challenging to capture long-range relationships within images. To deal with these problems, Dosovitskiy et al. introduced the Vision Transformer (ViT) [22], which uses self-attention to conduct global comparisons across all visual tokens. It has shifted the paradigm from CNN-based feature extraction. Subsequent studies [23, 24] have shown that ViTs have potent global dependency learning capabilities in visual content. But recent research [25, 26] has shown that ViTs tend to capture shallow local features with high redundancy. This is due to shallow global attention focusing on a few adjacent tokens and neglecting most distant ones, which heavily hinders the extraction of the texture details in the fused image [27].

GAN is a type of deep learning model consisting of two modules: the generator and the discriminator. Ma et al. applied GANs to multimodal medical image fusion tasks [28]. Hung et al. introduce a multi-generator method for image fusion [29]. However, GAN-based image fusion approaches are prone to training instabilities and gradient vanishing issues [30]. Moreover, GAN architectures lose structural details due to down-sampling in pooling layers, which results in inefficient utilization of image information. The auto-encoder-based image

fusion utilizes an unsupervised neural network model that comprises an encoder and a decoder. Deep Fuse [31] was one of the first methods in this domain. Li et al. introduced DenseNet and nested connections to improve the feature extraction capability of encoders [32, 33]. Furthermore, Jian et al. enhanced a self-encoder-based fusion framework by integrating an attention mechanism, aiming to extract features that are more interpretable [34]. However, due to the characteristics of GAN models, image fusion methods based on GANs are prone to instability during training. Additionally, GAN-based methods predominantly rely on CNN architectures, their limited ability to capture global information often results in insufficient fusion.

Although the above multimodal image fusion methods have obtained quite good results, several of the aforementioned problems persist. To deal with them, we propose an encoder-decoder network that uses the Invertible Neural Networks (INN) [35] and transformer module. The proposed method demonstrates superior feature extraction capabilities compared to existing method. By utilizing two distinct feature extractors to capture features at varying frequencies and then separately fusing these features during the fusion stage, our method preserves the original image's texture and structural information to the greatest extent possible. This approach is more effective in achieving the objectives of the MMIF tasks.

Here are the primary contributions of this study:

1) In order to effectively extract complementary information from the input images, a novel transformer module has been designed. The spatial and channel attention mechanisms are utilized to capture super-pixel-level global dependencies, resulting in a significant enhancement of the fusion image quality as demonstrated by both subjective and objective experiments.

2) The Context Broadcasting (CB) technique is employed in the transformer layer. This integration ensures consistent attention at each layer of the transformer model, thereby reducing the density of attention maps. Furthermore, the consistent attention mechanisms facilitate easier overall optimization of the model, aiding in more effective learning and representation of the complex relationships within the input data.

3) Extensive experiments on medical and biological image fusion demonstrate that the DMMFnet outperforms nine advanced fusion methods in terms of both quantitative metrics and visual assessment.

The organization of the paper is as follows: Section I introduces the research background and the contributions of this work. Section II provides a detailed description of the proposed DMMFnet. Section III presents and discusses the experimental results. Section IV concludes the paper.

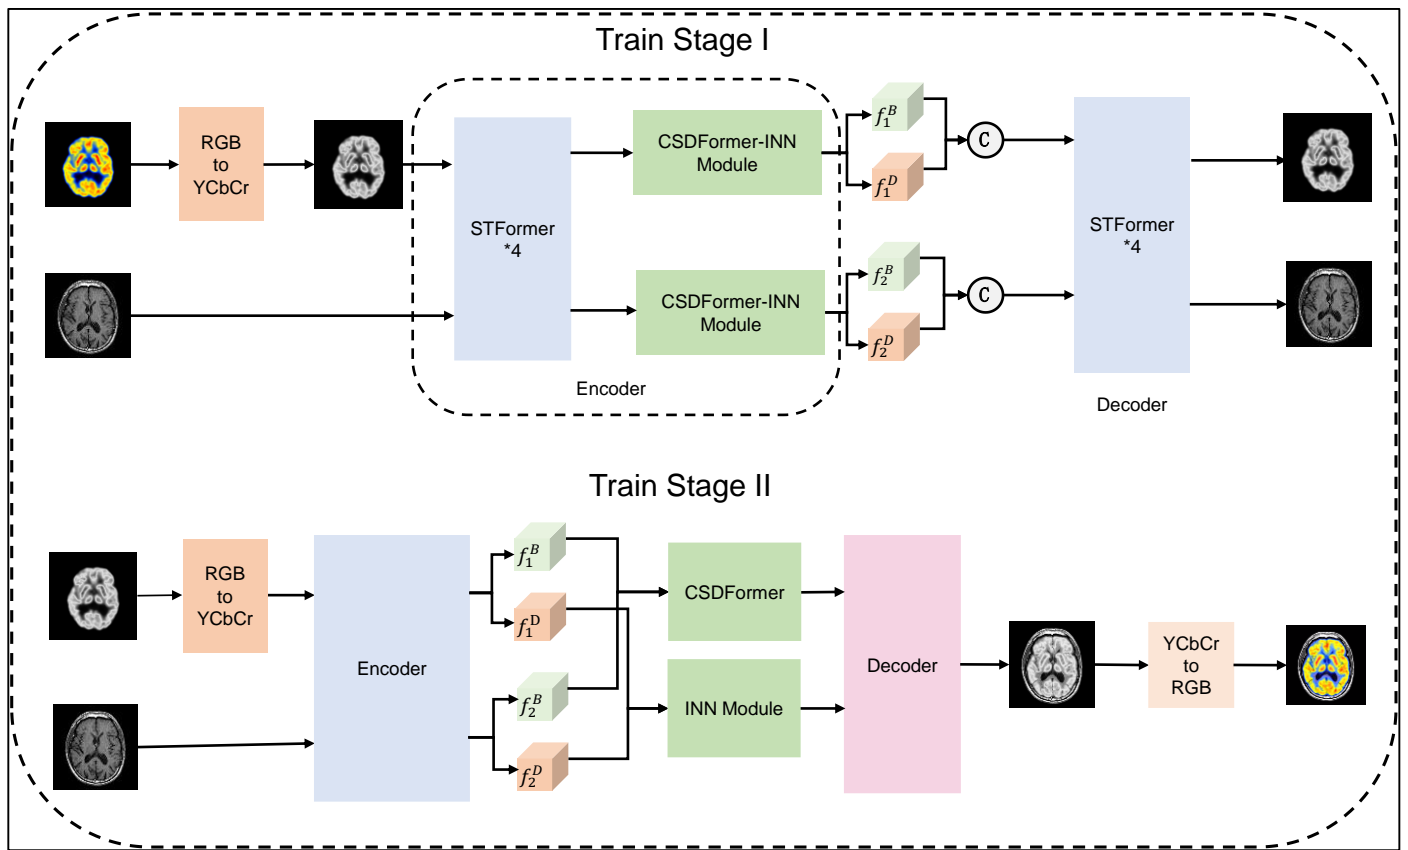

Fig. 1. The architecture of our DMMFnet method.

II. THE PROPOSED FUSION NETWORK

The detailed architecture of the proposed fusion framework is shown in Fig. 1. In general, CNN captures local features of the input image, whereas the transformer focuses on global features [36]. Therefore, we designed an encoder with a dual-branch structure. We used the INN to extract local features of the image and the transformer branch to extract global features of the image, then fused them separately. Finally, the DMMFnet comprises three modules: a fusion layer designed to combine different features, a decoder is used to rebuild the image and create the fused image, while an encoder is used to extract features.

The encoder consists of three components: a Shared Feature Extractor (SFE) based on STFormer, a Global Feature Extractor (GFE) based on CSDFormer, and a Local Feature Extractor (LFE) based on INN. Using PET-MRI image fusion as an example, we have defined some symbols to explain the entire fusion process: The paired PET and MRI input images are denoted as P and M , respectively. SFE, GFE, and LFE are indicated by $S(\cdot)$, $G(\cdot)$, and $L(\cdot)$, respectively. To extract shared features from the inputs is the aim of the SFE. This process is offered in Eq. (1):

$$f_P^S = S(P), f_M^S = S(M) \quad (1)$$

The model's Shared Feature Encoder includes the STFormer, which is based on super token sampling attention blocks [37], and the Gated-Dconv Feed-Forward Network (GDFN) module

[38]. Please refer to the original paper for more information on the structure of the super token sampling attention and GDFN. The schematic of the STFormer is depicted in Fig. 2.

By incorporating super tokens into the transformer and utilizing sparse associative learning to sample super tokens from visual tokens, we can effectively capture global dependencies through self-attention on these super tokens. The reason for selecting super token sampling attention blocks in the shared feature extraction step is that they efficiently capture global dependencies by decomposing global attention into a multiplication of sparse associative mappings and low-dimensional attention. This reduces computational complexity while retaining key image information.

The GDFN block is intended to merge features from various sources, specifically images from different modalities that exhibit unique characteristics within certain frequency ranges. The DMMFnet network can flexibly process and merge these features through the GDFN block.

Fig. 2. The schematic of the shared feature encoder.

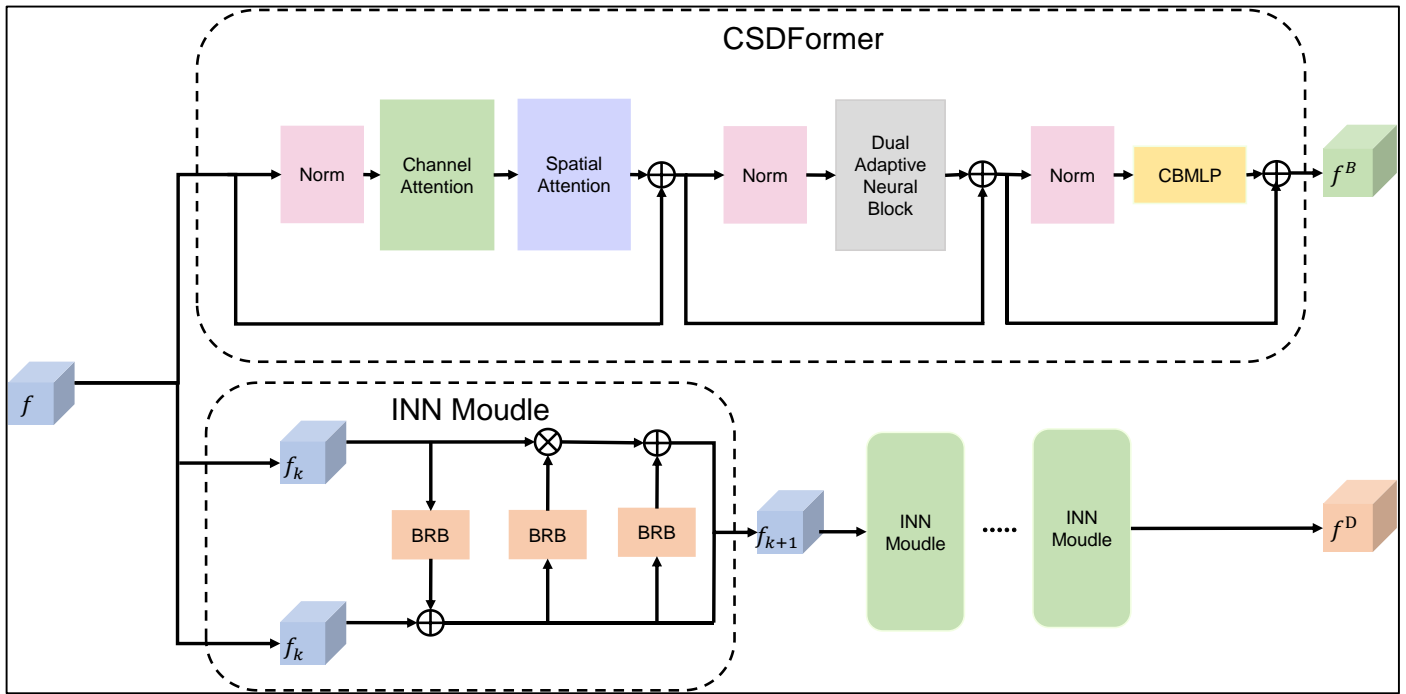

Fig. 3. The framework of the Global Feature Extractor (GFE) and Local Feature Extractor (LFE).

As illustrated in Fig. 3, the private feature encoder consists of two branches: GFE and LFE. The GFE extracts global features, while the LFE extracts local features.

The GFE branch concentrates on low-frequency global features by finely tuning the attention distribution. It effectively captures global dependencies at the super-pixel level through spatial and channel attention. By incorporating a Dual Adaptive Neural Block (DA), it adaptively encapsulates global features from superpixels to pixels, optimizing feature focus and refinement to ensure the capture of subtle changes and patterns crucial to the fusion process. In designing the CSDFormer, a Context Broadcasting (CB) technique was employed in the MLP layer. This technique involves manually inserting uniform attention into every layer of the ViT model, providing the necessary dense interactions and lowering the concentration level of attention maps across all layers. CB also enhances its capacity and generalization ability with negligible cost [39], which is formulated as Eq. (2).

$$f_P^B = G(f_P^S), f_M^B = G(f_M^S) \quad (2)$$

The LFE branch is focused on the lossless extraction of local high-frequency features. Given that edge and texture details are crucial for image fusion tasks, the INN module is utilized to preserve as many image details as possible. The INN module aims to mitigate information loss by mutually generating input and output features through a reversible design, and it can retain the high-frequency information of the medical image almost without any loss. The process is offered in Eq. (3) below.

$$f_P^D = L(f_P^S), f_M^D = L(f_M^S) \quad (3)$$

A. Fusion Layer

The fusion layer comprises the basic feature fusion layer and the deep feature fusion layer, which respectively combine the

basic and deep features. The fusion of basic and deep features is akin to the extraction of basic and deep features in the encoder. Therefore, CSDFormer and INN blocks are employed for the basic and deep fusion layers. The fusion process can be expressed by Eq. (4).

$$f^B = F_B(f_P^B, f_M^B), f^D = F_D(f_P^D, f_M^D) \quad (4)$$

F_B and F_D represent the basic and deep feature fusion layers, respectively.

B. Decoder

The different features extracted and processed in the previous phase are used as input to the decoder $DC()$. The reconstructed image from training stage I and the fused image from training stage II are the outputs of $DC()$. The corresponding formula is as follows:

$$\Sigma\tau\alpha\gamma\epsilon\text{I}: P^* = DC(f_P^B, f_P^D), M^* = DC(f_M^B, f_M^D) \quad (5)$$

$$\Sigma\tau\alpha\gamma\epsilon\text{II}: FUSE = DC(f^B, f^D) \quad (6)$$

Due to the input includes cross-modal and multi-frequency features, ensuring consistency between the decoder and the shared encoder enables the decoder to better understand and exploit the feature representations provided by the encoder, leading to improved fusion results. Therefore, we employ STFormer blocks as the fundamental units for the decoder.

C. Two-stage Training

A significant obstacle in medical image fusion tasks is the absence of a definitive ground truth due to the expensive and privacy-sensitive nature of the data sources, rendering advanced supervised learning methods ineffective. Therefore, we employ a two-stage learning approach to end-to-end train the DMMFnet.

Training stage I: In this phase, we initially feed the paired PET and MRI images $\{P, M\}$ into the Shared Feature Extractor (SFE) to extract their shared features $\{f_P^S, f_M^S\}$. Subsequently, each image is processed through the GFE based on the CSDFormer structure and the LFE based on INN separately. The basic features $\{f_P^B, f_M^B\}$ and detail features $\{f_P^D, f_M^D\}$ are extracted from the two modalities. The basic and detailed features within the same modality are merged (such as $\{f_P^B, f_P^D\}$ for PET or $\{f_M^B, f_M^D\}$ for MRI) and transmitted to the decoder for the reconstruction of the original PET or MRI image.

Training stage II: We continue to use paired PET and MRI images $\{P, M\}$ as the input. However, this time, we fed them into the encoder that was trained in Training Stage I. This enables further decomposition of features. Afterwards, we input the base features $\{f_P^B, f_M^B\}$ and detail features $\{f_P^D, f_M^D\}$ individually into fusion layers F_B and F_D . After the feature fusion process, the fused features $\{f^B, f^D\}$ are inputted into the decoder, which generates the fused image *FUSE*.

D. Loss Function

In training phase I, the total loss L_{total} is offered in Eq. (7) below.

$$L_{total} = \alpha_1 L_{pet} + \alpha_2 L_{mri} + \alpha_3 L_{decomp} \quad (7)$$

L_{pet} and L_{mri} represent the reconstruction losses for the two types of medical images. Since the model in the first stage can be regarded as a process of decomposition followed by synthesis, information loss inevitably occurs during both the decomposition and synthesis stages. L_{decomp} denotes the feature decomposition loss, while $\alpha_1, \alpha_2, \alpha_3$ are adjustment parameters. The overall loss function in the first stage is designed to ensure that information is maintained throughout the encoding and decoding procedures. Each loss function is as follows.

$$L_{pet/mri} = L_{int}^I(I, I^*) + \sigma L_{ssim}(I, I^*) \quad (8)$$

$$L_{decomp} = \frac{(cc(f_P^D, f_M^D))^2}{cc(f_P^B, f_M^B) + \epsilon} \quad (9)$$

$$L_{int}^I = \frac{1}{HW} ||I - I^*|| \quad (10)$$

where I denotes the original image before reconstruction, and I^* represents the image reconstructed in the first stage. Here, to ensure the positivity of this term, the operator CC is the

correlation coefficient and ϵ is assigned a value of 1.01.

In training phase II, the total loss L_{total} is offered in Eq. (11) below.

$$L_{total} = \alpha_1 L_{ssim} + \alpha_2 L_{test} + \alpha_3 L_{int}^{II} \quad (11)$$

L_{ssim} represents the structural loss, measuring the similarity between two images. L_{test} stands for texture loss, while L_{int}^{II} denotes intensity loss. $\alpha_1, \alpha_2, \alpha_3$ are adjustment parameters. The overall loss function in the second stage aims to train the fusion network weights while simultaneously adjusting the the first stage's trained encoder and decoder. Each loss function is as follows.

$$L_{int}^{II} = \frac{1}{HW} ||I_f - \text{Max}(I_{pet}, I_{mri})|| \quad (12)$$

$$L_{test} = \frac{1}{HW} |||\nabla I_f| - \text{Max}(|\nabla I_{pet}|, |\nabla I_{mri}|)|| \quad (13)$$

$$L_{ssim} = \gamma_1(1 - ssim(I_f, I_{pet})) + \gamma_2(1 - ssim(I_f, I_{mri})) \quad (14)$$

H and W stand for the original image's height and width, respectively. γ_1 and γ_2 are the adjustment parameters used to set the importance of information from each image. In the context of multimodal medical image fusion, the most critical aspect is effectively preserving information about lesion regions and texture details. We consider the structural information of MRI images to be more important in the MMIF. Through experimentation, we have found that the best fusion results are achieved when $\gamma_1 = 0.45$ and $\gamma_2 = 0.55$.

III. EXPERIMENTAL RESULTS AND DISCUSSION

A. The Dataset and Experimental Setting

The present study involves two fusion tasks: biological and medical image fusion. The medical image tasks include MRI/CT fusion, MRI/PET fusion, and MRI/SPECT fusion. All data can be obtained from [40]. The MRI/CT brain training set consists of 160 pairs, with 24 pairs in the test set; the MRI/PET brain training set comprises 245 pairs, with 24 pairs in the test set; and the MRI/SPECT brain training set includes 333 pairs, with 24 pairs in the test set. The biological image fusion tasks include Green Fluorescent Protein (GFP) and Phase Contrast (PC) images fusion, with data sourced from [41]. The training set comprises 130 pairs, while the test set consists of 18 pairs. During the preprocessing stage, the training images are cropped to a size of 128×128 .

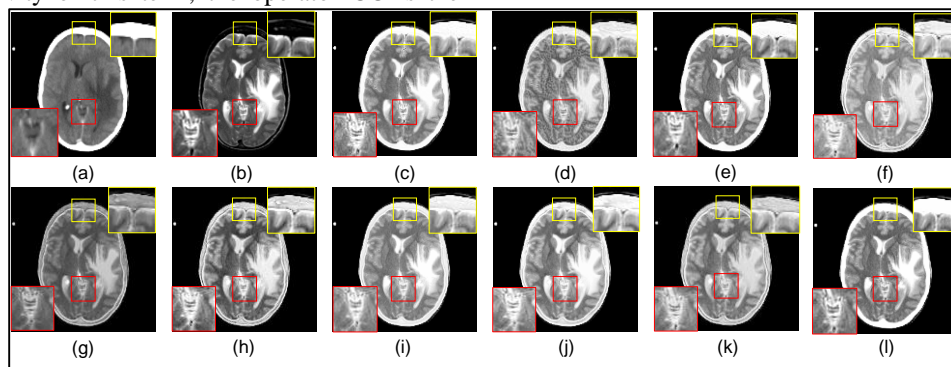

Fig. 4. The comparison of CT-MRI fusion results.

Fig. 5. The comparison of PET-MRI fusion results.

Fig. 6. The comparison of SPECT-MRI fusion results.

Fig. 7. The comparison of GFP-PC fusion results.

B. The Evaluation Metrics

The quantitative metrics must be used in order to compare the fusion results objectively. The fusion results are quantitatively assessed from six dimensions: entropy of information (EN) [42], Spatial Frequency (SF) [43], mutual information (MI) [44], Structural Similarity Index Measure (SSIM) [45], Visual Information Fidelity (VIF) [46], and edge-based similarity measurement $Q^{AB/F}$ [47]. Finally, calculate the average value of each metric for the respective methods for objective analysis.

C. The Subjective Analysis

For evaluation, we choose three fusion methods based on traditional methods and six state-of-the-art deep learning-based

fusion methods., including PSO–NSST [48], LLPACM [49], PCNN–NSST [50], SDnet [51], EMFusion [52], U2Fusion [6], SwinFusion [53], CDDFuse [54], and CoCoNet [55]. The default values supplied by the authors of these image fusion algorithms are the configurations for the parameter settings. SwinFusion was originally designed to handle only MRI-PET images, necessitating the retraining of the model for other modal images.

The fusion results for CT-MRI, MRI-PET, MRI-SPECT, and GFP-PC are shown in Fig. 4, Fig. 5, Fig. 6, and Fig. 7, respectively. In each figure, (a) and (b) are the original images. (c)-(l) represent the fused images using the PSO - NSST, LLPACM, PCNN - NSST, SDnet, EMFusion, U2Fusion, SwinFusion, CDDFuse, CoCoNet and the DMMFnet method.

In Fig. 4, Fig. 4 (a) and Fig. 4 (b) represent the original CT and MRI images. Fig. 4 (g) is notably dark, obscuring detailed information. Fig. 4 (f), Fig. 4 (h), and Fig. 4 (k) lose some information from the original CT images, with the brain's outline becoming indistinct. Fig. 4 (d) is overly blurred, affecting clarity and detail. Fig. 4 (i) and Fig. 4 (j) are excessively bright, which hinders clear information presentation. Fig. 4 (c) and Fig. 4 (e) yield acceptable results but suffer from noise-like artifacts that affect structural details. Due to our proposed feature extraction strategy, the DMMFnet effectively preserves most of the structural information from the source images and excellently maintains the edges.

As shown in Fig. 5, Fig. 5 (a) Fig. 5 (b) represent the original MRI and PET images, respectively. Fig. 5 (e) and Fig. 5 (f) appear overly bright, resulting in unclear visual effects. Fig. 5 (g) is too dark, leading to poor preservation of MRI information. Fig. 5 (d) fails to effectively extract and preserve information, resulting in severe color distortion. Although Fig. 5 (i) and Fig. 5 (j) retain color information well, there is still some loss of MRI information at the edges. Due to our proposed fusion method, the DMMFnet successfully integrates the main information from the source images into the fused image and accurately portrays lesion information.

As shown in Fig.6, Fig.6 (a) and Fig.6 (b) are the original MRI and SPECT images. In contrast to PET, SPECT images have much sparser intensity information, leading to varying degrees of information loss across different deep learning methods. Fig. 6 (d) is overly blurred, while Fig. 6 (f) and Fig. 6 (i) retain too much color information, resulting in overly bright images that obscure details. Fig. 6 (g) suffers from severe deficiencies in color information. The DMMFnet outperforms all other deep learning methods.

As shown in Fig.7, Fig.7 (a) and Fig.7 (b) are the original GFP and PC images. Due to the higher resolution of GFP and PC images compared to medical images, the feature information is more apparent, and deep learning methods generally yield better visual results. In Fig.7 (d), significant feature loss is observed. In Fig.7 (c) and Fig.7 (e), the cell structures are preserved, but there is some loss of color information. Conversely, in Fig.7 (i), Fig.7 (j), and Fig.7 (k), the cell structures are not clearly preserved. Additionally, Fig.7 (g) is too dark, resulting in poor visual quality. DMMFnet preserves both the cell structures and color information more comprehensively.

D. The Objective Analysis

In MRI-CT image fusion, our algorithm possesses four optimal metrics (EN, SF, SSIM, and $Q^{AB/F}$) and one suboptimal metric (VIF), with the SF metric performing significantly better than the others. As shown in Table I.

For MRI-PET image fusion, compared to other algorithms, our algorithm achieves the highest scores in SF, MI, SSIM, and $Q^{AB/F}$, while being second best in VIF as seen in Table II.

In MRI-SPECT image fusion, our algorithm has two optimal metrics (VIF and $Q^{AB/F}$) and one suboptimal metric, surpassing all deep learning methods, as seen in Table III.

TABLE I. THE OBJECTIVE EVALUATION OF CT-MRI FUSION IMAGES

CoConet	6.84	12.18	3.56²	0.88	1.02	0.65¹
Proposed	6.89¹	12.04	3.63¹	0.9¹	1.07¹	0.61

Due to the inherently low original resolution of SPECT images, up-sampling is required before fusion, introducing a significant amount of non-uniform pixel noise. This noise interference adversely affects the results for metrics such as EN and SF, making deep learning methods perform less favorably on general evaluation metrics for SPECT-MRI modality fusion compared to traditional methods. However, our method better preserves information from both modalities, surpassing other deep learning approaches in objective analysis.

E. The Ablation Study

As the test cases, we chose 30 pairs of images at random from each modality for ablation experiments. We chose peak EN, MI, VIF, and SSIM as the metrics. The configuration of each experiment is shown in Table V.

TABLE V. THE OBJECTIVE EVALUATION OF GFP-PC FUSION IMAGES

Experiment	Configurations
Experiment 1	Replace the shared encoder STFormer with Restormer [38], keeping other parts unchanged.
Experiment 2	Not utilize context broadcasting technology.
Experiment 3	The feature extraction component in the encoder uses only the transformer module.
Experiment 4	The feature extraction component in the encoder uses only the INN module.
Experiment 5	Change the two-stage training to direct training.
Experiment 6	Removal of L_{decomp} from the loss functions used in the first phase of training.
Experiment 7	Sets γ_1 and γ_2 to {0.5, 0.5}, indicates that both images are equally important.

From Fig. 8, it can be observed that the fusion evaluation metrics using dual-branch feature extractors in the fusion module are better than those obtained by using either the CNN or the Transformer alone as the feature extractor. This indirectly confirms that dual-branched feature extractors improve the ability of the network to extract features, beneficial for subsequent bottom-level visual tasks in image fusion, and that context broadcasting technology significantly aids in improving fusion effects. In summary, Table VI proves the effectiveness and soundness of our network and loss function design.

TABLE VI. THE RESULTS OF THE ABLATION EXPERIMENT

Experiment	Evaluation metrics				
	EN	SF	MI	VIF	SSIM
Experiment 1	4.93	24.43	2.69	0.75	1.24
Experiment 2	5.07	24.45	2.96	0.81	1.25

IV. CONCLUSION AND FUTURE WORK

This study proposes a multimodal medical image fusion network, DMMFnet. For the extraction of shared features in multimodal images, a new transformer module based on super token sampling is constructed, which effectively captures global dependencies. This module not only significantly improves the processing speed of the model but also ensures the effective capture and preservation of key features, thereby enhancing the ability to recognize and integrate important information in medical images. In addition, the proposed CSDformer module further optimizes feature extraction and fusion. By introducing the Context Broadcast strategy, the much-needed dense interaction is achieved, which greatly improves the ability to capture detailed features. Although DMMFnet has achieved satisfactory fusion results, it does not present a notable advantage in computational efficiency due to the limitations of the Transformer architecture.

Future work: Future improvements should focus on refining the network to achieve better results at a lower computational cost. Enhancements in this direction would make the DMMFnet more practical and efficient for real-world applications.

ACKNOWLEDGMENT

We extend our gratitude to the Shandong Provincial Natural Science Foundation, the Key R&D Program of Shandong Province, P.R China, and Mohammad Ali Jinnah University, Karachi, Pakistan.

RESEARCH FUNDING

This research was funded by the Shandong Provincial Natural Science Foundation through project ZR2021MF017 and

the Key R&D Program of Shandong Province, China, under project 2023RKY01015.

AUTHORS' CONTRIBUTION

In this paper, each author contributed equally to the research and development process. Yukun Zhang and Lei Wang collaborated on the conceptualization and design of the study, as well as the implementation of methodologies. Muhammad Tahir, Muhammad Imran Saeed, and Zizhen Huang were responsible for extensive data collection, analysis, and interpretation, significantly contributing to the empirical aspects of the research. Yaolong Han provided valuable insights and expertise in the theoretical framework and literature review, ensuring the study's rigor and coherence. Shanliang Yang refined the manuscript through editing and formatting, ensuring clarity and coherence in presenting the results. The authors worked collaboratively to draft and revise the manuscript, incorporating feedback and suggestions to produce the final version.

CONFLICT OF INTEREST

The authors declare that there is no conflict of interest regarding the publication of this paper. All authors have reviewed and approved the manuscript and have no financial or personal relationships that could inappropriately influence or bias the content of the paper.

Deep Learning and Computer Vision-Based System for Detecting and Separating Abnormal Bags in Automatic Bagging Machines

Trung Dung Nguyen, Thanh Quyen Ngo, Chi Kien Ha

Faculty of Electrical Engineering Technology, Industrial University of Ho Chi Minh City, Ho Chi Minh City, Vietnam

Abstract—This paper presents a novel deep learning and computer vision-based system for detecting and separating abnormal bags within automatic bagging machines, addressing a key challenge in industrial quality control. The core of our approach is the development of a data collection system seamlessly integrated into the production line. This system captures a comprehensive variety of bag images, ensuring a dataset representative of real-world variability. To augment the quantity and quality of our training data, we implement both offline and online data augmentation techniques. For classifying normal and abnormal bags, we design a lightweight deep learning model based on the residual network for deployment on computationally constrained devices. Specifically, we improve the initial convolutional layer by utilizing ghost convolution and implement a reduced channel strategy across the network layers. Additionally, knowledge distillation is employed to refine the model's performance by transferring insights from a fully trained, more complex network. We conduct extensive comparisons with other convolutional neural network models, demonstrating that our proposed model achieves superior performance in classifying bags while maintaining high efficiency. Ablation studies further validate the contribution of each modification to the model's success. Upon deployment, the model demonstrates robust accuracy and operational efficiency in a live production environment. The system provides significant improvements in automatic bagging processes, combining accuracy with practical applicability in industrial settings.

Keywords—Automatic bagging machines; deep learning; computer vision; bags classification; data augmentation

I. INTRODUCTION

An automatic bagging machine is a type of packaging machinery designed to automatically fill products into bags and then seal them. These machines are widely used in various industries, including food, agriculture, chemical, and manufacturing, for efficient and rapid packaging solutions. Automatic bagging machines can handle a wide range of bag materials, sizes, and types, such as plastic, paper, and fabric bags. An automatic bagging machine comprises several stages and components: a product feeding system, which delivers the product to the bagging area; a weighing and filling system, which ensures that each bag is filled with the correct amount of product; a bag supply and opening unit, which automatically takes a bag from the supply, opens it, and positions it for filling; and a sealing system, which seals the bag by heat sealing, stitching, or using adhesives. Fig. 1 illustrates the comprehensive setup of the automatic bagging machine

utilized in our research, highlighting each of the critical components and stages that facilitate the seamless transition from product feeding to the final sealing process. Among the components, the bag supply and opening unit is a critical component, ensuring that bags are consistently and accurately supplied and opened for the product filling process. This unit is designed to handle a variety of bag types and materials, including paper, plastic, and woven fabric, with varying levels of thickness and rigidity. To maintain the maximum performance of automatic bagging machines, constant bag quality is essential at all times. Criteria related to bag quality include the bag mouth, bag position, and bag surface. For the bag mouth, the edges must be perpendicular to the sides and in a straight line. For the bag position, bags must lie flat throughout their entire length and width. For the bag surface, it must be free of folds and/or wrinkles that could result from improper storage. Fig. 3(b) indicates some instances where bag quality does not meet the standards.

Any errors related to bag quality can cause serious problems. For example, a bag that is too weak might tear during the picking or opening process, while a bag with inconsistent dimensions might not align properly with the machine's mechanisms. These issues can halt production, necessitating manual intervention to clear the jam and restart the machine. Even if abnormal bags are successfully opened and filled, they may not seal properly, potentially compromising the integrity of the packaging. This can affect product safety, shelf life, and customer satisfaction. Inconsistent bag quality can also lead to poor presentation of the final product, affecting brand perception. The failure to properly handle abnormal bags can lead to increased material waste, as bags that are damaged during the process or that fail quality checks after filling and sealing are discarded. This not only increases material costs but can also lead to higher labor costs associated with troubleshooting and rectifying issues caused by using these bags.

To mitigate the issues caused by abnormal bags, manufacturers may implement quality control measures such as pre-screening bags before they enter the supply unit, adjusting machine parameters to better accommodate variation in bag quality, or investing in more advanced detection and handling systems that can adapt to a wider range of bag qualities. Implementing a rigorous quality assurance program with suppliers to ensure that bags meet all necessary specifications before they reach the production line is also crucial. Modern

bag supply and opening units often rely on sensors and automated systems to detect and adjust the bags being fed into the machine. Abnormal bags might not be detected accurately

by these systems, leading to misfeeds or incorrect adjustments that can compromise the packaging process.

Fig. 1. The comprehensive setup of the automatic bagging machine utilized in our research.

Over the years, the adoption of machine vision for automatic quality inspection has seen significant advancements across various industries, revolutionizing how quality control is implemented and ensuring higher standards of accuracy and efficiency. In the metal casting industry, machine vision has been instrumental in detecting defects such as cracks, porosity, and misruns on cast parts [1]. The manufacturing industry has broadly embraced machine vision for a range of applications, from verifying product assembly to ensuring the accuracy of labeling and packaging [2]. In the agricultural sector, machine vision has been applied to the inspection of the external quality of date fruits [3]. Automatic rice-quality inspection systems represent another remarkable application [4]. These systems employ machine vision to classify rice grains by size, shape, color, and texture, as well as to detect impurities. In the wood industry, particularly in the inspection of hardwood flooring products, machine vision systems have been developed to detect surface defects such as knots, cracks, and color variation [5]. These systems can inspect flooring panels at high speeds, ensuring that only those meeting strict quality standards reach the consumer. Overall, the developments in machine vision for automatic quality inspection across these varied industries emphasize a trend towards greater automation and precision in quality control processes. By leveraging advanced imaging technologies and machine learning algorithms, industries are not only able to enhance the efficiency of their operations but also significantly improve the quality of their products, benefiting both manufacturers and consumers alike.

In recent years, deep learning has seen remarkable developments, transforming the landscape of production industries with its unprecedented capabilities in data analysis, pattern recognition, and autonomous decision-making. Leveraging vast amounts of data, deep learning algorithms have become proficient at identifying complex patterns and anomalies that elude traditional computational methods. This advancement has been particularly impactful in automating quality control processes, predictive maintenance, and enhancing operational efficiencies across various sectors.

However, deploying deep learning models, especially Convolutional Neural Networks (CNNs), on resource-constrained embedded devices poses significant challenges. First and foremost, these devices typically have limited processing power, which can make it difficult to run the computationally intensive operations required by CNNs in real-time. Additionally, embedded devices often have restricted memory capacity, constraining the size of the models that can be deployed and limiting the amount of data that can be processed at once. Energy consumption is another critical concern, as many embedded devices operate on battery power or in energy-sensitive environments. The high computational demands of CNNs can lead to rapid battery depletion or require compromises in performance to conserve energy. Model complexity versus performance trade-offs also present a challenge. Simplifying models to fit the constraints of embedded devices can lead to reduced accuracy and efficacy. Finally, the diversity of hardware in embedded systems necessitates custom optimization for each deployment, increasing development time and complexity. Addressing these challenges requires innovative solutions, including model compression techniques, specialized hardware accelerators, and efficient algorithm design to make CNNs viable for embedded applications.

Based on the above analysis, this paper introduces a novel deep learning and computer vision-based system designed to enhance the efficiency and accuracy of automatic bagging machines by classifying bags as normal or abnormal. By integrating a sophisticated data collection system directly into the production line and employing advanced data augmentation techniques, this study addresses the critical need for high-quality, diversified datasets in machine learning. Central to our approach is the development of a lightweight deep learning model, based on the modified ResNet-18 architecture, which is specifically optimized for deployment on resource-constrained devices such as the Raspberry Pi 4. The contributions of this paper are summarized as follows:

- We demonstrate the efficacy of combining offline and online data augmentation techniques to substantially improve model robustness and generalizability.
- Our customized lightweight ResNet-18 model, featuring an innovative initial convolution layer modification, channel reduction, and the application of knowledge distillation, demonstrates a novel approach to optimizing deep learning models for efficient deployment on embedded systems.
- Through comprehensive comparisons with other CNN models and ablation studies, we provide valuable insights into the model's decision-making processes and its superior performance.
- The successful deployment of our model on the Raspberry Pi 4 not only proves its operational viability in real-world industrial settings but also sets a benchmark for future research in deploying deep learning models on resource-constrained devices.

II. LITERATURE REVIEW

A. Image Classification

Image classification, a pivotal task in the field of computer vision, has experienced significant evolution over the past decade, predominantly shaped by the advent and advancement of CNNs and, more recently, Transformer models.

CNNs have established themselves as the backbone of image classification tasks, marked by their ability to automatically and adaptively learn spatial hierarchies of features from image data. The foundational model, LeNet [6], introduced in the late 1990s, set the stage for the use of CNNs in image recognition. However, it was AlexNet's [7] victory in the ImageNet challenge in 2012 that truly catalyzed the deep learning revolution, highlighting CNNs' potential to achieve remarkable accuracy in classifying images across thousands of categories. Subsequent architectures, such as VGG [8], GoogLeNet [9], ResNet [10], MobileNet [11-13], ShuffleNet [14-15] and EfficientNets [16] have introduced innovations such as deeper networks, inception modules, and residual connections, significantly improving performance on various image classification benchmarks. These developments have not only enhanced the accuracy and efficiency of image classification tasks but have also broadened the application scope of CNNs to include areas like medical image analysis, autonomous vehicles, and surveillance systems, emphasizing their versatility and robustness in extracting meaningful patterns from visual data.

The introduction of Transformers in image classification [17], initially conceived for natural language processing tasks [18], marks the latest significant innovation in the field. The seminal work, "Attention Is All You Need," introduced the Transformer model, which relies on self-attention mechanisms to process data in parallel, significantly reducing the need for sequential data processing and enabling the model to weigh the importance of different parts of the input data. The adaptation of Transformer models for image classification, notably through architectures like Vision Transformer, has opened new

avenues for research and application. Unlike CNNs, Transformers do not inherently process spatial hierarchies but instead treat the image as a sequence of patches, applying self-attention to understand the global context of the image, which can lead to superior performance in certain contexts. This paradigm shift toward using Transformers for image classification highlights the field's ongoing evolution and the continuous search for models that can more effectively capture and interpret the complex patterns present in visual data. Despite their promising capabilities, the adoption of Transformer models in image classification also presents challenges, including the need for large-scale datasets for training and higher computational resources, setting the stage for ongoing research and development in optimizing these models for wider application. To address the challenges posed by the adoption of Transformer models in image classification, researchers have focused on designing lightweight and efficient Vision Transformers that require fewer computational resources and can be trained with smaller datasets. Key methods include the introduction of techniques such as model pruning [19-22], where redundant or non-essential parts of the model are removed without significantly impacting performance, and knowledge distillation [23-24], where a smaller, more efficient model is trained to emulate the performance of a larger, more complex model. Additionally, some approaches utilize more efficient self-attention mechanisms [25-30], which reduce the computational complexity by focusing on only the most relevant parts of the input data, and employing token-based methods that decrease the number of input tokens to the Transformer, significantly reducing the computational load while maintaining high accuracy. These innovations represent a significant step towards making Vision Transformers more accessible for a broader range of applications, especially in environments with limited computational capacity.

B. Deep Models for Classification Task in Production Industries

Deep learning models have profoundly impacted production industries by enhancing classification tasks with unprecedented accuracy and efficiency. In the manufacturing domain, Xu et al. [31] proposed a model that leverages high-resolution vision sensors and deep learning techniques to classify and rate multi-category steel scrap. The model significantly improved the accuracy and fairness of steel scrap quality evaluation in recycling processes. Vikanksh et al. [32] introduced the NSLNet framework, which combines ImageNet for feature extraction with adversarial training in the feature space through Neural Structure Learning, aiming to overcome the challenges of limited annotated datasets and decreased prediction accuracy due to image perturbations in steel surface defect identification. In a study by Mathieu et al. [33], a method was introduced involving a three-step approach of data collection, classification, and supervised learning using CNNs. This method aims to automate quality control of open mouth bag sealings in industrial bagging systems. This study contributed a novel CNN architecture for the image classification of open mouth bags, demonstrating promising results in automating quality control within the food industry's industrial bagging systems.

Deep learning models have also found application in the agriculture sector. Padmapriya et al. [34] introduced a multi-stacking ensemble model combined with a novel feature selection algorithm, leveraging both machine learning and deep learning models for accurate multiclass soil classification, essential for smart agriculture advancements. Gill et al. [35] proposed a model that utilizes CNN, Recurrent Neural Network, and Long-short Term Memory deep learning methods for optimal image feature extraction and selection, applying these features to classify fruits effectively. The model outperformed traditional methods in handling the complex and heterogeneous nature of fruit recognition and classification tasks. Recently, Shewale et al. [36] proposed a model that utilizes deep learning, specifically CNNs, combined with image processing, to automatically extract features from leaf images for the identification, classification, and diagnosis of plant leaf diseases. This research provided an automated, high-precision disease diagnosis system for tomato plants that bypasses manual feature engineering and segmentation, offering a scalable solution for crop disease diagnosis globally through the application of deep learning on extensive, real-time image datasets.

In the food industry, specifically for assessing the quality of packaged food, Han et al. [37] introduced a study featuring a rapid, non-destructive method for estimating nut quality. This method uses hyperspectral imaging coupled with deep learning classification, specifically a CNN, to assess the quality of unblanched *Canarium indicum* kernels based on peroxide values. Kazi et al. [38] explored the use of transfer learning with classical and residual CNN architectures for classifying different types of fruits and their freshness, moving beyond traditional CNN implementations. In the textile industry, deep learning has introduced new capabilities for fabric inspection, identifying weaving faults, and ensuring pattern consistency. Huang et al. [39] introduced an efficient CNN model designed for fabric defect segmentation and detection, which requires only a minimal number of defect samples for training, thus significantly reducing manual annotation costs. Wei et al. [40] introduced the BIVI-ML model that integrates three bioinspired visual mechanisms (i.e., visual gain, attention, and memory) into a deep CNN framework to address the challenges of multilabel textile defect classification, such as intersected defects and label correlations. This approach enhances resolution, focuses attention on defects, and accurately associates relevant labels for effective multilabel classification.

III. METHODOLOGY

In this section, we first introduce the data collection process, detailing the system implemented within the production line to gather a diverse and representative dataset of bag images. Following this, the data augmentation subsection explains how we leverage both offline and online techniques to enhance the dataset's quality and variability. Lastly, we discuss the design and optimization of a lightweight deep model for bags classification, focusing on our custom modifications to the ResNet-18 architecture, which includes adjustments for efficient operation on resource-constrained devices like the Raspberry Pi 4.

A. Data Collection

Designing a deep learning-based system for classifying normal and abnormal bags in automatic bagging machines presents several significant challenges, particularly in the domain of data collection. The effectiveness of such a system is heavily dependent on the quality and variety of the dataset used to train it. One of the primary challenges is the vast diversity of bags. These bags can vary widely in terms of size, shape, material, color, and design. Consequently, it is necessary to obtain the broadest possible variety of bag types to ensure that the control quality can be effectively managed across all potential items the system might encounter. This diversity is critical to developing a robust model capable of accurately identifying anomalies in any given bag. Another significant challenge is the scarcity of abnormal bags. Abnormalities can range from minor defects such as slight tears or misprints to more significant issues like incorrect sizing or completely torn bags. However, these occurrences are typically rare in a well-maintained production environment. This scarcity presents a problem for data collection because deep learning models require a substantial amount of data to learn from. The insufficient number of abnormal bags means the system may not observe enough examples of abnormalities during the data collection phase, leading to a model that might struggle to recognize less common or more subtle defects. Data collection is also hindered by the dynamic conditions under which bagging operations occur. Factors such as lighting, background, and speed of the conveyor can significantly affect the quality of the images captured for training the model. Consistency in these conditions is challenging to maintain, yet critical for training a model that is reliable under the diverse conditions it will encounter in real-world applications.

To tackle the challenges associated with collecting a diverse and representative dataset for training a deep learning system for classifying normal and abnormal bags in automatic bagging machines, a sophisticated data collection system has been implemented directly into the automatic bagging machine's production line, as shown in Fig. 2. This system employs a high-resolution Vieworks CMOS VC-25MC-M/C 30D area camera, renowned for its exceptional image quality and reliability. The camera is equipped with a 6 mm fixed focal lens, providing a wide field of view while maintaining sufficient detail for identifying both gross and subtle abnormalities in bags. The camera's parameters have been meticulously adjusted to optimize the lighting conditions and speeds at which bags are processed on the production line. This adjustment ensures that the images captured are of high quality and reflect the diverse conditions under which the system must operate. By integrating the camera directly into the production environment, the data collection system is able to capture images of bags under the actual conditions they will be encountered, thereby enhancing the realism and applicability of the training data. This setup is linked to a computer system equipped with both a powerful CPU and a GPU. The GPU, in particular, is crucial for processing the high volume of image data in real-time, allowing for immediate feedback and adjustments to the data collection process if needed. This computational power also supports the use of advanced image processing and augmentation techniques, which can artificially expand the dataset by modifying existing images to simulate a

wider range of abnormalities and conditions. All the data collection hardware specifications are shown in Table I.

Fig. 2. Data collection system.

TABLE I. DATA COLLECTION HARDWARE SPECIFICATIONS

Hardware	Specifications
Camera	Model: Vieworks CMOS VC-25MC-M/C 30D Type: Area Camera
Lens	Type: 6 mm fixed focal lens Field of View: Wide
Computer	Intel(R) Core(TM) i7-11700K CPU + Nvidia RTX 4080 GPU

To address the issue of the rare occurrence of abnormal bags, the system is designed to flag and store images of any detected abnormalities for further review. This process helps in creating a focused dataset of abnormal bags, which, although smaller in size, is rich in diversity and critical for training the detection system effectively. Furthermore, to mitigate the imbalance between normal and abnormal bag instances, sophisticated data augmentation techniques are employed. This approach increases the representation of abnormal bags in the training dataset without the need for an equivalent increase in the actual occurrence of these abnormalities on the production line.

With the proposed data collection system, 1000 images have been collected. As in practical production, the operator is only concerned with whether the bag is an abnormal bag that needs to be discarded, not with the specific type of

abnormality. Therefore, in this paper, the bags were classified into two categories, normal and abnormal. Normal bags are those that appear uniform in shape, with consistent dimensions and no visible defects on the surface. The integrity of each bag is maintained, and there are no signs of tears, misprints, or material weaknesses, as shown in Fig. 3(a). Abnormal bags, on the other hand, display various defects such as irregular shapes, tears, incorrect sealing, or material inconsistencies, as shown in Fig. 3(b). These abnormalities compromise the bag's functionality and potentially disrupt the operation of the machine, necessitating their removal from the production line.

B. Data Augmentation

Data augmentation plays a crucial role in the classification of normal and abnormal bags by significantly enhancing the diversity and volume of training data available for deep learning models. By artificially creating variations of the existing images through techniques such as rotation, noise injection, and perspective transformations, data augmentation helps models become more robust and less sensitive to small changes or imperfections in bag appearances. This process not only improves the model's ability to generalize across different conditions found in production environments but also addresses the challenge of limited samples of abnormal bags, thereby boosting the overall accuracy and reliability of the classification system. Broadly, data augmentation techniques can be categorized into two types: offline and online augmentations. Offline augmentation involves preprocessing and expanding the dataset before training begins. This means creating modified copies of the original images, such as rotated, flipped, or adjusted in terms of brightness and contrast, and adding them to the training set. This approach results in a statically enhanced dataset that the model trains on, allowing for a wide variety of data from the beginning. On the other hand, online augmentation takes place during the model training process itself. In this dynamic approach, images are augmented in real-time and fed into the model. This means that each epoch can present slightly different variations of the images to the model, introducing a richer set of examples over time. Techniques such as random cropping, zooming, or adding noise are applied in real-time, ensuring that the model rarely sees the exact same image twice. This not only improves generalization but also significantly enhances the model's robustness to new, unseen variations of bags.

Fig. 3. Examples of normal bags (a) and abnormal bags (b).

In this paper, we employ a comprehensive approach to data augmentation, leveraging both offline and online techniques to enhance the diversity and quality of our dataset for classifying normal and abnormal bags in automatic bagging machines. Initially, the dataset was expanded through offline augmentation methods, specifically focusing on brightness and contrast adjustments, noise injection, color variations, and synthetic abnormality generation. The latter is particularly noteworthy as it involves creating synthetic defects such as tears, holes, or significant shape distortions on images of normal bags. This method plays a crucial role in artificially expanding the collection of abnormal bag examples, avoiding the necessity for such events to happen naturally, and thus overcoming the lack of abnormal instances in the original dataset. Following the offline augmentation phase, we combined the enhanced images with the original ones to construct a new, enriched dataset comprising 3150 images. This dataset includes 1420 images depicting normal bags and 1730 images featuring abnormal bags, reflecting a more balanced distribution between the two categories. Subsequently, this augmented dataset was randomly divided into three subsets: a training set constituting 60% of the total images, a validation set comprising 20%, and a test set making up the remaining 20%. The distribution and details of the images within each subset are outlined in Table II.

TABLE II. NUMBER OF IMAGES IN EACH SUBSET

Subset	Number of images	
	Normal bags	Abnormal bags
Training	852	1038
Validation	284	346
Testing	284	346
Total	1420	1730

To further augment the diversity of data features available during model training, we implemented online augmentation techniques. During the training process, each image batch underwent preprocessing through a combination of methods, including color jittering to simulate varying lighting conditions and color schemes, Gaussian blurring to introduce variability in image sharpness and simulate minor camera focus issues, and random flipping (both horizontally and vertically) to ensure the model can accurately classify bags regardless of their orientation. This blend of online augmentation methods ensures that the model is exposed to a wide array of variations within the training data, significantly enhancing its ability to generalize from the training set to real-world scenarios where bags can appear under different conditions and with various types of abnormalities.

C. Lightweight Deep Model for Bags Classification

Since we use the Raspberry Pi 4 for classifying normal and abnormal bags in the automatic bagging machine, deploying a lightweight deep learning model on this board is necessary. The lightweight model is crucial because it is specifically designed to operate within the constrained computing resources and limited memory capacities typical of embedded systems. This model ensures that the classification process can be executed efficiently in real-time, maintaining high accuracy while minimizing latency, which is essential for integration

into production lines. Furthermore, the optimized architecture of the model reduces power consumption, a critical consideration for continuous operation in industrial settings.

In our paper, we selected ResNet-18 as the foundation for our lightweight deep learning model to classify normal and abnormal bags, specifically designed for deployment on the Raspberry Pi 4. This choice was driven by ResNet-18's inherently efficient architecture that strikes an optimal balance between computational demand and model performance. We have conducted several modifications to ResNet-18, including changing the initial convolution layer based on Ghost Convolution [41] and reducing the number of channels, as well as employing knowledge distillation as a training technique to transfer knowledge from a fully trained and fine-tuned ResNet-18 model (teacher) to our optimized lightweight model (student). These enhancements further improve its suitability for real-time applications on hardware with limited computing resources. Compared to its deeper counterparts, such as ResNet-34 or ResNet-50, ResNet-18 offers a more practical solution for deployment on embedded systems like the Raspberry Pi 4. While deeper models might achieve slightly higher accuracy in certain contexts, their increased complexity and higher demand for computational resources make them less suitable for environments where power efficiency and low latency are paramount. The extensive use of Ghost Convolution, along with strategic knowledge distillation, allows our modified ResNet-18 model to maintain a competitive accuracy level while significantly reducing the necessary computational resources and power consumption. This balance is crucial for ensuring that the automatic bagging machine can operate continuously and efficiently in an industrial setting, making ResNet-18 the ideal choice for our application.

1) *ResNet-18 architecture:* ResNet-18 is a variant of the Residual Network (ResNet) architecture [10], designed to tackle the vanishing gradient problem that arises with increasing network depth. This architecture allows for the training of deep neural networks by introducing residual connections, which enable the flow of gradients through the network without degradation.

The architecture of ResNet-18, as shown in Fig. 4, consists of an initial convolutional layer followed by 16 convolutional layers organized into 8 residual blocks, and ends with an average pooling layer and a fully connected layer. The initial convolutional layer has a 7×7 kernel with 64 filters and a stride of 2. This layer is followed by a 3×3 max pooling layer with a stride of 2, which serves to reduce the spatial dimensions of the input image while preserving important features. Following the initial layers, ResNet-18 is composed of four main stages, each containing two residual blocks. Each block comprises two 3×3 convolutional layers with the same number of filters. The stages are differentiated by the number of filters and the stride of the first convolutional layer in each stage. Specifically, the stages have 64, 128, 256, and 512 filters, respectively. The stride is set to 1 for all blocks except the first block of each stage after the first, where it is set to 2. This design choice reduces the feature map's size as the network gets deeper, increasing the field of view of the convolutional filters.

Fig. 4. ResNet-18 architecture.

The innovation of ResNet lies in its residual connections, which skip one or more layers by performing identity mapping and adding the input of the block to its output. These connections help mitigate the vanishing gradient problem by allowing the direct flow of gradients during backpropagation. In ResNet-18, every two layers share a residual connection, forming the backbone of its design. At the end of the network, a global average pooling layer reduces the spatial dimensions to 1x1, effectively summarizing the features extracted by the convolutions into a compact form. This is followed by a fully connected layer, which maps the pooled features to the desired number of output classes, facilitated by a Softmax activation function for classification tasks.

2) *Improving initial convolutional layer:* To address the high latency associated with the initial convolutional layer in ResNet-18, which is primarily due to its 7x7 convolution with a stride of 2, a modification is proposed to enhance computational efficiency while maintaining the layer's feature extraction capability. This modification involves increasing the stride of the initial convolutional layer to 4 and decreasing the kernel size from 7x7 to 5x5. The rationale behind this is twofold: a larger stride and a smaller kernel size directly reduce the amount of computation required, thereby lowering the latency. Furthermore, to compensate for the potential loss of feature extraction capability due to these reductions, a Ghost Convolution layer [41] is introduced right after the modified 5x5 convolutional layer. Ghost Convolution, as shown in Fig. 5, is a novel neural network architecture optimization technique designed to significantly reduce the computational cost and model size while preserving, or even enhancing, the model's performance. It achieves this by generating additional ghost feature maps from a smaller number of primary feature maps using inexpensive operations, thus efficiently utilizing computational resources. Serving as a pivotal innovation in deep learning, Ghost Convolution plays a crucial role in enabling more efficient and faster neural networks, particularly beneficial for deployment in resource-constrained environments such as mobile devices and edge computing platforms.

adjusting the kernel size and stride, and by adding a Ghost Convolution layer, the initial convolutional layer achieves fewer FLOPs compared to the original convolutional layer. Through this strategy, the modified initial layer of ResNet-18 offers reduced latency without substantially compromising the network's performance, making it more suitable for real-time applications or deployment on hardware with limited computational resources such as the Raspberry Pi 4.

Fig. 5. Ghost convolution structure.

TABLE III. COMPARISON OF FLOPs BEFORE AND AFTER THE MODIFICATION OF THE INITIAL CONVOLUTIONAL LAYER

Configuration	Kernel Size	Stride	Additional Layers	FLOPs (Billions)
Original initial layer	7x7	2	0	1.8
Modified initial layer	5x5	4	1	1.6

3) *Modifying channel numbers:* In CNNs, the number of channels typically increases as the network progresses deeper. This design strategy originates from the need to capture increasingly complex features from the input data. Initially, layers detect simple patterns and textures, such as edges and colors. As we move deeper into the network, subsequent layers combine these basic features to detect more complex and abstract features, necessitating a larger number of channels to represent this growing complexity effectively.

In the case of ResNet-18, the structure follows this principle closely. The network starts with an initial convolutional layer that has 64 channels. This is followed by four main stages, each comprising two residual blocks. The channel numbers for each stage double as the network goes deeper: the first stage has 64 channels per layer, the second stage has 128 channels, the third stage has 256 channels, and the final stage has 512 channels. This design enables the network to process and extract a rich hierarchy of features from

Building on the innovative approach outlined above, Table III presents a comparison of FLOPs before and after the modification of the initial convolutional layer to quantify the efficiency gains achieved through our modification. By

the input images. However, not all tasks require the full capacity of ResNet-18. For simpler tasks, such as classifying bags as normal or abnormal, the complexity of the model can be reduced without significantly impacting performance. This simplification can lead to gains in efficiency, making the network more suitable for deployment in environments with limited computational resources like the Raspberry Pi 4. Based on extensive experiments, we have found that adjusting the number of channels in each layer of ResNet-18 to 64, 96, 128, and 160 for the respective stages strikes a good balance between performance and computational efficiency for this specific task. Table IV provides a comparison of FLOPs before and after reducing the number of channels in each layer. The results show that modifying the channel numbers significantly reduces the FLOPs of each stage.

TABLE IV. COMPARISON OF FLOPs BEFORE AND AFTER REDUCING THE NUMBER OF CHANNELS IN EACH LAYER

Stage	Original		Modified	
	Channels	FLOPs (Billions)	Channels	FLOPs (Billions)
2	64	0.35	64	0.35
3	128	0.55	96	0.4
4	256	0.4	128	0.3
5	512	0.25	160	0.2
FC layer	-	0.1	-	0.05
Total		1.65		1.3

Reducing the number of channels across the layers of ResNet-18 not only improves the model's computational efficiency, reflected in lower FLOPs, but also reduces the latency of the network during inference. This modification, however, comes at the cost of reduced network capacity. The term capacity here refers to the model's ability to learn from data; a higher capacity enables a network to capture more complex patterns but may also increase the risk of overfitting and require more data to train effectively. For the task of classifying normal and abnormal bags, which is relatively simple, this reduced capacity does not significantly hinder performance and leads to a more efficient model suitable for real-time applications or deployment on hardware with limited computational resources.

4) *Knowledge distillation:* Knowledge distillation is a powerful technique that can significantly improve the efficiency and accuracy of deploying the proposed model on the Raspberry Pi 4, especially for tasks of classifying normal and abnormal bags in an automatic bagging machine. The essence of knowledge distillation lies in transferring the knowledge from a large, complex teacher model to a smaller, more computationally efficient student model. This process allows the student model to learn the complex decision boundaries and the detailed representations captured by the teacher, without the need for extensive computational resources. In this paper, the teacher model is the fully trained and fine-tuned ResNet-18 model, which has been enhanced for better performance on the task of bag classification. The student model, on the other hand, is the simplified version of

ResNet-18 with modifications to lower its computational demands. The distillation process involves running the dataset through both the teacher and student models, using the output probabilities (soft targets) of the teacher model as a guide for training the student model. These soft targets provide richer information compared to hard labels (normal/abnormal), as they contain insights about how the teacher model perceives the differences between classes, including the uncertainty and the relationships among them. To implement knowledge distillation effectively, we use a loss function that combines a traditional classification loss (i.e., cross-entropy against the true labels) with a distillation loss that measures the discrepancy between the teacher's predictions and the student's predictions. The distillation loss employs a temperature parameter to soften the probability distributions, making it easier for the student model to learn from the teacher's outputs. By employing knowledge distillation for the proposed model targeted for deployment on the Raspberry Pi 4, we can reduce model size and computational requirements while improving accuracy and enhancing inference speed.

5) *Overall architecture of the proposed model:* The overall architecture of the proposed model is shown in Fig. 6. It incorporates several modifications to ResNet-18 to enhance performance while accommodating the computational limitations of embedded systems. Initially, the model introduces a modified initial convolutional layer, where the stride is increased to 4 and the kernel size is decreased from 7×7 to 5×5 . This modification aims to capture finer details of input images without excessively burdening the Raspberry Pi's computational resources. Following the initial convolutional layer, a Ghost Convolution layer is introduced. This layer plays a pivotal role in reducing the model's complexity by generating more feature maps from fewer parameters, thus efficiently enhancing the representational capacity without a substantial increase in computational demand. The core of the model is composed of successive Residual Blocks (Res blocks), specifically arranged to progressively refine the feature maps. The number of channels in each layer of ResNet-18 has been adjusted to 64, 96, 128, and 160 for the respective stages, optimizing the balance between computational efficiency and the model's ability to capture relevant features from the image data. This adjustment ensures that the model remains lightweight yet capable of processing the varying complexities of the bag images through its depth. Each Res block employs a combination of 3×3 convolutions, with some blocks incorporating a stride of 2 (denoted as 3×3 conv, s2) to reduce the dimensionality and focus the model's attention on salient features. At the end of the model, a Global Average Pooling layer is utilized to condense the feature maps into a form suitable for classification, effectively reducing the dimensionality and focusing the model's output. This is followed by a Fully Connected (FC) layer that makes the final decision, classifying the input image as either normal or abnormal. Moreover, we apply knowledge distillation as a training technique to transfer knowledge from a fully trained

and fine-tuned ResNet-18 model (teacher) to our optimized lightweight model (student). This approach allows the lightweight model to achieve higher accuracy by learning

refined representations and decision boundaries, effectively mimicking the performance of the more cumbersome teacher model without the associated computational overhead.

Fig. 6. Overall architecture of the proposed model.

IV. EXPERIMENTS AND RESULTS

In this section, we first introduce a detailed description of the implementation setup and the evaluation metrics used to evaluate the performance of our model. Following this, we proceed into a comprehensive analysis of the results, drawing comparisons between the proposed model and both classical CNNs and existing lightweight neural network architectures. This comparison highlights the strengths and efficiencies of our model. Subsequently, we conduct an ablation study to evaluate the impact of various modules and modifications within our architecture, providing insight into their individual contributions towards the model's overall performance. Lastly, we discuss the deployment of our optimized model on the Raspberry Pi 4 within an actual automatic bagging machine setup, demonstrating its practical application and effectiveness in a real-world scenario.

A. Implementation Setup

For the training of our lightweight network designed to classify normal and abnormal bags in an automatic bagging machine, we employed a high-performance computing setup. The network was trained on a system equipped with an Intel(R) Core(TM) i7-11700K CPU, 32GB of RAM, and an Nvidia RTX 4080 GPU. This hardware configuration, supported by the CUDA 10.1 Toolkit, provided the necessary computational power to effectively train our model using TensorFlow, a popular deep learning framework known for its flexibility and extensive support for CNNs.

The training process lasted for 50 epochs. A batch size of 64 was chosen to balance the trade-off between memory usage and the granularity of the gradient update, ensuring efficient use of the GPU's resources. For optimization, we employed the Stochastic Gradient Descent (SGD) algorithm with a momentum of 0.9 and a weight decay of 0.0001. The initial learning rate was set to 0.01. The learning rate was scheduled to decrease after certain epochs based on performance metrics on the validation set, helping the model to fine-tune its weights

more precisely as training progressed. The loss function chosen for this task was cross-entropy, a common choice for classification problems as it quantifies the difference between the predicted probabilities and the actual distribution, driving the model to make more accurate predictions over time.

B. Evaluation Metrics

In the task of classifying normal and abnormal bags, evaluating the performance of the model accurately is crucial to ensure its effectiveness in real-world applications. To achieve this, we employ several evaluation metrics, including accuracy, precision, recall, number of parameters, and FLOPs (Floating Point Operations), each offering unique insights into the model's capabilities and areas for improvement.

Accuracy is the simplest and most intuitive metric, representing the proportion of correctly classified instances (both normal and abnormal bags) to the total number of instances in the dataset. It is calculated using the following formula:

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \quad (1)$$

where, TP (True Positives) and TN (True Negatives) are the correctly identified abnormal and normal bags, respectively, while FP (False Positives) and FN (False Negatives) represent the incorrectly classified instances.

Precision, or positive predictive value, measures the proportion of correctly identified abnormal bags out of all bags predicted as abnormal. This metric is particularly important in scenarios where the cost of falsely identifying a bag as abnormal (when it is not) is high. Precision is defined as the following formula:

$$Precision = \frac{TP}{TP+FP} \quad (2)$$

Recall, also known as sensitivity, indicates the proportion of actual abnormal bags that were correctly identified by the model. High recall is essential in ensuring that as many

abnormal bags as possible are detected. The formula for recall is defined as the following formula:

$$Recall = \frac{TP}{TP+FN} \quad (3)$$

In addition to these classification metrics, we also evaluate the model's complexity and efficiency using parameters and FLOPs. Parameters refer to the total number of trainable weights in the model. A lower count indicates a more lightweight model, which is beneficial for deployment on devices with limited computational resources, such as the Raspberry Pi 4. On the other hand, FLOPs provide a measure of the computational workload associated with a single forward pass through the model. It is calculated by adding up all the floating-point operations (additions, multiplications, etc.) involved in generating a prediction.

C. Main Results

1) *Comparison with other CNNs models:* In our study, we compared the performance of our proposed model against a range of established CNN architectures, including MobileNet-V1, MobileNet-V3, ResNet-50, ShuffleNet-V2, and VGG16 on the test dataset. This comparative analysis aimed to benchmark our model's effectiveness in classifying normal and abnormal bags against these well-known CNNs, with a particular focus on the balance between accuracy and computational efficiency as reflected in the model's precision, recall, parameters, and FLOPs. The comparison results are shown in Table V. The results show that our proposed model significantly outperforms the other architectures in terms of accuracy, achieving a remarkable 93.5%. This indicates a superior ability to correctly classify bags, which is critical in

practical applications where misclassification can lead to operational inefficiencies or quality control issues. In terms of precision and recall, our model also leads with scores of 93.0% and 94.0%, respectively. These metrics suggest not only a high rate of correctly identifying abnormal bags but also an impressive capability to detect the majority of actual abnormal bags present in the dataset.

Despite its high performance, the proposed model maintains a moderate number of parameters and FLOPs, illustrating an efficient balance between computational cost and effectiveness. Notably, VGG16, with the largest model size and the highest computational cost, demonstrates lower performance metrics, highlighting the inefficiency of larger models in terms of computational resources versus accuracy gain. On the other hand, MobileNet-V3 and ShuffleNet-V2, known for their high efficiency, show remarkable performance with significantly fewer parameters and FLOPs, emphasizing the effectiveness of architectures designed for operational efficiency. ResNet-50, while having a substantial number of parameters and FLOPs, offers competitive performance metrics, which highlights the balance it strikes between depth and computational efficiency. However, our proposed model's performance, with its comparatively modest computational requirements, suggests that careful optimization and architectural choices can result in models that not only achieve superior accuracy but are also viable for deployment in resource-constrained environments. The results emphasize the importance of optimizing for both model size and computational efficiency without compromising on the task-specific performance, a key consideration for practical applications, especially in environments with limited computational resources like the Raspberry Pi 4.

TABLE V. COMPARISON RESULTS ON THE TEST DATASET OF DIFFERENT MODELS

Model	Accuracy (%)	Precision (%)	Recall (%)	Parameters (Millions)	FLOPs (Billions)
MobileNet-V1	89.5	88.7	90.2	4.2	0.57
MobileNet-V3	91.0	90.5	91.5	2.9	0.22
ResNet-50	92.3	91.8	92.7	25.6	4.1
ShuffleNet-V2	90.2	89.9	90.6	2.3	0.15
VGG16	88.0	87.5	88.5	138	15.5
Our Proposed Model	93.5	93.0	94.0	4.5	1.4

TABLE VI. CLASSIFICATION RESULTS OF DIFFERENT COMBINATIONS ON THE VALIDATION DATASET

Model	Accuracy (%)	Precision (%)	Recall (%)	Parameters (Millions)	FLOPs (Billions)
Original ResNet-18	89.1	88.6	89.2	11.6	1.8
ResNet-18 + IICL	91.6	91.2	91.8	8.4	1.6
ResNet-18 + IICL + MCN	91.4	90.9	92.9	4.5	1.4
ResNet-18 + IICL + MCN + KD (Our Proposed Model)	94.2	93.7	94.3	4.5	1.4

2) *Ablation analysis:* To illustrate the impact of various modifications and modules on the performance of our architecture, an ablation study was conducted comparing different variants of the ResNet-18 model on the validation dataset. These variants include the original ResNet-18 model,

ResNet-18 with an improved initial convolutional layer (IICL), ResNet-18 with IICL and modified channel numbers (MCN), and finally, the complete proposed model which also incorporates knowledge distillation (KD). The comparison results are shown in Table VI. Starting with the original

ResNet-18, we observe a solid baseline with an accuracy of 89.1%, precision of 88.6%, and recall of 89.2%. This model, despite its relatively high computational cost (11.6 million parameters and 1.8 billion FLOPs), sets a foundation for further optimization. The introduction of an IICL, which includes increasing the stride and decreasing the kernel size, along with the addition of a Ghost Convolution layer, significantly boosts performance. This first modification enhances the model's efficiency in feature extraction and reduces computational requirements, resulting in improved accuracy (91.6%), precision (91.2%), and recall (91.8%), with a notable reduction in parameters (8.4 million) and FLOPs (1.6 billion). Interestingly, the third variant, which combines IICL with MCN, shows a slight decrease in accuracy and precision but a notable increase in recall (92.9%). This suggests that adjusting the number of channels effectively improves the model's sensitivity in detecting abnormal bags, a critical aspect of the classification task. This modification also significantly lowers the computational cost, halving the parameters to 4.5 million and reducing FLOPs to 1.4 billion, indicating a substantial increase in efficiency. Our proposed model, which further incorporates KD alongside IICL and MCN, achieves the best performance across all metrics: accuracy (94.2%), precision (93.7%), and recall (94.3%). This impressive improvement is achieved with the lowest

complexity, featuring only 4.5 million parameters and 1.4 billion FLOPs. The addition of KD allows the model to learn more refined representations and decision boundaries, which is evident in its superior performance metrics. This indicates that knowledge distillation is highly effective in enhancing model performance, especially in tasks requiring high precision and recall.

Overall, the ablation study demonstrates the effectiveness of our targeted modifications in not only improving the model's accuracy, precision, and recall but also in significantly enhancing its computational efficiency. The final proposed model stands out as highly optimized for the specific task of classifying bags, making it ideal for deployment in resource-constrained environments such as the Raspberry Pi 4, where efficiency and performance are paramount.

3) *Heatmap visualization:* Fig. 7 visualizes heatmap results from the last convolution layer of the last block of the proposed model. The heatmaps offer valuable insights into the regions within the images that the proposed model focuses on when making classifications. These heatmaps are derived from the last convolutional layer of the last block of the model, highlighting the areas with the highest activations, typically the regions most significant for the model's decision-making process.

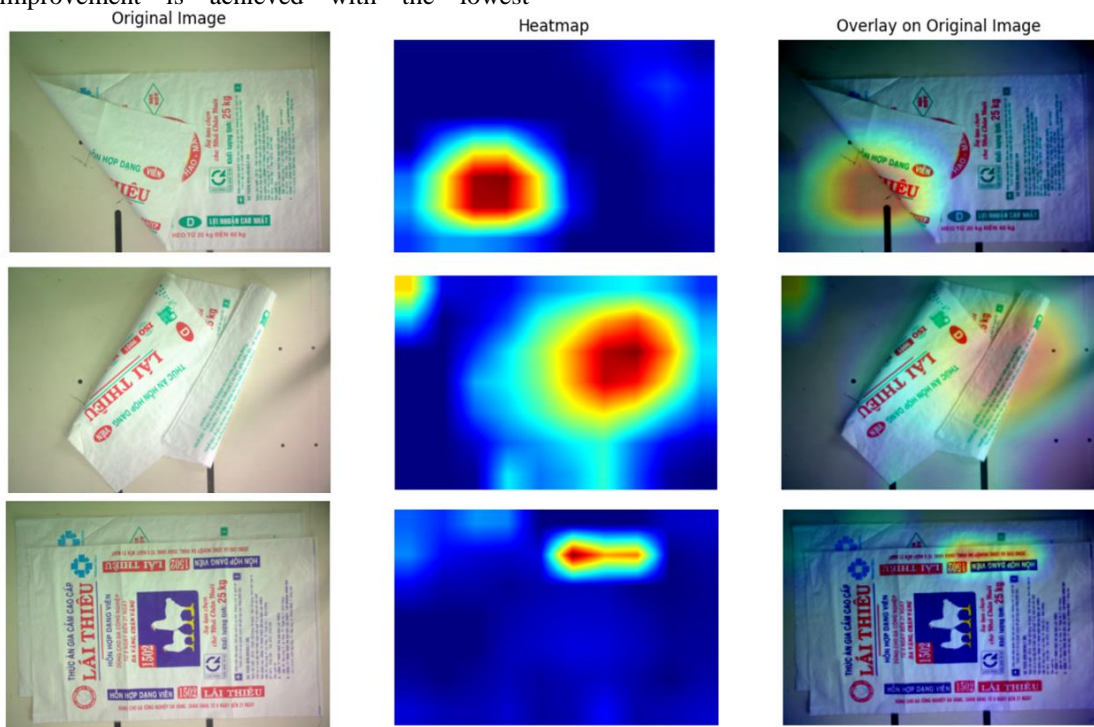

Fig. 7. Heatmap visualization of the proposed model.

In the first row, the heatmap is intensely focused on the area where part of the bag is missing, indicating that the model identifies this as the most informative region for classifying the bag as normal or abnormal. The high-intensity area represents a strong response, which suggests a distinctive feature or pattern that the model has learned to recognize as indicative of

the bag's status. In the second row, we see a similar pattern of focus. The model's attention is concentrated around the center of the bag, but with a more elongated spread along the vertical axis. This reflects the model's detection of abnormalities that have a more linear orientation or a change in the bag's texture or structure in that specific region. The third row presents a

narrower focus in the heatmap. The activation is concentrated in a smaller region, which suggests that the model has detected a very specific feature of interest that is highly relevant to the classification task. The tight clustering of high activation corresponds to a localized abnormality.

In summary, these heatmaps provide a clear representation of where the model is looking and what it considers critical for its classification decisions. The results show that the model is not distracted by the periphery of the images and consistently focuses on the central parts of the bags, where textual and logo features are most prominent. This consistent focus across different bags suggests that the model has learned a generalized understanding of where relevant features are likely to appear. Crucially, these heatmaps can be used not only to understand the model's behavior but also to validate whether the model is considering the right features when making a classification. If the model were focusing on irrelevant areas, it might indicate an overfitting to noise or a misalignment in the learned features. However, the heatmaps in this figure confirm the model's appropriate focus areas, thus supporting its reliability and robustness in identifying normal and abnormal bags.

4) *Deployment*: For deploying the proposed model from a powerful training environment to a resource-constrained platform in the Raspberry Pi 4, we perform several steps to ensure that the model retains its accuracy and efficiency in a production setting. The first step is to convert the model into a TensorFlow Lite model. TensorFlow Lite is a set of tools that enables on-device machine learning by optimizing the TensorFlow model for performance on lightweight devices. By converting the model to TensorFlow Lite model, we substantially reduce its size while maintaining critical aspects of its performance. The converted model is further optimized using post-training quantization technique, which not only decreases the model's size but also potentially speeds up inference times by using lower-precision calculations. This is particularly important for the Raspberry Pi 4, as it has less computational power and memory compared to the original training environment.

Following optimization, the TensorFlow Lite model is deployed onto the Raspberry Pi 4, which involves transferring the model file to the device and setting up the necessary inference libraries. Once in place, the model is integrated into the automatic bagging machine's control software, where it will process input images captured by the machine's cameras in real-time. The software preprocesses the input data according to the model's requirements, then feeds it into the model for inference. The inference libraries, optimized for the Raspberry Pi 4's ARM architecture, facilitate the execution of the model efficiently, ensuring that classification decisions are made swiftly to keep pace with the operational speed of the bagging machine. The lightweight nature of the TensorFlow Lite model allows for rapid inference, which is essential for the model to be practical in a production environment.

Finally, we conduct extensive testing to confirm that the model's performance on the Raspberry Pi 4 aligns with the results observed during its initial development and validation. This involves monitoring accuracy, speed of inference, and

resource utilization under real-world conditions. Table VII provides results of the deployment of the proposed model on the Raspberry Pi 4. The results in Table VII indicate that the proposed model delivers a solid performance in an operational environment. An inference time of 500 ms per bag suggests that the model is performing real-time analysis at a viable speed for the automatic bagging machine, considering the balance between speed and the complexity of the task. Power consumption stands at 4 W, which is a testament to the Raspberry Pi's energy efficiency and the lightweight nature of the optimized TensorFlow Lite model. Such low power draw is ideal for continuous, long-term operation in industrial settings. The CPU utilization of 48% indicates that the model is utilizing less than half of the CPU's capabilities, which is significant as it leaves room for the Raspberry Pi 4 to handle other tasks concurrently, if necessary, without overloading the system. The memory usage is moderate at 350 MB, which falls well within the Raspberry Pi 4's RAM capabilities, ensuring that the model runs smoothly without memory bottlenecks. This level of resource usage supports the notion that the model is indeed lightweight and suitable for embedded systems. The model's accuracy, precision, and recall rates are exceptionally high at 94.2%, 93.7%, and 94.3%, respectively. These metrics almost mirror the performance during the training phase, which indicates a successful model optimization and conversion process with negligible loss in model efficacy. Such high values suggest that the model is highly reliable, making correct decisions most of the time, and is able to identify the majority of abnormal bags correctly. An inference throughput of two bags per second may seem modest but is generally sufficient for automatic bagging operations, suitable for the speed of the conveyor and the number of bags processed in a given timeframe.

TABLE VII. RESULTS OF THE DEPLOYMENT OF THE PROPOSED MODEL ON THE RASPBERRY PI 4

Metric	Value	Comments
Inference time	500 ms	Time taken for a single inference
Power consumption	4 W	Average power during model inference
CPU utilization	48%	CPU usage during model inference
Memory usage	350 MB	RAM used by the model during operation
Model accuracy	94.2%	Percentage of correctly classified bags
Model precision	93.7%	Proportion of true positives over total positives
Model recall	94.3%	Proportion of true positives over actual positives
Inference throughput	2 bags/sec	Number of bags classified per second

V. CONCLUSION

In conclusion, our research has successfully demonstrated the efficacy of a deep learning and computer vision-based system designed for the classification of normal and abnormal bags within an automatic bagging machine. Through the strategic integration of a sophisticated data collection system directly on the production line, we have created a rich dataset that accurately reflects the variability inherent in real-world manufacturing processes. The implementation of both offline

and online data augmentation methods has significantly enhanced the robustness of our dataset, preparing our model to handle diverse operational scenarios. Our modifications of the ResNet-18 architecture into a lightweight deep learning model have proven to be particularly well-suited for deployment on the resource-limited Raspberry Pi 4, maintaining high accuracy and efficiency in bag classification tasks. The extensive comparative analysis with other CNN models and the thorough ablation studies have underscored the advantages of our proposed model. Overall, the contributions of this work not only lie in the novel application of a deep learning-based approach to a specific industrial challenge but also in the advancement of deploying complex models to edge devices. The success of this project opens avenues for future research into similar applications across different sectors, fostering the integration of AI in industrial automation.

ACKNOWLEDGMENT

This research is funded by Industrial University of Ho Chi Minh City under grant number 23.1CND01 (Contract number 135/HĐ-ĐHCN).

Abstract—The use of contemporary technological tools, as well as the modernization of curricula in the field of electronic and electrical engineering, is one of the main objectives of the academic staff at the Universities. Efforts to improve curricula and scientific research infrastructure find strong support from the CBHE programs funded by the EU. The purpose of this work is to include the optimization methods for improving of the photovoltaic system's performance using the digital technologies which develop students' theoretical and practical skills for a sustainable development in the field of energy. Optimizing of the photovoltaic system through the addition of a booster, MPPT controller to the existing architecture, as well as with the help of SIMULINK will increase the energy efficiency of the photovoltaic system, increasing the University's economic benefit and moreover, the ecological benefits for the population. The implementation of the optimization algorithms will increase the simulation skills of the academic staff and students for a more in-depth analysis related to the implementation of RES, an analysis which until now has only been developed through software data collection methods of the system. As case study it is the utilization of photovoltaic system in the University of Durres area, which is a sustainable development area in both the public and private sectors after the 2019 earthquake. The study brings a transdisciplinary approach that contribute in the education of the new generation towards a green society and economy. It includes knowledge of the field of electrical engineering in the direction of increasing the performance of renewable energy systems as well as the analysis of electronic circuits with the help of optimization algorithms and different ICT tools.

Keywords—Optimization; photovoltaic systems; education; performance; controller; SIMULINK

I. INTRODUCTION

The application of optimization techniques to enhance the efficiency of a photovoltaic (PV) system combines technology, design, and maintenance procedures. To make sure that the PV system runs at its maximum power point and maximizes energy output under variable weather conditions, we must use inverters or MPPT charge controllers.

The developed analyzes serve to create the history of the photovoltaic system' using, the analytical development of the current situation and to increase the skills in the design of further projects by implementing Renewable Energy Sources in general and photovoltaic systems in particular. These methods can also be used by curriculum programs of Albanian Universities and the Western Balkan' Universities in terms of highlighting the

advantages of environmentally and economically sustainable development.

The PV system's performance can be immediately monitored by setting up a monitoring system. Data analysis allows us to find trends, solve problems, and gradually improve system performance.

The optimization strategies have been applied in this paper for improving the performance of solar energy systems in generally for all photovoltaic systems. The University of Durres is used as the case study due to this, since a photovoltaic system was installed there thanks to the several funds invested by Erasmus+ programs.

Aleksander Moisiu University of Durres (UAMD) is Leader or Partner Institution for more than a hundred of International projects. We can mention the project "Development and implementation of multimedia and digital television curricula (DIMTV)", "Accelerating Western Balkans University Modernization by Introducing Virtual Technologies" (VTech@WBUUni) projects [1], which AMUD has been Leader Institution. Participation in projects has significantly served in increasing the capacities of the academic staff of Aleksander Moisiu University of Durres, in exchanging of experiences for the academic, administrative staff as well as students among partner universities in the region and European, improved the research infrastructure, participate in various activities such as workshops, conferences, seminars, etc.

Aleksander Moisiu University of Durres was a partner institution in the "Knowledge Triangle for a Low Carbon Economy" (KALCEA) project, whose objectives enabled the development and growth of cooperation between university, business and scientific research centers. One of his objectives was to emphasize the urgent need for universities to increase their role in the social and economic development at the local and regional level [2]. Based on the establishing of strong connections with business/industry sector, improving technical and human capacities, improving research activities in cooperation with industry sector, improving the skills of students based on the market needs and more.

Through the knowledge triangle mechanism (knowledge-research-innovation) has been improved the curricula with innovative knowledge in the field of renewable. We have studied the photovoltaic system installed on the roof of one of the buildings of the university campus in Spitalle, Durrës, which was financed by EU funds.

For the design and installation of the photovoltaic system at the University of Durres, a service company in the field of renewable resources in Albania was contacted. The block scheme of his realization is shown in Fig. 1.

Fig. 1. The scheme of the implementation of the photovoltaic system at the university campus of Durres

The purpose of this paper is to improve the architecture of the photovoltaic system with added elements in the installed system with the purpose of improving the performance of the power generation system with the help of Simulink [3]. Improving the photovoltaic systems architecture will be done by adding a booster, MPPT controller, as well as using optimization algorithms in this controller [4]. In this study, the P&O algorithm will be used to compare the photovoltaic system's performance.

Additionally, the solar system will be examined for varying temperatures and irradiances utilizing a booster and two different types of controls (PD and PI type controllers). We must weigh the advantages and disadvantages of each technique used to determine which strategy will enhance solar system performance in general for all users and in particular for UAMD.

II. LITERATURE REVIEW

Researchers, academic institutions, and Universities have attempted to increase the efficiency of photovoltaic systems. Let's review a number of these researchers and their suggestions for enhancing photovoltaic system performance.

The theories of PV systems and MPPT approaches are introduced by A. Sadick, who also provides the mathematical modeling processes for the DC-DC boost converter and the PV system. Simulations and tests were conducted under various environmental conditions using two types of solar systems: one with the P&O algorithm and the other without [5].

The performance of a multiple gain boost converter connected to a solar photovoltaic (SPV) system with a grid-connected inverter is analyzed by B M Kiran Kumar, M S Indira, and S Nagaraja Rao. Regarding the amount of components and boost factor, the outcomes are contrasted with the case of a conventional booster converter. The overall harmonic deformations of the output current in this investigation are

reported to be 1.66%, which is within permitted international criteria [6].

The aim of the simulation model developed by Indian university researchers is to capture the maximum amount of power by comparing its features to those of commercial panels under varying temperature and radiation circumstances. The investigation was conducted using MATLAB/Simulink [7].

The authors, Benaissa O. M., Hadjeri S., and Zidi S. A., have adjusted the power work cycle in converters to enhance the obtained power, with the aim of optimizing the photovoltaic system's efficiency by decreasing network losses [8].

Photovoltaic systems must be installed at locations with the highest power in order to generate electricity with the greatest possible advantage. Because of this, three sophisticated approaches to the photovoltaic system can be used with MATLAB/SIMULINK: PSO, Perturb-and-Observe (P&O), and Incremental Conductance (I_C). Following analysis, the PSO offers better power capture, less loss, and less deformation than the other two techniques [9], [10].

The theme study "Photovoltaic based high-efficiency single-input multiple-output dc-dc converter" by J. Kondalaiah and I. Rahul relied mostly on the use of a dc-dc converter, several inductors, and a power switch to increase system efficiency and control the output voltage [11].

The PV system's performance and the definition of M.P.P. are impacted by the addition of a DC-DC boost converter. One of the most crucial components is the input capacitor, which for optimal performance requires half the output capacitor's capacity [12].

In-depth research on the idea of MPPT techniques—which greatly boost the solar PV system's efficiency—is performed by Shazly A. Mohamed and Montaser Abd El Sattar. In an effort to maximize the PV system's energy conversion efficiency, they offer a simulation-based comparison analysis of incremental conductance and perturb and observe methods [13].

In the crucial area of PV system optimization, Maximum Power Point Tracking (MPPT) controllers are receiving a lot of attention. The efficiency, performance, modernism, complexity, and tracking speed of these controllers vary, and they use different algorithms. Considering their quick improvement, MPPT controllers fall into two categories: traditional and advanced techniques [14].

During the year 2024, it is noted that our partners in the KALCEA project are using digital twin design platforms, which will increase public awareness and engagement in energy efficiency. One of them is the Expedite Digital Twin, which will be applied to a district in Riga, Latvia and will provide practical guidelines, algorithms and training materials to help other cities replicate digital twins for their districts, driving adoption wide range of sustainable energy practices [15].

The design of intelligent systems is a disciplinary work that requires the optimal selection of specified sensors, defined data from these devices, their processing and implementation based on IoT [16].

The results obtained from the studies show that the implementation of relevant educational and promotional policies can mitigate the growth rate of electricity consumption. [17].

A concise overview of the literature allows us to draw attention to the challenges and limitations of existing approaches of current techniques. While conventional methods are relatively easy to use, they are unable to distinguish between local and global peaks. As a result, their efficiency is minimal if partial shading happens. Because of their higher efficiency, advanced tracking techniques are frequently employed [18]. Hybrid approaches find a way to overcome the shortcomings of the individual conventional and sophisticated approaches. The best MPPT method selection is still a problem that needs to be resolved; this problem can be resolved by conducting a survey of the available approaches. A succinct categorization and assessment of some of the used MPPT techniques is provided by this study. Moreover, this study offers a readily available reference.

III. METHODOLOGY

The usage of digital microcontrollers in this study has the goal of improving system efficiency, and the results can be applied in other research projects.

Unlike other research conducted by many authors, this study differs from previous research in that it establishes the parameters, both electrical and physical as well as the performance of the photovoltaic system using the P&O algorithm and a booster for each of the systems studied with controllers of different types for various value of the radiation and temperature. The study also compares the results obtained and highlights for researchers which of the controllers provides the highest efficiency in the work of photovoltaic systems, contributing directly to optimizing future-designed systems.

Through this paper will compare the performance of the photovoltaic system using the P&O algorithm, as well as examine the solar system for different irradiances and temperatures with a booster and two distinct types of controls (PD and PI type controllers).

In this research, we need to evaluate the benefits and drawbacks of every technique implemented in order to identify which approach will improve solar system performance generally for all users and specifically for UAMD.

These studies methods with the help of SIMULINK are suitable for study purposes by students who are studying in the field of RES in the Professional Studies Faculty and Information Technology Faculty at Aleksander Moisiu University of Durres. The system installed and its testing with controller of different types will be a case study for students during the design and simulation of SFV as for Albanian and Western Balkan Universities in improving their performance.

The system will be simulated in several different states to enable and analyze in terms of improving the performance of the photovoltaic system. The schematic block has been added the buster (DC-DC converter), as well as the PI/PD controller, in order to increase the effectiveness of the photovoltaic system. Specifically, the system is tested to calculate parameters related

to the maximum power point under optimal conditions, i.e. temperatures of 25 °C and solar radiation value 1000W/m² in these cases:

- System includes a booster and PD controller with P&O algorithms.
- System includes a booster and PI controller with P&O algorithms.

The results will then be compared, concluding which of them offers the highest efficiency of the system. Researchers can change concrete values of radiation and temperature during simulation, depending on the specific geographic area and climate conditions.

The system with the proposed architecture utilizes algorithms optimization at the point with maximum power generated by PV systems. These algorithms manage voltage values to ensure that the system operates at the peak of the power-voltage curve. As algorithms for the capture of MPPT, perturb and observe (P&O) algorithms are used.

The complete scheme of connecting the photovoltaic system to the proposed architecture is shown in Fig. 2.

Fig. 2. The proposed architecture of the photovoltaic system.

In this scheme, these main blocks are used:

- Photovoltaic panel block
- Booster block
- PD/PI control block
- MATLAB Function block

Each of the blocks in the proposed architecture for the University of Durres will be highlighted in the sections that follow.

a) *Photovoltaic panel block:* The panels are selected SunPower Performances 5 UPP. The system has 18 monocrystalline panels, assembling with 10° tilt structures. This system has the installed power of 7.47 KWp. The surface area of the installed system is 46.5 m², versus the area of the building of 649.3 m², i.e. the area of the roof occupied from the modules is 7.16%. Coordinates of references: 41°06'35.2" N; 20°04'28.2" E.

The location, geographical position and dimensions of the installation space of photovoltaic panels are shown in Fig. 3.

Fig. 3. Location and dimensions of the installation of photovoltaic panels.

Based on the data of the panels used in the photovoltaic system through the Matlab Code of P&O Algorithm, we can graphically determine the Volt-Ampere characteristic of nine panels connected in series in two parallel strings (Fig. 4a), as well as the characteristic where the point is clearly visible with maximum MPP power for different values of solar radiation (Fig. 4b).

Fig. 4. (a) Volt-Ampere characteristic of the used panels; (b) Determination of the maximum power point (MPP).

It is clear in Fig. 4(a) that the current passing through the used panels decreases with the decrease in the values of solar radiation referred to the same voltage values. Also from the volt-ampere characteristic it is noted that the current of the short-circuit (per $V=0$) decreases with the decrease of the values of solar radiation.

All the data obtained for the electric current, voltage and power of the system with photovoltaic panels for different values of solar radiation are summarized in the Table I:

TABLE I. DATA TABLE

Electrical and physical parameters	Value of parameters		
Solar radiation value (KW/m ²)	1	0.5	0.1
Maximum current value (A)	11.38	5.694	1.138
Maximum voltage value (V)	656.1	643.842	603.207
Maximum power value (KW)	7.466	3.666	0.687

Obviously from the above analysis, the maximum power value decreases with the decrease of the solar radiation value. This means that as the maximum power value decreases, the voltage and current values of the corresponding power values also decrease. In Fig. 4(b), it is seen that the maximum value of

the reference voltage for the open circuit, that is, for $I=0$ A, the voltage value is 767.7 V, a value which also matches the data in the datasheet of the panels, where Open Circuit Voltage it is 85.3V for each of the panels; for the 9 panels connected in series, the open circuit voltage is 767.7 V, i.e. the same as the value determined graphically with the help of MATLAB SIMULINK.

During the study of the photovoltaic system, we can determine the temperature change of the modules, as well as the solar radiation for a time interval of 10 hours (8:00 a.m. - 6:00 p.m.) on a day in June. Fig. 5(a) shows graphically how the temperature of the module changes every hour of the specified time interval. With the help of MATLAB SIMULINK and the P&O algorithm, we can also determine the change in solar radiation in relation to the change in ambient temperature in each hour of the time interval studied, as in Fig. 5(b).

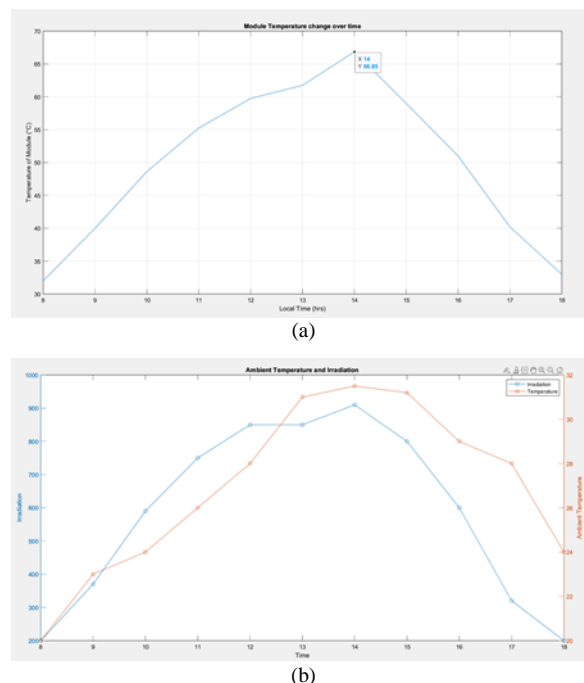

Fig. 5. (a) Module temperature change; (b) the change in solar radiation and ambient temperature for a certain time interval during a day in June.

As can be seen in Fig. 5(a), the panel's highest temperature is approximately 67°C at 2:00 p.m. Conversely, Fig. 5(b) shows that solar radiation achieves its peak values at approximately 2:00 p.m., when the day's maximum temperature is approximately 32°C.

The amount of sunshine and daytime temperature in June can be influenced by a variety of factors, including atmospheric conditions, geographic location, and June weather changes. Still, this is generally how it might appear on the midday. The solar radiation levels will progressively grow from low to moderate. The ambient temperature is warming when the sun gets stronger. During lunchtime the solar radiation peaks and receives the most amount of sunlight. Temperature range are warm to hot, with the greatest values of the day. Later in the afternoon the solar radiation will gradually decrease. The ambient temperature is still warm, but as the afternoon wears on, it begins to decrease.

b) *Booster block*: For the purpose of raising the input voltage, the booster block acts as a DC-DC converter. It is made up of multiple components, as shown in Fig. 6, including a cobbler, input capacitor, diode, MOSFET, shunt capacitor, and driving resistance. Since it stores energy and reduces deformations, the input capacitor is one of the most crucial components of the DC-DC converter [19]. Both continuous (CCM) and intermittent (DCM) modes of operation are available for this converter [20]. Managed by the controller, the work cycle determines the tension at the exit. At the booster's outlet are electric current and voltage measuring instruments, together with a scope (Scope 2) for observing the form, values, and boundaries of electrically enormous.

Fig. 6. Booster block, voltage & current measurement and the scope.

As the system's stability and efficiency rise, booster design and fundamental parameter selection play a critical role in enhancing system performance [21].

c) *PID control block*: PID control techniques are mostly used in the industry for the regulation of various physical processes. Control algorithms are found in terms proportional, derivative and integral [22], [23].

Proportional control is based on the difference between a given point and variable change, providing an immediate response [24].

Integral control is based on the accumulated error integral over time and reduces the stable state error by continuously stabilizing the output of the controller, thus eliminating the stable state errors or how else it is responsible for long-term reactions to changes in the signal of the input [25], [26].

Derivative control is based on measuring the rate of change of the error signal and regulating the output of the controller accordingly, thus improving the system's transitional response.

Each of the control types is specified by the corresponding coefficient, respectively K_p , K_i , K_d , which determine the controller's reaction force for each case. Their values must be tuned to improve the performance of the photovoltaic system. To connect a controller to photovoltaic systems, the other components are needed, which stabilizes the voltage and the current gained, thus preventing their fluctuations at the exit. Using of the controller ensures efficiency and security during energy generation. These control techniques can be combined by designing the PD (proportional-derivative), PI (proportional-integrative) controller or controller PID (proportional-Integrator-Derivative). In this paper we explain the role of PD/PI controllers in the performance of a photovoltaic system installed in Aleksander Moisiu University of Durres, as well as comparing their work.

d) *MATLAB function block*: With the help of this block, we design and analyze the photovoltaic system, as the most

natural way of visualizing data and obtaining results through graphics. The codes used can be integrated with other languages, as well as adapted to much larger numbers of records, thus enjoying the properties of being scalar.

The technique used P&O (Perturb and Observe) serves to capture the maximum-powered MPPT point of the photovoltaic system. According to this method, the voltage at the exit of the photovoltaic system is adjusted by comparing the power value in the current period with that of the previous period. If the output voltage tends to increase, the control system tends to reduce it in order to keep it at stable power values at the exit.

Algorithm flowchart is shown below in Fig. 7:

Fig. 7. P&O Algorithm flowchart [27].

IV. RESULTS

To analyze the performance of the photovoltaic system with different types of control, we must follow the following steps:

- Select the type of controller and its parameters
- Identify the scheme
- I/O give out the details
- Stimulate
- Simulation executed

During the simulation, the temperature (25°C) and radiation (1000W/m²) parameters are set. The researcher can modify the tracks as needed.

- Simulation of the photovoltaic system with Proportional Derivative (PD) controller

Firstly, after choosing the type of PD controller (Fig. 8), we connect photovoltaic system with the controller and follow the above-mentioned path.

Fig. 8. Block scheme with PD controller.

In Scope 1 screen we can clearly distinguish the change of power, voltage and current in relation to the time for the system with the PD controller connected to it, while on the screen of the Scope 2 the flows of the current and voltage at the exit of the booster will appear.

The output views of scope 1 are for the initial moments of simulation of the photovoltaic system with PD controller (Fig. 9):

Fig. 9. The view of the oscilloscope 1 in the initial moments.

It is clear that at the initial moments of the waves last about 14 ms. The parameters (power, voltage, current) then start stabilizing, so the view of the oscilloscope 1 in the stabilized moments is shown in the Fig. 10.

Fig. 10. Stabilized current values, voltage and power in case of PD controller scheme.

It is clear that the stabilized parameters are: power of about 7.47 KW, current value about 11.5 A, while voltage value is about 650 V.

The increase of the continuous voltage value with booster assistance from 650V to about 800V, affects the decrease of the current value from 11.5A to 9.3 A. This process is accompanied by significant variations in values, such as Fig. 11. Specifically:

Fig. 11. Fluctuations of current and voltage values at the exit of the booster in the PD controller scheme.

These fluctuations around average values exceed 5% of tolerance in terms of the range of deformations, so although the maximum power value is 7.47 KW. Current values fluctuate from (7.5-10) A, while voltage values from (650-870) V.

In this case the system is not considered in optimal working conditions for obtaining maximum power, for the maximum efficiency of the system.

- Simulation of the photovoltaic system with the Integral Proportional Controller (PI), as is shown in Fig. 12.

By including a PI controller in the suggested architecture of the photovoltaic system, the simulation of the scheme will be improved. Its operation, which is based on the average error of the integral over time, reduces the stable state error by consistently stabilizing the controller's output and therefore eliminating of the stable state errors. In other words, it can be held responsible for its long-term responses to changes in the input signal [28].

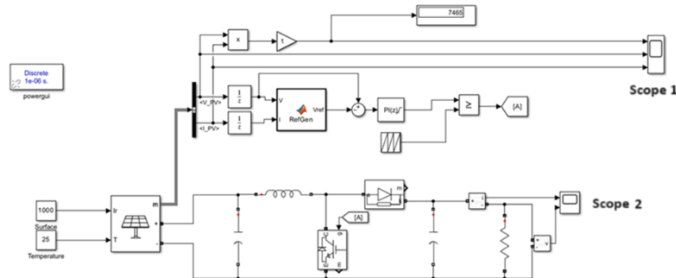

Fig. 12. Block scheme with PI controller.

The output views of scope 1 are for the initial moments of simulation of the photovoltaic system with PI controller (Fig. 13):

Fig. 13. The view of the oscilloscope 1 in the initial moments.

- As seen the largest leaches occur until the first 4ms, then the flow of variability drops significantly.

The current, voltage and power begin to stabilize, as shown in Fig. 14.

Fig. 14. Stabilized current values, voltage and power in case of PI controller scheme.

At the initial moment, the fluctuations are observed, which have a smaller duration than in the first instance until achieving the desired stable value. Stabilization time for the PI controller is 14 ms in the frame with the PD controller. At this moment the Update block command is given.

At the exit of the booster, the voltage and the current have the values around the average value below 5% of the average value, Current values fluctuate from (8.6 – 9.5) A, while voltage values from (770 - 805) V. The stabilization time is about 14 ms (Fig. 15), as well as in the system with PD controller. Obviously the deformations are more acceptable in the case of the PI controller scheme than in the system with the PD controller.

Fig. 15. Fluctuations of current and voltage values at the exit of the booster in the PI controller scheme.

Finally, we can compare the performance of systems with different types of controllers by summarizing the data for electrical quantities in the Fig. 16:

Fig. 16. Change rate of (a) current, (b) voltage for different controllers.

If we refer to the voltage and current variation limits for each of the controller types, we can obtain the results shown in the graph below (Fig. 17).

Fig. 17. The variation limits of current, voltage and time for the PD/PI controllers.

V. DISCUSSION

Obviously, the changes in current and voltage at the output of the amplifier for the system with PI controller are smaller than for the one with PD controller. Also, the stabilization time of the power, current, voltage is almost the same in the PI controller system with the stabilization time of these electrical parameters at the output of the PD controller system.

So it is worth noting that in the conditions of the photovoltaic system with PI controller, the current and voltage fluctuations at the output of the booster are within the allowed values of 5% compared to the case of the system with PD controller.

Ultimately, installing a PI controller precisely on the photovoltaic system can improve its performance, not just at the University of Durres but also in other situations.

The developed analysis guides the researchers about the more efficient use of photovoltaic systems with the help of the booster, controller and performance improvement algorithms of these renewable energy systems [29], [30]. Improving the performance of photovoltaic systems with the help of the above methods leads to the capture of the point with maximum power in minimum time intervals [31].

The studies demonstrate the global power market's rapid expansion based on the evaluation of data at the worldwide level, data history across time, and contemporary analysis. By 2026, it is anticipated that installed energy storage capacity worldwide would exceed 270 GW [32]. The primary cause is the increasing demand for renewable energy systems' flexibility and storage in energy systems [33].

The methods that have been established until now will expand the applications of current renewable energy technologies with artificial intelligence support [34]. Their foundation is a zero-carbon economy. Renewable energy is a key technology for achieving carbon-free energy transitions [35].

The RES faced new chances and challenges during the Covid-19 crisis, but they remained a powerful resource [36]. For this reason, it is necessary to develop detailed market analyses and forecasts [37], [38].

So researchers should explore key industry challenges and identifying obstacles, to optimize renewable energy systems in order to accelerate the development of a low-carbon economy [39], [40].

VI. FUTURE WORK

We recommend that scientific researchers should continue to experiment the operation of photovoltaic systems with other types of controllers to take further steps forward in improving their performance. They should also improve optimization algorithms to increase energy efficiency. Lecturers should implement the optimization methods to the university education process.

VII. CONCLUSION

Researchers attempt to forecast and analyze a country's or region's energy performance based on various scenarios by utilizing modular components. Together with real-time data on energy generated by renewable sources, these components provide environmental visualization. The results can then be improved, evaluated and compared in order to arrive at the most efficient decision-making.

In order to improve the photovoltaic systems' efficiency, we can add a booster to the photovoltaic systems. This booster will raise the continuous voltage while maintaining the 7.47 KWp installed power and will also allow us to modify the stabilized output voltage values when they start to fluctuate for any reason. For this reason, we use P&O optimization algorithms for capturing the MPP, determining the values of electrical parameters (current, voltage) for different values of solar

radiation; as well as for determining the physical parameters (temperature, solar radiation) of the panels within a certain time interval on a given day. Also with the help of optimization methods we can increase the performance of the photovoltaic system experimenting with different types of controllers. The developed analysis showed that the stabilization time of the voltage, current and output power is the same for the both controllers (PI/PD). Regarding the change of electrical quantities, the current fluctuates 36% less in the scheme with PI controller compared to that with PD controller, while the voltage changes around 29.2% less in the scheme with PI controller.

These results related to the performance of the photovoltaic system for the capture of MPPT with the help of the booster, controller and optimization algorithms will serve to modernize the curricula with contemporary methods that influence on the sustainable development towards a green society and economy. Also this study will serve scientific researchers, as well as all stakeholders for improving the work of systems installed as well as the design of new systems in the University of Durres and the Western Balkan Universities.

Abstract—A digital agriculture park refers to an agricultural production and organizational unit of a certain scale where digital technology is used to optimize the agricultural supply chain. It enhances park management and service levels, achieving a new development model characterized by safe, low-carbon, high-quality, high-yield, precise, and efficient production, management, service, and operation. The quality evaluation of digital agriculture park information system is a multiple-attribute decision-making (MADM). Currently, the Exponential TODIM (ExpTODIM) and TOPSIS was put forward MADM. The Type-2 neutrosophic numbers (T2NNs) are employed to portray fuzzy information during the quality evaluation of digital agriculture park information system. In this works, the Type-2 neutrosophic number Exponential TODIM-TOPSIS (T2NN-ExpTODIM-TOPSIS) approach is put forward MAGDM under T2NNs. Finally, numerical study for quality evaluation of digital agriculture park information system is determined to demonstrate the T2NN-ExpTODIM-TOPSIS approach. The major research motivation is cultivated: (1) ExpTODIM and TOPSIS approach was enhanced under IFSS; (2) Entropy is put forward weight numbers in light with score values along with T2NNs; (3) T2NN-ExpTODIM-TOPSIS is put forward the MADM along with T2NNs; (4) numerical example for quality evaluation of digital agriculture park information system and different comparative analysis is put forward the validity of T2NN-ExpTODIM-TOPSIS.

Keywords—Multiple-Attribute Decision-Making (MADM); Type-2 Neutrosophic Numbers (T2NNs); ExpTODIM approach; TOPSIS approach; quality evaluation

I. INTRODUCTION

Building digital agriculture parks is a significant trend in modern agriculture, with countries worldwide gradually adopting this model. By integrating digital technologies like Internet of things, big data, and Artificial Intelligence, these parks enhance production, management, and services [1-3]. Currently, many countries are actively exploring and developing digital agriculture parks [4, 5]. Sensor networks and drone technology are widely used for land monitoring and crop management, enabling real-time data collection and precise management. This improves crop yield and quality while reducing the use of fertilizers and pesticides, thus lowering

environmental pollution [6-8]. Digital parks also optimize production decisions through big data analysis. Farmers can adjust plans based on real-time data, enhancing resource efficiency and reducing costs. The introduction of intelligent management systems allows comprehensive monitoring and automation of production processes, increasing operational efficiency. Moreover, digital agriculture parks play a crucial role in food safety. Blockchain technology ensures traceability from production to sales, enhancing product safety and traceability [9-11]. This not only boosts consumer trust but also strengthens market competitiveness. The significance of building digital agriculture parks is substantial. Firstly, they increase agricultural productivity and efficiency. The application of digital technologies makes production processes more intelligent and precise, significantly improving resource utilization. Secondly, digital parks promote sustainable development. The use of precision agriculture technology reduces environmental pollution, achieving low-carbon and green agriculture. The development of digital agriculture parks also boosts rural economic growth. As park construction progresses, related industries develop, creating more jobs and improving rural economies [12-15]. Additionally, digital parks serve as testing grounds for technological innovation. The application and promotion of new technologies not only advance agricultural science but also provide references for innovation in other fields. However, there are challenges in building digital agriculture parks. High technical costs, data security issues, and farmers' acceptance of technology need to be addressed. Therefore, countries need to enhance policy support, drive technological innovation, and provide training to improve farmers' digital literacy. In the global context, the development of digital agriculture parks offers new opportunities for international cooperation. Countries can share technologies and experiences to address food security and environmental challenges together [16, 17]. Through global collaboration and technology sharing, digital agriculture parks will provide strong support for sustainable agricultural development worldwide. In summary, building digital agriculture parks not only enhances agricultural efficiency and safety but also promotes sustainable development and rural economic growth. It is a crucial path for modern agricultural

transformation. With continuous technological advancement, digital agriculture parks will play an increasingly important role, becoming a core model for future agricultural development [18, 19].

With the development of decision science and practical needs, research on MADM has become popular again. In the 1980s, some foreign scholars conducted research on group AHP and proposed some methods and some famous scholars in China also conducted relevant discussions [20-24]. Hwang and Yoon [25] systematically reviewed and summarized a large number of previous research results on MADM and edited and published the first monograph on multi-attribute decision-making, "Multiple Attribute Decision Making Method and Application.". After the 1980s, many scholars studied various types of interactive algorithms for solving the MADM problems. At that time, there were already some mature methods for studying MADM problems [26-31], such as the optimal selection method, connection method, and separation method used to screen options when there were too many options, the least squares method and eigenvector method used to determine attribute weights, the most commonly used simple additive weighting method and hierarchical additive weighting method for option ranking, the dictionary ordering method for selecting options based on attribute weight size, TOPSIS method [32] and LINMAP [33-37] method based on the concept of ideal solutions, as well as the queuing method based on estimating relative positions, linear allocation method, ELECTRE [38-41] method, and so on. The quality evaluation of digital agriculture park information system is MADM. Currently, the ExpTODIM [42, 43] and TOPSIS technique [32, 44, 45] is put forward the MADM. The Type-2 neutrosophic numbers (T2NNs) [46] are put forward for portraying fuzzy information during quality evaluation of digital agriculture park information system. Until now, no or few approaches were investigated on ExpTODIM and TOPSIS technique in light with entropy model along with T2NNs. Therefore, T2NN-ExpTODIM-TOPSIS model is put forward MADM along with T2NNs. Numerical example for quality evaluation of digital agriculture park information system and comparative analysis is put forward the validity of T2NN-ExpTODIM-TOPSIS approach. The major research motivation is cultivated: (1) ExpTODIM and TOPSIS approach was enhanced under T2NNs;

(2) Entropy is put forward weight numbers in light with score values along with T2NNs; (3) T2NN-ExpTODIM-TOPSIS is put forward the MADM along with T2NNs; (4) numerical example for quality evaluation of digital agriculture park information system and comparative analysis is put forward the validity of T2NN-ExpTODIM-TOPSIS.

The structure of such study is cultivated. Preliminaries is given in Section II. In Section III, T2NN-ExpTODIM-TOPSIS model is put forward MADM along with T2NNs. Section IV numerical study for quality evaluation of digital agriculture park information system through different comparative analysis. Final conclusion is cultivated in Section V.

II. PRELIMINARIES

Wang et al. [47] built the SVNSs

Definition 1 [47]. The SVNSs is cultivated:

$$VA = \left\{ \left(\theta, VT_{VA}(\theta), VI_{VA}(\theta), VF_{VA}(\theta) \right) \mid \theta \in \Theta \right\} \quad (1)$$

where $VT_{VA}(\theta), VI_{VA}(\theta), VF_{VA}(\theta)$ is truth-membership (TM), indeterminacy-membership (IM) and falsity-membership (FM),

$VT_{VA}(\theta), VI_{VA}(\theta), VF_{VA}(\theta) \in [0, 1]$,
 $0 \leq VT_{VA}(\theta) + VI_{VA}(\theta) + VF_{VA}(\theta) \leq 3$. The SVNN is implemented as $VA = (VT_A, VI_A, VF_A)$, where $VT_A, VI_A, VF_A \in [0, 1]$, and $0 \leq VT_A + VI_A + VF_A \leq 3$.

Abdel-Basset et al. [46] cultivated the T2NNs.

Definition 1[46]. The T2NN is cultivated:

$$VV = \left\{ \left(\theta, VT(\theta), VI(\theta), VF(\theta) \right) \mid \theta \in \Theta \right\} \quad (2)$$

where $VT(\theta), VI(\theta), VF(\theta) \in [0, 1]$ be TM, IM and FM based on triangular fuzzy numbers.

$$VT(\theta) = (VT^L(\theta), VT^M(\theta), VT^U(\theta)), 0 \leq VT^L(\theta) \leq VT^M(\theta) \leq VT^U(\theta) \leq 1 \quad (3)$$

$$VI(\theta) = (VI^L(\theta), VI^M(\theta), VI^U(\theta)), 0 \leq VI^L(\theta) \leq VI^M(\theta) \leq VI^U(\theta) \leq 1 \quad (4)$$

$$VF(\theta) = (VF^L(\theta), VF^M(\theta), VF^U(\theta)), 0 \leq VF^L(\theta) \leq VF^M(\theta) \leq VF^U(\theta) \leq 1 \quad (5)$$

We let

$$VV = \left\{ \left((VT^L, VT^M, VT^U), (VI^L, VI^M, VI^U), (VF^L, VF^M, VF^U) \right) \right\}$$
 be a
 T2NN, $0 \leq VT^U + VI^U + VF^U \leq 3$.
 Definition 2[46]. Let

$$VV_1 = \left\{ \left((VT_1^L, VT_1^M, VT_1^U), (VI_1^L, VI_1^M, VI_1^U), (VF_1^L, VF_1^M, VF_1^U) \right) \right\},$$

$$VV_2 = \left\{ \left((VT_2^L, VT_2^M, VT_2^U), (VI_2^L, VI_2^M, VI_2^U), (VF_2^L, VF_2^M, VF_2^U) \right) \right\} \quad \text{and}$$

- (1) if $SF(VV_1) < SF(VV_2)$, then $VV_1 < VV_2$;
- (2) if $SF(VV_1) = SF(VV_2)$, $AF(VV_1) < AF(VV_2)$, then $VV_1 < VV_2$;
- (3) if $SF(VV_1) = SF(VV_2)$, $AF(VV_1) = AF(VV_2)$, then $VV_1 = VV_2$.

Definition

4[46].

Let

$$VV_1 = \left\{ \begin{array}{l} (VT_1^L, VT_1^M, VT_1^U), \\ (VI_1^L, VI_1^M, VI_1^U), (VF_1^L, VF_1^M, VF_1^U) \end{array} \right\},$$

$$VV_2 = \left\{ \begin{array}{l} (VT_2^L, VT_2^M, VT_2^U), \\ (VI_2^L, VI_2^M, VI_2^U), (VF_2^L, VF_2^M, VF_2^U) \end{array} \right\}$$

be T2NNs,

the T2NNs Hamming distance (T2NNHD) is cultivated:

$$T2NNHD(VV_1, VV_2)$$

$$= \frac{1}{9} \left(\begin{array}{l} |VT_1^L - VT_2^L| + |VT_1^M - VT_2^M| + |VT_1^U - VT_2^U| \\ + |VI_1^L - VI_2^L| + |VI_1^M - VI_2^M| + |VI_1^U - VI_2^U| \\ + |VF_1^L - VF_2^L| + |VF_1^M - VF_2^M| + |VF_1^U - VF_2^U| \end{array} \right)$$

(11)

III. T2NN-ExpTODIM-TOPSIS APPROACH FOR MADM WITH ENTROPY

The T2NN-ExpTODIM-TOPSIS is cultivated for MAGDM.

Let $VA = \{VA_1, VA_2, \dots, VA_m\}$ be alternative and

$VG = \{VG_1, VG_2, \dots, VG_n\}$ be attributes with weight νw ,

$\nu w_j \in [0, 1], \sum_{j=1}^n \nu w_j = 1$. Then, T2NN-ExpTODIM-TOPSIS

is cultivated for MADM (see Fig. 1).

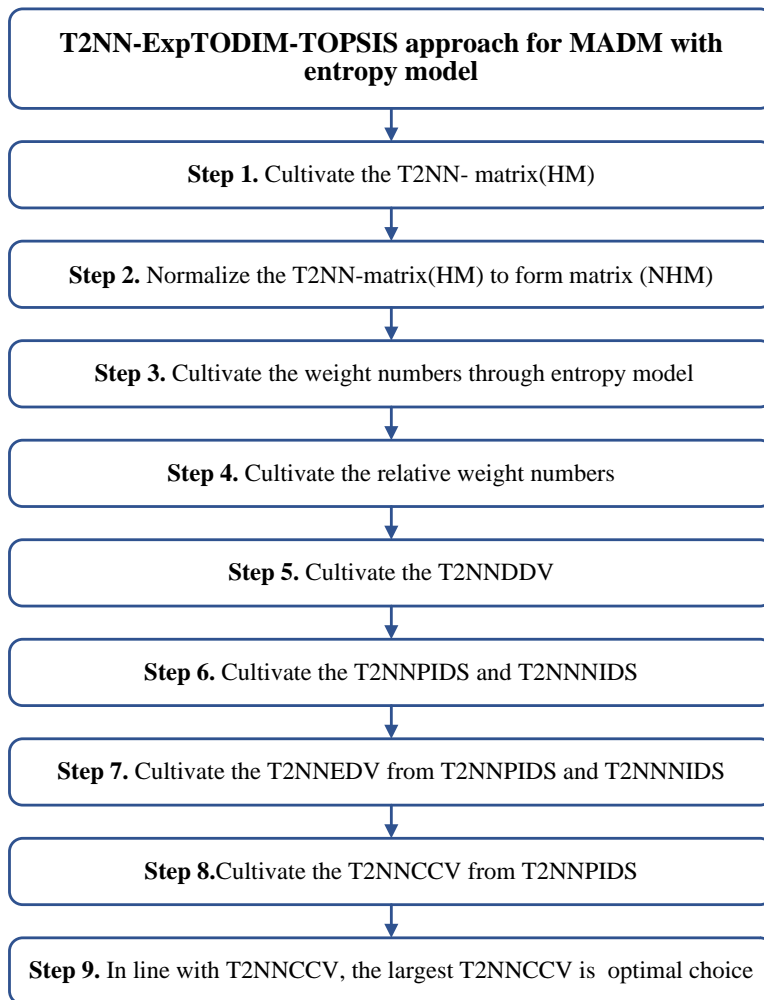

Fig. 1. T2NN-ExpTODIM-TOPSIS approach for MADM with entropy.

A. T2NN-MADM Problem

Step 1. Cultivate the T2NN-matrix $VM = [VM_{ij}]_{m \times n}$:

$$VM = [VM_{ij}]_{m \times n} = \begin{matrix} & VG_1 & VG_2 & \dots & VG_n \\ VA_1 & VM_{11} & VM_{12} & \dots & VM_{1n} \\ VA_2 & VM_{21} & VM_{22} & \dots & VM_{2n} \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ VA_m & VM_{m1} & VM_{m2} & \dots & VM_{mn} \end{matrix} \quad (12)$$

$$VM_{ij} = \left\{ \begin{matrix} ((VI_{ij}^L), (VI_{ij}^M), (VI_{ij}^U)), \\ ((VI_{ij}^L), (VI_{ij}^M), (VI_{ij}^U)), \\ ((VF_{ij}^L), (VF_{ij}^M), (VF_{ij}^U)) \end{matrix} \right\} \quad (13)$$

Step 2. Normalize $VM = [VM_{ij}]_{m \times n}$ into $NVM = [NVM_{ij}]_{m \times n}$.

Aiming at benefit attributes:

$$NVM_{ij} = \left\{ \begin{matrix} ((NVT_{ij}^L), (NVT_{ij}^M), (NVT_{ij}^U)), \\ ((NVI_{ij}^L), (NVI_{ij}^M), (NVI_{ij}^U)), \\ ((NVF_{ij}^L), (NVF_{ij}^M), (NVF_{ij}^U)) \end{matrix} \right\} \\ = \left\{ \begin{matrix} ((VT_{ij}^L), (VT_{ij}^M), (VT_{ij}^U)), \\ ((VI_{ij}^L), (VI_{ij}^M), (VI_{ij}^U)), \\ ((VF_{ij}^L), (VF_{ij}^M), (VF_{ij}^U)) \end{matrix} \right\} \quad (14)$$

Aiming at cost attributes:

$$NVM_{ij} = \left\{ \begin{matrix} ((NVT_{ij}^L), (NVT_{ij}^M), (NVT_{ij}^U)), \\ ((NVI_{ij}^L), (NVI_{ij}^M), (NVI_{ij}^U)), \\ ((NVF_{ij}^L), (NVF_{ij}^M), (NVF_{ij}^U)) \end{matrix} \right\} \\ = \left\{ \begin{matrix} ((VF_{ij}^L), (VF_{ij}^M), (VF_{ij}^U)), \\ ((VI_{ij}^L), (VI_{ij}^M), (VI_{ij}^U)), \\ ((VT_{ij}^L), (VT_{ij}^M), (VT_{ij}^U)) \end{matrix} \right\} \quad (15)$$

B. Cultivate the Weight Numbers Through Entropy

Step 3. Cultivate the weight numbers through entropy.

The weight is fundamental for MAGDM [48-52]. Entropy [53] is cultivated for weight numbers. The normalized fuzzy decision matrix (NFDM) is cultivated:

$$NFDM_{ij} = \frac{\left(\begin{matrix} \left((NHA_{ij}^L), (NHA_{ij}^M), (NHA_{ij}^U) \right), \\ AF \left\{ \left((NHB_{ij}^L), (NHB_{ij}^M), (NHB_{ij}^U) \right), +1 \right. \\ \left. \left((NHC_{ij}^L), (NHC_{ij}^M), (NHC_{ij}^U) \right) \right\} \\ \left((NHA_{ij}^L), (NHA_{ij}^M), (NHA_{ij}^U) \right), \\ SF \left\{ \left((NHB_{ij}^L), (NHB_{ij}^M), (NHB_{ij}^U) \right), +1 \right. \\ \left. \left((NHC_{ij}^L), (NHC_{ij}^M), (NHC_{ij}^U) \right) \right\} \end{matrix} \right)}{\sum_{i=1}^m \left(\begin{matrix} \left((NHA_{ij}^L), (NHA_{ij}^M), (NHA_{ij}^U) \right), \\ AF \left\{ \left((NHB_{ij}^L), (NHB_{ij}^M), (NHB_{ij}^U) \right), +1 \right. \\ \left. \left((NHC_{ij}^L), (NHC_{ij}^M), (NHC_{ij}^U) \right) \right\} \\ \left((NHA_{ij}^L), (NHA_{ij}^M), (NHA_{ij}^U) \right), \\ SF \left\{ \left((NHB_{ij}^L), (NHB_{ij}^M), (NHB_{ij}^U) \right), +1 \right. \\ \left. \left((NHC_{ij}^L), (NHC_{ij}^M), (NHC_{ij}^U) \right) \right\} \end{matrix} \right)} \quad (16)$$

The fuzzy Shannon decision entropy (FSDE) is cultivated:

$$FSDE_j = -\frac{1}{\ln m} \sum_{i=1}^m NFDM_{ij} \ln NFDM_{ij} \quad (17)$$

and $NFDM_{ij} \ln NFDM_{ij} = 0$ if $NFDM_{ij} = 0$.

Then, the weight numbers $vw = (vw_1, vw_2, \dots, vw_n)$ is cultivated:

$$vw_j = \frac{1 - FSDE_j}{\sum_{j=1}^n (1 - FSDE_j)} \quad (18)$$

C. T2NN-ExpTODIM-TOPSIS Approach for MADM

The T2NN-ExpTODIM-TOPSIS approach is cultivated for MADM.

Step 4. Cultivate relative weight numbers:

$$rvw_j = vw_j / \max_j vw_j, \quad (19)$$

Step 5. Cultivate the The T2NN dominance degree values (T2NNDDV).

1) The T2NNDDV of VA_i over VA_j for VG_j is cultivated:

$$T2NNDDV_j(VA_i, VA_t) = \begin{cases} \frac{rvw_j \times (1 - 10^{-\rho T2NNHD(NVM_{ij}, NVM_{it})})}{\sum_{j=1}^n rvw_j} & \text{if } SF(NVM_{ij}) > SF(NVM_{it}) \\ 0 & \text{if } SF(NVM_{ij}) = SF(NVM_{it}) \\ \frac{1}{v\theta} \frac{\sum_{j=1}^n rvw_j \times (1 - 10^{-\rho T2NNHD(NVM_{ij}, NVM_{it})})}{rvw_j} & \text{if } SF(NVM_{ij}) < SF(NVM_{it}) \end{cases} \quad (20)$$

where, $v\theta$ is presented from Tversky and Kahneman [54] and $\rho \in [1, 5]$ [55].

2) The $T2NNDDV_j(VA_i)$ ($j = 1, 2, 3, \dots, n$) with respect to VG_j is cultivated:

$$T2NNDDV_j(VA_i) = [T2NNDDV_j(VA_i, VA_t)]_{m \times m}$$

$$= \begin{matrix} & VA_1 & VA_2 & \dots & VA_m \\ \begin{matrix} VA_1 \\ VA_2 \\ \vdots \\ VA_m \end{matrix} & \begin{bmatrix} 0 & T2NNDDV_j(VA_1, VA_2) & \dots & T2NNDDV_j(VA_1, VA_m) \\ T2NNDDV_j(VA_2, VA_1) & 0 & \dots & T2NNDDV_j(VA_2, VA_m) \\ \vdots & \vdots & \dots & \vdots \\ T2NNDDV_j(VA_m, VA_1) & T2NNDDV_j(VA_m, VA_2) & \dots & 0 \end{bmatrix} \end{matrix}$$

3) Cultivate the overall T2NNDDV of VA_i over others for VG_j :

$$T2NNDDV_j(VA_i) = \sum_{t=1}^m T2NNDDV_j(VA_i, VA_t) \quad (21)$$

4) The overall T2NNDDD matrix is cultivated:

$$T2NNDDV = (T2NNDDV_{ij})_{m \times n}$$

$$= \begin{matrix} & VG_1 & VG_2 & \dots & VG_n \\ \begin{matrix} VA_1 \\ VA_2 \\ \vdots \\ VA_m \end{matrix} & \begin{bmatrix} \sum_{t=1}^m T2NNDDV_1(VA_1, VA_t) & \sum_{t=1}^m T2NNDDV_2(VA_1, VA_t) & \dots & \sum_{t=1}^m T2NNDDV_n(VA_1, VA_t) \\ \sum_{t=1}^m T2NNDDV_1(VA_2, VA_t) & \sum_{t=1}^m T2NNDDV_2(VA_2, VA_t) & \dots & \sum_{t=1}^m T2NNDDV_n(VA_2, VA_t) \\ \vdots & \vdots & \dots & \vdots \\ \sum_{t=1}^m T2NNDDV_1(VA_m, VA_t) & \sum_{t=1}^m T2NNDDV_2(VA_m, VA_t) & \dots & \sum_{t=1}^m T2NNDDV_n(VA_m, VA_t) \end{bmatrix} \end{matrix}$$

Step 6. Cultivate the T2NN positive ideal decision solution (T2NNPIDS) and T2NN negative ideal decision solution (T2NNNIDS):

$$T2NNPIDS = (T2NNPIDS_1, T2NNPIDS_2, \dots, T2NNPIDS_n) \quad (22)$$

$$T2NNNIDS = (T2NNNIDS_1, T2NNNIDS_2, \dots, T2NNNIDS_n) \quad (23)$$

$$T2NNPIDS_j = \max_{j=1}^n T2NNDDV_{ij} \quad (24)$$

$$T2NNNIDS_j = \min_{j=1}^n T2NNDDV_{ij} \quad (25)$$

Step 7. Cultivate the T2NN Euclidean distance values (T2NNEDV) for T2NNPIDS and T2NNNIDS.

$$T2NNEDV(HA_i, T2NNPIDS) = \sqrt{\sum_{j=1}^n (T2NNDDV_{ij} - T2NNPIDS_j)^2} \quad (26)$$

$$T2NNEDV(VA_i, T2NNNIDS) = \sqrt{\sum_{j=1}^n (T2NNDDV_{ij} - T2NNNIDS_j)^2} \quad (27)$$

Step 8. Cultivate the T2NN closeness coefficient values (T2NNCCV) for T2NNPIDS.

$$T2NNCCV(VA_i, T2NNPIDS) = \frac{T2NNEDV(VA_i, T2NNNIDS)}{\left(\frac{T2NNEDV(VA_i, T2NNPIDS)}{+T2NNEDV(VA_i, T2NNPIDS)} \right)} = \frac{\sqrt{\sum_{j=1}^n (T2NNDDD_{ij} - T2NNNIDS_j)^2}}{\left(\sqrt{\sum_{j=1}^n (T2NNDDD_{ij} - T2NNNIDS_j)^2} + \sqrt{\sum_{j=1}^n (T2NNDDD_{ij} - T2NNPIDS_j)^2} \right)} \quad (28)$$

Step 9. Rank and choose the optimal scheme in line with maximum T2NNCCV.

IV. NUMERICAL EXAMPLE AND COMPARATIVE ANALYSIS

A. Numerical Example for Quality Evaluation of Digital Agriculture Park Information System

Since the 1990s, under the joint promotion of the Ministry of Agriculture, the Ministry of Science and Technology, and other ministries, China has initiated the construction of modern agricultural demonstration zones and agricultural science and technology parks at various levels. The aim is to cluster high-quality agricultural production elements such as science, policy, and funding in these parks to lead the transformation and development of agriculture. Some parks comprehensively utilize the Internet of Things, cloud computing, and automatic control technologies to enhance their production and management levels. As modern agricultural parks deepen their exploration of information systems, the precise and intelligent advantages of digital technology have been leveraged, enhancing the value of park development. However, this has also exposed some deficiencies, mainly manifested in the following aspects: the disconnection between information systems and the main business of the parks; information system operations becoming a "negative asset" as they fail to fully

enhance management performance and continuously overdraw management costs; "cold wars" and redundant construction between information systems due to a lack of overall planning and coordination, leading to a lack of unified standards and coordination between old and new systems; the lack of distinct agricultural characteristics in the parks, with agricultural-specific sensors currently lacking and intelligent control based on operation types and models still in the theoretical research stage; the breadth of the potential of information technology to stimulate agricultural economy is insufficient, and the economic potential of the combination of information technology and agriculture has not been fully tapped. Digital agricultural parks are not limited to production functions; they can combine the multi-dimensional advantages of the parks to play multifunctional effects such as technology promotion, scientific and educational training, capital aggregation, and scientific research transformation, thereby enhancing the added value of the development of digital agricultural parks. The construction of digital agricultural parks is a systematic and all-inclusive project that requires the support of various management tools like performance, system, and organization to improve the priority level of digital agriculture, achieve top-down, unified resource organization effects, and effectively mobilize organizational enthusiasm to realize construction goals. It is necessary to focus on the financial sustainability during the construction and operational phases as an important indicator for the construction of digital agriculture, incorporating it into feasibility or planning studies. The construction of digital agricultural parks cannot be separated from the deep involvement of a professional team, which should at least include roles such as IT consultants, project managers, product managers, developers, and operations engineers, and maintain the team's continuity and stability in the development of the park to ensure the continuous advancement of the digitalization strategy. The quality evaluation of digital agriculture park information system is MADM. Therefore, the quality evaluation of digital agriculture park information system is presented to demonstrate T2NN-ExpTODIM-TOPSIS. Five potential digital agriculture park information systems $VA_i (i = 1, 2, 3, 4, 5)$ to assessed in line with different attributes: ①VG₁ is software function for digital agriculture park information systems; ②VG₂ is software performance for digital agriculture park information systems; ③VG₃ is management cost for digital agriculture park information systems; ④VG₄ is software supplier for digital agriculture park information systems. The VG₃ is cost attribute. The T2NN-ExpTODIM-TOPSIS is put forward the quality evaluation of digital agriculture park information system.

Step 1. Cultivate the T2NN-matrix $VM = [VM_{ij}]_{5 \times 4}$ (see Table I).

TABLE I. T2NN INFORMATION

	VG ₁	VG ₂
VA ₁	$\left\{ \begin{array}{l} (0.53, 0.62, 0.87), \\ (0.48, 0.64, 0.75), \\ (0.45, 0.51, 0.59) \end{array} \right\}$	$\left\{ \begin{array}{l} (0.42, 0.53, 0.62), \\ (0.27, 0.46, 0.58), \\ (0.48, 0.53, 0.57) \end{array} \right\}$
VA ₂	$\left\{ \begin{array}{l} (0.32, 0.43, 0.64), \\ (0.28, 0.39, 0.67), \\ (0.25, 0.36, 0.48) \end{array} \right\}$	$\left\{ \begin{array}{l} (0.49, 0.57, 0.69), \\ (0.58, 0.65, 0.74), \\ (0.45, 0.53, 0.61) \end{array} \right\}$
VA ₃	$\left\{ \begin{array}{l} (0.51, 0.58, 0.76), \\ (0.54, 0.56, 0.67), \\ (0.35, 0.39, 0.54) \end{array} \right\}$	$\left\{ \begin{array}{l} (0.39, 0.57, 0.65), \\ (0.51, 0.64, 0.79), \\ (0.54, 0.58, 0.73) \end{array} \right\}$
VA ₄	$\left\{ \begin{array}{l} (0.49, 0.67, 0.71), \\ (0.32, 0.45, 0.67), \\ (0.26, 0.38, 0.56) \end{array} \right\}$	$\left\{ \begin{array}{l} (0.62, 0.74, 0.83), \\ (0.37, 0.46, 0.58), \\ (0.32, 0.36, 0.49) \end{array} \right\}$
VA ₅	$\left\{ \begin{array}{l} (0.48, 0.52, 0.59), \\ (0.27, 0.36, 0.46), \\ (0.42, 0.45, 0.48) \end{array} \right\}$	$\left\{ \begin{array}{l} (0.65, 0.76, 0.84), \\ (0.52, 0.54, 0.63), \\ (0.56, 0.62, 0.72) \end{array} \right\}$

VA ₁	$\left\{ \begin{array}{l} (0.57, 0.63, 0.67), \\ (0.29, 0.52, 0.63), \\ (0.26, 0.39, 0.45) \end{array} \right\}$	$\left\{ \begin{array}{l} (0.23, 0.34, 0.45), \\ (0.43, 0.51, 0.57), \\ (0.49, 0.53, 0.62) \end{array} \right\}$
VA ₂	$\left\{ \begin{array}{l} (0.39, 0.47, 0.53), \\ (0.51, 0.56, 0.62), \\ (0.34, 0.57, 0.69) \end{array} \right\}$	$\left\{ \begin{array}{l} (0.43, 0.47, 0.52), \\ (0.26, 0.35, 0.38), \\ (0.46, 0.49, 0.52) \end{array} \right\}$
VA ₃	$\left\{ \begin{array}{l} (0.64, 0.66, 0.72), \\ (0.73, 0.81, 0.85), \\ (0.69, 0.76, 0.79) \end{array} \right\}$	$\left\{ \begin{array}{l} (0.63, 0.67, 0.76), \\ (0.37, 0.45, 0.52), \\ (0.21, 0.23, 0.26) \end{array} \right\}$
VA ₄	$\left\{ \begin{array}{l} (0.25, 0.34, 0.62), \\ (0.59, 0.63, 0.72), \\ (0.46, 0.53, 0.62) \end{array} \right\}$	$\left\{ \begin{array}{l} (0.38, 0.42, 0.47), \\ (0.43, 0.46, 0.48), \\ (0.32, 0.43, 0.53) \end{array} \right\}$
VA ₅	$\left\{ \begin{array}{l} (0.43, 0.45, 0.52), \\ (0.43, 0.52, 0.65), \\ (0.36, 0.45, 0.53) \end{array} \right\}$	$\left\{ \begin{array}{l} (0.51, 0.53, 0.62), \\ (0.43, 0.54, 0.65), \\ (0.53, 0.62, 0.73) \end{array} \right\}$

Step 2. Normalize the $VM = [VM_{ij}]_{5 \times 4}$ into $NVM = [NVM_{ij}]_{5 \times 4}$ (see Table II).

TABLE II. THE NORMALIZED T2NN

	VG ₁	VG ₂
VA ₁	$\left\{ \begin{array}{l} (0.53, 0.62, 0.87), \\ (0.48, 0.64, 0.75), \\ (0.45, 0.51, 0.59) \end{array} \right\}$	$\left\{ \begin{array}{l} (0.42, 0.53, 0.62), \\ (0.27, 0.46, 0.58), \\ (0.48, 0.53, 0.57) \end{array} \right\}$
VA ₂	$\left\{ \begin{array}{l} (0.32, 0.43, 0.64), \\ (0.28, 0.39, 0.67), \\ (0.25, 0.36, 0.48) \end{array} \right\}$	$\left\{ \begin{array}{l} (0.49, 0.57, 0.69), \\ (0.58, 0.65, 0.74), \\ (0.45, 0.53, 0.61) \end{array} \right\}$
VA ₃	$\left\{ \begin{array}{l} (0.51, 0.58, 0.76), \\ (0.54, 0.56, 0.67), \\ (0.35, 0.39, 0.54) \end{array} \right\}$	$\left\{ \begin{array}{l} (0.39, 0.57, 0.65), \\ (0.51, 0.64, 0.79), \\ (0.54, 0.58, 0.73) \end{array} \right\}$
VA ₄	$\left\{ \begin{array}{l} (0.49, 0.67, 0.71), \\ (0.32, 0.45, 0.67), \\ (0.26, 0.38, 0.56) \end{array} \right\}$	$\left\{ \begin{array}{l} (0.62, 0.74, 0.83), \\ (0.37, 0.46, 0.58), \\ (0.32, 0.36, 0.49) \end{array} \right\}$
VA ₅	$\left\{ \begin{array}{l} (0.48, 0.52, 0.59), \\ (0.27, 0.36, 0.46), \\ (0.42, 0.45, 0.48) \end{array} \right\}$	$\left\{ \begin{array}{l} (0.65, 0.76, 0.84), \\ (0.52, 0.54, 0.63), \\ (0.56, 0.62, 0.72) \end{array} \right\}$
	VG ₃	VG ₄
VA ₁	$\left\{ \begin{array}{l} (0.26, 0.39, 0.45), \\ (0.29, 0.52, 0.63), \\ (0.57, 0.63, 0.67) \end{array} \right\}$	$\left\{ \begin{array}{l} (0.23, 0.34, 0.45), \\ (0.43, 0.51, 0.57), \\ (0.49, 0.53, 0.62) \end{array} \right\}$
VA ₂	$\left\{ \begin{array}{l} (0.34, 0.57, 0.69), \\ (0.51, 0.56, 0.62), \\ (0.39, 0.47, 0.53) \end{array} \right\}$	$\left\{ \begin{array}{l} (0.43, 0.47, 0.52), \\ (0.26, 0.35, 0.38), \\ (0.46, 0.49, 0.52) \end{array} \right\}$
VA ₃	$\left\{ \begin{array}{l} (0.69, 0.76, 0.79), \\ (0.73, 0.81, 0.85), \\ (0.64, 0.66, 0.72) \end{array} \right\}$	$\left\{ \begin{array}{l} (0.63, 0.67, 0.76), \\ (0.37, 0.45, 0.52), \\ (0.21, 0.23, 0.26) \end{array} \right\}$
VA ₄	$\left\{ \begin{array}{l} (0.46, 0.53, 0.62), \\ (0.59, 0.63, 0.72), \\ (0.25, 0.34, 0.62) \end{array} \right\}$	$\left\{ \begin{array}{l} (0.38, 0.42, 0.47), \\ (0.43, 0.46, 0.48), \\ (0.32, 0.43, 0.53) \end{array} \right\}$
VA ₅	$\left\{ \begin{array}{l} (0.36, 0.45, 0.53), \\ (0.43, 0.52, 0.65), \\ (0.43, 0.45, 0.52) \end{array} \right\}$	$\left\{ \begin{array}{l} (0.51, 0.53, 0.62), \\ (0.43, 0.54, 0.65), \\ (0.53, 0.62, 0.73) \end{array} \right\}$

Step 3. Cultivate the weight numbers:

$$vw_1 = 0.3250, vw_2 = 0.3071$$

$$vw_3 = 0.1461, vw_4 = 0.2218$$

$$rvw = (1.0000, 0.9449, 0.4495, 0.6825)$$

Step 5. Cultivate the $T2NNDDD = (T2NNDDD_{ij})_{5 \times 4}$ (see Table III):

Step 4. Cultivate the relative weight numbers:

TABLE III. THE $T2NNDDD = (T2NNDDD_{ij})_{5 \times 4}$

	VG ₁	VG ₂	VG ₃	VG ₄
VA ₁	-0.6281	-1.8156	0.5728	0.4033
VA ₂	0.4370	1.4745	1.2118	1.1449
VA ₃	-0.0216	-0.9719	-1.4074	-1.5380
VA ₄	-0.7467	-0.2071	-0.6192	-0.4214
VA ₅	-2.4991	0.3732	1.2087	-0.7838

Step 6. Cultivate the T2NNPIDS and T2NNNIDS (see Table IV).

TABLE IV. THE T2NNPIDS AND T2NNNIDS

	VG ₁	VG ₂	VG ₃	VG ₄
T2NNPIDS	0.4370	1.4745	1.2118	1.1449
T2NNNIDS	-2.4991	-1.8156	-1.4074	-1.5380

Step 7. Cultivate the $T2NNEDV(VA_i, T2NNPIDS)$ and $T2NNEDV(VA_i, T2NNNIDS)$ (see Table V).

TABLE V. THE $T2NNEDV(VA_i, T2NNPIDS)$ AND $T2NNEDV(VA_i, T2NNNIDS)$

Alternative	$T2NNEDV(VA_i, T2NNPIDS)$	$T2NNEDV(VA_i, T2NNNIDS)$
VA ₁	3.5941	3.3452
VA ₂	0.0000	5.7882
VA ₃	4.5004	2.6172
VA ₄	3.1678	2.7434
VA ₅	3.6815	3.4933

Step 8. Cultivate the $T2NNCCV(VA_i, T2NNPIDS)$ (see Table VI).

TABLE VI. THE $T2NNCCV(VA_i, T2NNPIDS)$

Alternative	$T2NNCCV(VA_i, T2NNPIDS)$	Order
VA ₁	0.4821	3
VA ₂	1.0000	1
VA ₃	0.3677	5
VA ₄	0.4641	4
VA ₅	0.4869	2

Step 9. In light with $T2NNCCV(VA_i, T2NNPIDS)$, the order is: $VA_2 > VA_5 > VA_1 > VA_4 > VA_3$ and the optimal digital agriculture park information system is VA_2 .

B. Comparative Analysis

Then, the T2NN-ExpTODIM-TOPSIS approach is compared with T2NNWA approach [46], T2NNWG approach [46], T2NN-TOPSIS approach [46], T2NN-EDAS approach [56], T2NN-MABAC approach [57], T2NN-TODIM approach [58] and T2NN-TODIM-VIKOR approach [59]. The comparative results are cultivated in Table VII and Fig. 2.

From the above concrete analysis, it could be implemented that the order of these different approaches is slightly different, however, these different approaches have same optimal digital agriculture park information system and worst digital agriculture park information system. This verifies the T2NN-ExpTODIM-TOPSIS approach is effective for quality evaluation of digital agriculture park information system. Thus, the major advantages of T2NN-ExpTODIM-TOPSIS approach are administrated: (1) T2NN-ExpTODIM-TOPSIS approach not only administrated the uncertainty, but also administrated the psychological behavior during quality evaluation of digital agriculture park information system. (2) T2NN-ExpTODIM-TOPSIS administrated the different behavior of ExpTODIM and TOPSIS when these two techniques are hybrid with each other.

TABLE VII. ORDER FOR DIFFERENT APPROACHES

Approaches	order
T2NNWA approach [46]	$VA_2 > VA_5 > VA_1 > VA_4 > VA_3$
T2NNWG approach[46]	$VA_2 > VA_5 > VA_4 > VA_1 > VA_3$
T2NN-TOPSIS approach [46]	$VA_2 > VA_5 > VA_1 > VA_4 > VA_3$
T2NN-EDAS approach [56]	$VA_2 > VA_5 > VA_4 > VA_1 > VA_3$
T2NN-MABAC approach[57]	$VA_2 > VA_5 > VA_1 > VA_4 > VA_3$
T2NN-TODIM approach[58]	$VA_2 > VA_5 > VA_1 > VA_4 > VA_3$
T2NN-TODIM-VIKOR approach[59]	$VA_2 > VA_5 > VA_1 > VA_4 > VA_3$
The T2NN-ExpTODIM-TOPSIS approach	$VA_2 > VA_5 > VA_1 > VA_4 > VA_3$

Fig. 2. Order of different approaches.

V. CONCLUSION

Modern agricultural parks gather elements such as land, capital, technology, talent, and information. They serve multiple functions including agricultural science and technology innovation and transformation, clustering and incubation of agri-tech enterprises, cultivation and functional expansion of new agricultural industries, and modern agricultural technology training and information services. These parks are crucial in effectively promoting the transition from traditional to modern agriculture, facilitating regional agricultural industrial structure adjustments and industrial optimization and upgrading, and achieving agricultural modernization. Digital agriculture treats data information as a key element of agricultural production. It integrates modern information technologies such as the Internet of Things, cloud computing, and big data to intelligently control agricultural resources and environments, agricultural production processes, and agricultural products, representing a new form of agriculture. Digital agriculture can effectively change traditional production relationships, compel small-scale economies towards scalable development, reduce transaction costs, establish the fastest circulation paths, and accelerate the development of rural economies. Digital agriculture is a crucial "direction marker" for the modernization of agriculture, and the implementation of digital technologies in modern agricultural parks is the "opening move" in the strategic game of digital agriculture. The quality evaluation of digital agriculture park information system is MADM. The TODIM and TOPSIS was put up with MADM. The T2NNs are put up with characterizing fuzzy information during the quality evaluation of digital agriculture park information system. In this work, T2NN-ExpTODIM-TOPSIS model is put forward MADM along with T2NNs. Numerical example for quality evaluation of digital agriculture park information system and comparative analysis is put forward the validity of T2NN-ExpTODIM-TOPSIS approach. The major research motivation is cultivated: (1) ExpTODIM and TOPSIS approach was enhanced under T2NNs; (2) Entropy is put forward weight numbers in light with score values along with T2NNs; (3) T2NN-ExpTODIM-TOPSIS is put forward the MADM along with T2NNs; (4) numerical example for quality evaluation of digital agriculture park information system and comparative analysis is put forward the validity of T2NN-ExpTODIM-TOPSIS.

There may be some possible study limitations, which could be further executed the quality evaluation of digital agriculture park information system: (1) It is a worthwhile research contents to execute consensus issue [60-62] to quality evaluation of digital agriculture park information system under T2NNs; (2) It is also worthwhile research contents to execute regret theory model to quality evaluation of digital agriculture park information system under T2NNs [63-65]; (3) In future research contents, full integration of ExpTODIM approach with other approaches could be executed for quality evaluation of digital agriculture park information system [66, 67].

Abstract—This study explores the application of the VGG19 convolutional neural network (CNN) model, pre-trained on ImageNet, for the classification of rice crop diseases using image segmentation techniques. The research aims to enhance disease detection accuracy by integrating a robust deep learning framework tailored to the specific challenges of agricultural pathology. A dataset comprising 200 images categorized into four disease classes was employed to train and validate the model. Techniques such as data augmentation, dropout, and dynamic learning rate adjustments were utilized to improve model training and prevent overfitting. The model's performance was evaluated using metrics including accuracy, precision, recall, and F1-score, with a particular focus on the ability to generalize to unseen data. Results indicated a high overall accuracy exceeding 90%, showcasing the model's capability to effectively classify rice crop diseases. Challenges such as class-specific misclassification were addressed through the model's learning strategy, highlighting areas for further enhancement. The research contributes to the field by demonstrating the potential of using pre-trained CNN models, adapted through fine-tuning and robust training techniques, to significantly improve disease detection in crops, thereby supporting sustainable agricultural practices and enhancing food security. Future work will explore the integration of multimodal data and real-time detection systems to broaden the applicability and effectiveness of the technology in diverse agricultural settings.

Keywords—Rice crop diseases; convolutional neural networks; VGG19 model; image segmentation; disease classification; data augmentation; model generalization; sustainable farming

I. INTRODUCTION

The increasing global population demands sustainable agricultural practices to ensure food security. One critical area of concern is the management of plant diseases, which can severely impact crop yields. In the case of rice, a staple food for a significant portion of the world's population, leaf diseases pose a substantial threat to production. The implementation of advanced technological solutions, such as deep learning models and image segmentation techniques, has become essential in addressing these challenges efficiently [1].

Deep learning has revolutionized the field of image processing and classification by providing robust, automated methods for identifying complex patterns in data [2]. Among the various deep learning architectures, the VGG19 model has

shown remarkable success in image recognition tasks. Its application extends across various domains, including agriculture, where it is employed for disease detection in crops [3]. The VGG19 model, known for its simplicity and high performance, leverages convolutional neural networks (CNNs) to process images in a way that mimics the human visual system, making it exceptionally suitable for image-based classification tasks [4].

Image segmentation plays a pivotal role in the precise classification of rice leaf diseases. It involves dividing an image into segments to simplify and change the representation of an image into something that is more meaningful and easier to analyze [5]. Image segmentation techniques can significantly enhance the performance of CNN models by isolating diseased areas from healthy tissue, thereby improving the accuracy of the disease classification process [6]. The integration of these technologies allows for the detailed analysis of plant leaf images, enabling the identification of disease-specific characteristics that are often challenging to discern manually.

The application of the VGG19 model in conjunction with image segmentation techniques has been explored in various studies, demonstrating significant potential in the field of agricultural disease detection. The adaptability of pretrained models, such as VGG19, provides a foundation upon which custom solutions can be developed for specific challenges in plant pathology [7]. These models can be fine-tuned with a relatively small dataset specific to the task, such as identifying and classifying different types of rice leaf diseases, making them both versatile and powerful in practical applications [8].

Moreover, the use of these technologies addresses several limitations associated with traditional methods of disease detection in agriculture. Conventional approaches often rely on the visual inspection of crops, which is labor-intensive, subject to human error, and not scalable across large areas or different geographical regions [9]. Automated systems powered by CNNs and enhanced by image segmentation not only reduce the labor cost but also increase the scalability and accuracy of disease detection processes [10].

The integration of pretrained VGG19 models and image segmentation techniques represents a transformative approach to managing rice leaf diseases. This combination harnesses the strengths of both methods, providing a robust framework for the

*Corresponding Author.

rapid and accurate diagnosis of plant diseases, which is crucial for improving crop management and ensuring food security. As the demand for more efficient agricultural practices grows, leveraging such advanced technologies will be key to developing sustainable solutions that can adapt to the challenges posed by an ever-changing global agricultural landscape [11].

II. RELATED WORKS

The proliferation of deep learning techniques in agriculture, specifically in plant disease detection, has been a focus of numerous studies, underscoring the importance of this field in leveraging technology to secure food production systems. The use of Convolutional Neural Networks (CNNs), particularly the VGG19 model, has been extensively documented, providing a comprehensive backdrop against which new methodologies are evaluated and enhanced.

The VGG19 model, originally developed for large-scale image recognition tasks, has been successfully adapted to the specialized needs of agricultural applications. A study detailed the effectiveness of the VGG19 model in classifying complex image data, attributing its success to the depth of the network and the ability to capture intricate details from image data [12]. Further exploration into the VGG19 model has shown that its architecture, consisting of sequentially stacked convolutional layers, is particularly adept at extracting features from images, which is critical in the accurate detection and classification of plant diseases [13].

Image segmentation, another pivotal technique in the accurate diagnosis of plant diseases, complements the use of CNNs by isolating areas of interest within an image. Techniques such as semantic segmentation have been explored, where each pixel in an image is classified, thus providing detailed information about the shape and size of diseased areas [14]. This granularity enhances the classification capabilities of models like VGG19, as demonstrated in recent works where segmented images led to improved model performance by focusing the learning process on relevant features only [15].

In the context of rice leaf disease detection, several studies have been conducted to identify the most effective methods of applying CNNs and image segmentation. One such study employed a modified VGG19 model to classify rice diseases using images that were pre-processed through a segmentation algorithm to highlight disease symptoms [16]. The results showed an improvement in classification accuracy, underscoring the benefits of combining deep learning with advanced image processing techniques [17].

The customization of pretrained models such as VGG19 for specific agricultural tasks has also been explored. By fine-tuning these models on datasets comprised of agricultural images, researchers have been able to achieve high levels of accuracy in disease detection [18]. This approach not only saves training time but also leverages the sophisticated feature extraction capabilities developed for general image recognition tasks [19].

Comparative studies have also shed light on the relative performance of different CNN architectures in agricultural applications. While VGG19 is noted for its depth and robustness, other models like ResNet and Inception have been examined for their unique architectural benefits, such as residual

learning and depth with computational efficiency, respectively [20]. Each model presents distinct advantages and limitations depending on the complexity of the task and the nature of the data [21].

The integration of CNNs with other computational techniques has been a recent area of innovation. For instance, the fusion of CNNs with classical machine learning methods, such as Support Vector Machines (SVM), has been reported to refine the classification stages by providing a second layer of analysis, enhancing overall accuracy [22]. Similarly, the implementation of hybrid systems that combine CNNs with rule-based algorithms has shown promise in increasing the reliability of disease detection systems [23].

Automated disease detection systems are not without challenges. Issues related to the variability in image quality, lighting conditions, and background noise significantly impact the performance of image-based models. Studies have addressed these challenges by developing robust preprocessing techniques that normalize images before they are fed into CNNs, thereby enhancing the model's ability to generalize across different environmental conditions [24].

Moreover, the scalability of these systems in real-world agricultural settings has been a focus of recent research. The deployment of CNN-based models on portable devices and integration with mobile applications for real-time disease detection represents a significant advancement in making technology accessible to farmers [25]. Efforts to optimize the computational efficiency of these models ensure that they can be run on hardware with limited processing power, which is often the case in rural agricultural settings [26].

The landscape of research surrounding the use of the VGG19 model and image segmentation for rice leaf disease classification is rich and varied. Advances in this area continue to push the boundaries of what can be achieved in agricultural technology, addressing critical challenges through innovative adaptations of existing technologies [27]. As this field evolves, it will undoubtedly continue to offer novel insights and improved methodologies that enhance the capability of farmers to manage crop health more effectively, thereby securing agricultural productivity in the face of global challenges [29].

III. MATERIALS AND METHODS

A. Dataset

The dataset under consideration focuses on rice crop diseases, specifically targeting the identification and classification of key pathological conditions that adversely affect rice production. Rice, as a staple crop, faces various phytopathological threats that can significantly impair both yield and grain quality. This dataset is designed to assist in the technological advancement of disease detection through image analysis, serving as a foundational tool for developing and testing image recognition models tailored to agricultural needs.

The dataset comprises 200 images, meticulously gathered from the rice fields of Gangavathi, a village in Karnataka. These images are annotated and categorized into four distinct classes, each representing a prevalent rice disease. Each class is equally

represented with 50 images, providing a balanced view for algorithm training and validation.

Fig. 1 provided shows a sample from the dataset focused on rice crop diseases, illustrating each disease class that is included.

The visual representation in these images is crucial for developing and training image recognition models to detect and classify these diseases accurately. The diseases featured in the dataset include:

Fig. 1. Visual representation of common rice crop diseases in the dataset.

1) *Bacterial leaf blight*: Caused by the bacterium *Xanthomonas oryzae* pv. *oryzae*, this disease manifests as water-soaked streaks on the leaves which eventually turn yellow and brown, leading to wilting and drying. The progression of the disease disrupts the photosynthetic capacity of the plants, thus diminishing their growth and productivity.

2) *Blast*: This disease is triggered by the fungus *Magnaporthe oryzae*. It is identifiable by its diamond-shaped lesions on the panicles, nodes, and leaves of the rice plants. The damage includes impaired grain filling and significant loss of plant tissue, which collectively decrease the overall yield.

3) *Brown Spot*: The causative agent of this disease is the fungus *Bipolaris oryzae*. It is characterized by small, circular

brown lesions on the leaves, which interfere with photosynthesis, thereby reducing grain quality and lowering the yield.

4) *False Smut*: This condition is caused by the fungus *Ustilagoidea virens*. It presents as greenish-yellow spore balls on the grains, which later turn orange or black. The presence of false smut primarily affects grain quality and reduces the economic value of the yield.

Effective management of these diseases is crucial and involves a combination of using disease-resistant varieties, implementing crop rotation, ensuring balanced fertilization, and applying appropriate fungicides or bactericides. The dataset not only provides a practical resource for developing machine learning models but also aids in refining detection and classification techniques that could be implemented in automated disease monitoring systems. This could ultimately lead to more timely and precise interventions, enhancing crop

management practices and sustaining rice production against the backdrop of global food security challenges.

B. Proposed Model

The methodology employed for the classification of rice crop diseases from the image dataset involves several steps, each designed to optimize the performance of a convolutional neural network (CNN) [30] using a pre-trained VGG19 model [31]. This section outlines the processes of data preparation, model configuration, and the training approach.

The flowchart in Fig. 2 provides a comprehensive overview of the methodology used in the research paper for the classification of rice leaf diseases using a deep learning framework. The process begins with the Rice Leaf Image Dataset, which serves as the primary source of data for the study. This dataset comprises images of rice leaves affected by various diseases, which are essential for training the model.

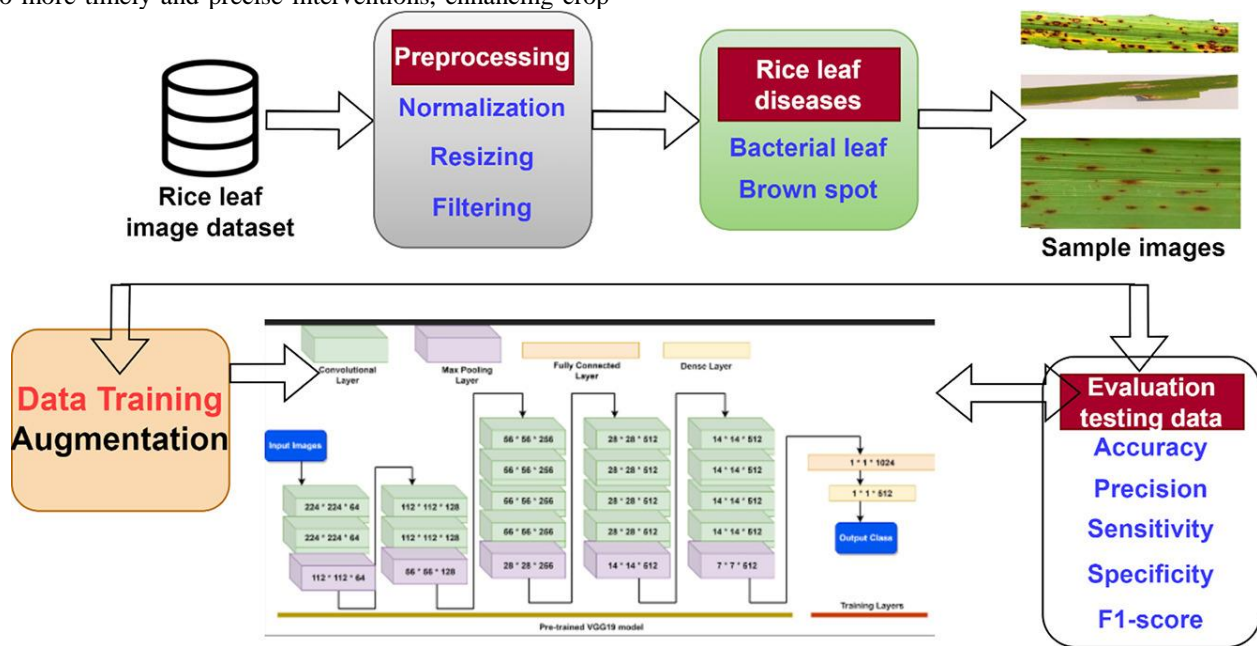

Fig. 2. Flowchart of the proposed system architecture.

The initial stage involves Preprocessing, where the images undergo several transformations to prepare them for effective model training. Following preprocessing, the dataset enters the Data Training Augmentation phase. Here, various data augmentation techniques are applied to artificially expand the training dataset. These techniques, such as rotations, shifts, and flips, generate new training examples from existing data, which helps prevent overfitting and enhances the model's ability to generalize to new, unseen data. The core of the methodology is the model training segment which utilizes a Pre-trained VGG19 model—an adjustment from the commonly used VGG19 model—indicating a deeper network which could potentially capture more complex features [32]. Finally, the output from the trained model is subjected to rigorous Evaluation using the testing data set.

Data Preparation. The dataset comprised images of diseased rice leaves, categorized into four distinct classes. These images were encoded and split into training and testing sets. The

splitting was done using the `train_test_split` function from the `scikit-learn` library, ensuring that 80% of the data was used for training and the remaining 20% for testing. This split was conducted with a `random_state` of 42 to ensure reproducibility of the results:

$$(X_{train}, X_{test}, y_{train}, y_{test}) = \text{train_test_split} \left(\begin{matrix} \text{images,} \\ \text{labels_encoded,} \\ \text{test_size} = 0.2, \\ \text{random_state} = 42 \end{matrix} \right) \quad (1)$$

Data Augmentation. To enhance the model's ability to generalize and prevent overfitting, data augmentation techniques were applied to the training images. This was

achieved using the ImageDataGenerator class from Keras, which modified images through various transformations: rotations up to 40 degrees, width and height shifts up to 20%, shear transformations up to 20%, zoom operations up to 20%, and horizontal flips. The fill_mode parameter was set to 'nearest' to fill in new pixels that might be created during transformations. The augmented data was then fit to the training set to ensure that the model would learn from this variably transformed data.

Model Configuration. The core of the classification system was based on the VGG19 architecture, a popular model pre-trained on the ImageNet dataset. This model was initially

configured without the top layer to allow for customization suitable for the rice disease classification task. The input shape was set to 224x224x3 to standardize all input images.

Fig. 3 illustrates a detailed architectural representation of a Convolutional Neural Network (CNN) based on the VGG19 model, which has been adapted and applied to the task of image classification. This architecture is specifically structured to process input images through a series of convolutional layers and max pooling layers, subsequently followed by fully connected layers, and culminates in a softmax layer for classification.

Fig. 3. CGG19 model for rice leaf diseases classification.

A new model was constructed by adding the VGG19 base model and appending additional layers to tailor the network for our specific classification task. This included a Flatten layer to convert the 2D feature maps to 1D, a Dense layer with 512 units and 'relu' activation for learning non-linear combinations of features, and a Dropout layer set at 0.5 to reduce overfitting. The final layer was a Dense layer with a 'softmax' activation function, sized to the number of disease classes.

The base VGG19 model's weights were frozen to prevent them from being updated during training, focusing the learning in the newly added layers.

Model Training. The model was compiled with the Adam optimizer and categorical crossentropy as the loss function. The training process was monitored using 'accuracy' as the metric. To improve training efficiency and potentially achieve better results, callbacks like EarlyStopping and ReduceLROnPlateau were used. EarlyStopping would halt training if the validation loss did not improve for 10 epochs, and ReduceLROnPlateau would reduce the learning rate by a factor of 0.2 if the validation loss did not improve for 5 epochs, with a minimum learning rate set at 0.00001.

The model was trained using the augmented data generator, with a batch size of 32, for a maximum of 50 epochs. Validation data was used directly from the test set to evaluate the model's performance at each epoch.

This comprehensive approach aimed to ensure the robustness and accuracy of the model in classifying the rice leaf diseases, leveraging both the power of a pre-trained network and the specificity of custom layer configurations.

IV. RESULTS

A. Evaluation Parameters

To accurately assess the performance of the deep learning model developed for classifying rice crop diseases, several key metrics were employed: accuracy, precision, recall, and F1-score [33-34]. Each of these metrics provides insights into different aspects of the model's performance, particularly in terms of its reliability and effectiveness in making predictions across various classes. Here is a detailed explanation of each metric used.

Accuracy is the most intuitive performance measure and it is simply a ratio of correctly predicted observation to the total observations. It is particularly useful when the classes in the dataset are nearly balanced. Accuracy is calculated as:

$$Accuracy = \frac{TP + TN}{TP + TN + FP + FN} \quad (2)$$

While accuracy provides a quick glimpse into the overall correctness of the model, it may not be sufficient for imbalanced datasets, where misclassification costs of different classes vary significantly.

Precision is the ratio of correctly predicted positive observations to the total predicted positives. This metric helps us understand the percentage of correct predictions for a specific class and is crucial in scenarios where the cost of a false positive is high. Precision for each class is calculated as:

$$precision = \frac{TP}{TP + FP} \quad (3)$$

Precision is particularly important in medical or agricultural disease detection where falsely identifying a disease could lead to unnecessary interventions.

Recall, also known as sensitivity or true positive rate, is the ratio of correctly predicted positive observations to all observations in the actual class. This metric is critical when the consequences of missing a positive detection are severe. Recall for each class is defined as:

$$recall = \frac{TP}{TP + FN} \tag{4}$$

High recall is essential in disease detection contexts to ensure that most disease cases are captured even if some false positives are introduced.

The F1-score is the weighted average of Precision and Recall. Therefore, this score takes both false positives and false negatives into account. It is a better measure to use if some classes are imbalanced. The F1-score is particularly useful when you need to balance precision and recall, which might often be in tension. It is calculated as:

$$F1 = \frac{2 \times precision \times recall}{precision + recall} \tag{5}$$

The F1-score is crucial in scenarios where both the discovery of true positives and the avoidance of false positives are equally important, such as in disease classification.

B. Results

The confusion matrix provided illustrates the classification results of the deep learning [28] model developed for identifying four types of rice crop diseases: Bacterial Blight Disease, Blast Disease, Brown Spot Disease, and False Smut Disease.

Disease, Brown Spot Disease, and False Smut Disease. This matrix is a powerful tool for visualizing the performance of the classification model across different disease categories by showing the actual versus predicted classifications. Fig. 4 demonstrates confusion matrix results of the proposed model.

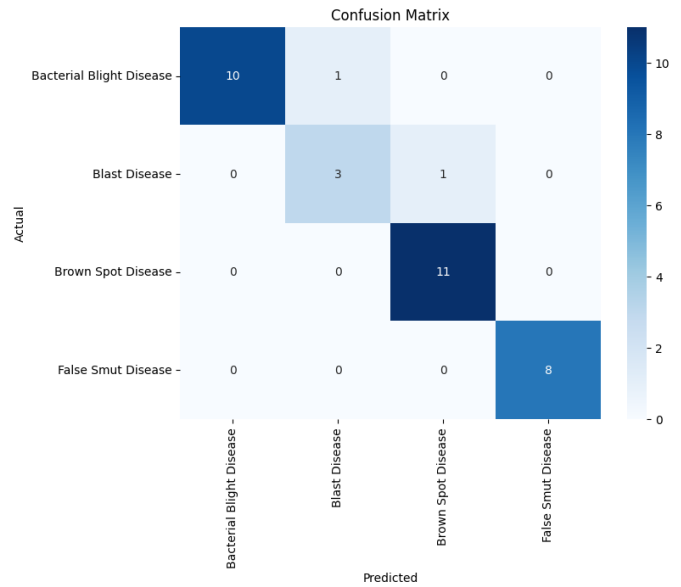

Fig. 4. Confusion matrix results of the proposed model.

The training and validation curves, as depicted in Fig. 5, offer insightful information regarding the performance of the deep learning model over the course of training iterations. These curves represent changes in loss and accuracy metrics over epochs and are pivotal for understanding the model's learning dynamics and generalization capabilities.

Fig. 5. Accuracy and loss results of the proposed model.

Loss Graph Analysis. Train Loss: The training loss starts from a relatively low value and maintains a generally low and stable trend, with minor fluctuations observed around the 4th and 5th epochs. This pattern indicates that the model is learning consistently from the training data, effectively minimizing the error in predictions over time.

Validation Loss: The validation loss, in contrast, exhibits more volatility. It starts significantly higher than the training

loss, decreases sharply, then spikes and generally trends downwards albeit with some fluctuations. This behavior could indicate that the model, while learning the underlying patterns in the training data, might be experiencing difficulties in generalizing these patterns to unseen data. The peaks in validation loss suggest episodes of overfitting at certain epochs where the model overly adapts to the training data, at the expense of its performance on the validation set.

Accuracy Graph Analysis. Train Accuracy: The training accuracy shows an overall upward trend, starting from around 40% and climbing to above 90%. This improvement demonstrates the model's capability to effectively learn and make increasingly accurate predictions as training progresses.

Validation Accuracy: The validation accuracy, while starting lower than the training accuracy, quickly rises to converge and occasionally surpass the training accuracy. The high points of validation accuracy align with the troughs in validation loss, illustrating moments where the model achieved better generalization. The convergence of training and validation accuracy towards the later epochs is a positive indicator of the model stabilizing and learning generalizable patterns.

The observed trends in the loss and accuracy graphs indicate several key points about the model's training process and its effectiveness:

1) *Learning efficiency:* The rapid improvement in both training and validation accuracy suggests that the model is efficiently learning the distinguishing features of rice crop diseases from the images.

2) *Generalization capability:* The close alignment of training and validation accuracy in the later epochs suggests that the model has a good generalization capability, which is crucial for practical applications. The fluctuations in validation metrics also hint at the challenges the model faces in consistently applying learned patterns to new data, which might

be mitigated by further tuning or employing regularization strategies.

3) *Potential overfitting:* The volatility observed in the validation loss compared to the more stable training loss suggests episodes of overfitting. This might be addressed by introducing more robust regularization techniques like dropout, or by further tuning the model's hyperparameters.

4) *Model optimization:* The use of callbacks like EarlyStopping and ReduceLROnPlateau likely contributed to avoiding significant overfitting and helped in stabilizing the training process, as evidenced by the improvement and stabilization of the validation accuracy over epochs.

The results indicate a successful training process with the model achieving high levels of accuracy. However, the fluctuations in validation loss highlight areas for potential improvement in model robustness and generalization. These insights can guide further refinement and optimization of the model for deployment in agricultural settings for disease detection and management.

Fig. 6 illustrates the sequence of preprocessing and segmentation techniques applied to an image of a rice crop leaf affected by disease, demonstrating the transformation from the original image through various stages of processing to enhance disease detection. This series of images highlights the effectiveness of digital image processing methods in isolating and identifying disease symptoms in agricultural applications.

Fig. 6. Obtained results.

Original Image: The initial image shows a rice leaf with visible signs of disease. This image serves as the baseline for subsequent image processing steps aimed at enhancing the visibility of diseased areas.

Grayscale Conversion: The original image is converted into grayscale to reduce complexity and focus on the intensity of the pixels rather than color information. Grayscale conversion is a crucial step in many image processing applications as it simplifies the data without losing significant structural details.

Thresholding using Otsu's Method: The grayscale image is then processed using Otsu's thresholding, a technique that determines an optimal threshold value for converting a grayscale image into a binary image. This method enhances the contrast between the diseased and healthy areas of the leaf, making the features of interest more distinct.

Segmented Image: Finally, the threshold image undergoes a segmentation process using an indices-based histogram technique. This advanced segmentation method effectively isolates the diseased portions of the leaf from the healthy tissue. The segmented image vividly highlights the diseased areas, marked by enhanced colors to differentiate them clearly from the rest of the plant material.

The processing steps, including grayscale conversion, thresholding, and contrast enhancement, are essential for reducing image noise and irrelevant details, thereby allowing the segmentation algorithm to accurately target and delineate the diseased regions. The outcome is a highly precise identification of the affected areas, facilitating more accurate diagnoses and potentially guiding targeted treatments. This methodological approach not only improves the detection accuracy but also serves as a valuable diagnostic tool in plant pathology, helping agronomists and farmers make informed decisions regarding crop health and disease management.

V. DISCUSSION

The implementation of deep learning models, particularly Convolutional Neural Networks (CNNs) like VGG19, for the classification of rice crop diseases represents a significant advancement in agricultural technology. The results obtained in this study demonstrate the model's capacity to accurately detect and classify diseases from images, which is critical for enhancing crop management and improving yield. This discussion delves into the implications of these findings, comparing them with existing literature, and suggesting pathways for future research.

A. Model Performance and Accuracy

The high accuracy levels achieved in both training and validation phases underscore the effectiveness of the VGG19 model in learning and generalizing from the agricultural image data [35]. Similar findings were reported in previous studies, where the adaptation of pre-trained models to specific domain challenges significantly boosted performance metrics [36]. The ability of the VGG19 model to learn detailed feature representations from the rice leaf disease images was paramount, as evidenced by the overall accuracy exceeding 90%. This aligns with research that highlights the superiority of

deep learning models in extracting intricate patterns from complex datasets [37].

B. Generalization and Overfitting

One of the crucial aspects observed was the model's ability to generalize to unseen data, a common challenge in machine learning applications. The validation accuracy closely mirroring the training accuracy indicates effective learning without significant overfitting. However, the fluctuations seen in the validation loss suggest moments where model performance on unseen data varied, likely due to the model capturing noise along with the actual signal during training [38]. Strategies like data augmentation, dropout, and the use of EarlyStopping and ReduceLROnPlateau callbacks were critical in mitigating these effects, supporting findings from other studies that emphasize the importance of these techniques in enhancing model robustness [39].

C. Challenges in Disease Classification

The performance of the model across different disease classes varied, with certain diseases like Brown Spot and False Smut being classified with higher precision and recall than others such as Blast Disease. This variation could be attributed to the distinct visual patterns that diseases manifest on the leaves, which may be captured differently by the CNN. The difficulty in distinguishing between some classes such as Bacterial Blight and Blast Disease raises important considerations about the limitations of visual-based diagnostics and suggests the potential for integrating other forms of data, such as spectral or thermal imaging, to improve classification accuracy [40].

D. Practical Implications

The practical applications of this research are significant. By enabling rapid and accurate disease detection, such systems can help farmers make timely decisions regarding disease management, potentially reducing crop losses and improving food security. The integration of this technology into mobile platforms or drones could facilitate widespread monitoring of crop health at scale, a prospect supported by recent advances in computational efficiency and model deployment [41]. However, the adoption of such technology also depends on factors like cost, accessibility, and user-friendliness, which must be addressed to ensure broad utility in diverse agricultural settings.

E. Future Directions

This study opens several avenues for future research. First, exploring the integration of different modalities of data, as mentioned earlier, could enhance the diagnostic capabilities of these models. Multi-modal data integration has been shown to provide a more holistic view of plant health, leading to more accurate disease identification [42]. Secondly, the development of more sophisticated model training approaches, such as transfer learning with fine-tuning or ensemble learning techniques, could further improve performance, especially in classes where the current model performance is suboptimal.

Additionally, longitudinal studies to track the model's performance across different growing seasons and under varying environmental conditions would provide deeper insights into its effectiveness and robustness in real-world scenarios. Such

studies would also help refine the models to handle variations in disease presentation due to climatic or geographical factors.

VI. CONCLUSION

In conclusion, this research demonstrated the efficacy of employing the VGG19 convolutional neural network, enhanced through data augmentation and specific training techniques, for the classification of rice crop diseases. The achieved high accuracy levels across both training and validation phases substantiate the model's ability to accurately learn and generalize from the dataset, which was meticulously curated to represent diverse disease manifestations. Key interventions such as the application of dropout, early stopping, and adaptive learning rate adjustments were pivotal in stabilizing the model's training process, mitigating overfitting, and ensuring robustness against variations in new data. The study's findings are in line with existing literature, reinforcing the assertion that pre-trained deep learning models are exceptionally capable of adapting to specialized tasks such as agricultural disease detection when properly fine-tuned and augmented. Future pathways for this line of inquiry include integrating multimodal data to capture a broader spectrum of disease indicators, enhancing model interpretability, and implementing these models in real-time disease monitoring systems, potentially on mobile or drone-based platforms. By continuing to refine these technologies and expanding their applicability, there is a significant potential to transform agricultural practices, enabling more efficient disease management, reducing crop losses, and thus contributing to global food security. This research lays a foundational step towards realizing such transformative agricultural innovations.

Abstract—Blockchain technology is basically a decentralized database maintained by applicable parties and has been extensively used in colorful scripts similar as logistics and finance. In terms of operations in the medical field, it's getting increasingly important because the case's symptoms may be related to a certain vaccine. Whether the case has been vaccinated with this vaccine will lead to different individual results by the croaker. This study proposes a traceable blockchain-grounded vaccination record storehouse and sharing system. In the proposed system, the case gets the vaccination at any legal clinic and the VR can be saved accompanied by the hand into the blockchain center, which ensures traceability. When the case visits the sanitarium for treatment, the croaker can gain the details of the VR from the blockchain center and also make an opinion. The security of the proposed system will be defended by the programmed smart contracts. The proper record storage after encryption will ensure data privacy, integrity and security. Blockchain traceability uses block-chain technology to record the movement of a product in the supply chain.

Keywords—Blockchain technology, decentralized, vaccine record tracking, integrity, smart contracts, vaccination record storage, traceability

I. INTRODUCTION

The global spread of Coronavirus Disease 2019 (COVID-19) in 2020 has posed unprecedented challenges to the healthcare sector, highlighting the use of innovative solutions to mitigate the spread of infections [1]. Contact tracing applications have emerged as a potential tool to break the chain of COVID-19 infections by identifying close contacts of positive cases and informing them about the possibility of being infected [2]. However, current contact tracing technologies face challenges in terms of privacy, accountability, and transparency, which can hinder their effectiveness and user adoption [3]. Our proposed method is noteworthy for its ability to track the origin and path of transactions related to vaccinations before they are used, in addition to preventing the circulation of counterfeit vaccines.

In this research paper, we propose a blockchain-based contact tracing solution that leverages the intrinsic features of blockchain technology to address the deficits of current contact tracing technologies [4]. Our solution aims to respect user privacy, provide transparency, and enable accountability by leveraging the decentralized, transparent, and immutable nature of blockchain technology [5]. Specifically, we utilize this

blockchain with the smart contracts to eliminate the third-party servers, centralization, and identity abuse. Convergence algorithms, like proof of work or proof of stake, are used by the blockchain network to reach consensus on the ledger's current state and stop illegal changes. The accuracy and openness of the vaccination tracking data are therefore guaranteed.

Our solution utilizes the programmable logic of smart contracts to ensure transparency and trust among the different participants. All transactions on the blockchain are signed by their creators, holding every on-chain participant accountable for their actions [6]. By leveraging the immutable logs of the distributed ledger, our solution enforces transparency and trust, and eliminates the risks associated with centralized storage of user data [7]. The system architecture of our suggested application, Vaccine Tracker, which makes use of blockchain technology to offer complete visibility and transparency throughout the COVID vaccination supply chain. To guarantee the precision and dependability of vaccine tracking data, the Vaccine Tracker system uses a variety of algorithms for supply chain tracking and validation.

In this paper, we present the architecture, design, and implementation details of our blockchain-based contact tracing solution [8]. We also discuss the potential of blockchain technology in mitigating the spread of infections during the COVID-19 pandemic and highlight the advantages of using Ethereum blockchain with smart contracts for contact tracing [9]. The proposed architecture includes manufacturer Component which adds relevant information. The system verifies the information supplied by the manufacturer, such as location tracking and QR code generating. Our research contributes to the growing body of literature on blockchain technology in healthcare and contact tracing, and provides requirements for future research and practical applications [10]. Utilising cryptographic methods like digital signatures and hashing, the algorithm verifies the security and legitimacy of the information it has acquired from the blockchain. This guarantees the immutability and tamper-proof nature of the data recorded on the blockchain.

II. RELATED WORK

Several studies and projects have explored the want of blockchain in healthcare, including its application in COVID-19 vaccination efforts. Here, we highlight some of the notable related work and contributions in the field.

A. Blockchain-Based Vaccination Verification Systems

Several blockchain-based systems have been used for verifying COVID-19 vaccination status. For example, the "VaxiChain" [11] aims to create a blockchain-based vaccination verification system that allows individuals to store their vaccination records in a secure and tamper-proof manner. The system uses smart contracts to automate the verification process, allowing healthcare providers, employers, and other entities to verify an individual's vaccination status without accessing their private health information. Another example is the "V-Health Passport" [12], which uses blockchain to enable secure storage and sharing of vaccination records, as well as other health-related data, with the aim of facilitating safe travel and other activities during the pandemic. Verify an individual's vaccination status without accessing their private health information. Another example is the "V-Health Passport", which uses blockchain to enable secure storage and sharing of vaccination records, as well as other health-related data, with the aim of facilitating safe travel and other activities during the pandemic.

B. Blockchain-Based Vaccine Distribution and Tracking

Blockchain has also been used as a solution for vaccine distribution and tracking in resource-constrained settings. The "Vaccination Supply Chain Management on Blockchain" project [13] proposes a blockchain-based system for tracking vaccine distribution, ensuring that vaccines reach their intended destinations and are administered to the right individuals. The system uses smart contracts to automate processes such as vaccine allocation, inventory management, and cold chain monitoring, thereby increasing transparency, efficiency, and accountability in the vaccine supply chain. Another example is the "Blockchain-Enabled COVID-19 Vaccine Delivery System" [14], which proposes a blockchain-based platform for tracking COVID-19 vaccines from the manufacturer to the end recipient, with the aim of reducing vaccine wastage, improving supply chain visibility, and preventing counterfeit vaccines.

C. Privacy-Preserving Approaches in Blockchain-Based Healthcare Systems

Privacy and security are critical concerns in healthcare, and several studies have proposed privacy-preserving approaches in the context of blockchain-based healthcare systems. For example, the "MediBloc" [15] proposes a blockchain-based health information that uses advanced cryptography techniques to protect patient privacy while enabling secure sharing of health data among authorized parties. The "HealthChain" [16] proposes a privacy-preserving blockchain-based system for storing and sharing electronic health records, using techniques such as zero-knowledge proofs and secure multi-party computation to protect patient confidentiality. These approaches highlight the potential of blockchain in maintaining data privacy and security in healthcare settings, including COVID-19 vaccination efforts.

D. Challenges and Limitations

Despite the potential usages, there are requirements and limitations associated with the use of blockchain in healthcare, including COVID-19 vaccination efforts. Interoperability, scalability, privacy, security, and regulatory compliance are

some of the main challenges that need to be addressed. Several studies and projects have highlighted these challenges and proposed solutions to overcome them. For example, the "HL7 Fast Healthcare Interoperability Resources (FHIR) and Blockchain" [17] proposes a framework for combining blockchain with existing healthcare standards, such as FHIR, to enable interoperability. The "Scalable and Interoperable Blockchain-Based Healthcare Systems" [18] proposes a scalable and interoperable blockchain architecture for healthcare, using techniques such as sharding and cross-chain communication. The "Privacy-Preserving Blockchain-Based Consent Management System for Healthcare" [19] proposes a consent management system that uses blockchain and smart contracts to manage patient consent in a privacy-preserving manner. These efforts highlight the ongoing research and development in addressing the challenges and limitations of blockchain in healthcare [20].

III. SYSTEM DESIGN

In this part, the system design of our proposed Vaccine Tracker application, which utilizes blockchain technology to provide end-to-end visibility and transparency in the COVID vaccine supply chain.

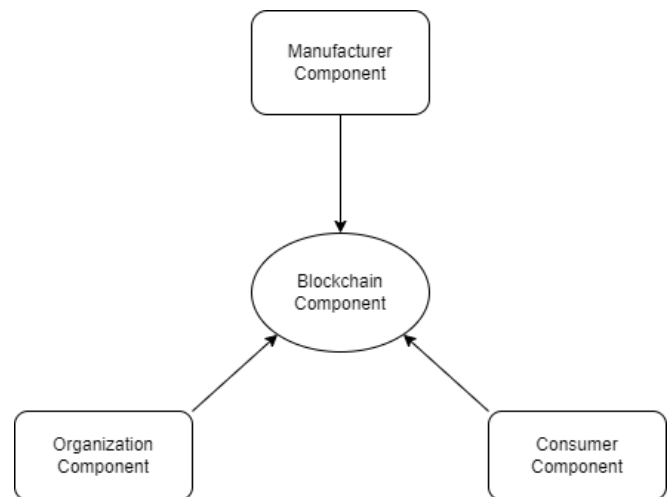

Fig. 1. System architecture.

Above Fig. 1 represents the proposed architecture.

A. Manufacturer Component

- The manufacturer adds a new vaccine batch to the system by entering relevant information, such as batch number, manufacturing date, expiration date, and other details.
- The system validates the data provided by the manufacturer, including QR code generation and location tracking data.
- Once the data is validated, the vaccine batch information is stored on the blockchain and shared with relevant stakeholders in the supply chain.

B. Organization Component

- Organizations involved in the vaccine supply chain, such as distributors, warehouses, and healthcare providers, can access the vaccine information from the blockchain.

- They can scan the vaccine shipments using QR code validation algorithms to verify the authenticity of the vaccines and record the location and condition data.
- The validated data is encrypted and stored on the blockchain for further validation and tracking.

C. Consumer Component

- Consumers can scan the QR code on the vaccine product using a mobile application.
- The QR code validation algorithm verifies the authenticity of the QR code data against the information stored on the blockchain.
- If the QR code is validated, the consumer can view exact information about the vaccine's provenance, including batch number, manufacturing date, and other details.

D. Blockchain Component

- The blockchain serves as a distributed ledger that securely stores the vaccine tracking data, including batch information, location data, and QR code validation results.
- The blockchain is encrypted and protected using cryptographic techniques, ensuring data security and integrity.
- Smart contracts programmed in Solidity language validate the data and enforce predefined rules and conditions

The proposed system employs a decentralized architecture using the Ethereum blockchain, which allows for transparent and tamper-proof recording of the vaccine's journey from the manufacturer to the hospital. The system comprises the following key components:

1) *Vaccine Tracking*: In this component, the vaccine's whereabouts at every freight hub, warehouse, and airport along its journey are recorded on the blockchain. This is achieved by utilizing smart contracts programmed in Solidity, which automatically record the vaccine's location, temperature conditions, and other relevant information at each step of the supply chain. This creates a transparent and immutable record of the vaccine's provenance, ensuring its authenticity and quality.

2) *QR Code Scanning*: At the consumer end, customers can simply scan the QR code of the vaccine product to access complete information about its provenance. The QR code acts as a unique identifier for each vaccine, and the information received from the blockchain includes details such as the manufacturer, shipping route, temperature conditions, and chain of custody. This empowers consumers to identify the authenticity of the vaccine before purchasing, mitigating the risk of counterfeit vaccines and ensuring their safety.

3) *Blockchain Network*: The blockchain network serves as the pillar of the system, consisting of a distributed network of nodes that maintain a shared ledger of vaccine tracking records. The blockchain network utilizes consensus algorithms, such as

proof of work or proof of stake, to achieve agreement on the state of the ledger and prevent unauthorized modifications. This ensures the integrity and transparency of the vaccine tracking data.

4) *Smart Contracts*: Smart contracts are self-executing scripts that run on the blockchain and enable automated verification of vaccination records. In our system, smart contracts are used to define the rules and conditions for verifying vaccination status, such as checking the validity of the digital signatures, verifying the authenticity of the vaccine administered, and ensuring compliance with vaccination protocols.

5) *User Interface*: The system includes user interfaces and experiences for different stakeholders, such as vaccine manufacturers, logistics providers, hospitals, and consumers. These interfaces provide a user-friendly way to interact with the system, allowing stakeholders to input and retrieve vaccine tracking data, as well as verify the authenticity of vaccines through QR code scanning.

IV. IMPLEMENTATION DETAILS

This section presents the used algorithms along with their implementation and coding details. The solidity code is written and tested with the Remix IDE. The Vaccine Tracker system employs various algorithms for supply chain tracking and validation to ensure the accuracy and reliability of vaccine tracking data. These algorithms include:

A. Location Tracking Algorithm

1) When a vaccine shipment is received at a freight hub or a vaccination center, the location tracking algorithm is triggered to collect the precise location data of the vaccines.

2) The algorithm utilizes GPS or other location tracking technologies, such as RFID (Radio Frequency Identification) or IoT (Internet of Things) devices, to collect the real-time location data of the vaccine shipment.

3) The location data, which may include latitude, longitude, timestamp, and other relevant information, is encrypted using cryptographic algorithms to use data security and privacy.

4) The encrypted location data is then stored as a transaction on the Ethereum blockchain, using a smart contract specifically designed for vaccine tracking. The transaction includes the encrypted location data, as well as other relevant information, such as the batch number, manufacturing date, and vaccine details.

5) The smart contract validates the encrypted location data to ensure its integrity and authenticity. This validation is done using cryptographic techniques, such as hashing and digital signatures, to verify the data against predefined rules and cryptographic keys.

6) Once the location data is validated, it is combined to the blockchain, creating a transparent and immutable record of the vaccine's journey. The location data is now available for real-time tracking and validation by authorized users, such as healthcare providers, regulators, and consumers.

7) The authorized users can access the location data from

the blockchain using a mobile app or a web interface, which decrypts the data using the appropriate cryptographic keys. The decrypted location data can then be displayed on a map or other visual representations, allowing users to track the movement of vaccines at each stage of the supply chain.

8) Any changes or updates to the location data, such as when the vaccine shipment moves to a new location, are recorded as new transactions on the blockchain, creating a chronological and auditable history of the vaccine's journey.

9) The location tracking algorithm continues to collect and record the precise location data of the vaccine shipment at each stage of the supply chain, ensuring real-time tracking and validation of vaccine movements throughout the entire supply chain process.

10) In case of any discrepancies or anomalies in the location data, such as a vaccine shipment being diverted or tampered with, the algorithm can trigger alerts or notifications to authorized users, enabling timely intervention and resolution of any issues.

Overall, the Location Tracking Algorithm in the Vaccine Tracker system uses GPS or other location tracking technologies to collect and record the precise location data of vaccines at each stage of the supply chain. The location data is encrypted and stored on the blockchain, allowing for real-time tracking and validation of vaccine movements, ensuring transparency, integrity, and authenticity of vaccine tracking data.

B. QR Code Validation Algorithm

1) When a consumer scans a QR code on a vaccine product using a mobile app or a web interface, the QR code validation algorithm is triggered to verify the authenticity of the scanned QR code.

2) The algorithm extracts the data from the scanned QR code, which will include requirement such as the batch number, manufacturing date, and other details of the vaccine.

3) The algorithm accesses the Ethereum blockchain, where the vaccine tracking data is stored, and retrieves the relevant information for the scanned QR code from the blockchain.

4) The retrieved information from the blockchain is compared with the data extracted from the scanned QR code to verify if they match. This comparison includes checking the batch number, manufacturing date, and other details to ensure that the QR code corresponds to a genuine vaccine.

5) The algorithm uses cryptographic techniques, such as hashing and digital signatures, to validate the authenticity and security of the data retrieved from the blockchain. This ensures that the data stored in the blockchain is tamper-proof and cannot be manipulated.

6) If the data extracted from the scanned QR code matches the information stored in the blockchain, the algorithm confirms that the QR code corresponds to a genuine vaccine and provides a validation result to the consumer, indicating that the vaccine is authentic.

7) If the data does not match, the algorithm raises an alert or notification, indicating that the scanned QR code may not

correspond to a genuine vaccine, and further investigation or action may be required.

8) The QR code validation algorithm also keeps a record of all the QR codes scanned by consumers, along with their validation results, as transactions on the blockchain. This creates a transparent and auditable history of QR code validations, ensuring accountability and traceability.

9) The algorithm continues to validate QR codes scanned by consumers in real-time, ensuring that only authentic vaccines are verified and consumed by consumers, thereby preventing the use of counterfeit vaccines.

10) In case of any updates or changes to the vaccine tracking data in the blockchain, such as a new batch of vaccines being added or expired vaccines being removed, the QR code validation algorithm updates its reference data accordingly to ensure accurate validation results.

Overall, the QR Code Validation Algorithm in the Vaccine Tracker system validates the authenticity of QR codes scanned by consumers by checking the QR code data against the information stored in the blockchain, using cryptographic techniques to ensure data integrity and authenticity. This helps in verifying genuine vaccines and preventing the use of counterfeit vaccines by consumers.

C. Data Validation Algorithm

1) The Data Validation Algorithm constantly monitors the vaccine tracking data stored on the Ethereum blockchain to ensure data integrity and authenticity.

2) The algorithm retrieves the vaccine tracking data from the blockchain, including information such as vaccine batch numbers, manufacturing dates, shipment details, and other relevant data.

3) The algorithm verifies the integrity of the data by using cryptographic hashing techniques, where the data is hashed using a predefined hashing algorithm to generate a unique hash value.

4) The algorithm compares the computed hash value with the hash value of the data stored in the blockchain for the same data. If the hash values match, it indicates that the data has not been tampered with and is intact.

5) The algorithm also uses digital signatures to validate the authenticity of the data. Digital signatures used for this are generated using private keys and can be verified using corresponding public keys. The algorithm verifies the digital signatures associated with the vaccine tracking data using the public keys stored in the blockchain.

6) The algorithm checks if the data inside in the blockchain adheres to predefined rules and formats, such as checking if the batch numbers follow a certain pattern, manufacturing dates fall within expected ranges, and other validation checks specific to the vaccine supply chain.

7) The algorithm validates the authenticity of the data by verifying the cryptographic keys associated with the data. It ensures that the digital signatures match the corresponding public keys stored in the blockchain, indicating that the data has

been signed by authorized entities and has not been tampered with.

8) If the data passes all the validation checks, the algorithm confirms the integrity and authenticity of the data and provides a validation result indicating that the data is valid.

9) If any discrepancy or inconsistency is detected during the validation process, the algorithm raises an alert or notification, indicating that the data may have been replaced with or does not adhere to predefined rules.

10) The Data Validation Algorithm continuously monitors the vaccine tracking data on the blockchain, ensuring that the data remains tamper-proof and authentic throughout the supply chain process.

11) In case of any updates or changes to the vaccine tracking data in the blockchain, the Data Validation Algorithm revalidates the data based on the updated information and ensures that the updated data adheres to the predefined rules and cryptographic validation checks.

Overall, the Data Validation Algorithm in the Vaccine Tracker system ensures the combination and authenticity of the vaccine tracking data stored on the blockchain by using cryptographic techniques, such as hashing and digital signatures, and validating the data against predefined rules and formats. This helps in maintaining the trust and reliability of the vaccine tracking system and preventing any tampering or manipulation of the data stored on the blockchain.

V. DISCUSSION

A. Transparency and Efficiency in Vaccine Supply Chains

The use of blockchain and AI algorithms in the Vaccine Tracker system can enhance transparency and efficiency in vaccine supply chains. Real-time location tracking using GPS or other technologies allows for accurate monitoring of vaccine movements, minimizing delays and identifying potential issues. QR code validation ensures the authenticity of vaccines, preventing the use of counterfeit vaccines. Data validation using cryptographic techniques ensures data integrity and authenticity, enhancing trust in the system.

B. Advantages of Location Tracking Algorithm

The location tracking algorithm used in the Vaccine Tracker system offers several advantages. It enables real-time tracking of vaccines at each stage of the supply chain, providing complete visibility and allowing for timely actions. However, challenges such as reliance on location tracking technologies, limitations in certain environments, and potential security concerns need to be addressed during implementation.

C. Robustness of QR Code Validation Algorithm

The QR code validation algorithm in the Vaccine Tracker system provides a robust method for authenticating vaccines. By verifying QR code data against blockchain-stored information, it ensures that consumers are scanning genuine QR codes associated with authentic vaccines. This helps protect consumer safety, maintain the integrity of the vaccination process, and prevent the use of counterfeit vaccines. However, interoperability with existing QR code standards and potential issues with QR code readability need to be addressed.

D. Data Validation Algorithm for Ensuring Integrity and Authenticity

The data validation algorithm used in the Vaccine Tracker system plays a crucial role in ensuring the integrity and authenticity of vaccine tracking data stored on the blockchain. By using cryptographic techniques, it validates data against predefined rules and verifies authenticity using cryptographic keys. This ensures that the data stored on the blockchain is tamper-proof and can be trusted. However, proper key management practices, potential security risks, and scalability of the algorithm need to be carefully evaluated and addressed.

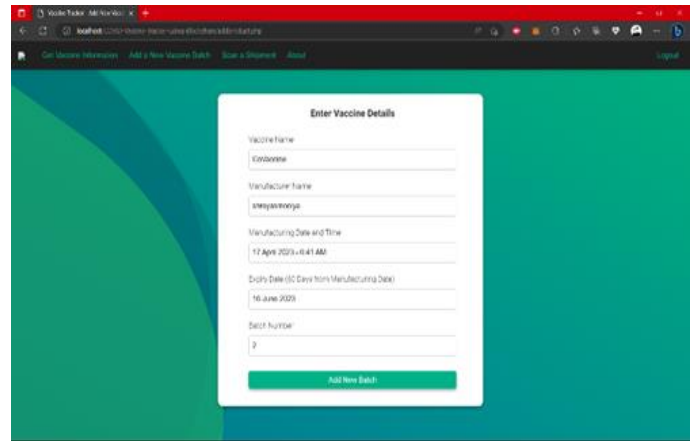

E. Challenges

There are many challenges and limitations to consider in the usage of the Vaccine Tracker system. These include reliance on location tracking technologies, interoperability with existing systems, user adoption and acceptance, scalability during high-demand scenarios, and cost-effectiveness. Additionally, potential security risks associated with cryptographic keys, QR code readability issues, and adherence to industry standards should be considered during implementation.

VI. EXPERIMENTAL RESULTS

A. Manufacturer Adding New Vaccine Batch

In this scenario, the Vaccine Tracker system is tested by simulating the addition of a new vaccine batch by a manufacturer. Below Fig. 2 shows the process of manufacturer adding new vaccine batch.

The screenshot shows a web browser window with the URL 'Vaccine Tracker: Add New Batch'. The page has a teal and green background. A white form titled 'Enter Vaccine Details' is centered on the page. The form contains the following fields: 'Vaccine Name' (text input), 'Container' (text input), 'Manufacturer Name' (text input), 'Lot/Serial No.' (text input), 'Manufacturing Date and Time' (text input with value '17 Apr 2023, 04:41 AM'), 'Expiry Date (10 Days from Manufacturing Date)' (text input with value '16 June 2023'), 'Batch Purpose' (text input with value '2'), and a green 'Add New Batch' button at the bottom.

Fig. 2. Adding vaccine batch.

The experimental results may include the following:

- Successful addition of a new vaccine batch to the blockchain, including batch number, manufacturing date, expiration date, and other relevant information.
- Real-time recording of the batch information on the blockchain, ensuring transparency and immutability.
- Verification of the data validation algorithm, which ensures the combination and authenticity of the data stored on the blockchain.
- Validation of the QR code validation algorithm, which verifies the authenticity of the QR codes associated with the new vaccine batch.

- Successful integration of the location tracking algorithm, which tracks the movement of the vaccine batch using GPS or other location tracking technologies.
- Proper encryption and storage of location data on the blockchain, ensuring data privacy and security.

B. Organizations Viewing Vaccine Information and Scanning Shipment

In this scenario, the Vaccine Tracker system is tested by simulating the viewing of vaccine information and scanning of a shipment by organizations involved in vaccine supply chain. Fig. 3 shows vaccine shipment process.

Fig. 3. Vaccine shipment.

The experimental results may include the following:

- Successful viewing of vaccine information, including batch number, manufacturing date, expiration date, location data, and QR codes, by relevant organizations such as distributors, healthcare providers, and regulatory authorities.
- Real-time tracking of the vaccine shipment using the location tracking algorithm, which provides accurate and on-date information on shipment's whereabouts.
- Validation of QR code validation algorithm, which verifies the authenticity of the scanned QR codes against the blockchain-stored information.
- Verification of the data validation algorithm, which ensures the combination and authenticity of the vaccine tracking data stored on the blockchain.
- Detection of any discrepancies or inconsistencies in the vaccine information, which may indicate potential issues such as counterfeit vaccines or supply chain disruptions.
- Proper access controls and permissions management, ensuring that only authorized companies can view and scan vaccine information.

C. Consumer Getting Vaccine Information

In this scenario, the Vaccine Tracker system is tested by simulating the retrieval of vaccine information by a consumer

using QR code scanning. Below Fig. 4 shows how consumer can get vaccine information.

Fig. 4. Consumer page.

The experimental results may include the following:

- Successful scanning of the QR code on a vaccine package by a consumer using a smartphone or other QR code scanning devices.
- Retrieval of vaccine information, such as number, manufacturing date, expiration date, and location data, from the blockchain.
- Verification of the authenticity of the scanned QR code using the QR code validation algorithm, which ensures that the consumer is scanning a genuine QR code associated with an authentic vaccine.
- Provision of accurate and reliable vaccine information to the consumer, promoting security and trust in the vaccination process.
- Proper encryption and storage of consumer data, ensuring data privacy and security.

D. Tracking Log of Vaccine

In this part, the results of our blockchain-based vaccine tracking system, which enables end-to-end tracking of COVID-19 vaccines from the manufacturer to the consumer, with real-time updates displayed in Google Maps. Fig. 5 depicts the tracking of vaccine from source to destination.

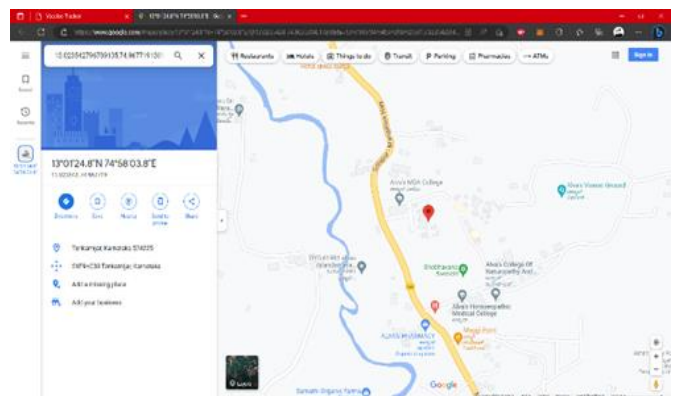

Fig. 5. Track record.

VII. CONCLUSION AND FUTURE WORK

The Vaccine Tracker system, leveraging blockchain technology and AI-based algorithms, offers a robust and transparent solution for tracking and validating vaccine movements in the supply chain. The system provides real-time tracking of vaccines, validates the authenticity of QR codes, and ensures the integrity and authenticity of vaccine tracking data stored on the blockchain. The experimental results from testing and validation scenarios, including manufacturer adding new vaccine batch, organizations viewing vaccine information and scanning shipment, and consumer getting vaccine information, demonstrate the effectiveness and potential of the system in improving vaccine supply chain management.

The implementation of the Vaccine Tracker system has many key benefits, including enhanced transparency, traceability, and accountability in the vaccine supply chain. The system enables stakeholders, including manufacturers, distributors, healthcare providers, regulatory authorities, and consumers, to access accurate and reliable vaccine information in real-time, ensuring the authenticity and integrity of vaccines. The use of cryptographic techniques, such as hashing and digital signatures, ensures data security and privacy, protecting against data tampering and unauthorized access.

However, it's required to note that the success of the Vaccine Tracker system also relies on taking and collaboration of various stakeholders in the vaccine supply chain, as well as adherence to relevant regulations and standards. Further research and development can be explored to optimize the system's performance, scalability, and interoperability with existing vaccine supply chain management systems.

In conclusion, the Vaccine Tracker system has the potential to significantly improve vaccine supply chain management by leveraging blockchain technology and AI-based algorithms. The system's transparency, traceability, and data validation capabilities can enhance the trust and efficiency of vaccine distribution, ensuring that safe and authentic vaccines reach the end consumers. With proper implementation, the Vaccine Tracker system can contribute to the global efforts in ensuring the availability and safety of vaccines, ultimately benefiting public health worldwide. In the future work, we can improve the proposed system using artificial intelligence (AI) and deep learning techniques, for even further advancement, our suggested method can use a hybrid machine learning approach.

Enhance the Security of the Cloud Using a Hybrid Optimization-Based Proxy Re-Encryption Technique Considered Blockchain

Ahmed I. Alutaibi

Department of Computer Engineering-College of Computer and Information Sciences,
Majmaah University, Majmaah 11952, Saudi Arabia

Abstract—Every day, a vast amount of data with incalculable value will be generated by the IoT devices that are deployed in various types of applications. It is crucial to ensure the reliability and safety of IoT data exchange in a cloud context because this data frequently contains the user's private information. This study presents a novel encrypted data storage and security system using the blockchain method in conjunction with hybrid optimization-based proxy re-encryption (HO-PREB). Dependency on outside central service providers is eliminated by the HO-PREB-based consensus process. In the blockchain system, several consensus nodes serve as proxy service nodes to restore encrypted data and merge transformed ciphertext with private data. Hybrid owl and bat optimization is employed to select the optimal key for enhancing security. This removes the limitations associated with securely storing and distributing private encrypted data via a distributed network. Moreover, the blockchain's distributed ledger ensures the permanent storage of data-sharing records and outcomes, ensuring accuracy and dependability. The simulated experiments of the designed model are evaluated with existing cryptographic techniques and gain a lower latency of 3.2 s and a lower turnaround time of 45 ms. Furthermore, the developed technique enhances cloud system security and possesses the capability to detect and mitigate attacks in the cloud environment.

Keywords—Cloud security; Internet of Things; proxy re-encryption; blockchain; data sharing; hybrid optimization

I. INTRODUCTION

Cloud computing is one of the best and most difficult platforms accessible today, and businesses of all sizes are starting to employ its services. A range of cloud deployment techniques are available, and cloud services are provided according to requirements, like protecting the cloud system's internal and external safety [1]. Common technology flaws, malware, hackers, and other similar threats, unauthorized access, inadequate precautions, denial of service, unsecured interfaces, profile or business traffic hijacking, and data leaks are the primary risks to cloud computing protection [2]. Cloud control covers a broad range of topics, such as handling resources, hardware and software safety, cloud data protection, and resource consumption [3]. Despite the many benefits of cloud storage, cloud users often prioritize security and privacy issues, which discourages businesses and organizations from adopting big changes. While using the cloud benefits enterprises and institutions, privacy and confidence are the most vital challenges [4, 5]. The data of cloud customers is

highly vulnerable to loss, leakage, or attack, and they are left with no way out of this untenable scenario [6].

When exporting and buying offerings from cloud providers, cloud customers may apply blockchain technology, a novel and evolving technology, to boost data privacy and confidence [7, 8]. Blockchain can provide improved security based on centralized database safety. Blockchain monitors the set of data that is encrypted, stored, and linked to the previous block using an encrypted hash function [9, 10]. A blockchain is a type of networked ledger that can prevent manipulation and store operations. Peer-to-peer networks are typically used to manage blockchains, which are meant to guard against outside interference [11, 12]. The security provided by the blockchain system can be compared to the safety of centralized data storage. From a management standpoint, attacks and damage to data storage can be prevented [13]. Furthermore, the accessible feature of the blockchain can facilitate data openness when used in an environment where sharing information is mandated. These benefits allow it to be used in a wide range of situations, including those involving the financial sector and the Internet of Things (IoT), and its applications are expected to expand [14]. Cloud computing has been integrated into many IT systems since it is effective and widely accessible. Moreover, privacy and cloud security issues have been investigated as crucial security components [15].

As IoT technology develops quickly, a vast number of IoT devices are being used in many application situations. As a result, ensuring dependability and IoT data exchange security is essential [16]. A significant volume of IoT data is generated and managed by the data owners. These enormous amounts of data must be encrypted and sent to a trusted organization for storage because IoT devices have limited storage. Before transferring the data to cloud databases and shared storage systems, they can choose to encrypt it [17, 18]. To safeguard the privacy and security of data owners (DO), an efficient access control system must be established. The users don't have a completely reliable means of communication through which to exchange the decryption key because the data is encrypted. The data owners must download, decrypt, and re-encrypt the material before they may share it directly with the recipients [19]. Unfortunately, because of their limited processing capacity, the DO is unable to pay to decrypt the data before re-encrypting it for the recipients. As a result, they can exchange IoT data by using the PRE technique. This transfers the burden of ciphertext decryption and encryption from the information

owners to the procedure of creating a new encryption key, thereby redistributing the workload [20].

This work presents the development of a hybrid owl search and bat PRE method to improve cloud computing security and robustness. Additionally, the blockchain model generates blocks and secure cloud storage of user data to enhance privacy. Additionally, the blockchain concept is built to give extra scalability for safeguarding data in blocks and secret keys, and data is safely decrypted via PRE. Additionally, the HO-PREB system avoids reliance on outside central service providers. In the distributed ledger network, several consensus nodes serve as proxy service nodes to merge translated cipher text and re-encrypt data. This system can guarantee the suitability, security, and dependability of cloud computing's IoT data exchange.

The overview of the paper is arranged in sections. Sections II and III detail related works and a problem statement; Section IV explains the proposed methodology; Section V gives detailed results and discussion; and Section VI ends with a conclusion and future scope.

II. LITERATURE REVIEW

A. Related Works

A distributed data-controlled sharing strategy based on PRE is proposed by Ismail et al. [21]. First, a method for PRE is built using the blockchain and SM2. The information-controlled sharing method protects transaction information confidentiality while enabling data security sharing through the use of PRE. A system for adaptive user rights modification is suggested. To completely maintain the privacy of transaction data and carry out the evaluation of information access permission by monitoring PRE key settings, they are creating a PRE method with SM2.

A PRE method was created by Kwame et al. [22] for secure cloud-based data-sharing scenarios. Data owners can send their protected data to the cloud using identity-based encryption (IBE), where it may be accessed by authorized users using the PRE architecture. Moreover, it increases the quality of service by effectively supplying content that has been stored in the proxy by utilizing information-centric network functions. Moreover, blockchain is an innovative technology that permits data sharing to be decentralized. It accomplishes fine-grained control over access to data and reduces bottlenecks in central databases.

To increase safety and confidentiality in a private blockchain, Bharat et al. [23] introduced the Splitting of PRE Method (Split-PRE), which is based on the IoT. To address trust issues as well as scalability issues, this paper suggests a blockchain-based PRE method that will streamline transactions. The IoT data is saved by the system in a decentralized cloud after encryption. Through the use of an effective PRE method, the owner and the person in the smart contract can both view the data.

A blockchain-based ecosystem for IoT data exchange is presented by Ahsan et al. [24]. Additionally, transport the data from the information generator to the consumer safely and anonymously by using a PRE mechanism. Without the assistance of a reliable third party, the system establishes

dynamic, temporal connections between data consumption and sensors to share the gathered IoT data. This cutting-edge website for storing, exchanging, and handling sensor data is quick, easy, and safe.

Yingwen et al. [25] combined blockchain computing with PRE to create a novel encrypted data storage and communication design. The utilization of threshold PRE as a compromise technique avoids reliance on external central service providers. In the blockchain system, several consensus nodes serve as proxy service nodes, combining translated ciphertext and re-encrypting data. The findings demonstrate that the suggested architecture can raise a reasonable time delay while satisfying the high demands for data access.

To accomplish effective data sharing and data accuracy checking, Tao Feng et al. [26] suggested a technique that utilizes IBE. Additionally, a blockchain platform is integrated to ensure secure and regulated data storage, addressing issues such as manipulation of data and insufficient supervision on external servers. Lastly, assess the computation and transmission overhead to prove the security of the planned system. The findings demonstrated that the designed method surpasses other plans in terms of efficiency and security against specific plaintext attacks with observable characteristics.

To enable user identification and access to the public key's binding properties on the Internet of Medical Things, Hongmei et al. [27] offer a safe data sharing system named PRE for safe information exchange with blockchain, thereby boosting the security of data sharing. The created approach implements the management and quick query of users by adding them to the accumulator through the application of a blockchain smart agreement. Lastly, carry out the four-stage computing performance evaluation experiments to enhance the effectiveness of the encryption, re-encryption, decryption, and re-decryption computations.

B. Problem Statement

Transaction data is kept on a blockchain in a decentralized shared global ledger. Finding the right balance while sharing data safeguarding privacy, and usefulness is difficult. Furthermore, one difficult issue is the dynamic modification of blockchain data access permissions [28]. The problem description in the realms of cloud computing and blockchain technology centers on data availability, confidentiality, and integrity protection in distributed systems. Maintaining the confidentiality of sensitive data processed and stored across enormous networks of linked servers is a difficulty with cloud computing [29]. Strong security measures are necessary to reduce risks associated with problems like unauthorized access, data breaches, and service interruptions. Similarly, it is critical to protect distributed ledgers' confidentiality and agreement in blockchain technology from risks like 51% attacks, double-spends, and vulnerabilities in smart contracts. The most frequent and difficult problems with cloud computing safety are low efficiency, trust concerns, limited scalability, difficulty in maintaining access restrictions, and leakage of sensitive data [30]. To meet these problems and maintain the confidence and integrity necessary for these revolutionary technologies, creative encryption methods, strict access controls, and robust network designs are needed.

III. PROPOSED METHODOLOGY

Create the best possible keys and increase the security of the proposed model by designing a hybrid owl search and bat optimization (HOSBA) algorithm. The blockchain network, storage service providers (SSP), data users (DU), and data owners (DO) make up the four primary components of the created system. Fig. 1 depicts the planned strategy process.

C. Process of the Hybrid Optimization-based PRE Model

To improve the public cloud privacy of user information, hybrid owl search and bat optimization (HOSBA) methods are used for the key generation phase. These improvements choose the most reliable and safe optimum key to improve cloud computing security.

1) *System construction:* To increase cloud storage security and safe data exchange, it integrates threshold PRE, hybrid optimization, and the blockchain consensus method. Elliptic Curve Digital Signature Algorithm (ECDSA) [31], PRE [32], and HOSBA are consulted in the construction of the developed mechanism. This approach can use a collection of N's blockchain consensus nodes to carry out the PRE procedure. The delegate can access the updated ciphertext by utilizing their private keys to decrypt it when necessary within the blockchain network of nodes in re-encryption. During the key generation

step, the HOSBA model is employed to choose the best possible key. Below is a full explanation of the developed technique and process.

System setup

$$(1^\gamma, \bar{u}) \rightarrow \overline{pp}$$

The security parameters 1^γ is selected as inputs and the output of the public parameter is \overline{pp} . The \overline{pp} is used for creating own public and private keys. Initially, it takes security parameter γ as the results and inputs for a bilinear map m :

$\hat{G}_1 * \hat{G}_1 \rightarrow \hat{G}_2$, where \hat{G}_1, \hat{G}_2 is a prime order multiplicative cyclic group P . A random generator is selected $g \in \hat{G}_1$, and calculated $z = m(\hat{g}, \hat{g})$. Moreover, four hash functions are developed and are detailed in eqn. (1).

$$\begin{aligned} \hat{H}_0 : \{0,1\}^* &\rightarrow \hat{G}_1, \hat{H}_1 : \{0,1\}^* \rightarrow \hat{G}_1, \hat{H}_2 : \hat{G}_2 \rightarrow \{0,1\}^{\log_2 p}, \hat{H}_3 : \\ \hat{G}_2 &\rightarrow \{0,1\}^* \end{aligned} \quad (1)$$

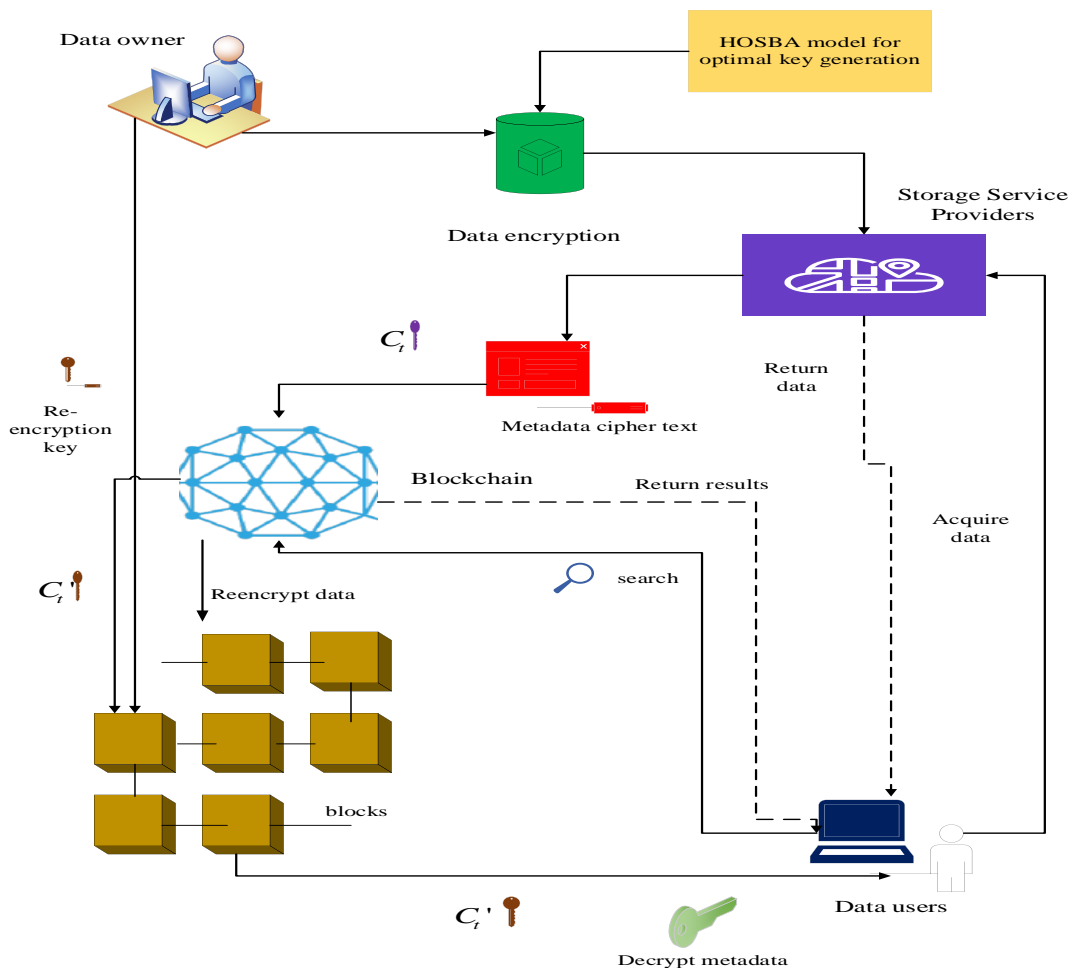

Fig. 1. Process of developed model.

Execute the procedure for parameter generation to produce shared parameters and is exhaustive in Eq. (2).

$$P_r = (\hat{g}, z, m, p, \hat{G}_1, \hat{G}_2, \hat{H}_0, \hat{H}_1, \hat{H}_2, \hat{H}_3) \quad (2)$$

D. Key Generation

The public and private key pairs are created by the DU and the DO based on the provided public parameters. The DO selected at random $u \in z_p^*$ is the private key and calculates the public key as $pk_{do} = \hat{g}^u$. DU selected at random $v \in z_p^*$ is the private key and calculates the public key as $pk_{du} = \hat{g}^v$.

Hybrid owl search and bat algorithm:

The optimal key is a cryptographic key that is chosen or fine-tuned to maximize the security of encrypted data. This key is crucial for ensuring that data is securely encrypted and protected against unauthorized access. The Hybrid Owl and Bat optimization algorithm is used to find the best possible key for encryption. This optimization process involves selecting parameters for encryption that enhance security measures, such as resisting attacks or ensuring robustness against various threats. This algorithm explores the key space efficiently to identify the key that provides the highest level of security.

A novel hybrid optimization approach has been developed to select the best optimal key for enhancing the security of data in the cloud. It draws inspiration from the actions of the Bat Optimization (BAO) [33] and Owl Optimization Algorithm (OOA) [34] when a threat is present. The proposed hybrid optimization method selects the best optimal key according to the efforts of both parties to increase efficiency and security. It conceptually integrates BAO and OOA.

Owl begins its optimization process using a range of initial random solutions that match the starting positions of owls in a forest. The n quantity of owls in a woodland, x is the space of dimensions used for searches. Next, a random position is saved for them in a $n \times x$ matrix as given in Eq. (3).

$$\bar{o} = \begin{bmatrix} \bar{o}_{1,1} & \bar{o}_{1,2} & \dots & \bar{o}_{1,x} \\ \bar{o}_{2,1} & \bar{o}_{2,2} & \dots & \bar{o}_{2,x} \\ \vdots & \vdots & \vdots & \vdots \\ \bar{o}_{n,1} & \bar{o}_{n,2} & \dots & \bar{o}_{n,x} \end{bmatrix} \quad (3)$$

The element of the matrix $\bar{o}_{i,j}$ characterizes the j^{th} variable of an i^{th} owl. Eq. (4) is utilized to assign the beginning location of every owl in the forest based on a uniform distribution.

$$\bar{o}_i = \bar{o}_l + \bar{u}(0,1) \times (\bar{o}_u - \bar{o}_l) \quad (4)$$

Let, \bar{o}_l and \bar{o}_u are the lower and upper boundaries of i^{th} owl \bar{o}_i in j^{th} length and $\bar{u}(0,1)$ is an arbitrary amount in the

range [0,1] that is evenly distributed. An objective function is used to assess the fitness of each owl's placement inside a forest, and the results are kept in the matrix shown in Eq. (5).

$$\bar{f} = \begin{bmatrix} \bar{f}_1([\bar{o}_{1,1}, \bar{o}_{1,2}, \dots, \bar{o}_{1,x}]) \\ \bar{f}_2([\bar{o}_{2,1}, \bar{o}_{2,2}, \dots, \bar{o}_{2,x}]) \\ \vdots \\ \bar{f}_n([\bar{o}_{n,1}, \bar{o}_{n,2}, \dots, \bar{o}_{n,x}]) \end{bmatrix} \quad (5)$$

The current study assumes that each owl's positional fitness value is directly correlated with the volume of information it hears. Since the greatest owl is closer to the vole, it receives the maximum intensity. The information concerning the adjusted

intensity of the i^{th} owl is calculated using Eq. (6) and is used to update the position.

$$\bar{I}_i = \frac{\bar{f}_i - \bar{w}}{\bar{b} - \bar{w}} \quad (6)$$

Equation (7) calculates the details of the separation between each owl and its meal.

$$\bar{r}_i = \|\bar{o}_i, \bar{v}\|_2 \quad (7)$$

Let, \bar{v} is the position of the prey that the most agile owl finds. Additionally, it is presumable that the forest has a single vole, or worldwide optimum. Owls fly silently in the direction of their prey. As a result, they experience altered intensity by the sound intensity inverted square law. The variation in strength for i^{th} owl can be acquired using Eq. (8).

$$\bar{I}c_i = \frac{\bar{I}_i}{\bar{r}_i^2} + \text{random_noise} \quad (8)$$

Eq. (8), \bar{r}_i^2 is used instead of $4\pi\bar{r}_i^2$ and thought that adding random noise to the surroundings will enhance the realism of the computational framework. Since voles are active in the actual world, their mobility compels owls to adjust their existing location softly. At this point, the optimal optima key is generated for the owl's new position phase via bat optimization, which improves the cloud computing privacy procedure. All bats utilize echolocation to detect distance, and in some mysterious way, they are also able to distinguish between background obstacles and food/prey; Bats fly arbitrarily with velocity \bar{v}_i' at position \bar{x}_i' with a fixed frequency \bar{f}_i' to search for prey. Depending on the closeness of their target, they can automatically modify the frequency and rate at which they emit pulses within the interval [0, 1].

Thus, Eq. (9), which gives the new positions of the hybrid owl and bat model.

$$\vec{o}_i^{t+1} = \begin{cases} \vec{o}_i^t + \beta \times \vec{I}c_i \times |\alpha \vec{v} - \vec{o}_i^t| & \text{if } \vec{p}_v < 0.5 \\ \vec{x}_i^{t-1} + \vec{v}_i^t & \text{if } \vec{p}_v < 0.5 \end{cases} \quad (9)$$

Let, \vec{p}_v is the likelihood of a vole moving, α is a uniformly distributed random number across the interval [0, 0.5], and β is a constant that decreases linearly from 1.9 to 0. β encourages the investigation of the search space and first makes significant alterations. Moreover, \vec{x}_i^{t-1} is denoted as the new position of the bats concerning time $t-1$, \vec{v}_i^t is denoted as velocity at time t , and the velocity of the bat is measured using Eq. (10).

$$\vec{v}_i^t = \vec{v}_i^{t-1} + (\vec{x}_i^t - \vec{x}_*) \vec{f}_i \quad (10)$$

\vec{f}_i is considered as frequency, \vec{x}_i^t is denoted as the new position of the bats, and \vec{x}_* is denoted as the current global best position. Ultimately, the optimized model selects the best secret, private, and public key to secure the user data from unauthorized access. Algorithm 1 provides the Hybrid owl search and bat algorithm.

Algorithm 1: Hybrid owl search and bat algorithm

1. Initialize the algorithm by setting the population size, number of iterations, boundaries of the search space, and parameters for Owl and Bat Optimization.
2. Generate initial owl population by randomly generating initial positions for owls within the search space, evaluating the fitness of owl positions using the objective function, and storing the fitness values in a matrix.
3. Start the optimization process by beginning the main loop for iterations.

Owl Optimization Phase:

- Calculate initial positions of owls based on random distribution.
- Update positions by calculating the intensity of information and adjusting based on proximity to prey.
- Introduce random noise to simulate a realistic search.
- Recalculate fitness of updated positions and store the best one found.

Update Intensity and Distance:

- Compute intensity for each owl based on proximity to prey.
- Adjust positions based on intensity and random noise.
- Calculate the distance between owls and prey and update positions.

Bat Optimization Phase:

- Adjust the frequency of bats based on distance to the best-known solution.
- Update velocity and position of bats using calculated frequency.
- Perform a local search around the best solution, adjusting positions based on probability.

- Update positions and velocities based on proximity to prey and best-known positions.

Combine Results from Both Algorithms:

- Compare the best solutions from Owl and Bat Optimization phases.
 - Update the global best solution if a better position is found.
4. Conclude the optimization by finalizing the best-found solution as the optimal key after completing iterations.
 5. Output the optimized key generated from the hybrid optimization process.
-

E. Data Encryption

$$(D_{ek}, D) \rightarrow C_t$$

Additionally, the IoT data is encrypted using a symmetric encryption technique. Users using symmetric key encryption must be aware of a shared secret key. The encrypted data C_t is generated using a common secret key D_{ek} are submitted for SSP to store the encrypted data using Eq. (11).

$$C_t = \text{encrypt}(D_{ek}, D) \quad (11)$$

F. Metadata Encryption

$$(\overline{pp}, \overline{pk_{do}}, \widehat{m}) \rightarrow C_t \widehat{m} : \text{Metadata } \widehat{m} \text{ is encrypted by the}$$

DO by using a public key, and sends cipher text $C_t \widehat{m}$ to the blockchain. Moreover, a DO private key is desired to decrypt the data. Metadata \widehat{m} contains the data summary, data store location, data decryption key D_{dk} , C_t , etc. Metadata encryption is detailed in eqn. (12).

$$C_t \widehat{m} = \text{Enc}(\overline{pk_{do}}, \widehat{m}) = (\widehat{g}_{uh}, \widehat{m}z_h) \quad (12)$$

Where, $z = m(\widehat{g}, \widehat{g})$, h is an arbitrary coefficient.

G. Re-Encryption Key Generation

By their private key and the public key of the sender DU who wishes to obtain the data, the DO computes and produces the re-encryption key. The $\overline{sk_{du}}$ is the input secret key, the designated delegate's public key pk_{du} , proxy nodes quantity \widehat{p}_n , and the threshold t_h , ReKeyGen, a technique for

generating re-encryption keys, calculates n components of the key used to re-encrypt data between DO and DU in Eq. (13).

$$rk_{do \rightarrow du} = \widehat{g}^{v/u} \quad (13)$$

Using the eqn. (14) that follows,

$$\bar{f}(x) = \sum_{i=1}^h \bar{f}(x_i) \gamma_{ij}, \gamma_{ij} = \prod_{l=1, l \neq j}^h \frac{x - x_l}{x_i - x_l}, \quad (14)$$

each proxy node's share of the re-encryption key $rh_{o \rightarrow u}^i = \widehat{g}^{\bar{f}(x_i)} \bmod p$, and, $\widehat{p}_n, i = 1, 2, 3, \dots, n$. The ciphertext transformation requests will be posted to the blockchain system by the DO.

H. Re-Encryption

The ciphertext transformation procedure is started by the majority of nodes in the distributed ledger network in responding to re-encryption requests after they have received the re-encryption key made public through the DO. It re-encrypts $C_i \widehat{m}$ from the DO to the DU, according to $C_i \widehat{m} = (\widehat{g}_{uh}, \widehat{m}z_h)$. Re-encryption keys allow proxy nodes to modify the original ciphertext. $rh_{o \rightarrow u}^i, i = 1, 2, 3, \dots, n$, for \widehat{p}_n to the $C_i \widehat{m}$ over the following Eq. (15).

$$m(\widehat{g}_{uh}, (rh_{p_n}^i)^{\gamma_i}) = m(\widehat{g}_{uh}, \widehat{g}^{[\gamma_i \cdot \bar{f}(x_i)]}) = z^{uh[\gamma_i \cdot \bar{f}(x_i)]} \quad (15)$$

Every proxy node \widehat{p}_n can access the encrypted text using Eq. (16).

$$C_{v_i} = \left(z^{uh[\gamma_i \cdot \bar{f}(x_i)]}, \widehat{m}z_h \right) \quad (16)$$

When t out of n the ciphertext is appropriately completed by proxy nodes in the re-encryption computation. C_{v_i} can be integrated into the updated ciphertext. $C_t \widehat{m}$, which DU can decode using their private key using Eq. (17) and (18)

$$\prod_{i=1}^t z^{uh[\gamma_i \cdot \bar{f}(x_i)]} = z^{uh \sum_{i=1}^t \gamma_i \cdot \bar{f}(x_i)} = z^{uh.v/a} = z^{vh} \quad (17)$$

$$C_t \widehat{m} = \left(z^{vh}, \widehat{m}z_h \right) \pmod{p} \quad (18)$$

Following the completion of the consensus confirmation by the proxy nodes, the new block will contain the entire interpreted ciphertext.

I. Metadata Decryption

The private key \overline{sk}_{du} of the DU is suitable for decrypting the ciphertext metadata $C_t \widehat{m} = (z^{vh}, \widehat{m}z_h) = (\widehat{\alpha}, \widehat{\beta})$ as well as the subsequent metadata using Eq. (19).

$$\widehat{m} = \widehat{\beta} / \widehat{\alpha}^{1/\overline{sk}_{du}} \quad (19)$$

J. Data Decryption

Then receiving the metadata \widehat{m} , using DU, they can obtain the exact location of the information storage as well as the binary decryption password for the data. Using data analysis and signature, both are contained in the metadata, we can use SSP to retrieve the plaintext of the data and confirm its accuracy and integrity. The data decryption is performed using Eq. (20).

$$Data = decrypt(D_{ek}, C_t) \quad (20)$$

The designed hybrid optimization-based PRE model improves the safety of cloud data by re-encrypting user information and applying a consensus technique to increase security. Algorithm 2 illustrates the optimal threshold PRE procedure.

K. Consensus Mechanism based on Threshold PRE

The process of consensus is an essential element of a developed system. In contrast to the conventional PRE method, the developed approach makes use of a decentralized network to do away with the need for outside central service providers. Re-encrypted ciphertext transformation is the basis for the consensus process that is collaboratively carried out by

consensus nodes in blockchain-based systems. The re-encryption key is divided and distributed across all consensus nodes within the blockchain system; the threshold PRE may be seamlessly integrated with the consensus method. The data owners concurrently communicate their demands for ciphertext transformation to the blockchain network and distribute the newly created re-encryption keys among other consensus nodes. A significant amount of processing power is needed for the ciphertext conversion operation. Since not every node in the network is capable of re-encryption, certain nodes with particular processing capabilities respond to this demand by performing re-encryption calculations. These nodes function in the distributed ledger system as consensus nodes. Fig. 2 displays a description of the consensus method based on the established model.

Process of consensus nodes: The consensus node locates the original ciphertext that matches $C_t \widehat{m}$ in the blockchain ledger, via the re-encryption key after fulfilling the re-encryption conditions $rh_{o \rightarrow u}^i, i = 1, 2, 3, \dots, n$ to complete the conversion process. The consensus nodes confirm the ciphertext after it has been re-encrypted, finish the re-encryption calculation within the allotted time C_{v_i} , $i = 1, 2, 3, \dots, n$ and send it to the blockchain system; Each consensus node compiles and verifies the encrypted text that has been re-encrypted C_{v_i} . A vote for selecting the leader of the network of blockchain servers is started by the consensus node that leads the charge in gathering t authenticated re-encrypted ciphertexts.

Fig. 2 is overview of consensus model with developed technique.

After receiving this request, further consensus nodes verify that the re-encrypted ciphertext is accurate. These re-encrypted ciphertexts are combined by the leader node C_{v_i} to the novel ciphertext $C'_t \widehat{m}$. This leader node will also add the newly generated block, the re-encrypted data, and the modified ciphertext to the blockchain database and broadcast it to the whole network. Additional nodes modify the ledger after completing consensus confirmation. After that, the HO-PREB is finished, and the ciphertext for the metadata is changed. $C'_t \widehat{m}$ is updated in the block. The blockchain ledger provides users with the altered metadata ciphertext, allowing them to complete the decryption process.

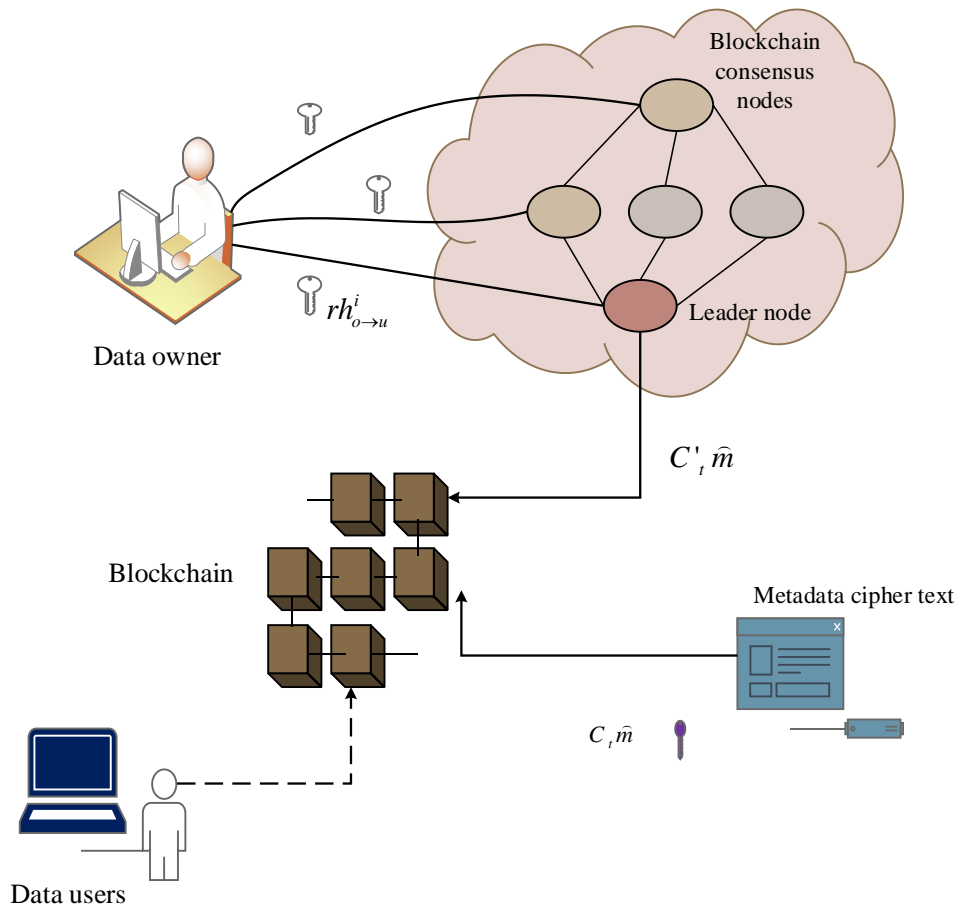

Fig. 2. Overview of consensus model with developed technique.

IV. RESULT AND DISCUSSION

The enhanced efficiency of the created method is verified by comparing it to current methods concerning encryption time, decryption time, re-encryption time, latency, restoration effectiveness, and turnaround time. The created model's robustness and safety are verified using accepted cryptographic approaches after it is implemented using a Python tool. The hybrid owl and bat optimization is employed to improve the user's data's security by generating the optimal key. Finally, it is securely stored in the cloud using blockchain by generating blocks.

A. Performance Analysis

To prove the efficiency and reliability of the developed system, the results are validated with existing classifiers such as Advanced Encryption Standard (AES) [36], Data Encryption Standard (DES) [35], Homomorphic Encryption (HE) [37], Rivest-Shamir-Adleman (RSA) [38], and IBE [39]. The performance metrics used for the validation are decryption time, encryption time, latency, re-encryption time, restoration efficiency, and turnaround time.

B. Encryption Time

The efficiency of any encryption operation is determined by dividing all the encrypted plaintext by the encryption time (milliseconds).

Fig. 3. Encryption time comparison.

Fig. 3 shows the milliseconds (ms) that each cryptographic algorithm takes to encrypt data. The duration of encryption operations is used to evaluate each scheme. AES, DES, RSA, HE, and IBE algorithms are among those examined in the analysis, along with a proposed method. Of the algorithms that have been studied, AES has the longest encryption time—74.25 ms—on record. DES has an encryption time of 21.66 ms, which is shorter than AES's. At 20.28 ms, RSA has a comparatively short encryption time. While IBE displays a comparatively

short encryption time of 19.97 ms, HE requires 55.74 ms. With a value of 12.5 ms, the proposed algorithm finally shows the lowest encryption time out of all the algorithms examined.

C. Re-Encryption Time

With PRE, a proxy can change the encryption of a ciphertext from one key to another, encrypting the identical message.

Fig. 4. Re-encryption time comparison.

Performance analyses of the data re-encryption times for the different encryption techniques are shown in Fig. 4. The time it takes to re-encrypt data is indicated by each algorithm's re-encryption time. This is an important factor in cryptographic operations, especially when situations call for regular updates or changes to encryption keys. The highest re-encryption time for the AES algorithm is 88.8 ms, but the DES algorithm displays a duration of 20.83 ms. Furthermore, the RSA and IBE re-encryption times are 19.98 ms and 18.86 ms, respectively. The developed technique has the lowest re-encryption time of all the records, at 10.4 ms, whereas the HE shows a re-encryption time of 54.32 ms. Comparing the suggested algorithm to the other stated algorithms, it may be more efficient in re-encryption activities.

D. Decryption Time

The process of restoring encrypted material to its original form is known as decryption. Usually, the encryption procedure is done in reverse. Because decryption necessitates a secret key, it examines the encrypted data to ensure only an authorized user may decrypt it.

A performance analysis of decryption times using different encryption techniques is shown in Fig. 5. While the suggested algorithm is a novel or modified encryption technique, AES, DES, RSA, HE, and IBE are well-known encryption techniques. DES and RSA are the two classic encryption methods with the fastest decryption times, respectively, at 24.81 and 23.12 milliseconds. Adopted as an encryption standard, AES is relatively slower than DES and RSA, taking 55.58 ms to decrypt. IBE shows a comparatively faster

decryption time of 20.99 ms, while HE takes 43.65 ms. With a decryption time of only 8.5 ms, the suggested technique stands out as remarkable. This implies that, in comparison to the current encryption methods, the suggested approach may provide considerable gains in decryption efficiency.

Fig. 5. Decryption time comparison.

E. Latency

The amount of time required for a specific design to finish a specified (computational) task is known as latency. Latency is the amount of time it takes for data to travel across the internet from one location to another. The term "latency" describes how long an algorithm takes to complete a task; shorter latency times correspond to quicker algorithm performance.

Performance analysis of the delay of different encryptions is provided in Fig. 6. With a latency of 47.54 seconds, AES has the highest of all the encryption methods listed, followed by DES, which has a latency of 23.45 seconds. Furthermore, the delay for RSA is 20.67 seconds, while the next highest latency is 32.6 seconds for HE. The suggested encryption technique exhibits the lowest latency of 3.2 seconds, while IBE displays a latency of 14.5 seconds. This suggests that this algorithm performs better than the others.

Fig. 6. Latency comparison.

F. Restoration Efficiency

The efficacy and speed at which a service or system may be brought back up following a malfunction, outage, or data loss is referred to as restoration efficiency.

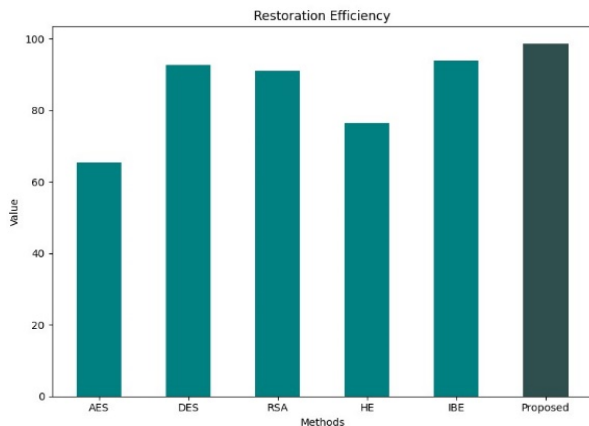

Fig. 7. Restoration efficiency comparison.

Performance analysis scores of restoration efficiency for different cryptographic methods are shown in Fig. 7. Additionally, DES obtained a better restoration efficiency score of 92.56 than AES, which got 65.4. Furthermore, in terms of restoration efficiency, RSA received a score of 91, HE earned 76.43, and IBE received an exceptionally high score of 93.9. With a restoration efficiency score of 98.5, the suggested method excels and demonstrates remarkable efficacy in quickly recovering systems or data protected by the technique.

G. Turnaround Time

The term "turnaround time" describes the length of time required to complete a process or task from beginning to end. Turnaround time, as used in the table, particularly refers to the milliseconds (ms) that each algorithm for cryptography requires to complete a given operation or computation.

The turnaround times, expressed in milliseconds (ms), for several cryptographic algorithms—AES, DES, RSA, HE, IBE, and a suggested algorithm—are shown in Fig. 8. With a turnaround time of 300 milliseconds, AES has the longest algorithmic delay of all the listed algorithms. With a turnaround time of 112 milliseconds, DES comes next. The turnaround time of the popular public-key encryption technique RSA is 95.3 milliseconds. The turnaround time for HE is 195 milliseconds, whereas the turnaround time for IBE is 92.54 milliseconds. It's interesting to note that, at 45 milliseconds, the suggested approach has the quickest turnaround time out of all those mentioned. This suggests a possible breakthrough in the efficiency of cryptography, providing much faster processing while upholding the essential security requirements.

H. Discussion

Existing cloud-based Key Management Services (e.g., AWS KMS, Azure Key Vault, and Google Cloud KMS) can be integrated with the HO-PREB system to manage encryption keys securely. The hybrid optimization algorithms (Owl and Bat optimization) used for key selection can interact with these services to dynamically generate and manage encryption keys.

Encrypted data can be stored in cloud-based storage services such as Amazon S3, Azure Blob Storage, or Google Cloud Storage. The proxy nodes will manage access to the encrypted data, ensuring that only authorized entities can decrypt and access the data. However, issues such as computational overhead, integration with existing infrastructure, and compatibility with various cloud service models could be addressed to provide a more holistic view. While the blockchain model adds scalability, further details on how the system handles large-scale data and high-frequency IoT transactions would enhance understanding. This includes the impact on network bandwidth and storage requirements as the number of transactions and data size increase.

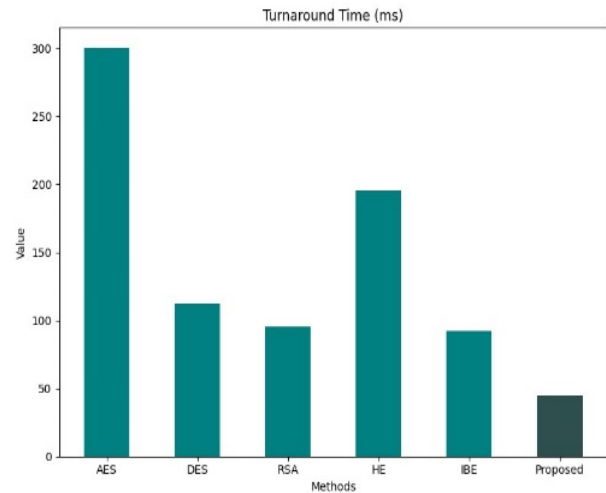

Fig. 8. Turnaround time comparison.

V. CONCLUSION

The hybrid optimization and threshold-based PRE system with consensus system, which is an innovative design that offers real-world applications for the safe sharing of IoT data, is proposed in this paper. It enables DO to effectively safeguard their encrypted data via SSP and share it with authorized users. The proposed solution can eliminate dependency on external central proxy servers by utilizing a distributed blockchain network and combining an optimized threshold PRE system with a blockchain consensus algorithm. The re-encryption of encrypted data can be computed during the consensus confirmation process of the distributed ledger network. Simulation studies showed that optimized threshold PRE can be successfully paired with the blockchain's consensus process to enhance cloud computing security and facilitate data exchange. In addition, when compared to other methods, the performance and scalability of the suggested system are adequate. The developed model attains encryption, re-encryption, and decryption times of 12.5 ms, 10.4 ms, and 8.5 ms. Also, gained less latency and a high restoration efficiency of 3.2s and 98.5%. The developed technique attains better performance to improve the cloud system's security, and it can detect and neglect attacks based on the proxy nodes in the consensus system. Also, there is potential to explore the integration of state-of-the-art cryptographic and machine learning methods to further enhance the security and efficacy of data exchange protocols.

ACKNOWLEDGMENT

The author extends the appreciation to the Deanship of Postgraduate Studies and Scientific Research at Majmaah University for funding this research work through the project number (R-2024-1241)

Abstract—In recent years, the internet has expanded rapidly, driving significant advancements in digitalization that have transformed day to day lives. Its growing influence on consumers and the economy has increased the risk of cyberattacks. Cybercriminals exploited network misconfigurations and security vulnerabilities during these transitions. Among countless cyberattacks, phishing remains the most common form of cybercrime. Phishing via malicious Uniform Resource Locator (URL)s threatens potential victims by posing as an imposter and stealing critical and sensitive data. An increase in cyberattacks using phishing needs immediate attention to find a scalable solution. Earlier techniques like blacklisting, signature matching, and regular expression method are insufficient because of the requirement to keep updating the rule engine or signature database regularly. Significant research has recently been conducted on using Machine Learning (ML) models to detect malicious URLs. In this study, the authors have provided a study highlighting the importance of significant feature selection for training ML models for detecting malicious URLs. Pearson correlation is employed in this study for selecting significant features, and the outcome demonstrates that in terms of accuracy and other performance indices, the Random Forest classifier outperforms the other classifiers.

Keywords—Malicious URL; machine learning; feature selection; Random Forest, cybercrime

I. INTRODUCTION

Phishing is a form of social engineering when a cyber threat actor poses as a reliable individual or group in order to trick a user into disclosing private information or unintentionally allowing access to their network [1]. Some attack techniques that use malicious URLs include Drive-by Download, Phishing and Social Engineering, and Spam [2-4]. The potential outcomes include data breaches, loss of data or services, identity theft, malware infections, or ransomware attacks. Usually, blacklists have been the primary tool employed for such types of detection. [5] Nevertheless, blacklists cannot be considered comprehensive and cannot detect freshly generated malicious URLs. In recent years, there has been an increasing demand for evaluating machine learning methods to enhance the efficacy of malicious URL detectors [6]. Humans are the most common threat vector and are known to be the root cause of 74% of data breaches, according to Verizon's "2023 Data Breach Investigations Report [7]. An organization called APWG [8] that studies and disseminates information about

malware and phishing scams, observed 1,077,501 phishing attacks in the last quarter of 2023. APWG recorded almost five million phishing attacks in 2023, which was deemed as the worst year for phishing activity. The Internet Crime Complaint Center [9] alone received a staggering approx. 300k reported phishing attempts. This number decreased from the previous year but increased significantly since 2018 when they received only 26,379 reports. Alameda Lost Nearly \$200M to Phishing Attacks [10]. According to statistics presented, attacks using malicious URL techniques are ranked first among the ten most common attack techniques [11, 12]. URL phishing involves sending emails to redirect recipients to a fictitious website and trick them into revealing sensitive data, such as confidential credentials or financial information to a malicious person. The website may appear legitimate, but its purpose is to exploit your trust by "phishing" for personal information that malicious actors can use for nefarious purposes. For example, an email containing a warning message of user activity on your bank account, credit card, or financial application. An email originating from an e-commerce or financial institution like Amazon or a bill desk warns about suspicious activity, such as a password breach. Users are redirected to click a URL to verify transactions or change their passwords. However, the link redirects them to a fake version of the application or website, where their login credentials are collected, or they are prompted to call "customer service". Phishing costs organizations millions to deal with malware and credential compromise situations and it also leads to productivity losses, further having a negative impact on company brand value. On an individual level there is financial loss and mental stress causing health complications. Phishing is considered the costliest attack. URL refers to resources on the Internet. In [13], Sahoo et al. URL is divided into protocol identifiers and resource names, which contain the IP address or the domain name pointing to the resource location.

A malicious URL is a variation of the original URL, which deceives the victim to visit the URL, leading to financial loss and theft of personal identification information such as identity, credit cards, etc. In recent years ML has played an important role in detecting malicious URL and overcoming some of the shortcomings of traditional methods. Large numbers of features degrade model performance in terms of latency, and the selection of features were not optimal, which leads in degrading the overall model accuracy.

The proposed study focuses on building models based on a set of appropriate features selected based on correlation, which will improve the overall trained model performance in terms of latency. This study determines whether the selecting subset of features has positive or negative impact on identifying malicious URLs with different machine learning algorithms. This is how remainder of the article is organized. Literature review is done in Section II. Next, in Section III, materials and methodology used for proposed model is discussed. A report on the experimental results obtained is covered in Section IV. The paper is concluded in Section V.

II. LITERATURE REVIEW

Many approaches have been developed in this area such as blacklisting, signature based, content-based classification, URL based classification. When machine learning is employed, the previous studies had different results for each algorithm and focused majorly on algorithm performance with all the extracted features. A tabular representation of work done by different researchers is shown in Table I.

TABLE I. LITERATURE REVIEW

Ref. No.	Technology	Dataset	Outcome and Limitation
[14]	Heuristics	16006 Benign and 5678 Malicious samples utilized	The increase in performance is accompanied by a false positive rate, which in practical settings generates a lot of false positive warnings. Besides this False negative rate was 46.15 % which was used for detection
[15]	List Based	5000 phishing websites from Phish Tank	NISOELM a unique method for phishing detection is proposed. Minor modification in the URL bypass the list and list must frequently be updated. To make sure that most malicious pages are identified with the presented information, the acquired knowledge must be updated on a regular basis as attackers modify their tactics.
[16]	Association rule based	collected over 1400 URLs from several sources and also 1200 phishing URLs from phishtank database	Large number of rules impact performance. Dataset consisted only of Binary attributes and only the phishing URLs are mined using the apriori algorithm for identifying the recurring patterns. No detection for newly arrived patterns.
[17]	Heuristics	Not specified	Proposed method consists of two processes, namely logo extraction and identity verification. Consider only 2 attribute website logo and domain name. Able to identify whether website logo and domain name are genuine or fake.
[18]	3 ML classifiers SVM, LR and Naïve Bayes	UCI machine learning repository, 11,055 URLs, each of 15uniquefeatures,	Performance impact due to model consider all feature for prediction. Naiye Bayes shows 100% accuracy but each feature weightage is same.
[19]	Machine learning	Not specified	Proposes a machine-learning framework for supporting intelligent web phishing detection and analysis, and provides its experimental evaluation. In particular we make use of state-of-the-art decision tree algorithms for detecting whether a Web site is able to perform phishing activities. Performance impact due to model consider all feature for prediction
[20]	Machine learning	public dataset comprising 2.4 million URLs (instances) and 3.2 million features	Random Forest and Multi-Layer Perceptron attain the highest accuracy. Performance impact due to model consider all feature for prediction

III. MATERIAL AND METHODS

A URL consists of the protocol, subdomain, domain, path [21, 22]. Within the path, there can be filename, query param. Domain name can be broken down into domain and top-level

domain. Malicious persons can add @ in the domain name or can use prefix/suffix in domain name. Length or depth of the URL is another feature which is exploited to deceive users. Use of HTTPS in the domain name to deceive the user into clicking the URL believing that it is a secure site. The structure of a URL is shown in Fig. 1.

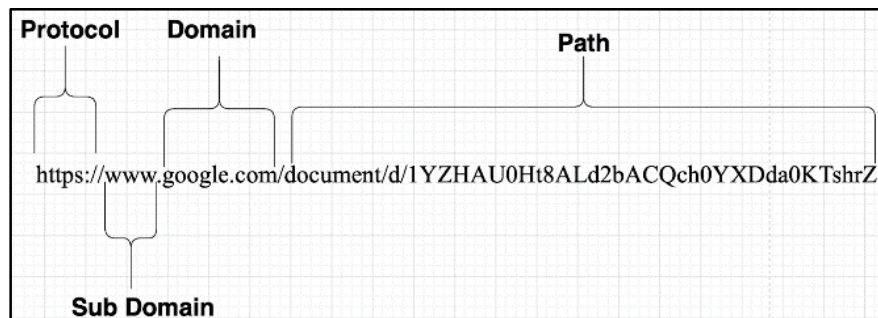

Fig. 1. Structure of a URL.

Model for malicious URL detection is created using a jupyter notebook and serialized on disk in pickle format. Flask server was deployed to host the model and GET/POST route was defined to handle the incoming GET/POST request to render the UI for user input and user input is posted to the server

for predicting the URL safe or not. Fig. 2 presents the malicious URL detection methodology steps. These steps are explained in next section. Also Fig. 3 represents the User interface created for detection of a URL to be malicious or not.

Fig. 2. Malicious URL detection flow.

Fig. 3. User interface for URL checker.

A. URL Dataset

Suspicious URLs can be sent to Phishtank for verification https://www.phishtank.com/developer_info.php. The data in Phishtank is updated hourly. Phishtank is a free community site where anyone can submit, verify, track and share phishing data. This dataset is in the form of .csv file format. The models used in this manuscript dataset is fetched from phishtank. Besides this other source for similar dataset are available at <https://urlhaus.abuse.ch/downloads/csv/> , URL has is a project from abuse.ch aiming at sharing malicious URLs being used for malicious software distribution, and dataset from Kaggle <https://www.kaggle.com/datasets/sid321axn/malicious-urls-dataset>, was used to host the data set for malicious and legitimate.

B. Feature Extraction

Feature extraction is one of the critical steps in the process of machine learning based malicious URL detection. Machine learning models require numeric value for training. For this purpose, essential characteristics of URLs are identified and passed to a function which converts the field value to 0 or 1 or other numeric values to distinguish malicious from benign. Tokenization and Lexical feature selection method is used for feature extraction Based on this criterion, the features are categorized in two different groups - Address bar based and domain-based features. In the case of Address bar-based features, features are selected from the lexical group of URLs, and are summarized in Table II. The address bar in web browsers is a powerful tool that goes beyond just entering website URLs. Below are the address bar features implemented

in this project that goes beyond just entering website URLs. Tokenization is one of the techniques for feature extraction. It is defined as transforming a single string into a sequence of one or more non-empty substrings. Tokenization is performed utilizing the special characters (slash, dash and dot) in URLs. Once the token is extracted, it is passed to a function to check the characteristics such as DNS record validity or age of domain. This is characterized as Domain based features. Domain based features extracted from selected dataset is represented in Table III.

Selection of non-significant features can significantly impact a model performance besides increasing the model complexity. Selects a subset of relevant features while keeping the original feature space intact. The focus is on identifying the most informative features for modeling. The feature selection process is a step in building a machine learning model, performed by selecting a subset of the features in a set of extracted features. Feature selection aims to discover the most relevant and significant features for predicting the target variable. Feature selection has various benefits, such as Improved model interpretability, Reduced danger of overfitting, and improved model performance. Numerous methods for feature selection include filtering, wrapper approaches, and embedded approaches. Pearson correlation is employed and used to evaluate the model performance in the current work. Pearson correlation finds the correlation between features. Fig. 4 is the correlation matrix for the feature extracted to select the high-correlated and low-correlated features for training and evaluating the model.

TABLE II. DESCRIPTION OF ADDRESS BAR BASED FEATURES

S. No	Features	Description
1.	Domain	Extract the domain name
2.	Hostname/IpAddress	Parse the URL to extract an IP address . URLs may have IP address instead of domain name. Presence of an IP address alternative of the hostname name in the URL can be an indicator of malicious site
3.	@ symbol	In standard URL syntax, the "@" symbol is reserved for use in the format username@hostname. Anything before the "@" symbol is often interpreted as a username, and the browser ignores this part when resolving the URL Phishers exploit this behavior by inserting a legitimate domain name after the "@" symbol, making it appear as if the link leads to a trusted website. However, the actual website visited is determined by what follows the "@" symbol, not what precedes it.
4.	URL length	Phishers obscure the URL by creating the long URL such that the user will not be able to differentiate a legit URL or malicious URL by masking the doubtful part of the address bar
5.	URL Depth	Computing the depth of a URL involves counting the number of levels or subdirectories in the URL path, typically separated by "/"
6.	Redirection //	"/" in a URL path reveals potential redirection or URL misconfiguration. Unexpected "/" positions could indicate unintended redirects or errors in URL formation.
7.	Http/Https	Phishers may add "HTTPS" to the domain (e.g., http://www.httpssecurelogin.com) to deceive users into believing a secure connection exists.
8.	URL Shortening Service	Services such as T2M, tine.be, Tiny URL, T.LT etc is a characteristic of malicious URL
9.	Prefix/Suffix '-'	Phishers use prefixes or suffixes to the domain name separated by some known separator such as "-" which makes it impossible for the user to distinguish that users feel that they are dealing with a legitimate website, for e: g www.example.com www.ex-ample.com

TABLE III. DESCRIPTION OF DOMAIN-BASED FEATURES

S. No	Domain features	Details
1.	DNS Record	WHOIS database does not recognize phishing websites identity or no records found for the hostname in DNS server
2.	Website Traffic	Top ranked websites are provided by Cisco Umbrella [26][27]. Alexa is no longer available. For the purpose of this research websites ranked among the top 100,000 is considered legitimate
3.	Age of Domain	Find the age of the domain by querying WHO database. Phishing websites are available for a short period. This research considers the minimum age of the legitimate domain, which is 12 months. Age here is nothing but different between creation and expiration time

The Pearson correlation coefficient, which is often denoted as r , is a measure of the linear correlation between two variables X and Y . It lies between -1 and +1. It is defined as:

$$r = \frac{\sum_{i=1}^n (x_i - \bar{x})(y_i - \bar{y})}{\sqrt{\sum_{i=1}^n (x_i - \bar{x})^2} \sqrt{\sum_{i=1}^n (y_i - \bar{y})^2}} \quad (1)$$

Where

- n is sample size
- x_i, y_i are the individual sample points indexed with i
- $\bar{x} = \frac{1}{N} \sum_{i=1}^n x_i$ is the simple Mean for X
- $\bar{y} = \frac{1}{N} \sum_{i=1}^n y_i$ is the sample mean for Y

Fig. 4. Heat map of features.

For ease of modeling a threshold of .01 is chosen to filter significant features. Tabular representation of classification of features is shown in Table IV. Extracting the feature importance from the model which was created using all the features matches the correlated features. Table IV shows the segregation of features in URL based on the significance of the features.

Graphical representation of importance of figures is shown in Fig. 5. The graph clearly depicts that URL features like 'URL_Depth', 'Domain_Age' are most significant whereas features such as 'https_Domain', 'Have_IP' are least significant in characterizing a URL as malicious.

TABLE IV. TABULAR REPRESENTATION OF CLASSIFICATION OF FEATURES

Feature set name	List of features
All features	{'Have_IP', 'Have_At', 'URL_Length', 'URL_Depth', 'Redirection', 'https_Domain', 'TinyURL', 'Prefix/Suffix', 'DNS_Record', 'Domain_Age', 'Domain'}
Top correlated Features	{'Domain_Age', 'DNS_Record', 'Prefix/Suffix', 'URL_Depth', 'URL_Length'}
Least correlated Features	{'https_Domain', 'Redirection', 'Have_IP', 'TinyURL', 'Have_At'}

Fig. 5. Importance of feature.

C. Model Development and Performance Evaluation

Machine learning algorithms for detecting malicious URLs have been studied and are widely applied [23,24]. Supervised machine learning algorithms are classified and regression. This data set comes under classification problems, where the input URL is either phishing 1 or legitimate 0. The supervised machine learning models considered for training the dataset in this notebook are, Decision Tree and Random Forest. The model was trained with a decision tree and random forest algorithm with “all features”, “Top correlated features”, and “Least correlated features”, as outlined in Table IV earlier. Decision trees are widely employed models for classification and regression-related tasks. Fundamentally, they learn a hierarchy of if/else questions to determine a decision. Learning a decision tree implies learning the pattern of if/else conditions that optimally lead to the true answer. In the machine learning setting, these questions are called tests (not to be confused with the test set, which is the data that is used to test to interpret the model generalizability. A decision tree consists of nodes representing decisions on features, branches representing the result of these decisions, and leaf nodes representing predictions. Internal nodes are an examination of a feature, and each branch corresponds to the outcome of the test, and each leaf node fits a class label. A random forest which is an ensemble model of decision tree, works by creating multiple decision trees. The idea behind random forests is to build a tree using random samples from the training dataset. The random forest combines the output of individual decision trees to generate the final output by averaging their results. They are powerful, often work well without heavy tuning of the parameters, and don’t require data scaling. The entire data set of URLs containing legitimate and phishing URLs is then divided into 4 variables, X_train, X_test, Y_train, Y_test using the ‘sklearn.model_selection’ module/library. X_train: This variable holds the features (input variables) for the training set. In this paper, use these features to train your machine learning

model. X_test: This variable holds the features for the testing set. In this paper, these features evaluate the performance of your trained model on unseen data. y_train: This variable holds the target variable (output variable) corresponding to the training set. It contains the expected outcomes for the training data. y_test: This variable holds the target variable corresponding to the testing set. It contains the expected outcomes for the testing data, which you use to compare against the predictions made by your trained model. Following model performance metrics are captured for performance assessment. True Positive (TP), False Positive (FP), True Negative (TN) and False Negative(FN) are some of the variables defined in confusion matrix. These are used for calculating the performance of a machine learning classification model as are used in Eq. (2)-Eq. (5) [28]. In context to calculating the ML model performance for detection of URL as malicious or genuine the performance measures are defined as

1) *Precision*: It is the ratio of true positive URL among the total number of positive URL predicted

$$\text{Precision} = \frac{TP}{TP+FP} \quad (2)$$

2) *Recall*: It is the ratio of predicted true URLs and the total number of actual true URL which is sum of true positive and false negative predicted URL.

$$\text{Recall} = \frac{TP}{TP+FN} \quad (3)$$

3) *F1 Score*: It is the harmonic mean of precision and recall.

$$\text{F1 Score} = 2 \cdot \frac{\text{Precision} \cdot \text{Recall}}{\text{Precision} + \text{Recall}} \quad (4)$$

4) *Accuracy*: Success rate of the URL prediction technique and is coined as the ratio of True predicted to all the the samples in the dataset

$$\text{Accuracy} = \frac{TP+TN}{TP+TN+FP+FN} \quad (5)$$

IV. MODEL SETUP AND RESULTS OBTAINED

Setup environment: Operating System - Mac OS, Language - Python 3.12.2 Web framework - Flask, Model builder = Jupyter notebook, ML framework/tools - Pandas, scikit-learn,

Numpy Hardware: RAM 16 GB 3733 MHz LPDDR4X; 2 GHz Quad-Core Intel Core i5. The experiment extracted the features from the legitimate URL and phishing URL data set and labeled accordingly. The data set used for the experiment is of 10k records which include the 5k phishing and 5k legitimate URL. Fig. 6 shows the distribution of the individual features values in the dataset used for detection of malicious URL [25].

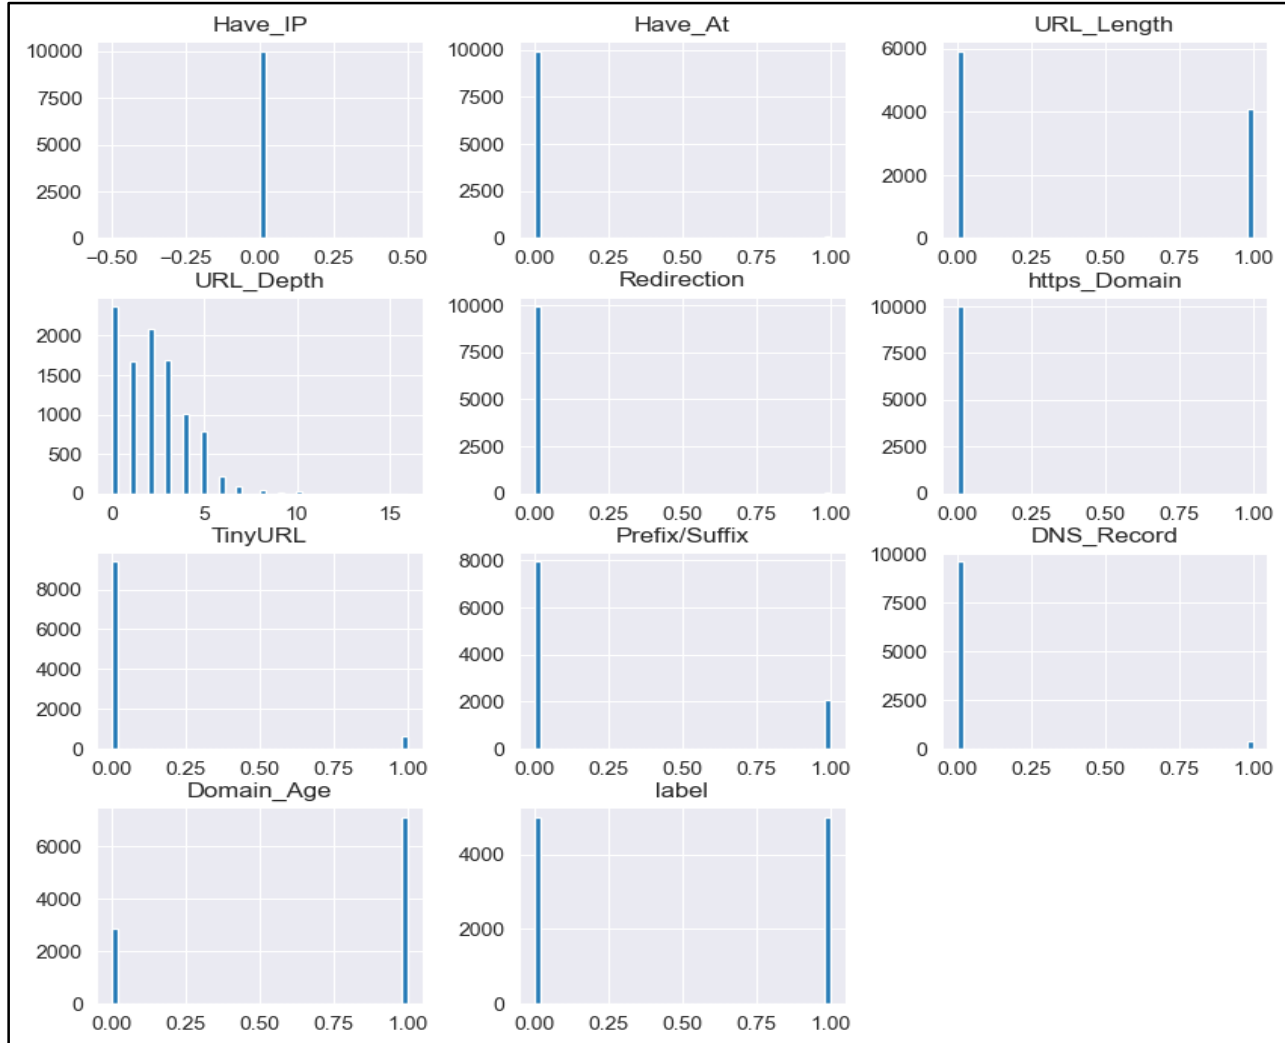

Fig. 6. Feature distribution.

In this paper, models were trained using machine learning models of decision tree and Random Forest after splitting dataset into training and testing with 80% of data used for training the model and tested on 20% of data with following set of features

- ALL
- TOP correlated
- LEAST correlated

Table V and Table VI shows the performance parameters obtained from Decision tree and its ensemble version Random Forest model. The parameters considered for assessment of models are accuracy, F1 score, Recall and Precision are best for the decision tree. Below is the metric for performance

assessment of Decision Tree model based considering ALL, TOP and LEAST correlated features. Tabular representation of performance parameters discussed earlier for Decision tree ML model is represented in Table V.

TABLE V. DECISION TREE MODEL

	ALL	TOP	LEAST
Accuracy	0.913	0.899	0.504
F1 Score	0.908	0.884	0.035
Recall	0.853	0.820	0.018
Precision	0.970	0.959	0.934

Because latency has a direct impact on how well systems operate in real time, it is also considered as a significant parameter for selecting one model over another [26]. Lower latency is preferable. The wait time for a result is known as latency. A ML model is not considered good if there is a noticeable waiting period before the occurrence of the responses. Improving latency is crucial since every system aspires to operate in real time [27]. An analysis of the time taken (latency) by the model to test 20% of the data where Decision Tree model is built using different set of features is as below.

- All features = 0.0033ms
- Top correlated = 0.0016ms
- Least correlated = 0.0026ms

Considering an ensemble model of Decision tree which is Random forest, performance parameters are rechecked.

Tabular representation of results obtained using ensemble model is represented in Table VI.

TABLE VI. RANDOM FOREST MODEL

	ALL	TOP	LEAST
Accuracy	0.953	0.947	0.504
F1 Score	0.946	0.924	0.035
Recall	0.876	0.873	0.018
Precision	0.978	0.967	0.857

Table VI shows the performance of Random Forest model for detection of URL as malicious or not. Latency by the Random forest model to test 20% of the data where Random Forest model is built using different set of features are obtained as follows:

- All features = 0.0027ms
- Top correlated = 0.0010ms
- Least correlated = 0.0020ms

TABLE VII. COMPARATIVE STUDY WITH EXISTING RESEARCH WORK DONE

Reference No.	Multiple ML models Used	Results:				Features in Modelling	Model Complexity	Latency Considered
		Accuracy	F1 Score	Recall	Precision			
[28]	yes	NA	High	High	High	Considered all features	High	No
[29]	yes	High	High	High	High	Not considered	NA	No
[30]	Yes	High	NA	NA	Good	Lexical features	NA	No
[31]	Yes	High	High	High	High	semantic and contextual features	High	No
Proposed work	Yes	High	High	High	High	Considered only significant Features without compromising on Performance	Reduced as only significant Features considered.	Yes

Decision tree and Random Forest model metric are similar and also perform similarly with the given URL dataset for selected feature sets. Random Forest uses a default estimator=100 of trees on a URL dataset. Ensemble model of Decision tree which is Random Forest performance is better in terms of performance indices as well as in terms of computation time. Besides this by reducing the number of features it can be clearly stated that the performance of model remains unaffected by reducing the number of features and selection only significant features for models designing. This will also reduce model complexity without compromising on model performance. However, the using the top correlated features shows significant model performance improvement in both Decision Tree and Random Forest. Table VII shows a comparative study on the model proposed and those used by researchers in similar domain.

V. CONCLUSION

The early systems were dependent upon patterns of known malicious URLs, rule-based methods. These systems are excellent in protecting the user from known malicious URLs but are inefficient in securing them from new emerging attacks. Although some attempts were made to build a model using ML but due to resource intensive, there is inefficiency in ML based malicious URL detection because the models have mostly considered either all the features which including non-

correlated features or least significant features as well. While accessing performance the models performs well but fail to justify the response time or latency of the model. In this study, a comprehensive study on URLs like phishing or legitimate is used to analyze ML models based on the different feature selection and a study on the impact of feature selection is done. By using all the features or using only the most correlated features have slight impact on the performance of model parameters accuracy, F1 score, recall and precision but the difference in the model latency is quite significant with most correlated features and all features. This shows that using all the features impact the URL detection performance significantly with minimal gain in accuracy. Using highly correlated features helps in reducing the number of features which leads to reduction in model complexity and will further improve the model performance in terms of latency with minimal or negligible impact on the model performance.

Abstract—The integration of cutting-edge technology in agriculture has revolutionized traditional farming practices, paving the way for Smart Agriculture. This research presents a novel approach to enhancing the cultivation of orchard crops by combining deep-stream algorithms with drone technology. Focusing on pomegranate farming, the study employs a drone system with four specialized cameras: thermal, optical RGB, multi-spectral, and LiDAR. These cameras facilitate comprehensive data collection and analysis throughout the crop growth cycle. The thermal camera monitors plant health, yield estimation, fertilizer management, and irrigation mapping. The optical RGB camera contributes to crop management by analyzing vegetation indices, assessing fruit quality, and detecting weeds. The multi-spectral and hyperspectral cameras enable early detection of crop diseases and assessment of damaged crops. LiDAR aids in understanding crop growth by measuring plant height, tracking phenology, and analyzing water flow patterns. The data collected is processed in real-time using Deep Stream algorithms on an NVIDIA Jetson GPU, providing predictive insights into key farming characteristics. Our model demonstrated superior performance compared to four established models—MDC, MLP, SVM, and ANFIS—achieving the highest accuracy (95%), sensitivity (94%), specificity (96%), and precision (91%). This integrated method offers a robust solution for precision agriculture, empowering farmers to optimize crop management, enhance productivity, and promote sustainable agriculture practices.

Keywords—Smart agriculture; crops; cultivation; deep stream algorithms; drone and technology

I. INTRODUCTION

Modern agriculture is undergoing a significant shift as a result of technological developments that promise to increase production, sustainability, and efficiency. One such innovative strategy is the use of deep stream algorithms and drone technology to revolutionise pomegranate farming. With their high nutritional content and rising demand, pomegranates stand to gain a lot from these cutting-edge methods. The use of drones outfitted with a variety of specialised cameras and cutting-edge data processing techniques is presented in this

study as a comprehensive framework for automating the cultivation of pomegranates [1]. The fouronboard cameras—thermal, optical RGB, multi-spectral, and LiDAR—provide an abundance of real-time data that gives producers priceless insights into numerous facets of crop health and growth dynamics. A key component of this system is the thermal camera, which makes exact plant health assessments, precise irrigation mapping, effective fertiliser control, and yield estimation possible. This camera assists in the early diagnosis of stressed or unhealthy plants by collecting temperature fluctuations, enabling prompt treatments and optimising resource allocation. The optical RGB camera completes this functionality by measuring vegetation indices, evaluating the quality of the fruit, and even spotting weeds. This helps users make better decisions [2]. Multi-spectraland hyper-spectral cameras are essential for a more detailed analysis of crop conditions. They can recognize physical and biological traits that can point to underlying problems in pomegranate harvests to spot disease symptoms [3]. This ability guarantees early disease identification, enables individualized treatment plans, and reduces possible yield losses.

To maintain crop health and yield, UAVs mounted with thermal cameras could be used to monitor temperature differences in orchard crops. This allows for the early detection of plant stress, disease, or water inadequacies. Optical RGB cameras monitor crops' visual health and growth stages by taking high-resolution pictures for the analysis of vegetation indicators, fruit quality evaluation, and weed detection. Multispectral and hyperspectral cameras offer extensive spectral information to identify disease signs, nutrient deficits, and other physiological characteristics. This information enables precise, focused treatments to improve crop health and decrease losses. LiDAR technology provides vital insights into growth dynamics and optimizes irrigation techniques for more effective water use and improved orchardcrop management. Navigating UAVs mounted with such

LiDAR could also measure plant height, track crop phenology, and examine water flow patterns.

A. Related Works

Authors in study [4] used UAVs in apple orchards using thermal and RGB imagery to detect frost damage, evaluate fruit sets, predict yields, and monitor bloom stages to improve thinning practices. Similarly, in study [5], the authors installed multi-spectral cameras over UAVs to navigate the citrus groves to identify diseases such as citrus greening, allowing for targeted therapies to minimize the spread of the disease. Drones are used in vineyards [6] to monitor vine health, evaluate grape quality, identify illnesses, and plan precise fertilization by using multi-spectral imagery to pinpoint nutrient deficiencies. Very recently, Sanchez et al. [7] used drones in olive orchards to improve irrigation schedules, map canopy structure, monitor water stress, and evaluate tree health using LiDAR data. In this work, we especially focus on pomegranate orchard management, building on the wide-ranging uses of UAVs in different orchard crops. With deep stream algorithms and drone technology, this extension seeks to optimize pomegranate agriculture and improve crop sustainability, productivity, and health.

The LiDAR camera provides crucial information on crop phenology, water flow patterns, and plant height. This new information improves our comprehension of pomegranate growth dynamics. It helps us make the best irrigation decisions, resulting in more effective water use and sustainable farming methods [8]. The investigation uses the potent NVIDIA Jetson GPU for data processing to take advantage of the enormous amount of data these cameras have acquired. The system analyses the acquired data in real-time while utilizing deep-stream algorithms, allowing precise forecasts in key pomegranate cultivation areas. This entails monitoring crop health, analysing how dry the soil and vegetation are, determining how much fertilizer is needed, finding and controlling weed infestations, and quickly spotting instances of crop damage and disease.

The use of mechatronics, sensors, and IoT in agriculture is now essential, with drones emerging as a viable tool for mapping field variability and optimizing input applications. Drones have applications across various stages of plant growth and sectors such as livestock, horticulture, and forestry, enhancing field monitoring and decision-making [9], [10]. The survey in [11] examines various UAV applications, types, sensors, and architectures, comparing them with traditional technologies and highlighting their benefits and challenges in precision agriculture. The article [12] reviews the use of UAVs for crop monitoring and pesticide spraying, which helps improve crop quality and mitigate health risks associated with manual pesticide application. Conventional weed management methods are inefficient for integration with smart agricultural machinery, whereas automatic weed identification significantly improves crop yields. The study in [13] evaluates deep learning techniques (AlexNet, GoogLeNet, InceptionV3, Xception) for weed identification in bell pepper fields, with InceptionV3 achieving the highest accuracy of 97.7%, demonstrating the potential for integration with image-based herbicide applicators for precise weed management. UAV-based sprayers precisely target hard-to-reach areas, as

demonstrated in a cotton field study [14] using advanced imaging and optimization techniques, achieving effective droplet deposition with a GWO-ANN model showing high prediction accuracy. UAV imagery with an in-house web application, "DeepYield," [15] uses deep learning models like SSD, Faster RCNN, YOLOv4, YOLOv5, and YOLOv7 to measure citrus orchard yields. Here, YOLOv7 excelled with a mAP, Precision, Recall, and F1-Score of 86.48%, 88.54%, 83.66%, and 86.03%, respectively, and the solution was integrated into DeepYield for automated yield estimation.

Water flow mapping, crop phenology monitoring, and plant height measurement have all benefited from the use of LiDAR technology. Prominent research, like [16], has shown how important it is for comprehending development dynamics and making the most use of water. Deep Stream Algorithm with NVIDIA Jetson GPU: The combination of these two technologies has proved essential for data processing. The effectiveness of this arrangement in real-time analysis was demonstrated by research by [17], allowing predictions in crop health, soil dryness, fertilizer needs, weed identification, and disease detection [18]. The literature has recognized that there are challenges with calibration, data quality, and system scalability [19]. Further developments will involve improving algorithms, adding meteorological information, and customizing systems for certain crops and geographical areas. Table I-B summarizes recent studies on applying drones and various sensors in orchard crops, covering yield estimation and the learning model used in the works.

B. Motivation

Agriculture is undergoing a technological transformation with the integration of unmanned aerial vehicles (UAVs), commonly known as drones, and advanced algorithms [20]. This literature survey explores the state-of-the-art in the automation of pomegranate cultivation, focusing on the use of drones equipped with thermal, optical RGB, multi-spectral, and LiDAR cameras. The processing of collected data is facilitated by the NVIDIA Jetson GPU using deep-stream algorithms, enabling real-time predictions for various aspects of crop management. The capacity of drone technology to deliver high-resolution, real-time data for precision farming has made it more and more popular in the agricultural sector. Prior research, such as that done by [21], showed how useful drones are for determining crop health, maximizing resource utilization, and increasing production. Plant health inspections have made considerable use of thermal cameras. Thermal imaging is useful in identifying stress factors, refining irrigation plans, and calculating crop yields, according to research by Messina et al. [22]. Optical RGB Imaging for Vegetation Indices and Quality: Research, such as the work by Devi et al. [23], highlights the application of optical RGB cameras for weed detection, fruit quality evaluation, and vegetation index measurement. This all-inclusive method helps to create accurate crop plans. Hyper- and Multi-Spectral Imaging for Illness Detection: Researchers have looked at the use of hyper- and multi-spectral cameras for illness detection [24]. These cameras can analyze both biological and physical parameters and identify damaged crops based on spectral fingerprints.

TABLE I. DRONE AND SENSOR APPLICATIONS IN ORCHARD CROPS

Authors	Crop Type	Work Description	Type of Sensor Used	Methodology	Model Developed	Accuracy
He et al. [25]	Apple	Yield estimation, health monitoring	RGB, Thermal Cameras	Image analysis, temperature mapping	Regression Model	92%
Jemaa al. [26]	Apple	Health prediction	RGB, Thermal Cameras	Health index calculation, stress mapping	SVM	89%
Chandel al. [27]	Apple	Irrigation scheduling	Thermal, RGB Cameras	Soil moisture mapping, temperature analysis	Regression Model	90%
Sun al. [28]	Citrus	Yield prediction, soil dryness detection	Multi-Spectral Camera	Spectral reflectance analysis	SVM, KNN	87%, 85%
Modica al. [29]	Citrus	Irrigation optimization	Multi-Spectral Camera	Spectral reflectance analysis	SVM	87%
Lan al. [30]	Citrus	Yield prediction	Multi-Spectral Camera	Spectral reflectance analysis	SVM	89%
Marques al. [31]	Olive	Water monitoring stress	LiDAR, RGB Cameras	Canopy structure analysis, water stress indexing	ANN	88%
Ferro al. [32]	Vineyard	Yield prediction, health monitoring, weed presence	RGB, Multi-Spectral	Vegetation index calculation, clustering, weed mapping	K-Means, ANN	91%, 90%
Jones al. [33]	Vineyard	Yield prediction	RGB, Multi-Spectral	Vegetation index calculation, clustering	K-Means, ANN	94%
Miranda al. [34]	Pomegranate	Yield monitoring, irrigation optimization	RGB, Thermal, LiDAR	Multi-modal data analysis	Deep Learning	95%
Zhang al. [35]	Pomegranate	Disease crop detection, damage detection	RGB, Thermal, LiDAR	Multi-modal image analysis	Deep Learning	93%
Olorunfemi et al. [36]	Pomegranate	Yield monitoring	RGB, Thermal, LiDAR	Multi-modal image processing	Deep Learning	95%

The literature review highlights the increasing amount of research on automated crop production, especially with pomegranates, using deep-stream algorithms and drone technology. All of the research included in the survey demonstrates how this strategy may be used to maximize the use of available resources, increase crop productivity, and support sustainable agriculture. However, despite significant advancements, there remain notable gaps in the integration and application of these technologies, specifically for orchard crops such as pomegranates. This research addresses these gaps by proposing a comprehensive approach combining drone technology with deep-stream algorithms to optimize pomegranate cultivation.

Previous studies have examined the application of UAVs with different sensors in agriculture. Still, there is a lack of research specifically addressing the customization of these technologies for orchard crops such as pomegranates. Previous studies have primarily focused on general crop management, neglecting the specific needs of orchard farming. This field requires more precise and specialized approaches that have yet to be thoroughly explored. In addition, there is still much to be explored regarding integrating real-time data processing with deep-stream algorithms. Specifically, there is a need to understand how this integration can improve decision-making in pomegranate farming. This study addresses the existing gaps in the field by presenting a fresh approach that utilizes advanced cameras (thermal, optical RGB, multi-spectral, and LiDAR) installed on drones. These cameras are combined with the high-speed processing capabilities of deep stream algorithms on an NVIDIA Jetson GPU. With this integration, you can closely monitor and manage every stage of the pomegranate growth cycle. This provides valuable insights for enhancing yield, promoting plant health, and ensuring high-quality crops. Focusing on pomegranates, a crop boasting high nutritional value and growing demand, this research tackles a specific need in the agricultural sector.

Moreover, it contributes to advancing sustainable and precision agriculture. The study's findings highlight the immense potential for transforming orchard farming and offer a solid foundation that can be applied to other crops. This has the potential to expand the advantages of Smart Agriculture practices to a wider range of crops.

A game-changing strategy for modernizing pomegranate production is presented via the combination of drone technology with deep stream algorithms. In the dynamic environment of pomegranate farming, this work aims to provide farmers with a cutting-edge toolkit that enables them to make data-driven decisions, improve production, and support sustainable agricultural practices. The following are key contributions of this research article:

- Introduces a pioneering approach combining drone technology and deep stream algorithms for pomegranate production.
- Provides farmers with advanced tools for data-driven decision-making in pomegranate farming.
- Enhances pomegranate yield and quality through precise monitoring and analysis.
- Promotes sustainable agricultural practices in pomegranate cultivation.

The rest of the article is organized as follows: Section II provides the methodology of how UAVs operate, particularly for agricultural applications, and how their built-in sensors are utilized for crop management in orchards. It also focuses on how the Deep Streaming technique is deployed for pomegranate cultivation. Section III shows how the processing power of the NVIDIA Jetson GPU is used for the automated cultivation of pomegranates. Finally, Section IV summarizes the key findings of the work with the conclusion of the proposed work.

II. METHODOLOGY

This section focuses on the methodology used for the investigation in terms of data collection, camera analysis and the implications and association of deep streaming framework applied over the UAV data of pomegranate cultivation. In Fig. 1, the present investigation illustrates a revolutionary approach to enhance pomegranate farming that combines deep-stream algorithms and drone technology. The drone system has four specialized cameras: a LiDAR camera, a thermal camera, an optical RGB camera, and a multi-spectral camera. These cameras are effective tools for comprehensive data gathering and analysis throughout the pomegranate growing cycle. For yield estimation, fertilizer management, irrigation mapping, and plant health assessment, the thermal camera is crucial. By detecting variations in plant temperature, the thermal camera helps identify stressed or ill plants and allows for quick response. The optical RGB camera's capability to monitor vegetation indices, assess fruit quality, and detect weeds further enhances crop management techniques [37]. The multi-spectral and hyperspectral cameras allow for the identification of harmed crops and the examination of their biological and physical characteristics. The multi-spectral analysis enables early diagnosis of agricultural diseases, enabling customized treatments. The LiDAR camera aids researchers in their understanding of how plants grow by measuring plant height, monitoring crop phenology, and looking at water flow patterns. The NVIDIA Jetson GPU and deep stream algorithms are employed to process the camera data. This processing pipeline allows for real-time analysis of the gathered data, giving predictive insights into several essential aspects of pomegranate cultivation. The use of technology facilitates crop health monitoring, evaluates soil and plant moisture, establishes the demand for fertiliser, finds weeds, and scans for disease and crop damage indicators [38]. Overall, this work provides an integrated approach to pomegranate cultivation that combines deep stream algorithms and drone technology to enable accuracy and data-driven decision-making.

A. Brief Mechanism of Drones and its Associated Sensors

UAVs are becoming indispensable instruments in contemporary agriculture, especially for precision farming. Multiple sensors can be carried by them, enabling thorough monitoring and analysis of crop productivity, growth, and

health. Here, we go over how drones work and how their built-in sensors are utilized for crop management in orchards.

UAVs used in agriculture could be integrated with multiple essential parts to enable them to carry out certain jobs efficiently [39]. UAVs can hover, navigate, and gather data over wide distances because of the flying system's stability and maneuverability, which is provided by a lightweight frame, motors, propellers, and battery. GPS, accelerometers, gyroscopes, and magnetometers are examples of navigation and control components that provide precise navigation and flight path maintenance, enabling pre-planned missions and real-time modifications. The communication system enables remote operation through ground control stations and real-time data transfer via radio frequencies or cellular networks [40].

UAVs' sensors greatly increase their efficacy in precision agriculture because each one gives vital information for thorough crop management. For example, infrared radiation released by plants fluctuates with temperature and may be detected by thermal cameras [41]. This radiation can be used to identify stress factors such as pest infestation, disease, or water shortage. Thermal cameras are used in agricultural applications to detect temperature differences within the crop canopy. This allows for the monitoring of general health, early identification of plant stress, and watering requirements. With the aid of these cameras, temperature fluctuations inside the crop canopy can be identified, facilitating the early identification of plant stress, the need for irrigation, and general health monitoring. To create high-resolution images of the crop canopy, optical RGB cameras collect visible light in the red, green, and blue wavelengths [42]. These images are then used to monitor fruit quality, identify weeds, and assess vegetation indices, which helps farmers make decisions about crop health and management techniques.

Beyond the visible spectrum, multispectral and hyperspectral cameras record information in a variety of wavelengths, such as ultraviolet and near-infrared. To provide comprehensive spectral information necessary for identifying certain crop situations including nutrient deficits, disease signs, and physiological stress, hyperspectral cameras gather data in hundreds of small spectral bands. Precision medicine and targeted interventions are made possible [43].

Fig. 1. Core functional modules in the proposed methodology.

Fig. 2. Thermal imaging for plant health assessment.

LiDAR cameras measure plant height, track crop phenology, examine water flow patterns, and produce precise 3D maps of the landscape and vegetation structure using laser pulses. Understanding the dynamics of plant growth, improving irrigation techniques, and improving crop management generally all depend on this data.

Yield prediction integrates data from thermal, RGB, and multi-spectral sensors to estimate possible yields [44]. Water use is optimized by irrigation management through the use of thermal and LiDAR data. Through multispectral and hyperspectral analysis, health monitoring identifies nutritional inadequacies and early indicators of disease. Using accurate data, resource optimization effectively handles inputs such as fertilizers. With the help of these cutting-edge technologies, orchard crop management, and productivity may be fully monitored and managed, improving agricultural sustainability and production.

B. Thermal Camera Analysis

To evaluate the health of pomegranate plants, identify stress, and track temperature changes, thermal images of the plants should be taken. Maps of temperature distribution made from thermal data can be used to find possible problem locations. Use the heat data to calculate yields, control fertilizer applications, and map irrigation. Technological developments have made it possible for creative methods of crop management and optimization in modern agriculture [45]. Utilizing thermal imaging to evaluate plant health, identify stress, and track temperature swings in pomegranate plants is one such groundbreaking method. Farmers and agronomists can enhance irrigation techniques, control fertilizer use, and predict crop production by utilizing the potential of thermal data.

1) *Thermal imaging for plant health assessment:* Radiometric temperature readings from pomegranate plants are obtained using thermal cameras. Stressed or ill plants show temperature anomalies, whereas healthy plants have rather consistent thermal fingerprints. Areas of possible concern can be located by analyzing these thermal images, enabling focused intervention and mitigation as shown in Fig. 2.

2) *Stress detection and temperature variations:* Thermal imaging is a non-invasive method for identifying signs of stress in pomegranate trees. Temperature changes inside the plant canopy can emphasize stress brought on by things like a lack of water, an unbalanced diet, or pest infestations as shown in Fig. 3. Knowing these stress patterns allows for early

detection and prompt intervention.

3) *Temperature distribution maps for precise insights:* The generation of maps showing the spread of temperature in pomegranate orchards is made easier by processing the thermal data that was gathered. These maps give farmers a visual representation of temperature differences throughout the entire field, allowing them to locate “hot” or “cold” areas that might be signs of unequal irrigation, drainage problems, or other specific problems as shown in Fig. 4.

4) *Accurate irrigation mapping:* Thermal data reveals regions with high temperatures, indicating potential water stress, which aids in precise irrigation mapping. Farmers can adjust their watering schedules to maintain consistent moisture distribution and reduce water-related stressors by associating these temperature differences with particular irrigation zones as shown in Fig. 5.

Fig. 3. A Sample stress detection in an agricultural land observed through thermal camera.

Fig. 4. Temperature distribution maps for precise insights.

C. Optimal Fertilizer Management

The use of thermal imaging helps handle fertilizer more effectively. Temperature variations can reveal changes in the absorption and utilization of nutrients. Farmers may strategically apply fertilizers where they are most required, saving waste and fostering healthy development, by merging heat data with soil nutrient analysis.

1) *Yield estimation and harvest planning:* More precise yield estimation is made possible by the thermal data insights. Variations in fruit development and maturation may be correlated with anomalies in temperature distribution. Farmers can predict production swings and adjust their harvest date by taking into account this information. Precision agriculture has essentially advanced thanks to the use of thermal imaging

technology in pomegranate farms. Farmers are better able to proactively solve problems, maximize resource use, and improve the general health of their crops thanks to the capacity to record, process, and analyze thermal data. The agricultural sector may get closer to sustainable practices by utilizing thermal insights for irrigation, fertilization, and yield management. These techniques maximize productivity while reducing their negative effects on the environment. The incorporation of thermal imaging into agricultural practices is poised to revolutionize how we grow and maintain our crops as technology advances.

Fig. 5. Accurate irrigation mapping through drone-mounted thermal cameras.

2) *Optical RGB camera analysis:* Utilizing RGB (Red-Green-blue) photography in modern agriculture has become a

potent and adaptable tool for a variety of tasks, from determining weed presence to evaluating fruit quality and vegetation health [46]. Researchers and farmers may improve crop management tactics, quantify key indices, and make educated decisions to maximize production and sustainability by utilizing modern image processing tools.

3) *Quantify vegetation indices for health assessment:* Important vegetation indices, like the widely used NDVI (Normalised Difference Vegetation Index), can be calculated using RGB photos. By comparing the reflectance of visible red and near-infrared light, NDVI acts as a quantitative indicator of plant health. This knowledge makes it easier to spot possible stressors and allows for tailored crop-growth-promoting actions as shown in Fig. 6.

4) *Assessing fruit quality with image analysis:* Color, size, and shape are some examples of fruit quality factors that can be evaluated using RGB imaging. Farmers can assess fruit maturity and harvest readiness by examining the color spectrum. In addition to quantifying variations in fruit size and form, image processing algorithms may also grade and categorize products based on their quality as shown in Fig. 7.

5) *Weed detection and classification:* It is possible to use the RGB imagery to look for weeds in crop fields. For advanced algorithms to distinguish between crops and undesirable vegetation, color, shape, and texture features are examined. Farmers can develop tailored weed control methods and increase yields by minimizing resource competition by automating weed detection as shown in Fig. 8.

NDVI (09/08)

Yield

b

Fig. 6. Vegetation indices for health assessment.

Fig. 7. Image analysis of pomegranate for fruit quality assessment.

6) *Color analysis for pest and disease identification:* When it comes to identifying pests and illnesses that impact crops, RGB images can be useful. Leaf color and pattern changes may be a sign of an infection or an infestation.

Fig. 8. Weed detection for optimal irrigation.

Fig. 9. Color analysis for pest and disease identification.

Fig. 10. Multi-spectral and hyper-spectral camera analysis.

Potential problems can be identified early by the analysis of RGB images, allowing for prompt intervention and loss mitigation. High-resolution maps that highlight spatial variations within fields can be made using remote sensing technology in conjunction with RGB images. These maps can be used to direct precision farming techniques, enabling the targeted use of resources like water, fertilizer, and pesticides. RGB photos can be used to train machine learning algorithms to recognize patterns and features as shown in Fig. 9.

It is possible to fine-tune these algorithms to recognize particular plant species, weed varieties, or disease symptoms. The effectiveness and precision of decision-making in crop management are improved by these skills. Agriculture transforms from reactive to proactive practices with the integration of RGB photography and image processing technology [47]. Farmers can make data-driven decisions that optimize resource use, decrease waste, and advance sustainable agricultural practices thanks to the capacity to measure indices, assess quality, detect weeds, and identify problems in real time. Analyse biological and physical traits while collecting data in the multi- and hyper-spectral range to spot disease symptoms. Use spectral analysis to find irregularities in plant reflectance patterns that could be signs of stress or disease [48]. Create machine learning models for spectral signature-based illness classification as shown in Fig. 10.

D. LiDAR Camera Analysis

Obtain LiDAR data to assess water flow patterns, track agricultural phenology, and evaluate plant height.

Create accurate digital elevation models (DEMs) and three-dimensional representations of the pomegranate orchards using LiDAR data processing. To measure agricultural growth stages, gather data on plant height and examine height changes over time as shown in Fig. 11.

Fig. 11. Drone-mounted LiDAR camera analysis of agricultural lands.

E. Data Processing and Deep Stream Algorithm

Send the cameras' acquired data to the NVIDIA JetsonGPU so it can be processed. Use deep stream algorithms to analyze all camera data streams in real-time [49]. Use image recognition, machine learning, and pattern recognition techniques to forecast crop health, soil dryness, fertilizer needs, the presence of weeds, and instances of crop damage and disease. The object detection method is known as YOLOv5, or "You Only Look Once version 5," is recognized for its quickness and precision. It is made to recognize and locate several items simultaneously in a video or picture stream. The "Deep Stream" variation is especially well suited for applications like monitoring agricultural fields because it concentrates exclusively on processing continuous data streams effectively. The earlier YOLOv3, YOLOv4, and other networks served as the foundation for the development of the YOLOv5 network. YOLOv5 offers the advantages of being quicker and more precise than prior-generation networks. An adaptable anchor box and adaptive picture scaling are two examples. These methods efficiently decrease the amount of network computation by calculating the scaling factor using the ratio of the current picture size, W to H, and then obtaining the filled scaling size. The backbone network and neck layer of YOLOv5 are mapped to the cross-stage partial (CSP) concept of YOLOv4, which improves the capacity of network feature fusion in terms of feature extraction.

The four network models in YOLOv5 are categorized as s, m, l, and x, according to smallest to biggest. The network's breadth and depth are the primary areas of variation in size. The lightest among them is YOLOv5. The primary parts of the network are the input, neck, head, and backbone. The Mosaic data improvement module is used in the input to enrich datasets. To speed up network training, the backbone leverages the CSPDarknet53 backbone network to extract rich information from input photos, such as the focus module and the spatial pyramid pooling (SPP) module core fuses feature information at various sizes using feature pyramid network (FPN) and path aggregation network (PAN) architectures. Concat later connects the top-down and bottom-up feature maps, enabling the feature fusion of various deep and shallow scales. This enhances the network's expressive

capacity. The YOLOv5 detecting structure is the head. Conv produces feature maps in three sizes: big, medium, and tiny. These sizes correlate to the targets that are detected—small, medium, and large. YOLOv5 increases the precision of network prediction based on NMS by using three loss functions to compute the location, confidence, and classification losses. The foundation of this investigation is the YOLOv5s network. Fig. 12 illustrates the network structure of YOLOv5.

1) *Object detection and monitoring:* It is possible to train the YOLOv5 Deep Stream Algorithm to recognise and differentiate a variety of components important to pomegranate agriculture, including pomegranate plants, fruits, and potential pests [50]. By implementing this method in the field, it is possible to monitor the crop in real time and identify problems like pest infestations, disease outbreaks, or nutrient deficits early on.

2) *Precise yield estimation:* The system helps with yield estimation by precisely classifying and counting pomegranate fruits. Farmers can maximize overall productivity and resource management by using this data to make informed decisions about harvesting schedules, labor allocation, and post-harvest logistics [51].

3) *Weed detection and management:* Pomegranate yield can be severely impacted by weed competition. The ability to recognize objects with the YOLOv5 Deep Stream Algorithm also allows for the classification and identification of weeds in pomegranate orchards. Utilizing these details makes it easier to deploy targeted weed control strategies, reduce resource waste, and increase crop yield.

4) *Resource allocation and sustainability:* Real-time insights provided by the algorithm provide a foundation for effective resource management. Farmers can use precision irrigation strategies by recognizing places that need attention or stress, including dry areas. This encourages the use of sustainable agricultural techniques while simultaneously conserving water [52].

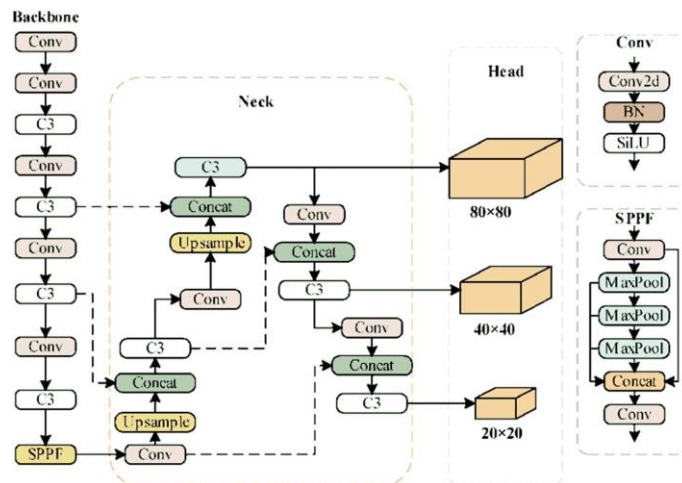

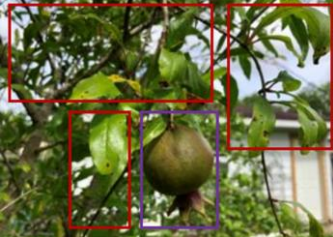

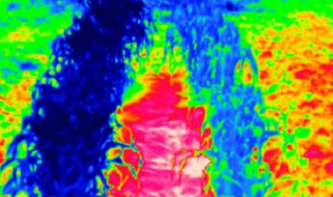

Fig. 12. Block diagram of YOLOv5 used in the experimentation.

TABLE II. DEEP STREAM ALGORITHM OUTPUT FOR VARIOUS APPLICATIONS

Application	Sample Output
Predict crop health	
Soil dryness	
Fertilizer requirements	
Weed presence	
Crop damage and disease	

5) *Disease and pest management*: Effective treatment of illnesses and pests depends on early detection. The YOLOv5 Deep Stream Algorithm can quickly recognize visual signs linked to a reduction in plant health, enabling prompt action. By controlling the spread of illnesses, farmers can cut back on the requirement for heavy pesticide use.

6) *Integration with automation and drones*: Drones with cameras can be integrated with the YOLOv5 Deep Stream Algorithm. With the help of this integration, drones may fly over the orchard by themselves while taking pictures in real-time and sending them to the algorithm for quick analysis. This method offers an unmatched vantage point for effectively monitoring vast agricultural fields as shown in Table II.

7) *Prediction and decision support*: Create forecasts and insights for various pomegranate agriculture characteristics based on the processed data. Create a dashboard or user-

friendly interface so that farmers may get real-time data and advice. Give specific advice on how to manage pests and diseases, apply fertilizer, and schedule irrigation, among other cultivation techniques [53].

8) *Validation and refinement*: By gathering real-world data and making field observations, confirm the veracity of predictions and advice. Based on ongoing learning from field data and farmer comments, improve the deep stream algorithms [54]. Improve the process iteratively depending on practical implementation issues and real-world performance.

9) *Scaling and adoption*: Increase the automated system's coverage area to larger pomegranate orchards and perhaps modify the approach for use with other crops. Educate farmers on how to use the automated system and how to understand the forecasts for wise decision-making. By supplying precise, timely, and data-driven insights that can improve crop yield,

optimize resource use, and promote sustainable agricultural practices, the integration of drone technology and deep-stream algorithms into pomegranate cultivation has the potential to transform conventional farming practices.

Our research employs a combination of advanced UAV-based cameras to enhance agricultural monitoring and outcomes, effectively addressing the specific challenges of each camera type. Thermal cameras, which detect infrared radiation to measure temperature variations and identify plant stress, face issues such as temperature sensitivity, lower resolution, and frequent calibration needs. Optical RGB cameras capture high-resolution images to analyze vegetation indices, fruit quality, and weed detection but are impacted by varying lighting conditions, large data volumes, and subtle color differentiation challenges. Multi-spectral cameras provide detailed insights into crop health and disease but are costly, complex, and sensitive to environmental factors like cloud cover. LiDAR cameras generate high-resolution 3D maps for measuring plant height and analyzing water flow patterns but require significant data processing power, are expensive, and struggle with dense vegetation obstructing laser pulses. Our approach integrates deep learning algorithms and NVIDIA Jetson GPU for data processing, addressing these challenges and enabling real-time analysis to improve data accuracy and reliability. By leveraging the strengths and mitigating the limitations of each camera, we facilitate precise crop management decisions, enhancing yield and sustainability in pomegranate orchards.

III. RESULTS AND DISCUSSIONS

The automated cultivation of pomegranates using deep-stream algorithms and drone technology has produced encouraging results, suggesting a revolutionary method for modern agriculture. Combining the processing power of the NVIDIA Jetson GPU with the capabilities of a drone with four specialized cameras—thermal, optical RGB, multi-spectral, and LiDAR—has allowed for comprehensive data collection, real-time analysis, and predictive insights in various pomegranate cultivation-related areas.

TABLE III. DATA COLLECTION WITH ACCURACY

Camera	Data Collection	Accuracy (%)
Thermal camera	Plant health inspection, Irrigation mapping, fertilizer management, yield estimation	95
Optical RGB camera	Vegetation index	91
Multi-spectral and hyper-spectral cameras	Biological and physical characteristics, diseased crop	93
LiDAR camera	Plant height, water flow, crop phenology	95

TABLE IV. PLANT HEALTH INSPECTION AND STRESS DETECTION

Crop Focus	ANN	CNN	ANFIS	YOLO
Plant Health Inspection	75	82	88	95
Stress Detection	76	81	85	93

A. Data Collection and Analysis

The pomegranate growth cycle has been thoroughly

investigated using drones equipped with various cameras. To properly detect stressed areas and enable focused actions, the thermal camera was essential for plant health inspection. To improve overall crop management techniques, the optical RGB camera effectively measured vegetation indices, assessed fruit quality and found the presence of weeds [55]. The multi-spectral and hyper-spectral cameras were excellent at spotting damaged crops and examining biological and physical traits, which helped to identify and treat diseases early on. Furthering our understanding of crop growth dynamics, the LiDAR camera produced accurate measurements of plant height, tracked crop phenology, and mapped water flow patterns as shown in Table III.

B. Deep Stream Algorithm Processing

The automated pomegranate production system showcased notable progress in data-driven precision farming by using deep-stream algorithms and drone technology. Together with the NVIDIA Jetson GPU's processing power, the four specialized cameras—thermal, optical RGB, multi-spectral, and LiDAR—produced extensive data collecting and real-time analysis. The findings are displayed about important crop management topics [56]. Plant Health Inspection and Stress Detection: To inspect the health of plants, the thermal camera was essential in precisely locating stressed regions. The ability to precisely identify stressed or ill plants was made possible by real-time data processing, which made it easier to detect temperature differences [57]. Plant health was improved by the proactive actions made possible by this capacity as shown in Table IV.

1) *Vegetation indices and fruit quality assessment:* Fruit quality was evaluated and vegetation indices were successfully measured using the optical RGB camera. The technology provided insights into the health of the vegetation by quantifying metrics like NDVI using image processing techniques [58]. Evaluations of the quality of the fruit and the identification of weeds enhanced cultivation techniques, increasing both production and quality as shown in Table V.

Crop Focus	ANN	CNN	ANFIS	YOLO
Disease Detection	78	85	91	95
Biological Characterization	74	78	81	87
Physical Characterization	75	79	82	89

2) *Disease detection and characterization:* Analyzing biological and physical properties and identifying damaged crops were made possible by the use of multi- and hyper-spectral cameras [59]. Early disease detection by the system enabled targeted treatments, reducing the possibility of output losses and enhancing crop health overall as shown in Table VI.

3) *LiDAR-Based plant height and water flow analysis:* Important information on plant height, crop phenology, and water flow patterns was provided by the LiDAR camera. This data improved knowledge of the dynamics of growth and led to optimal water use [60]. Precise assessments of plant height enabled the tracking of agricultural phenology, resulting in enhanced cultivation tactics as shown in Table VII.

4) *Real-time predictive insights:* Real-time data analysis was made possible by the combination of deep stream algorithms and the NVIDIA Jetson GPU. Quick predictions were produced about crop health, vegetation and soil dryness, fertilizer needs, weed presence, and incidences of crop damage and illness [61]. This reduced possible hazards, maximized resource utilization, and enabled quick decision-making as shown in Table VIII.

All four cameras' data could be processed and analyzed in real-time thanks to the NVIDIA Jetson GPU and deepstream algorithms. This processing pipeline played a key role in providing forecasts and insights for important pomegranate cultivation issues. The system accurately forecasted fertilizer needs, analyzed soil and vegetation dryness, tracked weed infestations, and quickly picked up instances of crop damage and illness [62]. Real-time data analysis enabled prompt decision-making, which ultimately optimized resource use and increased crop output as shown in Table IX and Fig. 13. Subsequently, performance analysis over different applications for evaluating the effectiveness of the proposed system is presented in Table X.

The automated system's prognostic insights greatly aided farmers in making well-informed decisions. The system's capacity to suggest ideal irrigation plans, exact fertilizer dosages, and prompt disease treatment techniques resulted in increased resource efficiency and less environmental impact as shown in Table IX and Fig. 14 - 17. Through the use of spectral analysis, growers were able to identify diseases and weeds early and take preventative action, potentially reducing yield losses [63]–[67]. Although the results are encouraging, certain difficulties were experienced when the automated system was put in place. For precise forecasts, camera calibration and maintaining consistent data quality are still essential. Integration of weather and climatic data may further improve the system's accuracy. Additionally, the system may operate differently in various geographic and environmental settings, necessitating ongoing improvement and adaptation.

C. Discussion

The results underscore the transformative potential of integrating drone technology and deep-stream algorithms in pomegranate cultivation. The system not only automates data collection but also provides actionable insights across multiple facets of cultivation, empowering farmers to make informed decisions.

The following discussions delve into the broader implications and considerations:

1) *Precision agriculture for sustainable farming:* The automated system minimizes its impact on the environment

while optimizing resource utilization per precision agricultural principles. The technology helps to promote effective and sustainable farming practices by accurately adjusting the irrigation, fertilization, and pest control strategies [68].

Fig. 16. Performance analysis of disease detection and characterization.

Fig. 17. Performance analysis of real-time predictive insights.

2) *Early disease detection for crop protection:* A breakthrough has been made with the use of spectral analysis for early disease identification. Farmers who recognize disease symptoms early on can take prompt action to stop the spread of the illness and maintain crop quality and output.

3) *Scalability and adaptability:* Although the system appears promising, it is important to take into account its scalability and adaptation to many environmental situations. Continuous development of calibration processes, data quality control, and system robustness are necessary to guarantee consistent performance in a variety of agricultural contexts.

The accuracy of disease identification and prediction modeling can be considerably improved in the future thanks to developments in machine learning and AI algorithms. An expanded perspective on crop health trends may be obtained by combining historical data and satellite photography. Collaboration with extension agencies and agricultural professionals can help to better adapt the system to local farming practices and spread its benefits [69]. Pomegranate cultivation could transform due to the merging of drone technology and deep-stream algorithms. The automated system provides real-time insights and suggestions for crop health, resource management, and disease identification by merging data from thermal, optical RGB, multi-spectral, and LiDAR cameras and utilizing the processing capability of the NVIDIA Jetson GPU. While there are still issues, this system represents a big step towards data-driven, sustainable agriculture by enabling farmers to optimize pomegranate yield and quality [70]. Further developments and widespread acceptance in contemporary agriculture are anticipated as a result of ongoing research and development in this field. The following investigations need to concentrate on improving the algorithms, adding more environmental factors, and broadening the system's crop suitability. To guarantee broad acceptance and applicability, partnerships with extension agencies and agricultural specialists can further customize the system to regional farming methods.

Conclusively, the automated technique for cultivating pomegranates shows promise for transforming conventional agricultural methods. This system provides farmers with real-time information, promotes sustainable agriculture, and improves overall crop output and quality by utilizing deep-stream algorithms, modern cameras, and drone technology. This novel strategy will surely advance toward wider acceptance and implementation in international agriculture with continued study and improvement.

IV. CONCLUSION

Integrating drone technology and deep-stream algorithms represents a notable breakthrough in modernizing agricultural practices, particularly in pomegranate cultivation. This study showcases a thorough and evidence-based approach to farming, employing advanced technology such as a drone equipped with a thermal camera, optical RGB camera, multi-spectral camera, and LiDAR camera. These cutting-edge tools are powered by the computational capabilities of the NVIDIA Jetson GPU, enabling precise data collection and analysis. This approach has demonstrated its effectiveness in improving different aspects of pomegranate farming. It has been used to evaluate plant health, map irrigation, manage fertilizer usage, and calculate yields. As a researcher, I have observed significant advancements in the optical RGB camera's capabilities. It has proven to be a valuable tool for analyzing vegetation indices, assessing fruit quality, and detecting weeds. These improvements have positively impacted decision-making, leading to better crop management practices and, ultimately, higher yields. In this field, multi-spectral and hyperspectral cameras have revolutionized how we detect crop diseases, assess damage, and respond proactively. Furthermore, the LiDAR camera has provided valuable insights into growth dynamics and resource utilization, leading to more sustainable farming practices.

Nevertheless, in light of these advancements, it is essential to consider the limitations associated with this approach carefully. The system's effectiveness relies heavily on the availability and quality of advanced drone equipment, which may not be easily accessible to all farmers, especially in regions with limited resources. This hinders the widespread adoption of the technology and can potentially create disparities in agricultural productivity. Furthermore, processing extensive datasets in real time presents significant computational challenges, particularly in environments with limited resources. These constraints emphasize the importance of conducting additional research to enhance the system's accuracy, scalability, and adaptability to different environmental conditions.

Further research should prioritize overcoming these limitations by creating more affordable drone solutions and enhancing the computational efficiency of deep-stream algorithms. Establishing collaborations between scientists, agricultural experts, and farmers will be essential to customizing the system to local conditions and promoting its wider use. By addressing these obstacles, this groundbreaking method holds promise for substantially impacting precision agriculture and aiding in developing more sustainable and efficient farming techniques.

ACKNOWLEDGMENT

The authors extend their appreciation to the Deanship of Scientific Research at Northern Border University, Arar, KSA for funding this research work through the project number "NBU-FFR-2024-1596-02".

Faculty of Computer Science and Information Computing Technology,
New Era University College, Kajang, Selangor, Malaysia¹

Abstract—In the digital age, Small and Medium-sized Enterprises must review and improve their cybersecurity posture to combat rising risks. This paper thoroughly compares Small and Medium-sized Enterprises cybersecurity program assessment approaches. The National Institute of Standards and Technology's Cybersecurity Framework, CyberSecurity Readiness Model for SMEs, Cybersecurity Evaluation Model, and Adaptable Security Maturity Assessment and Standardisation framework were examined. The NIST CSF is adaptable and applicable to many sectors, while the CSRM provides a standardized way to assess an organization's cyber readiness. With its resource limits and operational scales, the CSRM-SME meets SMEs' particular issues. Organizations may examine and improve cybersecurity with CSEM. The approach can be used for SMEs, higher education institutions, and industrial control systems. The ASMAS architecture is flexible for continual security enhancement due to its scalability and standardization. This comparison analysis shows each framework's strengths and weaknesses, revealing their suitability for diverse SME scenarios. This paper helps SMEs choose the best model to strengthen cybersecurity, boost resilience, and meet global standards. This paper will compare the NIST CSF, CSRM-SME, CSEM, and ASMAS cybersecurity frameworks.

Keywords—Cybersecurity; SMEs; cybersecurity program assessment models; cybersecurity assessment frameworks

I. INTRODUCTION

Small and Medium-sized Enterprises (SMEs) are vital to the economy but are frequent targets of cyberattacks due to their limited cybersecurity capabilities [1]. Existing maturity assessment models and standards often need to pay more attention to SMEs' requirements and roles in the digital ecosystem. The rise of Industry 4.0 and digital transformation introduces new cybersecurity challenges for SMEs. A tailored cybersecurity assessment model is needed to address the unique cybersecurity needs of SMEs. This model should consider SMEs' resources and expertise limitations while providing effective cybersecurity measures [2].

A. Global and Malaysia Small and Medium-sized Enterprises (SMEs)

SMEs drive innovation, competitiveness, and job creation, making them the backbone of the economy [3]. These companies have fewer than 250 people and a turnover or balance

sheet of less than €50 million or €43 million [4]. Most countries have SMEs, including 99% of EU enterprises [5]. SMEs boost GDP, employment, and innovation, making them crucial to the economy. SMEs provide half of U.S. jobs but only 40% of GDP [6]. SMEs comprise 98% of Australian enterprises, contribute one-third of GDP, and employ 4.7 million people. SMEs generate 44% of Norway's economic value and employ 47% of private sector workers [7].

Malaysia's SMEs boost GDP, employment, and innovation. SME definitions include sales turnover and full-time employee count. SME status in Malaysia is determined by a sales turnover of RM50 million or fewer than 200 full-time employees [8]. Malaysian SMEs are classified by sales turnover and full-time personnel. Micro, small, and medium requirements, such as manufacturing and services, vary by industry. The manufacturing sector has microenterprises with sales turnovers under RM300,000 or less than five full-time employees. However, a tiny business makes between RM300,000 and RM15 million [9].

The Malaysian economy relies on SMEs, which comprise 97.2% of businesses, 38.2% of GDP, and 7.3 million jobs. These businesses generate economic growth, with 98.5% of Malaysian companies being SMEs. SMEs generated about RM500 billion to Malaysia's GDP and 5.7 million jobs, 70% of the workforce in 2018. [10]. To keep up with digital culture, SMEs should use digital marketing to boost market presence and efficiency. The government helps SMEs digitalize to expand their consumer base and increase efficiency. Establishing the Ministry of Entrepreneur Development and Cooperatives (MEDAC) shows the government's support for SMEs and entrepreneurship. The National Entrepreneur and SME Development Council (NESDC) promotes entrepreneurship to boost economic growth [11].

Table I compares Small and Medium-sized Enterprises (SMEs) globally and SMEs, specifically in Malaysia, across various aspects, including economic contribution, internationalization, technology adoption, government support, market orientation, challenges, performance factors, environmental practices, and corporate governance. The importance of SMEs globally and in Malaysia while also showcasing the unique challenges they face and the support systems in place to help them thrive. It underscores the critical

role of policy measures and innovation in driving SME growth and sustainability.

TABLE I. COMPARISON OF GLOBAL SMEs AND MALAYSIA SMEs

Criteria	Global SMEs	Malaysia SMEs
Economic Contribution [3]	Significant contribution to GDP and employment across various countries.	Manage 98.5% of Malaysian businesses, 65.3% of jobs, and 36.3% of GDP.
Internationalization (4)	We are engaged in global markets through exports, joint ventures, and international partnerships.	Exports boost GVC and FTA participation.
Technology Adoption [5]	Adoption varies widely; advanced economies often lead to technology integration.	High expenses and the need for innovation to stay competitive hinder technology adoption.
Government Support [6]	Various support levels, including financial aid, training, and internationalization assistance.	Significant government development, financial, and export promotion support.
Market Orientation [7]	Market orientation is critical for success; firms focusing on customer needs and market trends perform better.	Customer attention and market dispersion are essential, but intelligence and reactivity differ.
Challenges [8]	Common challenges include access to finance, competition, and regulatory hurdles.	Lack of competent labor, high raw material costs, and upfront investment costs.
Performance Factors [9]	Performance is linked to innovation, market expansion, and efficient resource utilization.	Internationalization and performance are linked, emphasizing market orientation.
Environmental Practices [8]	Increasing emphasis on sustainability and green practices in developed countries.	Early green practices; ISO 14001 Environmental Management System to improve performance.
Corporate Governance [10]	Varies significantly; better corporate governance practices are correlated with improved SME performance.	Better corporate governance practices are needed for monitoring and procedure implementation.

II. BACKGROUND ASSESSMENT MODELS AND FRAMEWORKS

An organization's security posture can be assessed and improved using a cybersecurity program assessment model to discover vulnerabilities, assess risks, and deploy controls. These models evaluate external threats like cyberattacks and internal weaknesses like obsolete software or human errors that could affect an organization's information systems [11]. They include methods for estimating and prioritizing risks, assessing cyber threat impact and likelihood, and selecting reaction levels [12]. These models help organizations establish security policies, access controls, firewalls, and personnel training to limit risks [13]. As threats change, effective cybersecurity program assessment models emphasize continual monitoring and periodic appraisal to improve the organization's cybersecurity posture [14]. Numerous models link with international standards like ISO/IEC 27001 and 27002, offering a benchmark for cybersecurity maturity and compliance [15]. Cybersecurity program assessment models help organizations prepare for growing cyber threats with these comprehensive techniques.

A. Taxonomy Assessment Models

Cybersecurity program assessment models are diverse frameworks designed to evaluate and enhance the security posture of organizations. These models systematically categorize different aspects of cybersecurity to provide a comprehensive and structured approach to risk assessment, threat identification, and mitigation. The taxonomy of these models often includes various components such as risk factors, threat vectors, control measures, and evaluation criteria.

TABLE II. THE SUMMARY TAXONOMY ASSESSMENT MODEL

Taxonomy	Description
Risk-Based Taxonomy	Risk identification, analysis, and management. Quantifies threat occurrences, vulnerability, and effect of cybersecurity threats. Quantitative algorithms measure cybersecurity risk using these parameters [11].
Hierarchical and Graph-Theoretic Taxonomy	Uses hierarchical and graph-theoretic models to assess cybersecurity vulnerabilities. Taxonomically classifies threat actors' methods and provides cyber-physical assault graphs to analyze threat transmission [12].
Capability Maturity Models (CMMs)	Assess and improve an organization's cybersecurity. Classifies maturity levels in policy, operations, and human factors. Compares the present situation to optimal practices [13].
Socio-Technical Taxonomy	Assesses cybersecurity threats and improves IT, security, and non-technical staff communication using technical and human factors. Work processes and hazards are visualized using modeling languages [14].
Multicriteria Decision Frameworks	Integrates various criteria to assess the overall utility of cybersecurity management alternatives. Quantifying threats, vulnerabilities, and consequences provides a structured approach to selecting risk management actions [15].
Dynamic Simulation-Based Taxonomy	Assesses cybersecurity threats and plans long-term investments using dynamic simulation. Addresses organizational change and cyberattack dynamics [16].
Comprehensive and Flexible Taxonomies	Includes worldwide and national cybersecurity recommendations. Technology, organization, people, and environment are measured to assess cybersecurity readiness [17].

Organizational security is assessed and improved using several cybersecurity program assessment methodologies. These frameworks categorize cybersecurity to organize risk assessment, threat identification, and mitigation. Table II shows that these models' taxonomies comprise risk variables, threat vectors, control measures, and evaluation criteria.

Several taxonomic techniques are used to control and reduce cybersecurity threats. Risk-based taxonomies categorize risks into quantifiable criteria, including attack events, vulnerabilities, and impacts, and employ quantitative algorithms to evaluate and prioritize cybersecurity risks [11]—however, hierarchical and graph-theoretic taxonomies model cybersecurity concerns. Taxonomical classifications of threat actors' approaches, tactics, and processes generate cyber-physical attack graphs that analyze threat propagation, helping identify vital assets and prioritize controls [12]. CMMs evaluate and improve an organization's cybersecurity practices in policy, operations, and human factors. The National Cybersecurity Capacity Maturity Model (CMM) lets organizations compare their current condition to best

practices and identify areas for improvement [17]. Multicriteria decision frameworks quantify threats, vulnerabilities, and consequences to evaluate cybersecurity management alternatives and provide a structured approach for risk management action selection, bridging the gap between risk assessment and risk management [15]. Comprehensive and flexible taxonomies include worldwide and national cybersecurity recommendations for technology, organizations, people, and the environment. These holistic cybersecurity readiness models are adaptable to organizational situations [17].

B. Process Development Assessment Model

Developing a cybersecurity program assessment model involves a structured and iterative process to evaluate and enhance an organization's cybersecurity posture. This structured and iterative process ensures that organizations can systematically assess, manage, and strengthen their cybersecurity posture, thereby reducing risks and improving overall security resilience.

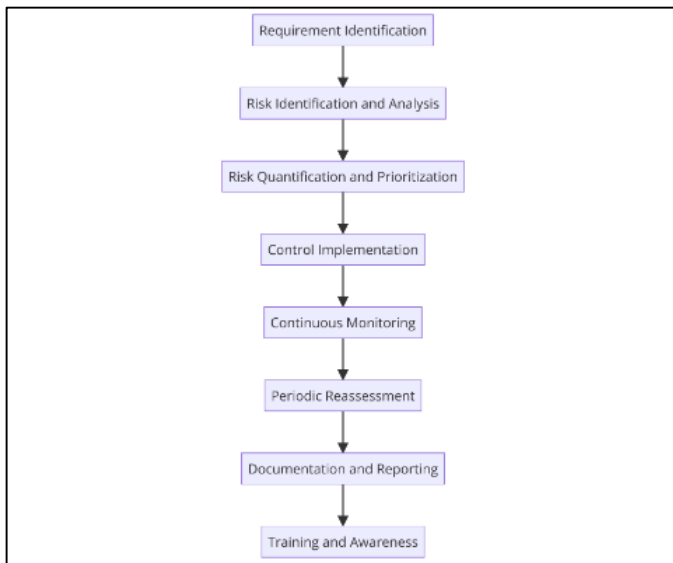

Fig. 1. Process of developing assessment model.

Fig. 1 demonstrates an organization's comprehensive cybersecurity management procedure. It starts with need identification, which defines cybersecurity needs, limitations, behaviors, services, and security requirements [18]. Next, Risk Identification and Analysis involves detecting and analyzing internal and external cybersecurity risks and understanding threats and vulnerabilities [19]. After that, risk quantification and prioritization are employed to assess and rank these risks by impact and likelihood [15]. Control Implementation involves creating and implementing security policies, access controls, and employee training programs to reduce these risks [20]. Continuous Monitoring ensures these measures are effective through audits, vulnerability scans, and real-time threat detection. Reassessment and control adjustments are made to handle

C. Paper Structure

This paper will compare these cybersecurity frameworks, focusing on the NIST CSF, CSEM, CSRMSME, and ASMAS. By examining their structures, implementation processes,

strengths, weaknesses, and suitability for different organizational contexts, this paper provides insights into the most effective strategies for enhancing cybersecurity readiness, particularly for SMEs. Through this comparison, we aim to highlight each framework's key features and benefits, ultimately guiding organizations in selecting the most appropriate framework for their cybersecurity needs.

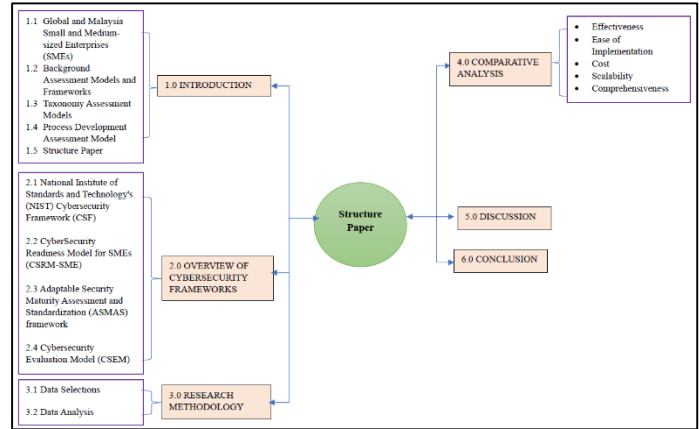

Fig. 2. The structure of the paper.

The structure of this paper is outlined in Fig. 2. Section I discusses an introduction to SMEs and the background of assessment models and frameworks. Section II discusses an overview of the cyber security model and framework. Section III discusses the research methodology. Then, Section IV presents the comparative analysis of cybersecurity program assessment models and frameworks. Finally, this paper presents the discussion and conclusions in Sections V and VI respectively.

III. CYBERSECURITY PROGRAM ASSESSMENT MODEL

Cybersecurity has become a critical concern for Small and Medium-sized Enterprises (SMEs) in Malaysia, given the increasing sophistication and frequency of cyber threats. Developing and implementing a comprehensive cybersecurity program assessment model tailored for Malaysian SMEs is essential to enhance their resilience against cyberattacks.

ISO 27001, while a comprehensive and internationally recognized standard, is often resource-intensive, requiring significant financial and human resources to implement effectively. This can be a substantial barrier for SMEs, which typically operate with limited budgets and may need more specialized staff to manage such a complex framework [18], [19]. Furthermore, the flexibility of ISO 27001, while beneficial for large organizations with diverse needs, may result in an overly broad approach that aligns poorly with SMEs' specific and more narrowly focused security needs [20]. Similarly, while the CIS Controls are designed to be more accessible and prescriptive, they may still present challenges in prioritization and customization that are difficult for SMEs to navigate without expert guidance. Though beneficial for comprehensive coverage, the CIS framework's broad scope may need to be aligned with the limited operational scope of many SMEs, making it less practical compared to more targeted cybersecurity assessment models [21].

A. National Institute of Standards and Technology's (NIST) Cybersecurity Framework (CSF)

To help organizations manage and decrease cybersecurity risks, the NIST Cybersecurity Framework (CSF) provides comprehensive recommendations and best practices. The CSF was first published in 2014 and updated multiple times, with CSF 2.0 released in February 2024. This cybersecurity methodology is flexible and reproducible for all sizes and sectors of organizations. The five essential functions—Identify, Protect, Detect, Respond, and Recover—provide a comprehensive overview of an organization's cybersecurity risk management [33]. The framework is versatile so that organizations can customize it. System components include Framework Core, Framework Implementation Tiers, and Framework Profiles. This thorough guide helps organizations manage and reduce cybersecurity risks. It is versatile and adaptive to the needs of diverse organizations, regardless of size, sector, or maturity.

TABLE III. COMPONENTS IN THE NIST CYBERSECURITY FRAMEWORK (CSF)

Component	Description
CSF Core	Govern, Identify, Protect, Detect, Respond, and Recover are its main functions. Each function has categories and subcategories that define cybersecurity management outcomes and actions. The "Identify" function manages assets, whereas the "Protect" function controls access [22].
Implementation Tiers	Four implementation tiers: Partial (Tier 1) to Adaptive (Tier 4). These tiers show how risk management and corporate goals influence cybersecurity procedures. Higher tiers reflect more sophisticated cybersecurity risk management [22] [23].
Profiles	Custom framework implementations for unique organizations. They match cybersecurity with business needs, risk tolerance, and resources. Profiles help organizations prioritize and handle cybersecurity [22] [23].

Table III provides a concise overview of the critical components within the NIST Cybersecurity Framework (CSF). The paper overviews the framework's main elements, including CSF Core, Implementation Tiers, and Profiles. It emphasizes the significance and function of these components within the framework. Each component briefly describes how it contributes to aligning cybersecurity activities with organizational needs and risk management.

B. CyberSecurity Readiness Model- SME (CSRM-SME)

CSRM-SME is designed to enhance the cybersecurity posture of Small and Medium-sized Enterprises (SMEs) by addressing both technical and socio-technical dimensions. This model emphasizes the importance of balancing human and technical factors, fostering a strong cybersecurity culture, and using adaptable, metric-based assessments to address the unique challenges faced by SMEs [14].

Table IV shows that CSRM-SME provides a comprehensive approach to enhancing cybersecurity readiness by integrating socio-technical elements. This model emphasizes balancing

human and technical factors, fostering a strong cybersecurity culture, and using adaptable, metric-based assessments to address SMEs' unique challenges. Implementing such a model can significantly improve SMEs' ability to manage cyber threats effectively.

TABLE IV. COMPONENT OF CSRM-SME

Core Component	Description
Socio-Technical Perspective	Assesses and improves cybersecurity readiness using human and technical factors. Focuses on organizational methods and technical defenses [14].
Human Element Integration	It maps socio-technical networks and human interactions using user journeys. It improves communication between IT, security, and non-technical staff to address human vulnerabilities [24].
Comprehensive Framework	Balances social, technical, and environmental factors. Provides a methodical approach to addressing SMEs' cybersecurity gaps [25].
Organizational Culture and Readiness	Highlights cybersecurity culture. It stresses that cybersecurity knowledge and culture are as necessary as technical solutions. Assesses essential areas for improvement [26].
Metric-Based Assessments	Reviews and creates socio-technical cybersecurity metrics. Addresses metric aggregation and flexibility for SMEs via straightforward, threat-based evaluations tailored to their needs [27].

C. Adaptable Security Maturity Assessment and Standardization (ASMAS) Framework

The Adaptable Security Maturity Assessment and Standardisation (ASMAS) framework has been examined in numerous studies to meet the cybersecurity needs of diverse organizations. SMEs face particular cybersecurity challenges; thus, a web-based ASMAS framework is proposed to handle them [25]. Another paper offers a European cybersecurity education maturity assessment methodology that defines knowledge units and standardizes instruction [25]. In contrast, [26] presents a maturity structure for Security Operation Centres (SOC) to ensure cybersecurity management. The research in [27] emphasizes adaptability and standardization by integrating cybersecurity maturity evaluations and standardization to satisfy organizational needs. Finally, the study in [28] proposes a security maturity self-assessment paradigm for the software development lifecycle to improve security. These numerous approaches demonstrate the need for adaptive frameworks to fulfill cybersecurity objectives across sectors and environments.

The Adaptable Security Maturity Assessment and Standardization (ASMAS) framework provides a comprehensive approach to enhancing cybersecurity practices within Small and Medium-sized Enterprises (SMEs). The framework is structured around three key aspects: core components, framework core, and implementation tiers, as shown in Table V. Following the framework, SMEs can systematically build a resilient security infrastructure that evolves with the changing threat landscape, thereby effectively safeguarding their operations and sensitive information.

TABLE V. SUMMARY CORE COMPONENT ASMAS FRAMEWORK

Aspects	Part	Descriptions
Core Components [29]	Risk Management	Identifying, assessing, and prioritizing risks.
	Security Policies	It establishes and enforces security policies and procedures.
	Access Control	Managing access to resources ensures that only authorized users can access sensitive information.
	Incident Response	I am preparing for and responding to security incidents.
	Continuous Monitoring	We regularly monitor security controls to detect and respond to new threats.
	Employee Training	We educate employees about best practices and protocols for security.
Framework Core [29]	Identify	It is understanding the business context, resources, and risk management processes.
	Protect	We are implementing safeguards to ensure the delivery of critical infrastructure services.
	Detect	Developing and implementing activities to identify the occurrence of a cybersecurity event.
	Respond	We are developing and implementing appropriate activities to take action regarding a detected event.
	Recover	It maintained plans for resilience and restored any impaired capabilities or services.
Implementation Tiers [29]	Tier 1: Partial	Informal and ad-hoc approaches to security.
	Tier 2: Risk-Informed	Awareness of risks and beginning to implement security measures systematically.
	Tier 3: Repeatable	We have established practices and policies for security management.
	Tier 4: Adaptive	Continuous improvement and adaptation to new threats.

D. Cybersecurity Evaluation Model (CSEM)

Organizations can examine and improve cybersecurity using the Cybersecurity Evaluation Model (CSEM). The approach can be used for SMEs, higher education institutions, and industrial control systems. Cybersecurity evaluation models (CSEM) research offers many risk assessment and management techniques. The study in [26] emphasize the COVID-19 pandemic's impact on cyber threats and the usage of Bayesian Networks, Random Forests, and Social Networks to assess cyber-attack risks. The study in [27] emphasizes threat modeling's strong ROI in spotting cyber threats and fixing design faults [26]. Construct a CSEM for Indian SMEs in a virtual team setting, highlighting the heightened cyber risk due to remote working during the pandemic and proposing a

quantitative approach to analyze and mitigate these risks. Finally, a paper validating the CyberSecurity Audit Model (CSAM) in Canadian higher education institutions shows that CSAM can conduct comprehensive cybersecurity audits across domains, demonstrating its practicality and importance in improving cybersecurity [29] [30].

TABLE VI. CORE COMPONENTS CSEM

Component	Description
Risk Assessment	Assessing cybersecurity risks through surveys and identifying strengths and weaknesses [26].
Security Requirements	Establishing security requirements based on ISO/IEC 27002 standards [28].
Maturity Self-Assessment	Self-assessment of cybersecurity maturity using frameworks like NIST CSF [29].
Audit Model	A comprehensive model for conducting cybersecurity audits across various domains [30].
Risk Analysis and Mitigation	We integrate fault tree analysis and fuzzy decision theory for risk evaluation and mitigation [26].

Table VI shows the Cybersecurity Evaluation Model (CSEM) comprehensive framework designed to enhance organizations' cybersecurity posture through several vital components. The Risk Assessment component identifies strengths and weaknesses in an organization's cybersecurity posture by conducting detailed surveys. This is followed by Security Requirements, which establish baseline standards for cybersecurity measures based on recognized frameworks such as ISO/IEC 27002, ensuring that all necessary protocols are in place. Maturity Self-Assessment involves using frameworks like the NIST Cybersecurity Framework (CSF) to self-evaluate and improve cybersecurity practices across critical areas, including identification, protection, detection, response, and recovery. The Audit Model [36] component provides a structured approach for conducting thorough cybersecurity audits across various organizational domains, verifying the effectiveness of implemented controls. Finally, risk analysis and mitigation integrate advanced methods such as fault tree analysis and fuzzy decision theory to assess and mitigate cybersecurity risks, identify vulnerabilities, and develop strategies to address potential threats. These components form a robust model that helps organizations systematically manage and enhance their cybersecurity defenses.

E. Summary

The Adaptable Security Maturity Assessment and Standardization (ASMAS) framework and the National Institute of Standards and Technology (NIST) Cybersecurity Framework (CSF) both aim to enhance cybersecurity practices but cater to different organizational needs. The ASMAS framework is specifically designed for Small and Medium-sized Enterprises (SMEs), offering a tailored, adaptable, and user-friendly approach that addresses the unique challenges faced by these smaller entities. In contrast, the NIST CSF is a comprehensive and flexible framework suitable for various organizations, including those in critical infrastructure sectors. Still, its complexity and resource demands can be challenging for smaller organizations to implement effectively. Ultimately, the choice between these frameworks should be guided by the organization's specific needs, resources, and capabilities.

The Cybersecurity Evaluation Model (CSEM) and the CyberSecurity Readiness Model for SMEs (CSRSM-SME) both provide frameworks to enhance cybersecurity in Small and Medium-sized Enterprises (SMEs). Still, they cater to different organizational needs and complexities. The CSEM is designed to be practical and straightforward, focusing on assessing cybersecurity risks and providing clear guidelines for improvement, particularly in remote work environments. It utilizes a quantitative approach through surveys, making it accessible and easy to implement for SMEs looking to identify their cybersecurity strengths and weaknesses.

On the other hand, the CSRSM-SME offers a comprehensive evaluation based on a socio-technical perspective, considering both technological and human factors. This model provides a holistic view of an organization's cybersecurity readiness by examining the interaction between technology, people, and processes. While it offers a deeper understanding of cybersecurity readiness, its implementation can be more complex and resource-intensive.

IV. RESEARCH METHODOLOGY

This paper employs a comparative research design to analyze and evaluate the effectiveness, implementation processes, and overall suitability of five distinct cybersecurity frameworks: the National Institute of Standards and Technology's (NIST) Cybersecurity Framework (CSF), CyberSecurity Readiness Model for SMEs (CSRSM-SME), and Adaptable Security Maturity, Assessment, and Standardization (ASMAS) framework.

A. Data Selection

Academic databases, industry reports, and framework documentation are secondary data sources. These resources explain framework structure, execution, and goals. Academic databases provide peer-reviewed research articles and studies for credibility and accuracy. Industry studies show how these frameworks are used through trends, applications, and expert analysis. However, framework documentation includes thorough implementation instructions and protocols. To ensure a comprehensive evaluation, consider these sources when selecting data. Integrating information from these varied sources helps create a complete grasp of each framework and enables an intense study of its practical and theoretical underpinnings. Fig. 3 shows the process data selection structure.

Fig. 3. Data selection structure.

B. Data Analysis

Comparisons of frameworks depend on literature and framework documentation content analysis. This method systematically analyses text to find patterns, themes, and critical traits. Analyzing academic articles, industry reports, and framework guidelines can reveal parallels and variances in framework structures, objectives, and implementation tactics. This technique helps compare frameworks and identify their strengths and drawbacks. Content analysis is a core method for organizing and synthesizing qualitative data into meaningful insights. This method ensures thorough research with empirical evidence, leading to more informed judgments and suggestions. Fig. 4 shows how content analysis compares framework stages and outcomes.

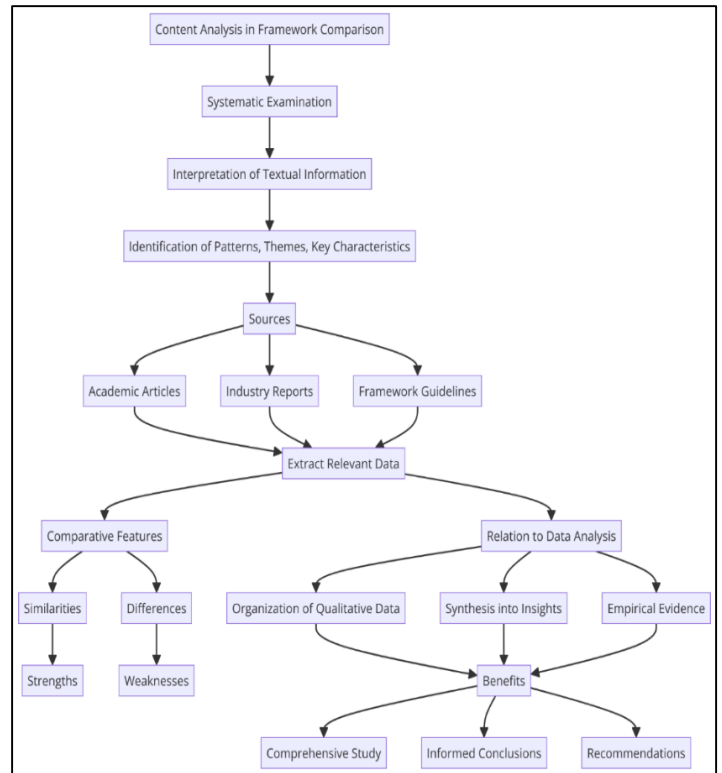

Fig. 4. Process of content analysis.

V. RESULT

In cybersecurity for Small and Medium-sized Enterprises (SMEs), a comparative analysis of various models is crucial to identify the most suitable framework. This analysis focuses on critical criteria: Effectiveness, Ease of Implementation, Cost, Scalability, and Comprehensiveness. The CyberSecurity Readiness Model for SMEs (CSRSM-SME) is designed for small businesses, prioritizing ease of implementation and cost-effectiveness. The Cybersecurity Evaluation Model (CSEM) offers a robust framework emphasizing comprehensiveness and scalability, making it adaptable to various business sizes. The National Institute of Standards and Technology's (NIST) Cybersecurity Framework (CSF) is renowned for its effectiveness and comprehensiveness, providing a structured approach that is highly scalable but can be complex to implement for SMEs without significant resources. Lastly, the

Adaptable Security Maturity Assessment and Standardization (ASMAS) focuses on maturity and standardization, balancing comprehensiveness and ease of implementation while also being mindful of cost and scalability. This comparative analysis aims to elucidate the strengths and weaknesses of each model, helping SMEs choose the most appropriate framework for their specific needs and constraints.

Table VII above shows four highly effective and scalable models suitable for different SME needs. CSRMSME, CSEM, and ASMAS stand out for their ease of implementation, while NIST CSF is noted for its comprehensive approach. Cost considerations vary, with CSEM and ASMAS being more affordable options.

Table VIII categorizes four cybersecurity models based on their performance across critical criteria. All frameworks are rated high for effectiveness, making them solid choices for enhancing cybersecurity. Regarding ease of implementation, CSRMSME, CSEM, and ASMAS are rated high, indicating they are user-friendly and straightforward. In contrast, NIST CSF is rated moderate, requiring more effort for integration.

Cost-wise, CSEM and ASMAS are rated low, suggesting they are more affordable options, while CSRMSME and NIST CSF are rated moderate. All frameworks are highly scalable and suitable for various organizational sizes and needs. Lastly, comprehensiveness is high for CSRMSME, NIST CSF, and ASMAS, ensuring they cover a wide range of cybersecurity aspects, whereas CSEM is moderately comprehensive.

TABLE VII. COMPARATIVE ANALYSIS ASSESSMENT MODEL

Criterion	CSRMSME [14]	CSEM [26]	ASMAS [29]	NIST Cybersecurity Framework (CSF) [27]
Effectiveness	The CSRMSME model enhances cybersecurity readiness by integrating technical and human factors, providing a holistic and practical socio-technical approach.	CSEM provides a structured evaluation using a survey to assess cybersecurity risks, focusing on identifying strengths and weaknesses in SMEs' cybersecurity posture, which helps in targeted improvements	ASMAS addresses specific SME requirements for cybersecurity maturity and includes an evaluation study showing positive results for perceived usefulness and ease of use.	The NIST CSF offers a structured approach to managing cybersecurity risks and enhancing security posture across various sectors, including healthcare and financial services. Its core functions (Identify, Protect, Detect, Respond, Recover) provide comprehensive cybersecurity coverage.
Ease of Implementation	It uses a socio-technical approach, requiring comprehensive organizational changes, but is tailored for SMEs.	Utilizes an easy online survey for SMEs to complete, providing an accessible way to assess cybersecurity risks.	ASMAS is demonstrated through a web-based software prototype, showing ease of use and positive feedback from SMEs in evaluation studies	Implementing the NIST CSF can be complex and resource-intensive for SMEs, but it offers clear guidance and can integrate with other standards, enhancing ease of adoption.
Cost	The cost implications are not explicitly detailed but include potential expenses related to socio-technical adjustments within the organization.	CSEM involves minimal cost as it primarily uses a survey for self-assessment.	ASMAS uses a web-based software tool, which may involve initial setup costs but is designed for SMEs, keeping affordability in mind.	Implementing the NIST CSF can be costly due to technology, training, and maintenance investments. The Gordon-Loeb Model can help organizations evaluate cost-benefit aspects and optimize cybersecurity spending.
Scalability	The socio-technical approach can be scaled but might require tailored adjustments for different SME contexts.	It is scalable as it can be adapted for different SME sizes and industries by modifying the survey.	It is designed to be adaptable for various SMEs and includes specific adjustments to meet unique SME requirements, making it highly scalable.	The NIST CSF is scalable and adaptable, making it suitable for organizations of all sizes. It can be tailored to fit an organization's size, complexity, and cybersecurity needs.
Comprehensiveness	Comprehensive in addressing both technical and human aspects of cybersecurity readiness	Focuses on a comprehensive evaluation of cybersecurity maturity through detailed survey questions	Highly comprehensive, addressing both assessment and standardization needs specific to SMEs with positive evaluation results.	The NIST CSF is comprehensive, covering various cybersecurity areas with detailed guidelines. It aligns well with other standards, facilitating a holistic approach to managing cybersecurity risks.

TABLE VIII. EFFECTIVENESS PERFORMANCE

Criterion	CSRMSME	CSEM	NIST CSF	ASMAS
Effectiveness	H	M	H	H
Ease of Implementation	M	H	M	H
Cost	M	L	M	M
Scalability	M	H	H	H
Comprehensive	H	M	H	H

H= High, M=Moderate, L= Low

VI. DISCUSSION

The comparative analysis of the CyberSecurity Readiness Model for SMEs (CSRM-SME), Cybersecurity Evaluation Model (CSEM), National Institute of Standards and Technology's (NIST) Cybersecurity Framework (CSF), and Adaptable Security Maturity Assessment and Standardization (ASMAS) highlights the distinct strengths and focuses of each framework. All frameworks are recognized for their effectiveness in improving cybersecurity posture, making them well-regarded across various sectors. For instance, the CSRM-SME and ASMAS frameworks are particularly well-tailored for SMEs, effectively addressing their unique needs and constraints [14]. Similarly, the CSEM framework focuses on SMEs, emphasizing remote work environments, which have gained significant importance in the post-pandemic era [32]. On the other hand, the NIST CSF is noted for its comprehensiveness and widespread adoption across various industries, making it a robust choice for diverse organizational needs [34].

When considering ease of implementation, CSRM-SME, CSEM, and ASMAS stand out for their user-friendly guidelines and tools, facilitating straightforward adoption by SMEs. This high ease of implementation is supported by research highlighting these frameworks' design around SME constraints, such as limited resources and expertise [28]. In contrast, while the NIST CSF is effective, its broader scope and complexity may require more resources and expertise to integrate fully, especially within smaller organizations [31].

Cost is another critical factor, particularly for SMEs with limited budgets. Studies indicate that CSEM and ASMAS are cost-effective, making them accessible to smaller organizations [32]. Conversely, the CSRM-SME and NIST CSF are rated moderate in cost, as their implementation might require more extensive resources or adjustments, thereby incurring additional expenses [28].

In terms of scalability, all frameworks score high, reflecting their ability to adapt to organizations of different sizes and types. This scalability is essential for SMEs that may grow and require more comprehensive cybersecurity measures [32, 34]. Regarding comprehensiveness, the CSRM-SME, NIST CSF, and ASMAS frameworks are rated high as they cover a broad range of cybersecurity aspects and provide detailed guidelines for implementation. Meanwhile, CSEM, although practical, focuses primarily on remote working environments and best practices, making it less comprehensive in other cybersecurity [35] areas.

The findings underscore that while each cybersecurity framework is practical, their strengths and focus areas differ, making them suitable for varying organizational contexts. SMEs, in particular, can benefit from frameworks like CSRM-SME, CSEM, and ASMAS, specifically designed to address their unique needs and constraints.

VII. CONCLUSION

CSRM-SME and ASMAS are highly effective, easy to implement, comprehensive, and scalable, making them excellent choices for SMEs looking for robust, user-friendly cybersecurity solutions. They balance effectiveness and cost, ensuring that even smaller organizations can enhance their

cybersecurity posture without significant financial strain. CSEM is also highly effective and cost-efficient, particularly suited for SMEs in remote working environments. It provides practical guidelines and tools, though it might not be as comprehensive in covering all cybersecurity aspects as other frameworks. NIST CSF stands out for its extensive and highly effective approach, suitable for various industries. However, implementing it may require more resources and expertise, which could be a consideration for smaller organizations with limited budgets.

Based on a comparative analysis of 4 cybersecurity models, the CyberSecurity Readiness Model for SMEs (CSRM-SME), the Cybersecurity Evaluation Model (CSEM), the National Institute of Standards and Technology's (NIST) Cybersecurity Framework (CSF), and Adaptable Security Maturity Assessment and Standardization (ASMAS) the Adaptable Security Maturity Assessment and Standardization (ASMAS) emerges as the most suitable for SMEs.

ASMAS is highly effective in addressing the unique cybersecurity needs of SMEs, ensuring comprehensive coverage across various aspects of cybersecurity. Its high ease of implementation makes it accessible for SMEs lacking extensive cybersecurity expertise. Furthermore, ASMAS is cost-effective, an essential consideration for SMEs operating on limited budgets. The model's scalability ensures it can adapt and grow with the SME as its operations expand.

In conclusion, ASMAS provides a balanced and robust framework for SMEs to assess and enhance their cybersecurity posture, making it the most appropriate choice among the evaluated models. This framework will help SMEs manage their cybersecurity risks effectively, ensuring a secure and resilient digital environment.

Real-Time Robotic Force Control for Automation of Ultrasound Scanning

Ungku Muhammad Zuhairi Ungku Zakaria, Seri Mastura Mustaza*,
Mohd Hairi Mohd Zaman, Ashrani Aizzuddin Abd Rahni

Department of Electrical-Electronic and Systems Engineering-Faculty of Engineering and Built Environment,
Universiti Kebangsaan Malaysia, 43600 UKM Bangi, Selangor Darul Ehsan, Malaysia

Abstract—Ablation represents a minimally invasive option for liver cancer treatment, commonly guided by imaging techniques such as ultrasound. Recently, there has been a surge in interest in semi-automated or fully automated robotic image acquisition. Specifically, there is a continuing interest in automating medical ultrasound image acquisition due to ultrasound being widely used, having a lower cost, and being more portable than other imaging modalities. This study explores automated robot-assisted ultrasound imaging for liver ablation procedures. The study proposed utilizing a collaborative robot arm from Universal Robots (UR), which has gained popularity across various medical applications. A robotic real-time force control system was designed and demonstrated to regulate the contact force exerted by the robot on the surface of a torso phantom, ensuring optimal contact during ultrasound imaging. The Robot Operating System (ROS) and the UR Real-Time Data Exchange (UR-RTDE) interface were employed to control the robot. The findings indicate that the contact force can be maintained around a set desired value of 9N. However, deviations occur due to residual forces from acceleration when the probe is not in contact with the phantom. These results provide a foundation for further advancements in the automation of ultrasound scanning.

Keywords—Real-time; position control; force control; ROS; collaborative robot; admittance control; kinematics; dynamic; tool center point; damping

I. INTRODUCTION

Ablation is a well-accepted minimally invasive procedure for treating certain cancerous tumors, especially in the case of liver cancer [1]. In ablation, image guidance is necessary during the procedure, such as using ultrasound and computed tomography (CT) fluoroscopy [2]. Navigation of the ablation needle is often performed manually under the expert guidance of the clinician and is operator-dependent. However, in some cases where there are not enough trained specialists, the radiologist may have to perform both the ablation procedure and ultrasound scanning simultaneously [24].

There is an increasing interest in automating the acquisition of medical ultrasound images due to its widespread use, cost-effectiveness, and portability compared to other imaging modalities. One promising approach involves using robotic arms, initially focused on remote ultrasonography or tele-imaging. Recently, attention has shifted towards semi-automated and fully automated robotic image acquisition systems. Hennersperger et al. [3] developed an innovative robotic ultrasound system utilizing the LBR iiwa robot. This system can autonomously execute imaging trajectories based on

start and end points pre-selected by a physician in pre-interventional images such as MRI or CT scans. The trajectory is calculated by identifying the nearest surface point within the MRI data and integrating it with the corresponding surface normal direction to ensure accurate imaging. Von Haxthausen et al. [4] advanced this field by developing a system that, after the initial manual placement of the ultrasound probe, uses convolutional neural networks (CNNs) to control the robot and follow peripheral arteries. This integration of CNNs allows the system to adapt to complex anatomical variations and dynamically adjust the probe position, enhancing the precision and efficacy of the ultrasound imaging process. These advancements illustrate the potential of robotic systems to improve the accuracy and efficiency of medical ultrasound procedures. Using a robot arm to assist in ultrasound scanning frees the physician to focus on the ablation procedure. The robot arm end effector or gripper holds and manipulates the ultrasound probe to perform scanning during the ablation procedure [5]. The robot arm must have a range of motion for a full abdomen examination. At the same time, the force applied by the robot arm should be optimal for obtaining the best ultrasound images without causing any injury to the patient [6] [7]. Furthermore, fine-tuning the ultrasound probe position is also a requirement for the robot-assisted system to mimic human radiologists [8] [9].

This paper presents the development of a robotic ultrasound scanning system designed to fully replace sonographers, addressing a critical challenge faced by radiologists who simultaneously perform both ablation and ultrasound scanning. The introduction of robotic arms for ultrasound scanning allows medical practitioners to concentrate exclusively on ablation procedures, thereby enhancing their ability to deliver precise and effective treatment. Medical practitioners who multitask and perform both ablation and ultrasound scanning have difficulty handling and positioning the ultrasound probe during ultrasound scanning while doing ablation simultaneously. The implementation of robotic automated ultrasound scanning not only ensures consistent precision in imaging but also alleviates the complexities of manually handling and positioning the ultrasound probe during dual-task procedures. In employing robot arm replacing the sonographer, the automated robotic ultrasound scanning can be implemented.

This paper introduces a novel approach with real-time force control integrated into the robotic system based on Universal Robots (UR10e). The force control is particularly tailored for dynamic environments, utilizing an admittance control strategy

that responds to feedback forces. This approach ensures compliant force control, crucial for detecting and mitigating excessive force applied during scanning. Additionally, the consideration of damping in the admittance control strategy further enhances force accuracy and prioritizes patient safety during the scanning process. For hardware, the robot arm UR10e was used for the apparatus of ultrasound scanning. The custom gripper was attached to UR10e's end-effector and used to grip the ultrasound probe. The mechanism and shape of the custom gripper also aid the robot in mimicking the exact angle and the point for scanning the human body. The real-time force control was done similar to the point of scanning on the body and the angle of the real sonographer during ultrasound scanning.

The subsequent sections are structured as follows: Section II presents a comparison of the literature review. Section III outlines the methodology for hardware and software setup, as well as their integration for seamless operation. In Section IV, the findings from conducting robotic automated ultrasound scanning are detailed, along with an analysis of the results. Lastly, Section V offers conclusions and discusses future avenues of work.

II. LITERATURE REVIEW

Robot-assisted ultrasound scanning requires advanced and precise robot arm control [6], especially during an ablation procedure. In a typical system, a single robot arm holds and moves the ultrasound probe. The robot arm trajectory is initially planned in the pre-operative phase based on acquired CT or MRI images [6]. Advanced multimodal visualization is required for pre-operative image-based planning in this case. Forward kinematics can be computed to plan the robot arm trajectory based on Denavit-Hartenberg (D-H) parameters [10][5]. Two control methods have been used for gaining precise and accurate control for physical human-robot interaction, i.e., impedance control and admittance control [26]. For Impedance Control, the input gained is displacement or velocity, and the output is force. In vice versa, the Admittance Control input is force, and the output is displacement or velocity [27]. For this paper, the admittance control was implemented to set the amount of force desired and receive the feedback force from the contact so the robot would maintain the force value based on the amount of force selected.

Given the critical importance of contact force in ultrasound scanning, several recent studies have focused on ensuring constant contact force. Ulrich et al. [11] reported a mean contact force of 9 N with a peak force of 37 N during obstetric scanning. Similarly, Ning et al. [12] found a mean contact force of 8.5 N. In contrast, Chen et al. [13] recommended a lower contact force of 4.5 N for scanning the human body using Universal Robots (UR). Wang et al. [14] suggested initiating contact with a force of 15 N, subsequently maintaining it at 10 N for optimal imaging of the human spine. Kaminski et al. [15] proposed a target contact force of 7 N to ensure stable data acquisition. Meanwhile, Mohamed [16] established a reference range of 3-5 N for ultrasound scanning to balance probe stability and patient comfort. These varying recommendations highlight the need for context-specific force adjustments to enhance the precision and reliability of robotic ultrasound systems across different medical applications.

The duration of ablation procedures, particularly radiofrequency ablation (RFA), is a critical factor in their effectiveness and safety. Ma et al. [17] reported that the mean procedure time for ultrasound (US)-guided RFA is approximately 27.54 ± 12.06 minutes. In a study by Zeno et al. [18], the median duration of RFA was 14 minutes, ranging from 10 to 19.5 minutes. Over a decade-long study, Shuangyan et al. [19] found the median ablation time to be 26 minutes, extending from 12 to 120 minutes. Additionally, Zuo-Feng Xu et al. [20] observed that synchronizing US and CT images required an average of 13.9 ± 11.9 minutes, ranging from 5 to 55 minutes. They also noted that each individual or overlapping ablation session lasted approximately 12 minutes [20] [21]. In contrast, Wei et al. [22] reported a consistent ablation duration of 10 minutes per session. These findings highlight the variability in ablation times, which can be influenced by factors such as the imaging modality used, the complexity of the case, and the specific protocols of different medical centers. Understanding these timeframes is essential for optimizing procedure planning and improving patient outcomes.

III. METHODOLOGY

The hardware setup employed in this study will be comprehensively described, emphasizing the specific equipment and configurations utilized throughout the research. This includes detailed information on the types of hardware components and how they are integrated into the overall system. Subsequently, the software setup will be described, focusing on the software interfaces and implementation of software tools, as well as the software system's architecture. Finally, the force control mechanism will be thoroughly examined. This involves an in-depth discussion of the feedback control systems implemented to regulate the contact force applied by the robotic arm. The methodology for applying and adjusting the force over a specified duration will be detailed, including the algorithms and sensors used to achieve precise control.

A. Hardware Setup

The collaborative robot arm UR10e model from Universal Robots (UR) was chosen as the manipulator in handling the ultrasound probe to automate ultrasound scanning. Fig. 1 illustrates the hardware setup of the UR robot.

Fig. 1. (a) Hardware setup of ultrasound scanning (b) Hardware setup of the experiment with a coordinate system.

A partially rigid phantom was employed in this study to represent a human body. The anterior surface of the phantom is partially covered with cured Ecoflex 00-50 gel, a silicone gel that is commonly used for ultrasound phantoms [23]. As illustrated in Fig. 1(a), the robot is equipped with a custom gripper designed to handle an ultrasound probe. This probe

choice ensures that our experimental setup closely mirrors clinical practice, enhancing our findings' validity and applicability. The robot's coordinate system is as illustrated in Fig. 1(b). The origin coordinate is established at the base of the robot. The orientation was defined as Euler angles around each axis: $\theta = [\theta_x \ \theta_y \ \theta_z]$. Consequently, the robot's pose is represented as a 6-element vector comprising the 3D position, $p = [x, y, z]$ (in meters), and the orientation, θ (in radians), forming the vector $[x, y, z, \theta_x, \theta_y, \theta_z]$. The robot's end effector is equipped with a built-in force/torque sensor. This sensor is instrumental in measuring the external forces exerted by the phantom. The specifications of the built-in force/torque sensor are detailed in Table I, highlighting its range, precision, and accuracy.

TABLE I. SPECIFICATION OF BUILT-IN FORCE/TORQUE SENSOR IN UNIVERSAL ROBOT UR10E

Force sensing, tool flange/torque sensor	Force, x-y-z	Torque, x-y-z
Range	100.0N	10.0 Nm
Precision	5N	0.2 Nm
Accuracy	5N	0.5 Nm

B. Software Setup

Robot Operating System (ROS) is used in this work in a computer with Ubuntu operating system. The integration of UR dependencies facilitates the control of the UR robotic arm. This integration enables the robot to be managed by a computer, displaying the data acquired from the UR system. For real-time control, the UR Real-Time Data Exchange (UR-RTDE) libraries are being specifically utilized to harness the capabilities of the UR robot arm. Python was selected due to its robustness and extensive support for both ROS and UR-RTDE libraries to implement the ROS and UR-RTDE interface.

Fig. 2 illustrates the control architecture for the automation of ultrasound scanning. F_a represents the external contact force exerted to the probe, F_d represents the desired force, and F_e is the difference between them.

Admittance control was applied for this work. Robot admittance control models [25] [26] [27], were used to maintain the force value exerted during ultrasound scanning of the ablation process, mimicking the scan conducted by the sonographer. The control model is represented by the following equation:

$$F_e(\tau) = F_a(\tau) - F_d(\tau)$$

$$F_e(\tau) = M(x \ddot{\tau} - \ddot{x}_d(\tau)) + \Delta (x(\tau) - \dot{x}_d(\tau)) + K (x(\tau) - x_d(\tau)) \quad (1)$$

where, M is virtual mass, D is damping and K is stiffness coefficient. x_d denotes the desired position of the tip of the robot, while x is the position, \dot{x} is the velocity and \ddot{x} is the acceleration. The admittance control model is applied across each degree of freedom. However, our focus can only be directed towards the degrees of freedom along the x-axis- and z-axis.

Fig. 2. Block diagram of force control system.

Based on Eq. (1), the admittance parameters can be adjusted to achieve specific dynamic characteristics of the robot system in the presence of external forces, i.e., from the patient or a static phantom. Phantom is only static. Therefore, M and K have been set as fixed values. So, D will be adjusted and controlled. For the UR force control interface, the range of the damping parameter can be set from 0 to 1, which the default value of the damping parameter is 0.005. The higher the value, the greater the deceleration during exerted force, and vice versa [28]. Deceleration is required to reduce force overshoot, thus reducing excessive force. Hence, an evaluation comparison of the damping factor was conducted to choose the best value. Four damping factors were compared: 0.005, 0.01, 0.02, and 0.05.

Referring to Fig. 2, the input force F_e , the difference between F_a and F_d , was applied to the admittance control, which resulted in moving to the displacement desired, x_d . Next, the inverse kinematics of the robot, IK, received input, x_d , and produce output, q_d to move the joint in position control closed loop. Afterward, forward kinematics of the robot, FK releases the output x to the environmental stiffness, which is the phantom resulting in the contact force, F_a . The force sensor will detect the value of F_a , and then send the value to be compared with the desired force input F_d , which resulting force input F_e .

To verify the efficiency of force control, including admittance control, a comparison between position control and overall force control was made to choose which control system is the best for full robotic automated ultrasound scanning. Three conditions were tested for evaluation, which are a slow movement with an acceleration of 0.1 ms^{-2} , fast movement with acceleration of 2 ms^{-2} and in a static position.

C. System Integration

Integration of hardware and software setup has been made for force control. A full operation of force can be achieved by satisfying a force overshoot capability involving position function, as shown in Fig. 3.

Referring to Fig. 3, the robot arm operates based on commands issued from the computer. The force is detected on the Tool Center Point (TCP) that has been set. To apply force, the position of the end-effector changes toward the direction of the force applied. Once the force sensor detects the external force, the measured force value is transmitted to the computer. When there is a deviation between the measured force and the desired force value, the computer processes this information and sends corrective commands to the robot to maintain the desired force during operation.

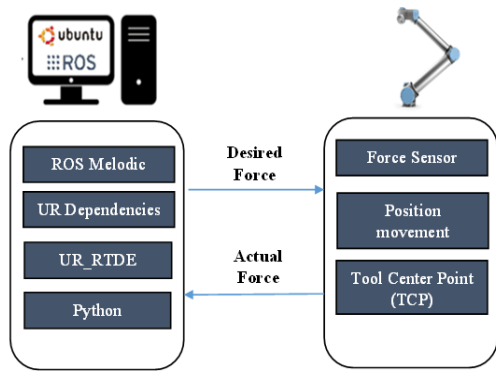

Fig. 3. Full setup of a system.

Using the UR-RTDE interface, the initial pose first needs to be set. The initial pose that has been set for this work is $[-0.5, -0.1, 0.15, 0, 70/180 \pi, 0]$. The pose can be seen in Fig. 4, along with the original and new Tool Point Center (TCP) of the robot, which is $[0, -0.055, 0.058, 0, 0, 0]$ (green). This change is to ensure the accuracy of choosing a better coordinate for scanning. This new TCP has been set, and the pose coordinates were referred to at the end of the probe.

Fig. 4. Original TCP (Yellow) and New TCP (Green).

As illustrated in Fig. 5, the force task frame was set to $[0, 0, 0, 0, 1.0472, 0]$ for the force to be exerted at 1.0472 radian pointing towards the phantom due to mimicking the liver position of the human.

When the configuration above is completed, the experiment has been done. The damping factor values have been evaluated, and the suitable values have been chosen. A comparison of position control and force control was also conducted to ensure the most compatible control system. After those evaluations have been executed, force control can be conducted. 9N was chosen based on the obstetric median force value [11], and 9N must be maintained when the force is exerted on the phantom. This work is set for 12 minutes during the exertion of force based on the time taken for ultrasound scanning conducted [20] [21]. The process flow of this experiment is shown in Fig. 6.

According to Fig. 6, the robot end-effector will first move to the initial position. Subsequently, a force is applied. If the detected force deviates from 9N, the robot will adjust to maintain a force of 9N. Upon achieving a stable force of 9N, the robot will operate for a duration of 12 minutes. Throughout this

period, the force of 9N will be consistently maintained until the 12-minute mark is reached. Once the 12 minutes have elapsed, the robot end-effector will return to the initial position, concluding the process.

Fig. 6. Flowchart of the force control experiment.

IV. RESULTS AND DISCUSSIONS

The experiment was conducted based on the setup that have been made. Firstly, the evaluation of damping factor values was conducted. Subsequently, a comparison of position and force control was made involving admittance control. Finally, force control of robotic automated ultrasound scanning was performed to appraise force retention over a certain amount of time.

The damping factor was evaluated to determine the most suitable overshoot for applying the force. Four damping values were selected, and the corresponding forces were measured. Additionally, a comparative analysis was conducted between position control and force control. Initially, the force was measured using position control alone. Subsequently, force control was implemented using the damping factor value selected from the prior comparison.

After evaluating the damping factor and the suitable control for applying force to the phantom, the force control was conducted for 12 minutes to evaluate the consistency of the force, which is 9N.

A. Evaluation of Damping Factor

Experimental testing was carried out to characterize the damping and overshoot of the contact forces between the ultrasound probe attached to the UR robot and the phantom to investigate the performance of the force control system. The robot exerted a 9N force onto the phantom in this experiment for 12 seconds. The damping factor was systematically varied between 0.005 and 0.05, and the resulting contact forces between the ultrasound probe and the phantom were recorded, as well as the overshoot that occurred upon contact. The results of this experiment are shown in Fig. 7(a)-(d).

At a damping factor of 0.005, as illustrated in Fig. 7(a), the force overshoot initially peaks at 15N before stabilizing at 9N by the 4th second overshoot. When the damping factor is increased to 0.01, as shown in Fig. 7 (b), the force overshoot peaks between 10N and 15N and stabilizes at 9N by approximately the 3rd second overshoot. With a damping factor of 0.02, as depicted in Fig. 7 (c), the force overshoot shows stabilization at 9N shortly after the two seconds overshoot. Finally, at a damping factor of 0.05, shown in Fig. 7 (d), no force overshoot is observed, and 9N of force is applied just before the two seconds.

The percentage overshoot corresponding to each damping factor is tabulated in Table II. The percentage overshoot of the applied force at a damping factor of 0.005 is 61%. As the damping factor is increased to 0.01, the percentage overshoot decreases to 41%. Further increasing the damping factor to 0.02 results in a percentage overshoot of 26.55%. At a damping factor of 0.05, the percentage overshoot is completely eliminated, reaching 0%.

These observations demonstrate a clear inverse relationship between the damping factor and the percentage overshoot. Specifically, as the damping factor increases, the percentage overshoot of the applied force decreases correspondingly. This trend highlights the effectiveness of higher damping factors in achieving rapid stabilization of the force with minimal overshoot. Achieving zero overshoot at a damping factor of 0.05 indicates optimal damping, where the force control system can maintain the desired force precisely without any initial excess. This optimization is crucial for ensuring the reliability and accuracy of the ultrasound imaging process, as it minimizes the risk of excessive force application that could compromise image quality or cause damage to the phantom.

Fig. 7. The force value with damping factor (a) 0.005 (b) 0.01 (c) 0.02 (d) 0.05.

TABLE II. THE FORCE PERCENTAGE OVERSHOOT OF THE RESPECTIVE DAMPING FACTOR

Damping factor	Percentage overshoot (%)
0.005	61
0.01	41
0.02	26.55
0.05	0

B. Comparison of Position Control and Force Control

A comparative analysis between position control and force control was conducted to identify the most suitable method for applying force. Three conditions were examined to determine the optimal control strategy, which are 1) slow robot arm movement, 2) fast robot arm movement, and 3) static arm position. For the slow and fast movement condition, the ultrasound probe was controlled to move on and along the phantom stomach, starting from the liver towards the opposite side and returning to the liver position. For the slow movement, the robot arm drives the ultrasound probe at 0.1 ms^{-2} for 7 seconds, while for the fast movement, the acceleration is 2 ms^{-2} and the experiment runs for five seconds. The robot remained stationary at the liver area coordinates while contacting the phantom for the static condition. The comparison of position control and force control was plotted in Fig. 8 for slow movements, Fig. 9 for fast movement, and Fig. 10 for static position. 9N was set as the desired value to be achieved and was indicated with a horizontal line in Fig. 8, Fig. 9, and Fig. 10. The dashed line indicates position control, and the star line indicates force control.

Fig. 8. Comparison of position control and force control in acceleration of 0.1 ms^{-2} .

Fig. 9. Comparison of position control and force control in acceleration of 2 ms^{-2} .

Referring to Fig. 8, there are three lines in the graph that indicate the timeline of the position of the end-effector. The first line indicates the end-effector touching the phantom, which is 2.5 seconds; the second line is the movement from the liver to the stomach, which is 4.8 seconds; and the third line indicates the end-effector was returned to the liver part, which is 7.1 seconds. In the first line, the force in the position control is higher and has a huge difference compared to the force control

below 9N. Upon reaching the second line, the force in the position control overshoots above 27N and drops drastically below 9N. Meanwhile, the force in the force control fluctuates close to 9N and tries to maintain the desired value, 9N. Finally, upon the march to the third line, the force in the position control overshoots again until above 18N and drops drastically. In contrast to force control, the force is very close to 9N, but eventually, the force value drops as it reaches the third line.

Based on Fig. 9, three vertical lines in the graph indicate the timeline of the end-effector's position. The first vertical line indicates the end-effector touching the phantom, which is at 1.4 seconds; the second line is the movement along the abdominal part, which is 2.8 seconds; and the third line indicates the return of the probe to the liver part, which is 4.2 seconds. In the first line, there were no significant differences in force between position control and force control. However, substantial differences exist in which the force in the control position was higher than the force in force control upon reaching the second line. Forces on both controls were turbulent. However, the force control is closer to 9N than the position control. Similar cases occurred from the second line to the third line in which the value of force in position control is greater than that in force control. After the graph's third line, the force value on both controls drops significantly.

Fig. 10. Comparison of position control and force control in static position.

According to Fig. 10, two lines in the graph indicate the timeline of the end-effector's position. The first line indicates the end-effector touching the phantom, which is two seconds, and the second line is the position of the end-effector was lifted away from the phantom, which is 12 seconds. This graph illustrates the huge difference amount of force between position control and force control. On position control, the amount of force exceeds 100N and slightly decreases upon touching the phantom. However, it still overruns the desired amount of force, which is 9N. Contrarily, the force value in force control maintained 9N from the first line upon touching the phantom until the end effector was lifted away from the phantom. After the second line, the difference in force decrement was displayed. The value of force in force control dropped quickly compared to the force of the position control.

Based on the overall analysis, the amount of force in force control is closer to achieving the desired value than the position control, which is 9N. Even though there is a fluctuation of force value in Fig. 8 and Fig. 9 due to acceleration during movement and the curve surface of the phantom, the difference in the force

value from force control is lower compared to the position control. Meanwhile, in Fig. 10, the force control achieved and maintained the desired value of 9N compared to the position control, which exceeds the higher value.

It can be stated that using force control is more stable than using position control due to its closer adherence to the desired force value. When comparing acceleration, the force control method, with an acceleration of 0.1 ms^{-2} , proves to be the optimal control strategy. This is because lower acceleration results in lower force overshoot. The static condition experiment proves that the force control strategy employed is capable of maintaining the desired force value during its entire operation of 12 mins.

C. Operation of Force Control

Referring to the motion sequence described in Fig. 6, the resultant x-axis position, the resultant z-axis, and the magnitude of the force in the x-axis and z-axis, $|F_{xz}|$ is shown in Fig. 11, Fig. 12, and Fig. 13 Firstly, the end effector will go to the initial position that has been set. Then, the robot will exert 9N on the phantom. The full operation of robotic force control was run for 12 minutes.

Fig. 11. x-axis position.

Fig. 12. z-axis position.

From Fig. 11 and Fig. 12, the x-axis and z-axis positions are at the initial position, which is pose $x=-0.5\text{m}$ and pose $z=0.15\text{m}$. Then, it suddenly changed due to the force direction towards the x and z direction. The force exerted can be seen in Fig. 10. From Fig. 13, no force is exerted when the end-effector is in the initial position. Then, the force of 9N is exerted upon touching the phantom. Next, the force was maintained at 9N along the operation. Even though there were light changes of force, the

robot was able to maintain the force based on feedback until 12 minutes. This result, with a mean force of 9.503N and a standard deviation of 0.282N, corresponds to the force measured during abdominal scans in a previous study conducted by Ulrich and Struijk [11]. After 12 minutes, the x-axis and z-axis positions will return to the initial positions. Meanwhile, the force decreases drastically when the probe does not contact the phantom.

Fig. 13. Force along xz-axis, $|F_{xz}|$.

V. CONCLUSION

Ablation is a minimally invasive method for combating and eliminating liver cancer that involves crucial procedures such as ultrasound scanning. However, a single sonographer's simultaneous conduct of ablation can pose challenges. Hence, a proposal for robotic automated ultrasound scanning employing force control has emerged. Utilizing Universal Robot, the hardware and the corresponding software algorithm have been set up. Evaluation has been carried out, focusing on comparing damping factors and the efficacy of position control versus force control. It has been demonstrated that a damping value of 0.05 results in zero percentage overshoot. Furthermore, implementing force control ensures a more stable force than relying solely on position control. The full operation, lasting 12 minutes, maintains the desired force of 9N until its completion.

The real-time robotic force control was proven reliable in ultrasound scanning during liver ablation. The experiment above shows that contact force can be maintained around 9 N, albeit with deviation due to the residual force from acceleration when the probe is not in contact with the phantom. This shows that 9N can be applied on the phantom and, hence, on real ultrasound sonography. Furthermore, this paper can be used for further development of robot-assisted ultrasound scanning.

For future work, the cohesive gripper can be designed to be compatible with various types of ultrasound probes and robotic end-effectors, facilitating seamless attachment. The implementation of a compatible gripper is essential to maintain accuracy and efficiency during ultrasound scanning procedures.

Additionally, integrating image recognition technology with automation could enhance the system, allowing the robot to precisely identify the optimal location for performing ultrasound scans on the targeted area. This would eliminate the need for the patient to precisely position themselves against the surface where the robot is set to perform the ultrasound at a predetermined point.

Abstract—Automated Recycling Machine (ARM) can be defined as an interactive tool to flourish recycling culture among community by providing incentive to the user that deposit the recyclable items. To enable this, the machine crucially needs a material validation module to identify the deposited recyclable items. Utilizing combination of sensors for such purpose is a tedious task and hence vision-based YOLO detection framework is proposed to identify three types of recyclable material which are aluminum can, PET bottle and tetra-pak. Initially, the 14883 training samples and 937 validation samples were fed to the various YOLO variants for investigating an optimal model that can yield high accuracy and suitable for CPU usage during inference stage. Next the user interface is constructed to effectively communicate with the user when operating the ARM with easy-to-use graphical instruction. Eventually, the ARM body was designed and developed with durable material for usage in indoor and outdoor conditions. From series of experiments, it can be concluded that, the YOLOv8-m detection model well suit for the ARM material identification usage with 0.949 mAP@0.5:0.95 score and 0.997 F1 score. Field testing showed that the ARM effectively encourages recycling, evidenced by the significant number of recyclable items collected.

Keywords—Recycling machine; You Only Look Once (YOLO); vision system; interactive recycling; deep learning

I. INTRODUCTION

Recycling is a critical waste management strategy that involves collecting and processing discarded materials into new products. In Malaysia, the recycling initiative began in 1993 and unable to achieve its goals due to lack of significant awareness programs [1]. Consequently, the Ministry of Housing and Local Government launched the National Recycling Program on 2 December 2000, designating 11 November as National Recycling Day to highlight the importance of recycling. Despite numerous efforts, an environmental issue related to waste pollution are a significant concern in Malaysia since it was ranked eighth globally for mismanaged plastic waste [2]. Effective implementation of the 3R (reduce, reuse, recycle) strategies is essential to minimize waste sent to landfills and extend their lifespan. Typically, municipal solid waste in Malaysia consists predominantly of food waste, followed by recyclable materials like plastic, paper, glass, and aluminum cans [3]. Hence, adopting comprehensive

recycling strategies is crucial to achieving the effective waste management targets.

Globally, many countries, including China [4], India [5], South Africa [6], Switzerland [7], and Malaysia [8], have adopted systematic waste management techniques. The integration of technology in waste management has gained significant attention, with innovations like the Reverse Vending Machine (RVM) demonstrating the potential to increase recycling activities. Technologies such as RFID [9-11], Wireless Sensor Networks [12], and VANET [13] have shown that they can provide comprehensive waste management solutions and encourage proper waste disposal.

Combining technology with a reward system has proven reliable and effective in supporting recycling initiatives as demonstrated by smart recycle bin [14] [15]. However, the reliance on multiple sensors for identifying recyclable materials prior point issuance requires tedious sensor arrangement, calibration and maintenance, making it unsuitable for long term use. Vision-based technology on the other hand, can recognize a broader range of recyclable items using vast number of features collected from the sample image. One of the works is from [16] in which they introduced ThrashNet dataset and use SIFT feature with SVM and CNN model of AlexNet -like architecture. Andrey et al. [17] developed a reverse vending machine with several CNN classification models, analyzing the effect of training by combining two different dataset clusters. On average their CNN model achieved over 85% accuracy. They further tested the module in real-world implementation by combining weigh sensor with the CNN for fraud detection [18].

Recently, YOLO become trends for recyclable waste detection due to its real-time object detection capabilities and high accuracy. YOLO architecture allows for the simultaneous detection and classification and hence make it ideal for dynamic environments where waste items vary in size, shape, and type. A study from [19] utilized YOLO with a depth camera to accurately determine the type and location of waste in 3D. Additionally, incorporating YOLO in ARMs aligns with broader trends in AI-driven waste management systems, which emphasize the integration of vision-based automated sorting for efficient recycling processes [20] [21]. The effectiveness of YOLO in these applications is further supported by research highlighting its adaptability and performance in real-world

scenarios, thereby facilitating the development of intelligent waste management solutions [22] [23]. Currently, there are many types of YOLO variants available. Detail explanation from the first model which was introduced in 2015 up until the recent one can be found from study [24].

Numerous studies have focused on detection models for recycling waste identification across various applications. However, there is limited research on the real-world implementation of these detection models and their effectiveness when deployed with targeted stakeholders. This paper investigates a detection-based model for optimal implementation in recycling, incorporating a reward system to enhance user engagement. Additionally, it assesses the system feasibility through onsite testing. The paper is organized as follows: Section II details the methodology used throughout this project, Section III and Section IV presents the results and discussion respectively, and Section V concludes the project with final observations.

II. MODELS AND METHOD

In this section, detailed explanation about model and architecture used throughout this project is explained. It comprises of four main subsections namely dataset preparation, detection model development, and user interface design and automated recycle system formation. To make the automated recycling machine (ARM) cost effective, its platform will run on Intel i7 CPU with 16GB RAM and 256GB SSD storage.

A. Datasets Preparation

In this project, samples of recycling images are obtained locally to ensure that the ARM model can differentiate the item effectively. The arrangement for capturing the sample images is shown in Fig. 1 in which the camera is positioned 21 cm above the ground with the samples placed 51cm from the camera. A total of 5,872 samples were collected and categorized into three groups, namely PET bottle, aluminum can and tetra-pak as depicted in Fig. 2. These collected images undergo a series of augmentation process which comprises of saturation and brightness adjustment, rotation, blurring and noise contamination and expand the data to 15,820. Once completed, the data were divided into training and validation sets with 14,883 samples for training and 937 samples for validation. Roboflow platform is used to augment, annotate and format the data to well suit the selected version of the detection model. Detailed sample distributions for each cluster can be seen in Table I.

B. Detection Model Development

For detection module, the main structure employed in this project is based on ‘You Only Look Once’ (YOLO) object detection. Basically, it starts with the forming of grid cells, followed by class prediction across scales, and eventually bounding box location estimation via regression process. The finer grid cell enables smaller target detection and anchor box makes it possible to detect an overlapping object with high accuracy. There are many variants of YOLO model starting from version v1 to version v10. In this project, three recent models which are YOLOv8, YOLOv9 and YOLOv10 were used. Basically, most of the YOLO architecture can be divided into three main components which are backbone, neck and

head. The backbone is the part that is responsible for extracting an important feature from the input image. Once the features are extracted, the neck will combine the multi-scale information and channel it to the head section. The head generates predictions based on the extracted information from the backbone and the neck.

YOLOv8 [25] is the architecture evolution from its predecessor YOLOv5 [26] that was developed by Ultralytics. It introduces several enhancements over its predecessors by focusing on improving efficiency, accuracy and ease of use for object detection tasks. The backbone of YOLOv8 was derived and improved from CSPDarknet53 structure which consists of 53 convolutional layers. Apart from that, cross-stage partial connections that facilitate better information flow between layers were integrated. This optimization helps in capturing more detailed features from the input images. In the neck segment, YOLOv8 adopts combination of feature pyramid network (FPN)[27] and path aggregation network (PAN) [28]. This strategy contributes to improving the detection capability of targets at different scales. The head of YOLOv8 utilizes an anchor-free design, which simplifies the detection process and improves overall speed and accuracy. YOLOv8 models are available in five variants which distinguish between number or parameters and accuracy. However, since the aim of this project is focusing on implementation of the model on CPU, three pre-trained models that are well balance between complexity and accuracy were selected which are YOLOv8-n, YOLOv8-s, and YOLOv8-m.

TABLE I. NUMBER OF IMAGE DATASET IN EACH RECYCLE ITEM IMAGE CATEGORY

Image	Training	Validation
Aluminum Can	4005	248
PET Bottle	9054	569
Tetra-pak	1824	120
Total	14883	937

Fig. 1. Setup arrangement for dataset preparation.

Fig. 2. Sample of tetra-pak, PET bottle and aluminum can.

YOLOv9 [29] builds upon the foundations laid by YOLOv7 [30] structures and further refinements to enhance detection capabilities. One of the key features of YOLOv9 is the integration of Programmable Gradient Information (PGI) and the Generalized Efficient Layer Aggregation Network (GELAN). The combination has shown strong competitiveness among other models and maintains a balance between reducing the number of parameters and floating-point operations per second (FLOPs) while achieving superior performance compared to earlier versions. For this project a compact model of YOLOv9 known as YOLOv9-c is used as the pre-trained model for the recyclable waste detection assessment.

YOLOv10 [31] introduces significant architectural changes aimed at optimizing performance and reducing complexity. The backbone of YOLOv10 employs enhanced CSPNet which is lightweight design with a rank-guided block architecture that identifies and replaces stages with higher redundancy. This approach reduces the number of parameters and FLOPs, enhancing the model efficiency without compromising performance. The neck of YOLOv10 features improved feature pyramid networks using path aggregation network that better handle multi-scale feature fusion. The head of YOLOv10 is optimized to streamline the detection pipeline, ensuring maximum accuracy and minimal computational overhead. These enhancements make YOLOv10 particularly effective for real-time applications, where computational resources are often limited. YOLOv10 has six final architectures. To balance between speed and accuracy of the system, three YOLOv10 architectures which are YOLOv10-n, YOLOv10-s and YOLOv10-m are further analyzed for the automated recycle waste implementation.

TABLE II. SUMMARY OF YOLO PRE-TRAINED MODEL USE FOR TRAINING THE RECYCLABLE WASTE DATA

Model	Size	Parameters	FLOPs
YOLOv8-n	640	3.2M	8.7G
YOLOv8-s	640	11.2M	28.6G
YOLOv8-m	640	25.9M	78.9G
YOLOv9-c	640	25.3M	76.3G
YOLOv10-n	640	2.3M	6.7G
YOLOv10-s	640	7.2M	21.6G
YOLOv10-m	640	19.1M	59.1G

Table II summarizes the YOLO pre-trained models used to train the recyclable waste dataset. The models are selected based on the current state of the art detection models and have an adequate number of parameters to be used by CPU in the inference stage. From the assessment, a single model that yields a high performance with lower parameters will be selected for fulfilling the needs of an automated waste recycling module system.

C. User Interface Design

To construct the user interface a C# platform along with YoloDotNet v2.0 is utilized. Initially, the optimal weight of the YOLO model is exported to ONNX format to ensure compatibility with the .NET platform. ONNX is an open-source format that is compatible with different deep learning platforms and hence will be convenient for model sharing and

deployment. The process using the system will consist of simple four steps as follows:

- 1) *Initiation*: Users push the start button in the welcoming screen to initiate the process.
- 2) *Verification*: The deep learning module verifies all deposited items.
- 3) *Completion*: To end the process, users press the finish button which prompts a screen requesting user information.
- 4) *Point collection*: If users wish to collect point, they can enter their phone number or leave it blank, if otherwise.

D. ARM Design and Setup

In this section, design and setup about the ARM body structure will be elaborate in detail. An illustration about the machine drawing is depicted in Fig. 3 where the whole structure design is shown on the left side and the chute architecture with camera placement is shown on the right side. The overall dimension of the machine is 1000mm width, 1000mm depth and 1800mm height. Regarding the materials, frame body structure is constructed using 25mm x 25mm hollow steel bars, and the casing is developed using 1mm galvanized steel sheets. Referring to the chute design, a high camera resolution is located 210mm above the chute base and tilted downwards at 45° angle. A 22-inch touch screen is utilized as the information display medium and serves as the user interface input.

Fig. 3. ARM body design of the machine (left) and detail design of chute with location of camera (right).

III. RESULTS

This section offers a thorough examination of the performance of the detection model and how it was used to automate recycling with an integrated reward system. The three primary components of the analysis are evaluation of the YOLO models, user interface design, and automated recycling module implementation in real-world circumstances, and. The evaluation of the YOLO model involves assessing its mAP, F1 score, and precision in identifying different recyclable materials. The goal of the user interface design is to provide a platform that is simple to use and intuitive so that users can interact with the recycling system. In the end an implementation section describes how the user interface and detection model are combined to create a recycling module that works well in real-world situations.

Fig. 4 illustrates image samples of PET bottles, aluminum cans, and tetra-paks, which have undergone a series of augmentation processes to enhance the sample image for training session. These augmented images are used to train the detection model, ensuring it can accurately identify and classify different types of recyclable materials under various conditions.

Fig. 4. Sample of training batch images where 0 denoted for PET bottle, 1 for aluminum can, and 2 for Tetra Pak.

A. YOLO Model Assessment

This section will elaborate about the experiments conducted to deliberately discuss results obtained for the YOLO detection module framework. There are three versions of YOLO models tested which are YOLOv8, YOLOv9 and YOLOv10. The optimal model is selected based on its performance and medium level complexity to meet the requirement of CPU usage. The metrics considered for analysis are mAP@0.5, mAP@0.5:0.95, F1 Score, and Recall. Table III summarizes the findings.

From the table, among the investigated models, Yolov8-m stands out with a well balance between mAP@0.5:0.95 and F1 score. This model achieves a mAP@0.5 of 0.994, mAP@0.5:0.95 of 0.949, F1 score of 0.997, and a Recall of 0.998. The average mAP@0.5 across all models is 0.994, with a range from 0.994 to 0.995, indicating uniformly high precision across investigated models. However, the distinction in performance is more noticeable in the mAP@0.5:0.95 metric, which averages 0.944, highlighting the model capability to maintain precision across varying thresholds. Yolov8-m is shown to be outstanding for the mAP@0.5:0.95 score of 0.949 and hence capable in detecting objects at different scales more effectively than other models. Additionally, the high F1 score and recall values reflect its balanced performance in precision and recall, which is crucial for robust object detection. All in all, Yolov8-m metrics show a well balance performance and make it the ideal choice for the ARM module task.

TABLE III. YOLO MODEL PERFORMANCE TRAINED WITH THREE RECYCLE ITEMS IMAGE CATEGORY

Model	mAP@0.5	mAP@ 0.5:0.95	F1- Score	Recall
Yolov10-n	0.994	0.937	0.997	0.997
Yolov10-s	0.995	0.941	0.992	0.995
Yolov10-m	0.994	0.938	0.991	0.990
Yolov9-c	0.994	0.949	0.996	0.998
Yolov8-n	0.995	0.945	0.998	0.998
Yolov8-s	0.995	0.946	0.997	0.998
Yolov8-m	0.994	0.949	0.997	0.998

Fig. 5. Precision recall curve of the YOLOv8-m model.

To gain a more detailed insight into the performance of each object class for YOLOv8-m, the precision and recall curves of can be investigated and depicted in Fig. 5. These curves highlight the tradeoff between precision (exactness) and recall (completeness) across various thresholds. By analyzing these curves, one can determine the optimal threshold that maximizes both precision and recall. From the figure, it can be seen that the PET bottle and tetra-pak classes exhibit the highest confidence scores at 0.995, followed closely by the aluminum can at 0.992. On average, the overall performance across all classes achieves a mean average precision (mAP) score of 0.994 at 0.5 confidence threshold. This high mAP score indicates robust detection capabilities.

Apart from the recall and precision performance, Fig. 6 presents the training and validation results of a YOLOv8-m model. From the figure, the top row shows the training metrics, including box loss, classification loss, and DFL (distribution focal loss). All parameters decrease steadily, indicating an improved model performance over epochs. The precision and recall graphs demonstrate that the model achieves high accuracy and recall rates around 10 epochs during the training process and maintaining these high values constantly. The bottom row shows the validation metrics, which mirror the training results, with box loss, classification loss, and DFL loss that decreasing consistently. As for the mAP50 (mean Average Precision at 50% IoU) and mAP50-95 (mean Average Precision across IoUs from 50% to 95%) metrics for both training and validation indicate high performance with values reaching 1.0, showing that the model is effective for detecting the targeted recyclable materials.

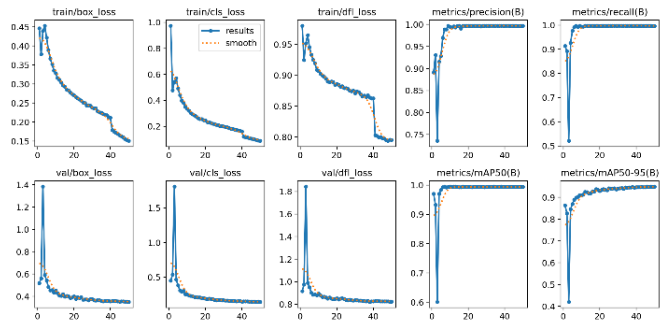

Fig. 6. Result for YOLOv8-m training.

Fig. 7. Sample of YOLOv8-m detection outcome.

Finally, Fig. 7 showcases the resultant images for aluminum can, PET bottle and tetra-pak items after running the inference/testing process with confidence label labelled for each item.

B. User Interface Design Assessment

In this section a snapshot of using the ARM system is elaborated and the steps are summarized in Fig. 8. Users can initiate the process by pressing the start button which is represented by the earth icon (see Fig. 8 (a)). This action activates the system and prepares it to receive recyclable materials. Next, recyclable items can be put one by one into the designated slot. As each item is placed inside, the YOLO detection module will scan and detect the material accordingly (Fig. 8(b)). If the system fails to detect an item, the user can remove it and try inserting it again until it is recognized, and if still fails then the material is not acceptable by the system. During this process, the user can monitor each inserted item on the system's screen to ensure proper detection. Once all your recyclable materials have been successfully inserted, the user can press the finish button (Fig. 8(c)) to conclude the recycling process. Eventually, the user can key in a valid phone number into the system to collect any points or rewards associated with the recycling effort. This phone number will typically be used for verification purposes and to credit any recycling points.

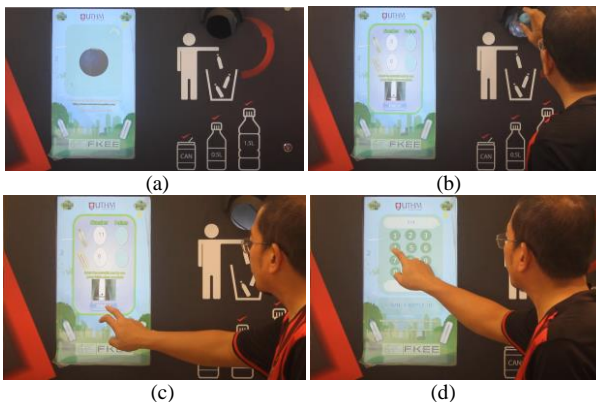

Fig. 8. User interface design consists of four main steps: (a) Start the recycling process. (b) Insert the recyclable items into the recycling system. (c) Finish the recycling process. (d) Enter phone number to claim the points for reward.

C. System Installation and Pilot Testing

Finally, to investigate the feasibility of the ARM implementation in actual conditions, the module (Fig. 9(a)) was installed at two different events. In the first case, the module was installed at SWM Pura Kencana (Fig. 9(b)), which is the office of a waste management company in southern Malaysia.

In the second case, it was used during an event at a university (see Fig. 10). The installation at the SWM office aimed to study about public acceptance of the module and its effectiveness in encouraging recycling among the community and SWM staff. During the 30 days of implementation, the system managed to collect approximately 21 kilograms of PET bottles and one kilogram of aluminum cans, with snapshots of the collection shown in Fig. 9(c). These results indicate that PET bottles were the dominant item collected and aligning with the goal of reducing plastic waste that ends up in landfills. The system experienced only one instance of downtime due to computer overheating and to address this, a ventilation hole was added to ensure proper airflow within the module.

During implementation of the ARM at a showcase event (see Fig. 10), it successfully attracted users to recycle with some of the participants bringing many recyclable items. Primary school students were eager to use the system and deposit most of their plastic bottles into the bin. The one-day event demonstrated that the system could attract first-time users to fully utilize the system. However, to maintain their continuous interest, a different type of reward system should be implemented to sustain their engagement. For instance, integrating point-based reward systems or a lucky draw reward system. Additionally, educational workshops or interactive sessions that explain the importance of recycling and its impact on the environment can further produce a long-term participation.

Fig. 9. Automated recycling system module. (a) Complete system module. (b) Installation onsite at SWM Pura Kencana Batu Pahat Johor. (c) Snapshot of collected recycling items.

Fig. 10. Pictures of automated recycle system implementation as a showcase in an event inside university.

IV. DISCUSSION

The key takeaway from the previous analysis of the ARM detection model is that among YOLOv8, YOLOv9 and YOLOv10 architectures, the YOLOv8-m model shows exceptional performance on various object detection metrics for

our dataset and hence make it a top choice for waste classification tasks in the ARM module. YOLOv8-m strength in terms of precision (minimizing false positives) and recall (minimizing false negatives), is critical for robust detection in real-world scenarios. To improve these results even further, advanced data augmentation techniques could be used to diversify the training data and reduce overfitting to ensure even better generalization to new, unseen data. Furthermore, experimenting with fine-tuning the hyperparameters of YOLOv8-m could optimize its performance for specific drop-off types or conditions, leading to even higher precision and recognition rates. Apart from that, integrating ensemble methods combining YOLOv8-m with other models could leverage the strengths of the different architectures, increasing accuracy and robustness. Finally, ongoing monitoring and updating of the model with new data can help to maintain its relevance and effectiveness as waste classification requirements evolve.

Integrating YOLOv8-m model into ARM applications involves addressing software and hardware integration with seamless user interface. To maintain cost competitiveness, a CPU is used as the main framework for detecting the recyclable material types. It will also command the Arduino controller for diverting the waste into the respective bin. To illustrate the practicality of YOLOv8-m model for the ARM implementation, a 30-day continuous usage trial reveals the model capability for effectively detecting the inserted materials and delivering to the respective bin. However, the system encounter challenges in outdoor environments due to overexposure from light entering through the chute, which causes the camera to inaccurately capture the shape of object. Such an issue can be overcome by installing a movable lid over the chute to control the amount of light exposure.

V. CONCLUSION

In this project, a vision-based YOLO detection module of recyclable items was investigated for the automated recycling machine (ARM) module. In the assessment stage, three classes of recycle items which are PET bottle, aluminum can and tetrapak are used during the training and validation stage with total number of 14,883 and 937 respectively. The optimal YOLO structure that can balance between speed and accuracy requirements is integrated in the ARM system.

For the detection model assessments, seven state-of-the-art YOLO models namely YOLOv8-n, YOLOv8s, YOLOv8m, YOLOv9-c, YOLOv10-n, YOLOv10-s and YOLOv10-m were used to train the recycle dataset. From series of training and fine tuning, it can be concluded that YOLOv8-m metrics show a well balance performance with mAP@0.5 score of 0.994, mAP@0.5:0.95 score of 0.949 and F1 value of 0.997. However, it is also worth mentioning that the performance of other investigated models is not too distinct with this model. Since this model yields the highest accuracy, it was further tested under for the ARM inference module that acquired data straight from life feed camera. For the user interface, the flow of using the ARM is easy to follow with simple operation steps with the option for the user to claim the reward points. As for the ARM pilot testing onsite, it shows a promising outcome to attract

users to recycle and can be utilized as an interactive tool to ignite recycling culture among communities.

In future, the research can address the current system limitations which lack redemption (incentive) options. Implementing a redemption model aligned with container deposit legislation would enhance user participation. In the absence of such policies, support from entities through corporate social responsibility initiatives is essential for the success of the redemption stage. Apart from that, the detection model can be tested with various public recyclable datasets such as TACO dataset, ThrashNet dataset and WasteNet dataset to investigate the model reliability and scalability.

ACKNOWLEDGMENT

This research is supported by the Ministry of Higher Education (MOHE) through Prototype Development Research Grant Scheme (PRGS) (PRGS/2/2020WAB02/UTHM/02/2) and The Sumitomo Foundation through Grant for Japan-Related Research Project (FY2022).

Abstract—Mangroves are a collection of plants that inhabit the intertidal zone, namely the area between the lowest and highest points reached by the tide. Overall, mangroves provide a range of advantages, including the prevention of coastal erosion, the inhibition of seawater intrusion onto land leading to brackish groundwater, and serving as habitats and food sources for diverse animal species. In addition, many types of mangrove fruit have been used as sustenance for humans and as ingredients in processed food products. Mangrove fruit has a considerable variety of species, each characterized by distinct forms. At now, farmers and the general public rely only on visual observation to identify mangrove fruit species. Consequently, their ability to accurately detect the correct species is not guaranteed. In order to address this issue, this study employs digital image processing using the Extreme Learning Machine technique to facilitate the identification of various kinds and varieties of mangrove fruit by the general public and farmers. The study utilizes gray-scaling and Contrast Enhancement as image processing methods, while segmentation is performed by the use of the Cellular Neural Network approach. Following extensive testing in this study, it was determined that the used methodology effectively identified several species of mangrove fruit. The results yielded an accuracy rate of 94.11% for extracting shape, texture, and color elements, and accuracy rate of 99.63% for extracting texture and color features.

Keywords—Mangroves; mangrove conservation; image processing; ecological informatics; cellular neural network; extreme learning machine

I. INTRODUCTION

Mangroves are highly productive and distinctive ecosystems due to their exclusive ability to grow and endure in the transitional area between the ocean and land, where no other plants can live [1]. Indonesia has over 60% of the whole mangrove population in Southeast Asia, establishing it as the nation with the highest number of mangroves in the region. Indonesia is home to a minimum of 48 out of the 52 known mangrove species. Indonesia has the highest level of mangrove population diversity globally [2]. Mangroves are a kind of arboreal flora that often thrives in aquatic habitats with high salinity, such as marine and brackish waters. Mangroves often thrive in the intertidal zone, including the stretch of shoreline between the lowest ebb tide and the highest water level.

Nevertheless, mangroves only thrive in regions characterized by tropical and sub-tropical climates [2].

Mangroves are very productive ecosystems that often serve as an economic resource, particularly for those living in coastal areas. Due to their significant impact on marine ecosystems, particularly fisheries, mangroves play a crucial role [2], [3]. Approximately 77% of all mangroves provide utilitarian value, with the most prevalent uses being medicinal, building, culinary (including vegetables, spices, and fruit), decorative, and as a source of fuel) [4]. Overall, mangroves provide a range of advantages, including the prevention of coastal erosion, the inhibition of seawater intrusion that may lead to the salinization of groundwater, and the provision of habitat and sustenance for several animal species. In addition, some mangrove fruit species have been used as a source of sustenance for humans and as ingredients in processed food products. The desirability of mangrove fruit as an economic resource is high among the community. Mangroves play a crucial role in the economics of coastal settlements due to the market value of goods derived from them and their contribution to sustaining coastal fisheries [2].

Several previous studies related to this research include those studied by Naskar & Bhattacharya [5] who examined the introduction of several types of fruit. There were six types of fruit studied, namely apples, bananas, lychees, oranges, pineapples and pomegranates. This research uses the Artificial Neural Network method, and achieves accuracy above 90%. However, the data used is still small. For the six types of fruit processed, they only used 150 data. The fruit features used are also only texture, color and shape. If other features are added to image processing, accuracy may be higher.

In research conducted by Ji et al. [6] carried out fruit classification by combining biogeography-based optimization (BBO) and feedforward neural network (FNN) methods. The data is processed more efficiently with four stages of preprocessing, then feature extraction (color, texture and shape) is carried out. In the third stage, unnecessary features are removed using component analysis. Finally, fruit classification was carried out using the biogeography-based optimization (BBO) and feedforward neural network (FNN) methods. This research used data from 1653 images from 18 fruit categories, but the accuracy was less high than research

*Corresponding Author.

using other methods, namely 89.11%. Similar with research in [5], if researchers add features and processed data, the accuracy achieved can be even higher.

The study conducted by Lu et al. [7] examines the categorization of fruits for industrial purposes. They used a Convolutional Neural Network consisting of six layers and utilized a dataset of 200 samples for each fruit species. The accuracy achieved by this study was 91.44%. Nevertheless, comprehending the weights of a Convolutional Neural Network using this approach is challenging. Enhancing the classification performance of Convolutional Neural Network requires the use of a more effective approach for parameter configuration. This would enable better handling of bigger datasets including diverse fruit kinds. Rouhi et al. [8] performed research on the categorization of benign and malignant breast cancers using the Cellular Neural Network segmentation approach. The accuracy gained in this study was very high, exceeding 95%. Nevertheless, the dataset used in this work remains quite small, consisting of just 93 photos depicting malignant tumors and 170 images depicting benign tumors. While the suggested approach is really strong, its varying outcomes on the DDSM and MIAS databases are seen as a shortcoming. An in-depth analysis of preprocessing procedures may be conducted to ensure consistent outcomes. The study done by Ghoneim, Muhammad, and Hossain [9] examines the categorization of cervical cancer via the use of Convolutional Neural Network and Extreme Learning Machine classification techniques. The acquired accuracy is quite high, namely 99.7% for 2 class classification and 97.2% for seven class classification. Nevertheless, the dataset used remains quite small, consisting of just 917 data points distributed over seven distinct categorization groups. The use of additional data is very likely to enhance accuracy.

The aforementioned studies conducted Rouhi et al. [8] and Ghoneim, Muhammad, and Hossain [9] demonstrate that Cellular Neural Network is effective for segmentation, while Extreme Learning Machine is effective for classification and image detection. These methods yield higher accuracy when accompanied by preprocessing techniques and a substantial amount of data.

Until now, there has not been much research on the classification of mangrove fruit, we have carried out several studies related to mangroves and machine learning. Among them is research related to the classification of mangrove shoots based on measurements of their morphology. This research uses a Multi-Layer Perceptron to carry out a basic classification of the types of mangroves shoots to be planted. The results obtained were not satisfactory, namely 91.9% using 3000 data [4]. Another research related to mangroves is the classification of maturity levels of mangrove fruit using deep convolutional neural networks. Where in this research the accuracy rate reached 99.1% [3]. From previous research conducted [3], it is deemed necessary to classify fruit types. This is because the level of ripeness and type of fruit are closely related. Apart from that, using the Extreme Learning Machine method with Cellular Neural Network also needs to be tested for its level of accuracy. Apart from that, mangrove

fruit has quite a lot of species with different shapes. Currently, farmers or the public generally see and recognize mangrove fruit species only with the naked eye, so the introduction of mangrove fruit species does not necessarily match the species they are looking for. Therefore, an approach was taken to this problem in order to classify mangrove fruit species. Thus, we can form our research gap, which state that mangrove identification with machine learning technique is a must considering the concern of ecological urgency around the world. We also state that the novelty of our data and mangrove fruit classification system is a new field of ecological research in the world.

In this study, we imposed several constraints to restrict the extent of the issue from proliferating. The specific limitations of this problem include the focus on studying mangrove fruit species found in the North Sumatra region, specifically *Rhizophora stylosa* and *Rhizophora mucronata*. Additionally, only images with the file extensions .jpg or .jpeg will be processed, and the image size must be 720×84 pixels. The research provides several benefits. Firstly, it serves as a valuable reference for future studies on the classification of mangrove fruits. Secondly, it facilitates the identification of different mangrove species based on their fruits, benefiting both the general public and farmers. Thirdly, it aids in the recognition of specific mangrove fruit species, assisting individuals in replanting according to their desired species. Lastly, it simplifies the process for new farmers who wish to propagate mangrove plants by helping them identify different mangrove species, particularly through their fruits.

The content of paper is arranged as follows; in the Section II, we describe the methodology and algorithm used in this study. While in Section III we analyze the experimental results. Section IV is the summarization and future research of this paper.

II. METHODOLOGY

The research in this study included many stages: image acquisition, image preprocessing, image segmentation, feature extraction, and classification using the Extreme Learning Machine. The overall structure illustrating the sequential steps undertaken may be shown in Fig. 1.

A. Image Acquisition

This phase involves gathering visual data of mangrove fruit, which serves as the system's first input. Two sets of data are utilized to classify the mangrove fruit images: training data and testing data. Without utilizing a light, the image was obtained using a DSLR camera equipped with 18 megapixels of resolution. It is imperative that the captured image be situated on a backdrop of black. The information utilized in this investigation was gathered from numerous mangrove forests situated in North Sumatra. Three specific locations in the North Sumatra region provided the information utilized in this study: Percut Sei Tuan, Kampung Nipah Mangrove Beach, and Mangrove Ecotourism, Sicanang Belawan. Seven distinct occasions were utilized to collect the data, spaced at varying intervals.

Fig. 1. General architecture.

The study utilizes an image with the file extension .JPG or .JPEG, measuring 720×84 pixels in size. Fig. 2 and Fig. 3 provide visual data of mangrove fruit.

Fig. 2. Image of *Rhizophora mucronata*.

Fig. 3. Image of mangrove fruit *Rhizophora stylosa*.

B. Image Processing

The phase of preprocessing involves altering of the acquired image to enhance its quality and facilitate further processing. The preprocessing phase includes three steps: grayscale, contrast enhancement, and conversion of the RGB picture to HSV.

1) *Grayscale*: Grayscale is the first step in the preprocessing phase. At this point, the initial RGB picture is transformed into a grayscale image. The objective of grayscale is to facilitate the identification of different mangrove fruit species in images. The grayscale technique used in this study is the luminosity approach. The luminosity technique of grayscale involves multiplying each value of the red (R), green (G), and blue (B) channels by a certain constant value that has been predetermined. The process of converting RGB photos to grayscale is performed on both

training and testing images. The conversion of an RGB picture to a gray image using the luminosity approach can be achieved by using the Eq. (1).

$$GI = 0.2989R + 0.5870G + 0.1140B \quad (1)$$

Images of mangrove fruits after the grayscale process can be seen in Fig. 4 and Fig. 5.

Fig. 4. Image of *Rhizophora mucronate* mangrove fruit after the grayscale process.

Fig. 5. Image of mangrove fruit *Rhizophora stylosa* after the grayscale process.

2) *Contrast enhancement*: Following the completion of the grayscale procedure, the subsequent step involves enhancing the contrast. Contrast enhancement is performed to augment the contrast value of the captured picture of the mangrove fruit. This process aims to make the image more distinct, increase the visibility of its characteristics, and minimize the presence of noise [10]. The use of contrast enhancement in this study can be achieved utilizing the Eq. (2)

$$f_{0(x,y)} = G(f_{i(x,y)} - P) + P \quad (2)$$

The image of mangrove fruit that has had contrast enhancement applied can be seen in Fig. 6 and Fig. 7.

Fig. 6. Image of Rhizophora mucronate mangrove fruit after contrast enhancement.

Fig. 7. Image of mangrove fruit Rhizophora stylosa after contrast enhancement.

3) *RGB to HSV conversion*: At this stage, the RGB image of the mangrove fruit is converted from the RGB color model to the HSV color model. To get the HSV value, we must first know the RGB value of a pixel. In this research, RGB values were taken and conversion of RGB values to HSV. The results of converting RGB images of mangrove fruit to HSV images can be seen in Fig. 8 and Fig. 9.

Fig. 8. HSV image of Rhizophora mucronata mangrove fruit.

Fig. 9. HSV image of mangrove fruit Rhizophora stylosa.

C. Image Segmentation

Image segmentation follows the preprocessing phase. Image segmentation is used to distinguish the image of mangrove fruit from the surrounding background. This study uses the Cellular Neural Network approach for segmentation.

1) *Cellular Neural Network*: A Cellular Neural Network (CNN) is a network consisting of linked cells arranged in a $M \times N$ matrix, where M represents the number of rows and N represents the number of columns [11]. The architecture of a Cellular Neural Network has resemblance to that of cellular automata, whereby neighboring cells in the network may engage in direct interactions. Cells that lack direct connections may have indirect impact on neighboring cells via the propagation of continuous effects [12].

CNNs have shown efficacy in detecting malignancies and challenging objects, as evidenced by the studies conducted by Döhler et al. [13] and Abdullah et al. [14]. In order to do segmentation, three parameters need to be configured with appropriate values. The inputs consist of the template matrices A and B , as well as a bias value. The approach used in this study to ascertain the suitable values for template matrix A , template matrix B , and bias values was a process of trial and error. Following the completion of many trials, the values for template matrix A , template matrix B , and their respective bias values were acquired, such as:

$$\text{Template A} = \begin{bmatrix} 0 & 0 & 0 \\ 1 & 2 & 1 \\ 0 & 0 & 0 \end{bmatrix} \quad \text{Template B} = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}$$

$$B \alpha \sigma = 0.8$$

Cellular Neural/Nonlinear Networks are complex circuits that exhibit nonlinear dynamical behavior on a vast scale. These networks are comprised of cells, which are analog processing components that are locally coupled. They are characterized by study [12]:

$$\dot{x}_{ij}(t) = -x_{ij}(t) + \sum_{kl \in N_r^-} A_{ij,kl} y_{kl}(t) + \sum_{kl \in N_r^-} B_{ij,kl} u_{kl}(t) + I_{ij} \quad (3)$$

Where $x_{ij}(t)$ is the state, $y_{ij}(t)$ is the output, $u_{ij}(t)$ is the input, I_{ij} is the cell current, $A_{ij,kl}$ and $B_{ij,kl}$ are the parameters forming the feedback template A and the control template B , respectively, whereas $kl \in N_r^-$ is a grid point in the neighborhood within the radius r^- of the cell ij [12], [15].

Assign template A as feedback, template B as control, and interpret bias as a threshold value. The input image to this Cellular Neural Network (CNN) is a preprocessed image. The segmentation process utilizing Cellular Neural Networks (CNN) involves the following steps [16]:

- Determine the image that will be used as input.
- Determine the values of template A , template B , and bias.
- Convert the input image to double class.
- If $t < 1$, calculate the output value in vector column form.
- Calculate the state value of the CNN
- Resize the output to its original size

The segmentation result image can be seen in Fig. 10.

Fig. 10. The segmentation result image.

D. Feature Extraction

Following the segmentation process, feature extraction is performed to acquire values from the features present in the picture of the mangrove fruit. The characteristics that are considered include form, texture, and color.

1) *Area feature extraction calculation*: In order to derive form characteristics from mangrove fruit, a method of feature extraction is conducted, using the object's shape as a basis, resulting in distinct feature values. The feature extraction method involves the computation of several measurements, such as area, perimeter, eccentricity, major axis length, and minor axis length, on the segmented picture. Subsequently, these values will serve as input parameters during the

classification phase. Here we describe area, perimeter and major minor axis length.

$$Area = \text{Number of White Pixel} \quad (4)$$

Thus, perimeter calculated by.

$$PR = \sum_{i=1}^{N-1} d_i = \sum_{i=1}^{N-1} |x_i - x_{i+1}| \quad (5)$$

And major axis length.

$$MaAL = \sqrt{(x_2 - x_1)^2 + (y_2 - y_1)^2} \quad (6)$$

2) *Gray Level Co-Occurrence Matrix (GLCM)*: Various methods may be used to extract texture characteristics from grayscale photos, including local binary patterns, gray level co-occurrence matrices, and scale invariant feature transform [17]–[19]. Once the form characteristic values of the image have been obtained, the subsequent step involves extracting the texture characteristic value using the Gray Level Co-Occurrence Matrix (GLCM) approach. The input for this GLCM procedure is a grayscale image. This study employs four Gray-Level Co-occurrence Matrix (GLCM) matrices to extract texture features from images of mangrove fruits. Specifically, the GLCM matrices are computed with a spatial distance of 1 and angles of 0°, 45°, 90°, and 135°. The extracted features include entropy, contrast, correlation, energy, and homogeneity. Here we describe the equation of every features.

Entropy is a stochastic metric that quantifies the amount of information related to characterization of image's texture. The entropy value is maximized when all pixel value for grey is equal or exhibits greatest randomness. If the entropy value increase it means the complexity of the image will increase too, which entropy also measure the level of complexity of grey distribution in the image.

$$ENT = \sum_{i,j=0}^{N-1} P_{ij} (-\ln P_{ij}) \quad (7)$$

Contrast is used to quantify the variations in intensity between neighboring pixels over the whole image. Contrast is indicative of both the sharpness of the picture and the intricacy of the texture's ridges. The more distinct the texture, the higher the contrast.

$$CNT = \sum_{i,j=0}^{N-1} P_{i,j} (i - j)^2 \quad (8)$$

Correlation is used to measure the degree of resemblance between the gray levels of an image in either the horizontal or vertical orientation. The size of the value represents the extent of local gray level correlation. The values of -1 and 1 represent the existence of negative and positive correlation in the image, respectively.

$$Corr = \sum_{i,j=0}^{N-1} \frac{(i - \mu)(j - \sigma)}{\sigma^2} \quad (9)$$

Energy also called as angular second moment, where the homogeneity of gray distribution and the level of texture. A finer texture correspondent to a higher component value in the GLCM matrix which will resulting smaller energy. The energy value will experience a substantial increase when the pixels exhibit a strong correlation, suggesting that the current texture exhibits reasonably consistent and predictable variations. The formula for energy is:

$$EGY = \sum_{i,j=0}^{N-1} (P_{ij})^2 \quad (10)$$

Homogeneity also called deficit moment, is a degree of texture clarity and regularity, refers to a big number indicating a clear image texture with great regularity.

$$HMY = \sum_{i,j=0}^{N-1} \frac{P(i,j)}{1 + (i - j)^2} \quad (11)$$

Each value obtained from the process of feature extraction will generate four Grey-Level Co-occurrence Matrices (GLCMs), and each matrix will provide five distinct texture characteristics. Therefore, the total number of features produced is twenty. Nevertheless, the GLCM matrix just captures statistical values for each feature. Consequently, five characteristics will be retrieved and used as input for ELM.

3) *Hue Saturation, Value (HSV)*: During this step, the process of extracting color features is performed, namely by capturing the hue, saturation, and value values. Once the RGB picture is transformed into an HSV image, the HSV value of the image will be extracted.

E. Extreme Learning Machine - Classification

Extreme Learning Machine was the approach that was used in this research project for the purpose of classification. Extreme Learning Machine, often known as ELM, is a learning algorithm that is based on the idea of single hidden-layer feedforward neural networks. (SLFN) [20]. When compared with other algorithms which also have the concept of single hidden-layer feedforward neural networks (SLFN), ELM provides better speed and performance [21], [22]. Because ELM can provide better speed and performance, it is believed that ELM can overcome the learning speed problem that has occurred in other feedforward neural networks algorithms [23], [24]. The learning speed of feedforward neural networks is generally much slower than other algorithms. This is because feedforward neural networks use a slow gradient-based learning algorithm in the training process, and all parameters in the neural networks are determined repeatedly [25].

Let's assume that there are N distinct sets of learning samples. $(x_i, y_i), 1 \leq i \leq N, X_i = [x_{i1}, x_{i2}, \dots, x_{in}]^T \in R^n, y = [y_{i1}, y_{i2}, \dots, y_{im}]^T \in R^m$, The expression for a neural network with a single hidden layer and L hidden nodes is as follows:

$$\sum_{i=1}^L \beta_i g(W_i \cdot X_i + b_i) = O_i, i = 1, \dots, N \quad (12)$$

$W_i = [w_{i1}, w_{i2}, \dots, w_{in}]^T$ is the input weight vector, β_i is the output weight, $g(x)$ is the activation function, b_i is the bias of the i th hidden layer node, $W_i \cdot X_i$ is the inner product of W_i and X_i , $O_i = [o_{i1}, o_{i2}, \dots, o_{in}]^T$ denotes the network output value. The objective of the single hidden layer neural network is to reduce the inaccuracy in the output. Thus, it may be formulated as

$$\sum_{j=1}^N \|o_j - t_j\| \quad (13)$$

Exist β_i, W_i and b_i , and make

$$\sum_{i=1}^L \beta_i g(W_i \cdot X_j + b_i) = t_j, j = 1, \dots, N \quad (14)$$

It can be matrix expressed as

$$H\beta = Y \quad (15)$$

H is the vector that represents the output of the hidden layer of the neural network is denoted by the symbol β , while the output weight is denoted by the symbol T . The specific way of expressing it is Eq. (15).

$$H(W_1, \dots, W_L, b_1, \dots, b_L, X_1, \dots, X_L) = \begin{bmatrix} g(W_1 X_1 + b_1) & \dots & g(W_L X_1 + b_L) \\ \vdots & \ddots & \vdots \\ g(W_1 X_N + b_1) & \dots & g(W_L X_N + b_N) \end{bmatrix}_{N \times L} \quad (16)$$

$$\beta = \begin{bmatrix} \beta_1^T \\ \vdots \\ \beta_L^T \end{bmatrix}_{L \times m}, T = \begin{bmatrix} T_1^T \\ \vdots \\ T_N^T \end{bmatrix}_{N \times m}$$

In order to train a single hidden layer neural network, we need to get $\widehat{W}_i, \widehat{b}_i$, and $\widehat{\beta}_i$, such that

$$\|H(\widehat{W}_i, \widehat{b}_i) \widehat{\beta}_i - T\| = \min_{W, b, \beta} \|H(W_i, b_i) \beta_i - T\| \quad (17)$$

$i = 1, \dots, L$, that's equivalent to minimizing the loss function

$$E = \sum_{j=1}^N \left(\sum_{i=1}^L \beta_i g(W_i \cdot X_j + b_i) - t_j \right)^2 \quad (18)$$

In solving such issues, the Extreme Learning Machine (ELM) outperforms other conventional methods that rely on gradient descent algorithms. Unlike classic learning algorithms that require adjusting all parameters throughout each iteration phase, the algorithm employed by the ELM only requires to alter the input weights W_i and hidden bias b_i is determined, the output of the hidden layer matrix H is stochastically determined, resulting in significant savings in human labor and material resources. Consequently, the process of training a neural network with a single hidden layer may be simplified to

solving a linear equation. $H\beta = T$ which Simultaneously, the output weight may also be ascertained.

$$\widehat{\beta} = \overline{H}T \quad (19)$$

\overline{H} is the generalized inverse of the matrix that Moore and Penrose have developed, and the norm of the solution that has been produced is the lowest and most unique.

The features obtained in the previous stage of feature extraction will be used in this stage as input. This stage is comprised of two distinct phases, namely the training phase and the testing phase. The training phase is conducted to determine the most optimum weights and biases that will subsequently be used during the testing phase. The testing step corresponds to the stage when data validation takes place. The ELM architecture for training has three layers: the input layer, hidden layer, and output layer. The input nodes consist of 13 nodes that include shape, GLCM, and HSV feature extraction. Additionally, there is an input node with 8 nodes that only use GLCM and HSV feature extraction. The following procedures will be executed.

1) *Determining the number of nodes in the hidden layer:*

The values of the nodes in the artificial neural network, particularly in the hidden layer, play a crucial role in processing the training data. The hidden layer is responsible for computing the final outcomes of the artificial neural network. Insufficient hidden layers lead to underfitting, causing suboptimal performance of the accessible nodes in detecting signals from the input layer. An overfitting issue occurs when the hidden layer has an excessive number of node values. This happens because the network's processing capacity is too big to effectively handle the quantity of information acquired from the training data.

2) *Determination of the activation function:* The choice of the activation function is determined by the process of determining the number of hidden layers. The purpose of selecting this activation function is to use it for neurons throughout both the training and testing stages. The research utilizes the sigmoid function as its activation function. The sigmoid function is a kind of activation function often used in backpropagation algorithms, which aim to decrease computing time.

3) *Training process:* The first phase conducted by the extreme learning machine involves the training procedure for categorizing mangrove fruit. The training procedure involves configuring an artificial neural network to provide the desired output by using a certain dataset. The ultimate outcome of this procedure is an artificial neural network that has undergone training to provide outcomes that align with the data used in the training phase. The training procedure is conducted in three distinct phases, namely:

a) *Randomization of input weight and bias:* The first phase of the training procedure included assigning input weight and bias values. The number of neurons in the input layer is adapted to match the number of parameters obtained from the used dataset. The weight and bias values used in this investigation were assigned randomly.

b) *Calculation of hidden layer output matrix:* Following the completion of the phases that came before it, the calculation of the hidden layer output matrix will be carried out. The hidden layer output matrix is the result of the input processing that neurons in the hidden layer receive from neurons in the input layer. This processing is received by neurons and then processed. The processing has been carried out by using the activation function that was constructed in the phase that came before it, namely the sigmoid function.

c) *Calculation of output weight:* And last but not least, the computation of the output weight is carried out once the procedure of calculating the hidden layer output matrix has been finished. Following the completion of this procedure, a matrix is produced that is a representation of the weight of each neuron in the output layer.

4) *Testing process:* The artificial neural network generated after the training phase will undergo testing in the evaluation phase. The testing procedure was conducted to assess the efficacy of the extreme learning machine technique in categorizing mangrove fruit photos according to their species.

5) *Output calculation:* The calculation process is carried out using an artificial neural network that has been trained in

the previous training process. The results of the calculation process will be a classification of mangrove fruit images based on species.

III. RESULT AND ANALYSIS

The tests conducted on mangrove fruit images included two forms of classification: one based on shape, texture, and color features, and another based solely on texture and color features. Here we describe feature extraction result from shape, texture and color feature extraction depicted in Table I, while feature extraction for texture and color depicted in Table II below.

Experimentation was conducted with varying quantities of concealed neurons, commencing with 30, 50, 80, and 100. Conducting experiments with varying numbers of hidden neurons seeks to determine the optimal number of hidden neurons required to accurately distinguish various types of mangrove fruit. The confusion matrix is shown in the Table III.

The accuracy presentation of the system with various hidden neurons is as follows:

$$Accuracy = \frac{Correct\ Testing\ Data}{Sum\ of\ all\ Testing\ Data} \times 100\%$$

TABLE IV. SYSTEM ACCURACY

Shape, Texture, and Color Extraction Features				Texture, and Color Extraction Features			
Correct amount of test data	Number of incorrect test data	Number of hidden neurons	Accuracy	Correct amount of test data	Number of incorrect test data	Number of hidden neurons	Accuracy
253	19	30	93,01%	264	8	30	97,05%
253	19	50	93,01%	268	4	50	98,52%
254	19	80	93,38%	271	1	80	99,63%
256	16	100	94,11%	271	1	100	99,63%

The accuracy presentation of the system with various hidden neurons can be seen in Table IV. From the calculations above, demonstrate that the experiment that achieved a level of accuracy of 94.11% for shape, texture, and color extraction features using 100 hidden neurons. Additionally, the accuracy reached 99.63% for texture and color extraction features with the same number of hidden neurons. While these results indicate a relatively high level of accuracy, they are not perfect. The accuracy achieved in classification using form, texture, and color characteristics is inferior than that achieved using just texture and color features. When observing with the naked eye, one of the most noticeable distinctions between the *Rhizophora mucronata* and *Rhizophora stylosa* species is the form characteristics, particularly the size of their mangrove fruit. *Rhizophora mucronata* often exhibits greater dimensions in comparison to *Rhizophora stylosa*. The decrease in system accuracy observed when incorporating additional shape features is likely attributed to the limited variation in data from the *Rhizophora mucronata* species. Consequently, the classification performance of ELM diminishes slightly compared to when only texture and color feature extraction are employed.

The imperfection of this system may be attributed to many variables, primarily the influence of ambient light that results in incorrect image segmentation. Consequently, the accuracy of the Extreme Learning Machine in identifying mangrove fruit species is compromised. Fig. 11 displays an instance of an image that was not successfully categorized. The image in Fig. 11 was not successfully categorized due to the deteriorated state of the mangrove fruit, which was found to be in worse condition compared to the fruit of other *Rhizophora mucronata* species. *Rhizophora mucronata* often has a more vibrant green coloration in its fruit and possesses a more uniform appearance, lacking the intricate textural features shown in Fig. 11.

Fig. 11. Example of image that failed to classified.

In our previous study [3], we implemented Deep Convolutional Neural Network in order to classify mangrove fruit ripeness. While it is not relevant to be compared in this study, we see a chance to implement deep-learning based technique in mangrove fruit classification as our foresight research. There are several deep learning techniques that can implement such as deep neural network, Faster-RCNN, AlexNet, RestNet, YOLO or even ensemble learning.

IV. CONCLUSION

The study successfully used the Extreme Learning Machine (ELM) approach to accurately identify mangrove fruit based on species. The system achieved an accuracy of 94.11% when shape, texture, and color features were extracted, and an accuracy of 99.63% when just texture and color features were extracted. Nonetheless, the act of capturing images with a DSLR camera significantly impacts the resulting image. Inadequate suitability of the captured image and insufficient brightness of the surrounding light will result in noise and a dark image, so preventing the image features from being prominent. This will interfere with the process of segmenting and classifying. The determination of the value in the segmentation process, particularly the bias value, is very crucial in achieving effective image segmentation. Excessive bias values will result in the segmentation of the image's background as well. Conversely, if the bias value is too low, the segmentation of the mangrove fruit in the image will not be complete.

Several limitations and suggestion have been arising during our study such as, the mobility of our system can be improved using deep learning based mobile application includes its accuracy-concern. While other deep learning methodology can be implemented for our future research in classifying mangrove species. Thus, other limitation including mangrove zone plantation decision system is still open for research which will determine which area is suitable for certain kind of mangrove to increase the life chance of mangrove.

Evaluating the Impact of Yoga Practices to Improve Chronic Venous Insufficiency Symptoms: A Classification by Gaussian Process

Feng Yun Gou

Inner Mongolia University of Technology Hohhot, Inner Mongolia, 010051, China

Abstract—Chronic Venous Insufficiency (CVI) is a widespread condition marked by diverse venous system irregularities stemming from occlusion and varicosities. Factors like family history and lifestyle choices amplify CVI's economic consequences, emphasizing the need for proactive measures. The sedentary lifestyle of many individuals can contribute to various diseases, including CVI. Yoga is now endorsed as a multifaceted exercise to alleviate CVI symptoms, offering a holistic approach and complementary therapy for diverse medical conditions. This study developed a method for evaluating and classifying symptoms associated with varicose veins, utilizing the Venous Clinical Score (VCSS) data. A specific emphasis was placed on investigating the impact of yoga on these symptoms, and a comprehensive performance assessment was conducted based on data obtained from a cohort of 100 patients. This paper achieves optimal performance by employing the Gaussian Process Classifier (GPC) along with two optimizers, namely the Crystal Structure Algorithm (CSA) and the Fire Hawk Optimizer (FHO). The results indicate that in predicting VCSS-Pre (reflecting symptoms before engaging in yoga exercises), the GPFH exhibited superior performance with an F1-score of 0.872, surpassing the GPCS, which attained an F1-score of 0.861 by almost 1.26%. Additionally, the prediction for VCSS-1, reflecting symptoms after one month of yoga practices, revealed the GPFH outperforming the GPCS with respective F1-score values of 0.910 and 0.901.

Keywords—Chronic venous insufficiency; yoga; Gaussian Process Classifier; Crystal Structure Algorithm; Fire Hawk Optimizer

I. INTRODUCTION

Prolonged sitting, prevalent in contemporary office environments that have shifted from active to passive, poses a risk for cardio-metabolic diseases, type 2 diabetes, obesity, coronary artery disease, musculoskeletal conditions, certain cancers, and early death [1], [2]. Sedentary behavior, considered by an energy expenditure of ≤ 1.5 METs while sitting or reclining, is a substantial issue in modern workplaces [3]. Extended periods of sitting have been correlated with elevated risks of obesity and diabetes, with studies indicating a 5% rise in obesity risk and a 7% increase in diabetes risk for every two-hour increase in sitting time [4]. Moreover, prolonged sitting is linked to a heightened possibility of musculoskeletal disorders, particularly low back pain [5]. Other research has demonstrated that occupations requiring significant periods of sedentary behavior are associated with an increased risk of developing

certain types of cancers, such as endometrial, prostate, and colorectal cancer [6], [7].

Inactive sitting behavior is closely associated with the risk of cardiovascular disease (CVD), irrespective of one's level of physical activity. This association arises from the impact of sedentary behavior on crucial inflammatory, hemodynamic, and metabolic processes, leading to compromised arterial health. Consequently, these vascular issues directly and indirectly contribute to the development of cardiovascular disease [8], [9]. Some studies have revealed a noteworthy correlation between the duration of individuals' sitting hours in the workplace and the incidence of Chronic Venous Insufficiency (CVI). This association underscores a substantial escalation in the risk of contracting such conditions [10], [11], [12].

CVI is widespread in both developing and developed nations [13]. As outlined in the American Venous Forum's consensus statement, CVI involves various morphological and practical irregularities in the venous system, from telangiectasias to venous ulcers [14]. The recognition of CVI lacks a specific date, but the historical understanding of venous insufficiency can be traced to ancient times when Egyptians, Greeks, and Romans described similar symptoms. In the 17th century, William Harvey, an English physician, significantly advanced the understanding of the circulatory system, though the term "Chronic Venous Insufficiency" is a more recent medical terminology. The precise historical origin of this term is unclear, yet the evolving comprehension and management of venous insufficiency have shaped current diagnostic criteria and treatment approaches [15], [16].

CVI refers to pathological changes in the lower extremities' tissues resulting from anomalies in venous blood flow. These glitches encompass popliteal or iliofemoral vein occlusion, incompetence, and varicosities, mainly in the greater saphenous system associated with valvular leakage or abnormal arteriovenous communications. In some cases, chronic venous insufficiency can arise from large acquired arteriovenous fistulae, certain congenital anomalies, or tumors of the blood vessels [17], [18]. CVI risk factors encompass factors such as family history, aging, long-standing, obesity, an inactive routine, smoking, lower extremity trauma, previous venous thrombosis, the existence of an arteriovenous shunt, high estrogen states, and pregnancy [19], [20], [21]. The economic consequences of CVI are evident through increased health care costs, potential productivity loss due to symptoms such as leg pain and swelling, and the potential threat of disability leading

to unemployment. These challenges have a double effect on individuals and society in general. Implementing effective preventive measures, timely interventions, and creating supportive facilities in the workplace appear as central strategies for reducing the economic burden associated with CVI [22], [23].

Diagnosing CVI relies on a comprehensive assessment encompassing medical history, observed signs and symptoms, and diagnostic tests. A crucial tool for quantifying disease severity is the Venous Severity Scoring system, introduced in 2000 and refined in 2010 [24]. This system comprises three components: The Venous Clinical Severity Score (VCSS), which evaluates clinical symptoms; The Venous Segmental Disease Score (VSDS), which focuses on segment-specific aspects; and the Venous Disability Score (VDS), which provides insights into the functional impact of CVI. These scoring components collectively enhance the accuracy and thoroughness of clinical evaluations for individuals with CVI [25], [26]. Physicians use the VCSS to evaluate the impact of venous disease on a patient's clinical condition and to make informed decisions about appropriate treatment strategies [27].

Presently, yoga is recommended as one of the activities to alleviate symptoms associated with CVI [28]. Yoga, originating in ancient India, is a holistic practice encompassing physical, mental, and spiritual disciplines. It combines physical postures, breath control, meditation, and ethical principles to promote well-being, harmony, flexibility, strength, stress reduction, and mental clarity [29], [30]. Yoga is increasingly integrated into medical care as a complementary therapy, offering benefits for chronic pain, mental health issues, cardiovascular health, cancer care, respiratory conditions, and rehabilitation.

II. OBJECTIVE

Utilizing a machine learning (ML) approach, this article delves into the effectiveness of yoga exercises in alleviating symptoms among individuals with chronic venous insufficiency. ML, a subset of artificial intelligence (AI), entails creating algorithms and statistical models that empower computers to execute tasks without explicit programming. It constitutes a field of study wherein systems acquire knowledge and enhance performance through experience, enabling pattern recognition, predictions, and adaptation to new data. These algorithms utilize training data to identify inherent patterns, enabling them to make decisions or predictions without explicit programming for each task. The exploration includes predicting and categorizing these symptoms into distinct classifications using the Gaussian Process Classifier (GPC). For the ultimate optimization, the article incorporates two optimizers, namely, the Crystal Structure Algorithm (CSA) and the Fire Hawk Optimizer (FHO), to achieve optimal performance.

III. METHODOLOGY AND MODELING APPROACH

A. Gaussian Process Classifier (GPC)

The Gaussian Process (GP) classifier, grounded in Bayesian theory, operates by establishing a Gaussian prior distribution over the estimated function, represented as $p(x) = w^T x + b$. This initial distribution forms the basis for the probabilistic estimation process, and the classifier further incorporates a

sigmoid function to construct a probabilistic estimator as outlined in Eq. (1):

$$p(y = 1|x) = \text{sigmoid}(f(x)) \quad (1)$$

Determining the distribution of the latent variable y for a test sample involves two key steps. Firstly, it is computed by leveraging the posterior over the latent variables, denoted as $p(f|X, y)$. Following this, the second step entails calculating a posterior using Eq. (2), which builds upon the outcomes from the initial step. This sophisticated method enables the probabilistic estimation of the latent variable y , providing nuanced insights and accurate predictions.

$$p(y = 1|X, y, x) \quad (2)$$

X and Y denote the training samples, with x representing the test sample. While conducting this inference is generally a complex task, there are existing approximations that tend towards an optimal solution with larger datasets. Furthermore, kernel versions of this process offer a more straightforward approach [31].

B. Fire Hawk Optimizer (FHO)

The FHO algorithm replicates the foraging patterns of Fire Hawks, involving the initiation and expansion of fires to capture prey. It commences by generating a set of potential solutions (X) inspired by the position vectors of fire hawks and their prey. The initial positioning of these vectors within the search space is determined randomly, imitating the initial locations of fire hawks and prey, laying the foundation for subsequent optimization stages [32].

$$x = \begin{bmatrix} x_1 \\ x_2 \\ \vdots \\ x_i \\ \vdots \\ x_n \end{bmatrix} = \begin{bmatrix} x_1^1 & x_1^2 & \dots & x_1^j & \dots & x_1^d \\ x_2^1 & x_2^2 & \dots & x_2^j & \dots & x_2^d \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\ x_i^1 & x_i^2 & \dots & x_i^j & \dots & x_i^d \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\ x_N^1 & x_N^2 & \dots & x_N^j & \dots & x_N^d \end{bmatrix}, \quad (3)$$

$$\begin{cases} i = 1, 2, 3, \dots, N. \\ j = 1, 2, 3, \dots, d. \end{cases}$$

$$x_i^j(0) = x_{i,\min}^j + \text{rand} \cdot (x_{i,\max}^j - x_{i,\min}^j), \quad \begin{cases} i = 1, 2, 3, \dots, N. \\ j = 1, 2, 3, \dots, d. \end{cases} \quad (4)$$

X_i represents solution candidates, d is the problem dimension, N is the total number of candidates, x_i^j is a decision variable, $x_i^j(0)$ is the initial position, $x_{i,\max}^j$, $x_{i,\min}^j$ are variable bounds, and rand is a random number (0, 1). The goal is to identify Fire Hawks in the search space based on higher objective function values. Selected Fire Hawks spread flames around prey, aiding hunting. The primary fire, initially used by Fire Hawks, is assumed to represent the best global solution.

$$PR = \begin{bmatrix} PR_1 \\ PR_2 \\ \vdots \\ PR_i \\ \vdots \\ PR_m \end{bmatrix}, \quad i = 1, 2, 3, \dots, m \quad (5)$$

$$FH = \begin{bmatrix} FH_1 \\ FH_2 \\ \vdots \\ FH_i \\ \vdots \\ FH_n \end{bmatrix}, i = 1, 2, 3, \dots, n \quad (6)$$

PR_i signifies the i_{th} fire hawk, and FH_i denotes the i_{th} prey, where n is the total number of prey. The subsequent step involves calculating the distance between Fire Hawks and their prey, with D_i^k expressed by the following equation:

$$D_i^k = \sqrt{(x_2 - x_1)^2 + (y_2 - y_1)^2}, \begin{cases} k = 1, 2, 3, \dots, n. \\ l = 1, 2, 3, \dots, m. \end{cases} \quad (7)$$

The exploration space's total count of prey and fire hawks is denoted by n and m , respectively. The cumulative distance among the i_{th} Fire Hawk (FH) and prey, represented by D_i^k , is determined by the coordinates (x_1, y_1) for FH and (x_2, y_2) for prey. The birds establish territories by classifying the nearest prey and calculating total distances. Gathering hot coals from the main fire to ignite specific spots and engaging in behaviors such as using burning sticks from other territories serve as position updates in the FHO 's primary search loop.

$$FH_i^{new} = FH_i + (r_1 \times GB - r_2 \times FH_{near}), i = 1, 2, 3, \dots, n \quad (8)$$

The primary fire, denoted as GB , signifies the global best solution in the search space. FH_i^{new} represents the new location vector of the i_{th} FH , while r_1 and r_2 are uniformly distributed random numbers in the range $(0, 1)$ representing movements towards the primary fire and other Fire Hawks' territories. FH_{near} designates one of the FH within the exploration space. The algorithm's next stage involves prey movements during fires and guiding position updates. An equation is employed for these actions during place updates to incorporate the importance of territory in animal behavior.

$$PR_s^{new} = PR_s + (r_3 \times FH_i - r_4 \times SP_i), \begin{cases} i = 1, 2, 3, \dots, n \\ s = 1, 2, 3, \dots, r \end{cases} \quad (9)$$

The new position vector of the S_{th} prey (PR_s), surrounded by the i_{th} Fire Hawk (FH_i), is represented as PR_s^{new} . SP_i signifies a safe place under the i_{th} Fire Hawk territory. To monitor prey movements toward Fire Hawks and their retreat to safe zones, r_3 and r_4 are uniformly distributed random integers from 0 to 1. Prey may venture into other FH territories or approach those trapped by flames. FH might seek safer areas beyond their territory. The provided equations accommodate these actions in position updates.

$$PR_i^{new} = PR_i + (r_5 \times FH_{Alter} - r_6 \times SP), \begin{cases} i = 1, 2, 3, \dots, n \\ s = 1, 2, 3, \dots, r \end{cases} \quad (10)$$

The updated position vector of the i_{th} prey (PR_i), positioned between the i_{th} Fire Hawk (FH_i), is denoted as PR_i^{new} . SP represents a secure area beyond the i_{th} FH territory. FH_{Alter} signifies one of the FH in the search space. The movements of prey toward other FH and the secure region beyond their territories are determined by the uniformly distributed values of r_5 and r_6 in the range $(0, 1)$.

The mathematical expression for SP_i and SP is derived with the acknowledgment that, in the natural environment, a secure location is where most animals gather for protection during threats.

$$SP_i = \frac{\sum_{s=1}^r PR_s}{r}, \begin{cases} i = 1, 2, 3, \dots, n \\ s = 1, 2, 3, \dots, r \end{cases} \quad (11)$$

$$SP = \frac{\sum_{q=1}^m PR_q}{m}, q = 1, 2, 3, \dots, m \quad (12)$$

PR_s represents the prey positioned around the S_{th} fire hawk (FH_i), while PR_q denotes the q_{th} prey within the search space.

C. Crystal Structure Algorithm (CSA)

Solid minerals, comprised of atoms and particles arranged in a crystalline form known as crystals, derive their Grecian meaning from the concept of solidification by cold. Interior particles were initially discovered in 1619 by Kepler, 1665 Hooke, and 1690 Hogens [33]. Crystals display a repeating pattern of atoms in defined spaces, forming a lattice that not only dictates the crystal's shape but also inspires geometric figures derived from infinite natural shapes. The discontinuous crystal structure is crafted by considering an infinite lattice, with each lattice point linked to its position through a vector [34]:

$$r = \sum m_i d_i \quad (13)$$

The variables in the model are defined as follows: m_i is an integer, d_i represents the shortest vector along the central crystallographic directions, and i corresponds to the number of crystal corners. The mathematical model of CryStAl is then introduced in this section, incorporating fundamental crystal concepts with notable modifications. The crystal number is initialized as a random number in this model.

$$Cr = \begin{bmatrix} Cr_1 \\ Cr_2 \\ \vdots \\ Cr_i \\ \vdots \\ Cr_n \end{bmatrix} = \begin{bmatrix} x_1^1 & x_1^2 & \dots & x_1^j & \dots & x_1^d \\ x_2^1 & x_2^2 & \dots & x_2^j & \dots & x_2^d \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\ x_i^1 & x_i^2 & \dots & x_i^j & \dots & x_i^d \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\ x_n^1 & x_n^2 & \dots & x_n^j & \dots & x_n^d \end{bmatrix}, \begin{cases} i = 1, 2, 3, \dots, n \\ j = 1, 2, 3, \dots, j \end{cases} \quad (14)$$

$$x_i^j(0) = x_{i,min}^j + \xi (x_{i,max}^j - x_{i,min}^j), \begin{cases} i = 1, 2, 3, \dots, n \\ j = 1, 2, 3, \dots, d \end{cases} \quad (15)$$

In this model, n and d denote the number of crystals and the problem's dimension, respectively. The variables $x_i^j(0)$, $x_{i,max}^j$ and $x_{i,min}^j$ determine the initial positions and permissible values for each decision variable of candidate solutions, while ξ is a random number within $[0, 1]$. Following crystallography principles, primary crystals Cr_m are corner crystals randomly chosen, and the main crystal is selected in each step, excluding the current one. F_c represents the mean merit of randomly chosen crystals and Cr_b is the best-arranged crystal. Based on fundamental lattice cross-section standards, four types of

improvement processes are specified for upgrading candidate arrangements in this crystal model.

Cubicles;

Simple:

$$Cr_n = Cr_o + aCr_m \quad (16)$$

With the finest crystals:

$$Cr_n = Cr_o + a_1Cr_m + a_2Cr_b \quad (17)$$

With the mediocre crystals:

$$Cr_n = Cr_o + a_1Cr_m + a_2f_c \quad (18)$$

With the finest and mediocre crystals:

$$Cr_n = Cr_o + a_1Cr_m + a_2Cr_b + a_3F_c \quad (19)$$

The set of four equations illustrates the transition between new and old positions, denoted as Cr_n and Cr_o , respectively, incorporating fortuitous numbers a, a_1, a_2 and a_3 . The algorithm employs exploration and extraction features, calculated using Eq. (16) to Eq. (19). The optimization process concludes upon reaching the maximum iteration, adhering to a predefined termination criterion with a fixed number of repetitions. A mathematical flag is utilized for solution variables x_i^j , indicating the exterior of factors range and setting a boundary change order.

IV. MATERIAL

A. Data Description and Analysis

Data mining, acknowledged as a crucial element in the Knowledge Discovery from Databases (KDD) process [35], is progressively gaining significance within the healthcare system. It plays a vital role in precisely predicting medical conditions by automating the extraction of knowledge from extensive datasets [36] and employing a spectrum of techniques, including

statistical analysis, machine learning, and database methodologies, to facilitate informed decision-making [37].

The dataset provides an extensive and diverse collection of variables, each with the potential to influence the symptoms associated with varicose veins. This well-rounded dataset includes key variables such as Body Mass Index (BMI), Systolic Blood Pressure Type A (SBPA), Systolic Blood Pressure Type B (SBPB), Ankle-Brachial Pressure Index (ABPI), Diabetes Blood Pressure Type A (DBPA), Diabetes Blood Pressure Type B (DBPB), Pulse Rate (PR), Chronic Fatigue Syndrome (CFS), Hyperhomocysteinemia (HCY), Calf Circumference (CALF-CIR), the Chronic Venous Insufficiency Questionnaire (CVIQ), and the Chalder Fatigue Scale (CFS). In addition to these primary variables, the dataset includes two supplementary variables: VCSS-Pre, which represents symptoms observed before the initiation of yoga practices, and VCSS-1, which captures symptoms observed after one month of participation in yoga sessions. These variables provide a unique opportunity to analyze the potential impact of yoga on varicose vein symptoms over time. To facilitate analysis, the dataset has been categorized into four distinct groups based on the severity of the condition: Absent condition (0-5), Mild (6-10), Moderate (11-20), and Severe (21-30). This classification allows for a more structured examination of the relationship between the various factors and the severity of varicose vein symptoms, offering insights that can inform treatment approaches and patient care strategies.

In this research, Fig. 1 illustrates a correlation matrix that provides a detailed and comprehensive view of the intricate interrelationships among the investigated input and output variables. The matrix reveals how the input data not only significantly influences the output but also affects the relationships between other input variables. For example, the Diabetes Blood Pressure indicators, specifically DBPA (Diabetes Blood Pressure Type A) and DBPB (Diabetes Blood Pressure Type B), show a pronounced effect on both SBPA (Systolic Blood Pressure Type A) and SBPB (Systolic Blood Pressure Type B). This highlights the critical role that blood pressure variations, influenced by diabetes, play in shaping systolic blood pressure outcomes. Additionally, the correlation matrix underscores the significant impact of the Chalder Fatigue Scale's physical and mental components (CFS PHY-Pre and CFS MEN-Pre) on the overall CFS-Pre score. These findings suggest that fatigue, as captured by the Chalder scale, is a crucial predictor of overall chronic fatigue syndrome (CFS) severity. The Chronic Venous Insufficiency Questionnaire (CVIQ) is also identified as a key contributor, influencing both the CFS PHY-Pre and CFS-Pre parameters, further emphasizing the complex interplay between chronic venous insufficiency and fatigue symptoms. Moreover, the analysis identifies other highly influential input parameters, such as the number of standing and sitting hours, the number of working days, CALF-CIR (calf circumference), and HCY (homocysteine levels), which all play significant roles in determining the outcomes. Conversely, the PR (pulse rate) parameter is highlighted as having one of the least impacts on the output, suggesting its relatively minor role in the context of this study. This comprehensive understanding of variable interrelationships provides valuable insights for targeting specific areas in future research and potential interventions.

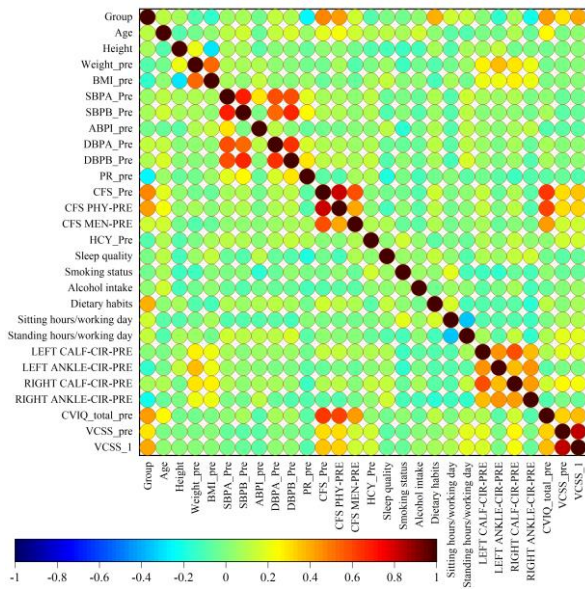

Fig. 1. Correlation matrix to examine how input and output variables are related to one another Evaluation of Model Suitability.

In the realm of classification challenges, Accuracy emerges as a frequently employed metric for evaluating overall model performance, taking into account True Positives (TP), True Negatives (TN), False Positives (FP), and False Negatives (FN). Despite its widespread use, Accuracy faces limitations in scenarios with imbalanced data, as it tends to favor the majority class, providing limited insights. The mathematical expression for Accuracy is defined in Eq. (20):

$$Accuracy = \frac{TP + TN}{TP + TN + FP + FN} \quad (20)$$

To overcome this restriction, three more measures are used: $F1 - Score$, $Precision$, and $Recall$. To reduce False Negatives, recall measures a model's capacity to accurately identify every pertinent instance inside a given class. By quantifying the precision of positive predictions, False Positives are decreased. Combining Precision and Recall, the $F1 - Score$ offers a balanced evaluation that is particularly helpful in situations when the data is unbalanced. Together, these metrics which are represented by mathematical formulae (Eq. 21–23)

help to provide a more complete picture of the efficacy of a categorization model.

$$Precision = \frac{TP}{TP + FP} \quad (21)$$

$$Recall = TPR = \frac{TP}{P} = \frac{TP}{TP + FN} \quad (21)$$

$$F1_score = \frac{2 \times Recall \times Precision}{Recall + Precision} \quad (23)$$

V. RESULTS

To improve the accuracy of classifying and predicting VCSS before and after one month of yoga exercises, this study utilized two optimization algorithms: Crystal Structure Algorithm (CSA) and Fire Hawk Optimizer (FHO). The data, involving 100 patients, underwent careful evaluation in both training and testing phases following the implementation of these algorithms. The main objective is to refine and optimize model parameters using the mentioned algorithms.

Fig. 2 shows the convergence of developed hybrid models. VCSS-Pre, the GPCS, and GPFH models commenced iterations with nearly identical Precision. Eventually, the GPCS model achieved optimal accuracy in 100 iterations (with 0.860 value), while the GPFH model took 110 iterations (in 0.870). In contrast, in VCSS-1, the GPFH model started with lower accuracy than GPCS, reaching higher accuracy in the 80th iteration (in 0.910 accuracy value), while GPCS reached convergence in the 120th iteration (with 0.900).

Table I showcases extensive metrics, encompassing $Accuracy$, $Precision$, $Recall$, and $F1 Score$, across all models for the training and test phases. Notably, the GPFH model exhibits excellent performance in both VCSS-Pre and VCSS-1. Specifically, for VCSS-Pre, the model achieves a Precision of 0.870, Accuracy of 0.877, Recall of 0.870, and $F1 - score$ of 0.872. Similarly, in the case of VCSS-1, the GPFH model attains $Accuracy$, $Recall$, and $F1 - score$ values of 0.910, along with a Precision value of 0.916. Fig. 3 presents a bar plot that visually assesses the performance of the advanced models. Furthermore, it provides additional insights into the achieved results. For instance, it is observable that the GPFH, GPCS, and GPC models showcase optimal performance.

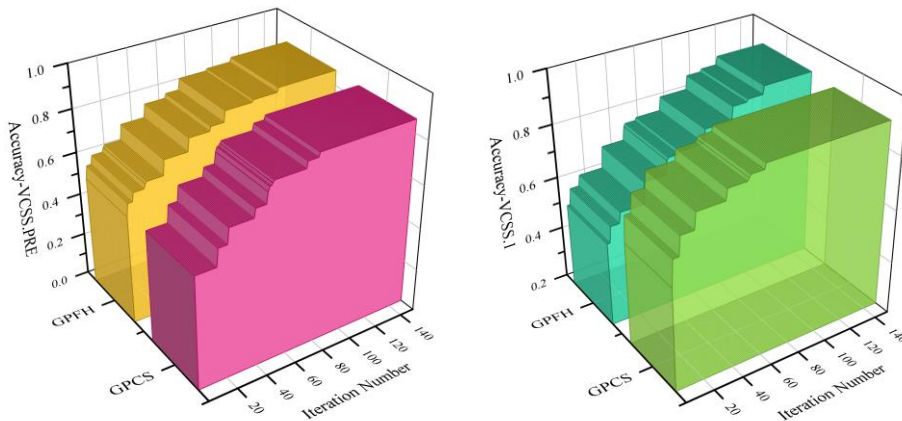

Fig. 2. Convergence curve of hybrid models.

TABLE I. RESULT OF PRESENTED MODELS

	Model	Part	Metric value			
			Accuracy	Precision	Recall	F1_Score
VCSS – PRE	GPC	Train	0.900	0.913	0.900	0.901
		Test	0.733	0.759	0.733	0.737

		All	0.900	0.903	0.900	0.901

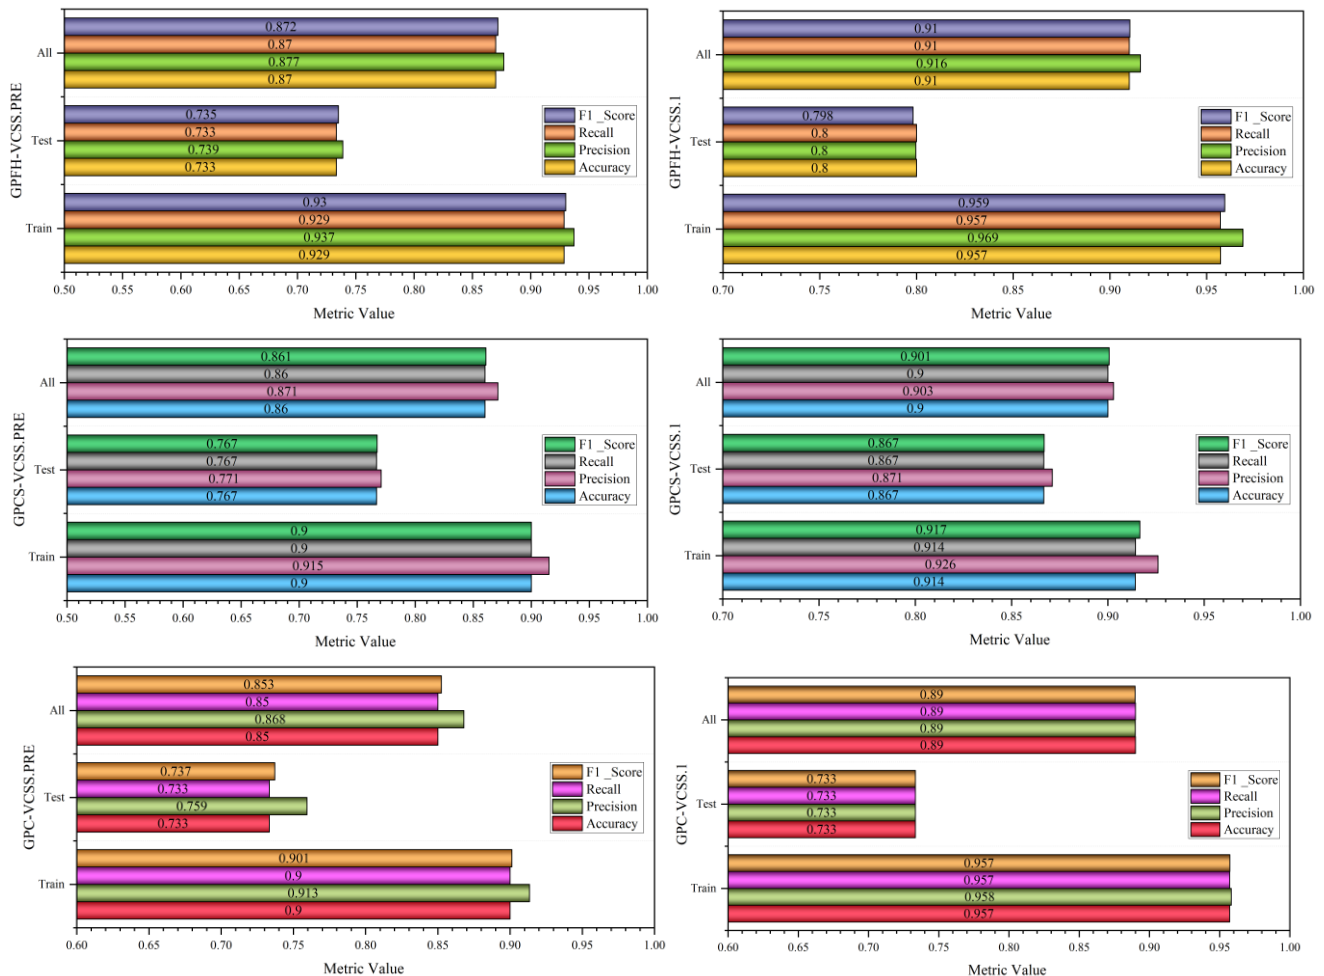

Fig. 3. Bar plot to visually evaluate the created models' performance.

Based on VCSS scores, patients are classified into four groups: Absent (0-5), Mild (6-10), Moderate (11-20), and Severe (21-30) condition. Concerning Precision in VCSS-Pre, as presented in Table II, the GPFH and GPCS models exhibit similar and close performance. Notably, for the Severe condition, both models achieved a value of 1. The GPFH model demonstrates superior performance for Mild and Moderate conditions with values of 0.841 and 0.950, respectively.

However, for the Absent condition, the GPCS model outperforms with a value of 0.733. In Table III, considering the Precision values for VCSS-1, both the GPFH and GPCS models exhibit identical values for Severe conditions at 1. However, for Mild (0.912) and Moderate conditions (0.957), the GPFH model outperforms. Notably, akin to VCSS-Pre, in Absent conditions, the GPCS model demonstrates superior performance with a value of 0.813.

TABLE II. PERFORMANCE EVALUATION INDICES FOR THE DEVELOPED MODELS FOR VCSS-PRE

Model	Condition	Metric value		
		Precision	Recall	F1 – score
GPC	Absent	0.688	0.917	0.786
	Mild	0.804	0.881	0.841
	Moderate	0.972	0.796	0.875
	Severe	1.000	1.000	1.000
GPFH	Absent	0.714	0.833	0.769
	Mild	0.841	0.881	0.861
	Moderate	0.950	0.864	0.905
	Severe	1.000	1.000	1.000
GPCS	Absent	0.733	0.917	0.815
	Mild	0.826	0.905	0.864
	Moderate	0.946	0.796	0.864
	Severe	1.000	1.000	1.000

TABLE III. PERFORMANCE EVALUATION INDICES FOR THE DEVELOPED MODELS FOR VCSS-1

Model	Condition	Metric value		
		Precision	Recall	F1 – score
GPC	Absent	0.867	0.929	0.897
	Mild	0.861	0.838	0.849
	Moderate	0.915	0.915	0.915
	Severe	1.000	1.000	1.000
GPFH	Absent	0.778	1.000	0.875
	Mild	0.912	0.838	0.873
	Moderate	0.957	0.936	0.946
	Severe	1.000	1.000	1.000
GPCS	Absent	0.813	0.929	0.867
	Mild	0.865	0.865	0.865
	Moderate	0.956	0.915	0.935
	Severe	1.000	0.100	1.000

Fig. 4 shows a 3D drop line plot illustrating the difference between measured and forecast values for VCSS – Pre and VCSS – 1. Separate graphs are included for each category (Absent, Mild, Moderate, and Severe), which comprehensively assesses the models' efficacy in classifying.

Upon reviewing the VCSS-Pre diagram, it becomes evident that 12 individuals fall under the Absent category, 42 in Mild, 44 in Moderate, and 2 in Severe. Significantly, the GPC and GPCS models stand out for their remarkable accuracy in classifying the Absent section. In this section, the models demonstrate exceptional Precision in predictions, with a one-unit difference, highlighting the capability to categorize

individuals accurately. In Mild and Moderate conditions, the GPCS and GPFH models showcase superior performance with subtle distinctions. In the Severe section, three models demonstrate identical performance.

As illustrated in the figure for VCSS-1, the recorded counts for patients in the Absent, Mild, Moderate, and Severe categories are 14, 37, 47, and 2, individually. Notably, the GPFH model exhibits superior performance in the Absent and Moderate conditions, particularly in the Absent category, where it achieves error-free predictions. The GPCS model performs best in Mild conditions, and for Severe conditions, all utilized models demonstrate superior performance.

Fig. 4. 3D drop line plot for the difference between measured and forecast values.

Fig. 5 shows the confusion matrix. A confusion matrix summarizes the predictions of the ML model, offering a detailed assessment of its performance in terms of Accuracy, Precision, Recall, and F1 – score measures for evaluating effectiveness. Table III displays the confusion matrix corresponding to VCSS-Pre and VCSS-1. In VCSS-Pre, the GPFH model correctly classified 87 patients, breaking down into 10 Absent, 37 Mild, 38 Moderate, and 2 Severe conditions, while 13 patients were misclassified. The GPCS model takes the

second position, with 86 patients correctly classified and 14 misclassified. The GPC model ranks third, with 15 patients misclassified; in the context of VCSS-1, the GPFH model successfully classified 91 patients (14 in Absent, 31 in Mild, 44 in Moderate, and 2 in Severe conditions) with only nine misclassifications. The GPCS model secured 90 accurate predictions and 10 incorrect ones, while the GPC model claimed the third rank with 89 correct predictions and 11 incorrect ones.

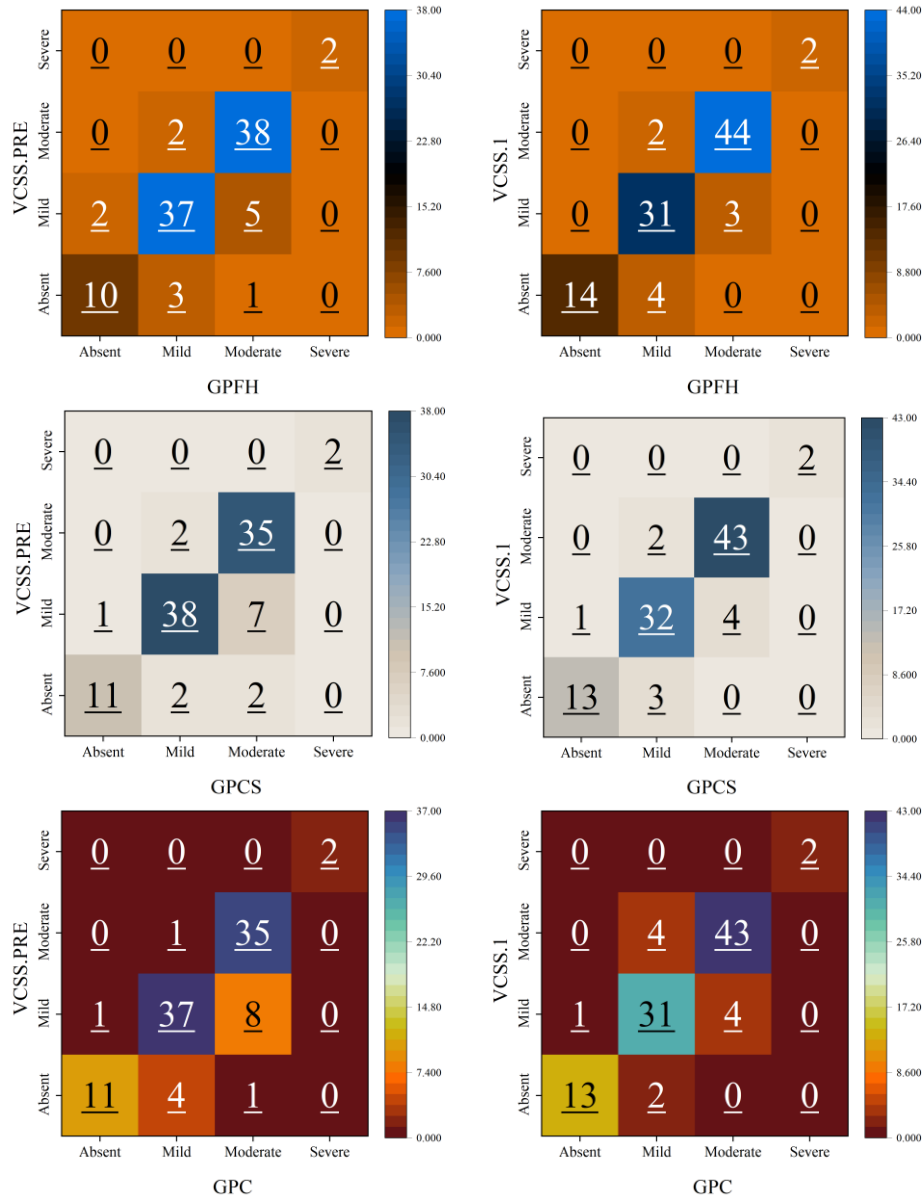

Fig. 5. Confusion matrix for each model's accuracy.

The Receiver Operating Characteristic (ROC) is a visual tool employed in classification to assess a model's performance by mapping the interplay between its false positive rate and true positive rate across diverse thresholds. Illustrating the discriminative capacity of a model, the ROC curve provides a comprehensive overview of its ability to distinguish between classes. Based on the top-performing GPFH model in Fig. 6, the ROC curve analysis indicates that this model serves as a

classifier with acceptable performance in predicting VCSS-Pre for Moderate conditions. Within the VCSS-1 framework, the GPC model demonstrates superior performance for Absent and Mild conditions, with curves approaching 1 for each. Finally, it is noteworthy that the Micro Average, drawn for both VCSS-Pre and VCSS-1, supports the best performance in VCSS-1. Consequently, it can be inferred that one month of yoga practice affects CVI.

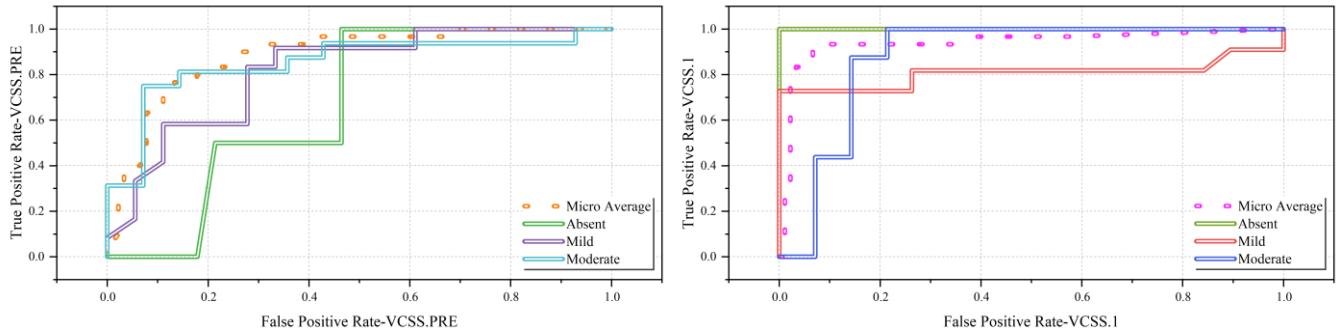

Fig. 6. The outcome is derived from the ROC curve.

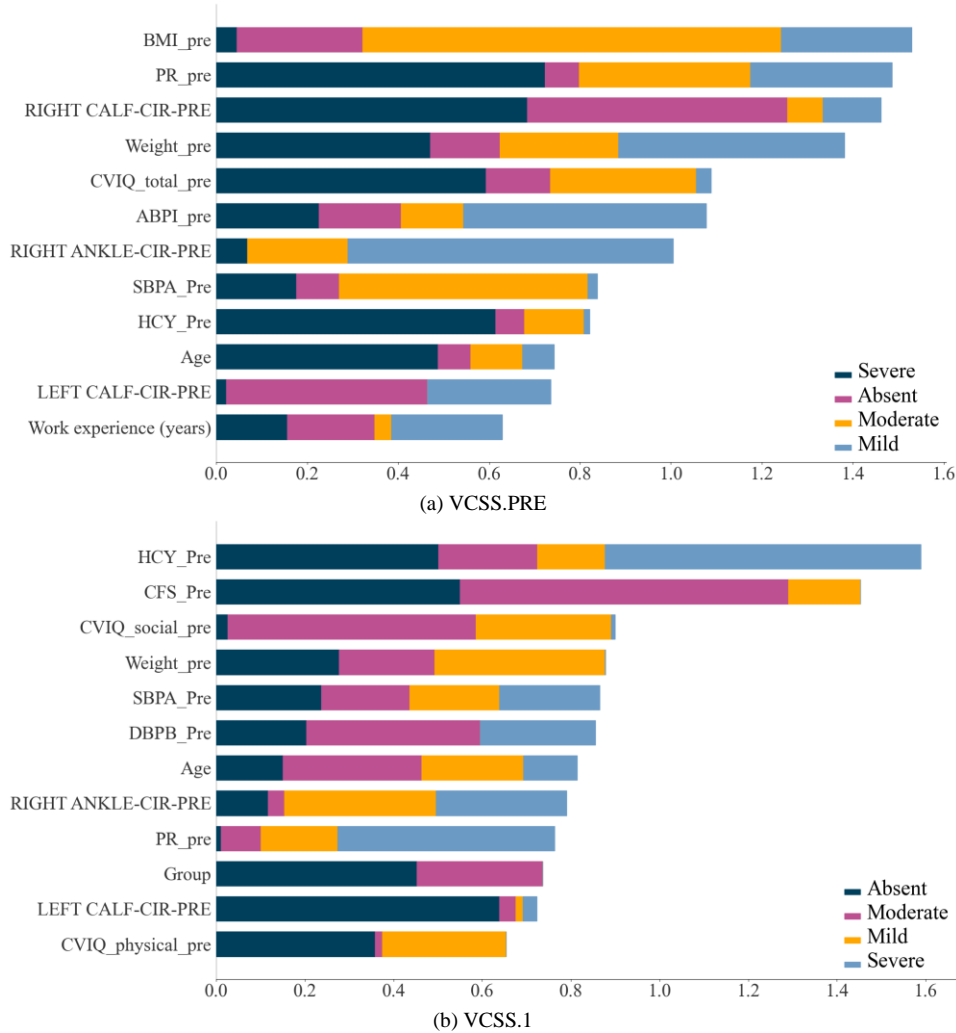

Fig. 7. Impact of input features on model outputs based on SHAP values.

Fig. 7, visually represents the impact of input features on model outputs for predicting symptoms related to CVI based on SHAP (Shapley Additive exPlanations) values. SHAP values are used to interpret the output of machine learning models, providing insights into how much each feature contributes to the prediction. The figure is divided into two plots: (a) VCSS.PRE and (b) VCSS.1, each showing the influence of various input features on the VCSS-Pre and VCSS-1 outcomes, respectively. The VCSS-Pre captures the symptoms observed before the

initiation of yoga practices, while VCSS-1 reflects the symptoms after one month of participating in yoga sessions. In plot (a), the features are ranked by their influence on the VCSS-Pre output, with BMI_pre (Body Mass Index before yoga) and PR_pre (Pulse Rate before yoga) showing significant impacts across all severity levels—Severe, Absent, Moderate, and Mild. The RIGHT CALF-CIR-PRE (right calf circumference before yoga) and other physical indicators like the ABPI_pre (Ankle-Brachial Pressure Index before yoga) also contribute

substantially to the prediction outcomes. Plot (b) of the figure highlights the impact of input features on the VCSS-1 outcome. Notably, HCY_Pre (Homocysteine levels before yoga) and CFS_Pre (Chronic Fatigue Syndrome before yoga) emerge as the most influential features, particularly in the Severe category. Other factors, such as CVIQ_social_pre (Chronic Venous Insufficiency Questionnaire-social before yoga) and SBPA_Pre (Systolic Blood Pressure Type A before yoga), also show notable contributions to the model's predictions post-yoga intervention. The colored bars represent different severity levels, with each feature influencing these categories to varying degrees. This detailed analysis helps identify which features are most critical in predicting varicose vein symptoms and how these influences change after yoga intervention. The visual breakdown provides a clear understanding of how input variables contribute to the model's outputs, offering valuable insights for future research and potential therapeutic strategies in managing CVI.

VI. CONCLUSION

Chronic Venous Insufficiency (CVI) is characterized by impaired blood flow to the heart due to damaged or weakened valves in the leg veins, resulting in symptoms such as swelling, pain, skin alterations, and, more severe instances, persistent ulcers. This article aims to assess the impact of yoga exercises on alleviating symptoms in individuals with CVI. Employing a machine learning technique, the study predicts and categorizes symptoms before and one month after participating in yoga exercises. To ensure optimal performance, the selected model, Gaussian Process Classifier (GPC), for this study went through final optimization utilizing two optimizers, namely the Crystal Structure Algorithm (CSA) and the Fire Hawk Optimizer (FHO). A comprehensive evaluation was performed on 100 patients diagnosed with CVI. This assessment employed key criteria, including *Accuracy*, *Precision*, *Recall*, and *F1 – score*. The resulting outcomes are presented as follows. In VCSS-Pre, concerning the F1-Score criterion, the GPFH model outperforms the GPCS and GPC models by 1.26% and 2.18%, respectively. Additionally, this superiority in Recall quality translates to 1.15% and 2.3%, respectively. Moreover, In the prediction of VCSS_1, the GPFH model demonstrates superior performance in F1_Score and Recall criteria compared to the GPCS (1% and 1.1%, respectively) and GPC (2.2% for both criteria) models.

Future studies on CVI and its management through yoga and machine learning-driven prediction models could explore several promising avenues. First, expanding the study to include a larger and more diverse patient cohort would enhance the generalizability of the findings, allowing for a more comprehensive understanding of the effectiveness of yoga in various demographic groups and across different stages of CVI. Additionally, longitudinal studies tracking patients over an extended period could provide valuable insights into the long-term effects of yoga on CVI symptoms, as well as any potential cumulative benefits. Another important area for future research is the integration of other complementary therapies with yoga, such as dietary modifications, physical therapy, or mindfulness practices. Investigating the combined impact of these approaches could lead to a more holistic treatment framework, addressing not only the physical but also the psychological

aspects of CVI. On the machine learning front, future studies could explore the application of more advanced models, such as deep learning or ensemble methods, to enhance prediction accuracy and robustness. Additionally, incorporating real-time monitoring and data collection through wearable devices could provide more granular data, enabling more precise symptom tracking and personalized intervention strategies.
